Since the establishment of the International Federation of Organic Agriculture Movements (IFOAM) in 1972 for the global development of organic farming practices, the first examples of which were developed in the early 20th century, developed countries have designed their own regulations. In 1991, the Regulation No 2092/91 entitled 'Organic Production of Agricultural Products and Indications Referring Thereto on Agricultural Products and Foodstuffs' entered into force for the first time in the EU. Subsequently, organic production and trade has been reshaped by the Council Regulation No 834/2007 on organic production and the labeling of organic products adopted in 2007 and enacted in 2009, Commission Regulation No 889/2008 laying down detailed rules for the implementation of Regulation No 834/2007, and Regulation No 1235/2008 entitled 'Detailed Rules for the Implementation of Council Regulation (EC) No. 834/2007 as regards the Arrangements for Imports of Organic Products from Third Countries (Abay et al.,2011). The new Commission Implementing Regulation (EC) No 2016/1842 of 14 October 2016 and the Regulation No 1235/2008 on the electronic inspection certificate for imported organic products have taken their final shapes today. In the United States, the access of organic products to the US market and the principles

of production were determined through the enactment of the National Organic Program (NOP) in 2002 by the US Department of Agriculture (USDA).

While the size of the total organic food market in the world was 15 billion dollars in 1999, it reached 89.7 billion dollars in 2016 and increased about six times from 1999 to 2016. According to data from the year 2016, about 90% of the organic food market value in the world is in North American and European countries (Willer & Kilcher, 2009; Sahota, 2018).

In the EU, the organic market is continuing to show more growth tendency than organic agriculture land. The fact that the increase in producers of organic products fall behind the increase of processors and importers in the EU shows that organic production is not able to meet the demand for increased organic products (Willer & Lernoud, 2017). For this reason, a significant part of the organic products consumed by the Member States of the EU is provided by imports from third countries.

The United States first made a mutual recognition agreement with Canada in 2009. Similar agreements with the United States continued with the EU in 2012 (EC, 2016), Japan and South Korea in 2014, and Switzerland in 2015. From the date on which these agreements entered into force, the parties to the treaty agreed on the control systems and standards of each other, so the products certified in one country can be sold in the other country. These agreements have had positive effects on the foreign trade of organic products (Jackie and Demko, 2015). In Turkey, organic agriculture has begun with the production of raisins, dried figs, dried apricots and nuts since the mid-1980s under the leadership of the European organic farming firms through contract farming. There was no national legislation to regulate organic production in Turkey between the years 1984-1993, and the production was carried out based on the rules of the importing country. Between 1994 and 2002, some developments took place at regulatory level. The first regulation, Regulation No 22145 on 'Ecological Production of Vegetable and Animal Products', entered into force on December 18, 1994. In this period, organic farming activities started to develop and spread especially in the Aegean region (Ersun and Arslan, 2011) Organic Farming Law was published on December 3, 2004, and following the 'Regulation on the Principles and Implementation of Organic Farming' which was put into effect on June 10, 2005, 'Regulation on the Principles and Implementation of Organic Farming' was published in the Official Gazette No 27676 in August 2010. In addition, Turkey has applied to take part in the EU Third Countries List (MFAL, 2010)

The number of organic farmers, organic agriculture land and organic production in Turkey has increased over time, and a significant number of organic products have turned towards export. Products such as dried figs, dried apricots, seedless raisins, chickpeas, red lentils, hazelnuts, as well as organic products such as pistachios, pine nuts and fig paste are the exported products. The countries of the European Union, particularly Germany and France, where the largest number of organic products are exported, constitute the largest markets with the USA together (USDA, 2015, 2016). In the world, organic products are exported to 68 countries. The fact that the exports of organic agricultural products are predominantly oriented towards the USA and the EU necessitates the monitoring of regulations and changes of access to these markets.

Despite having its own ecological advantages, being largely in compliance with the EU organic production regulations, expanding organic product range and showing an increase in production quantities of organic products, Turkey is not considered as equivalent by developed countries in terms of import regulations. Taking the growing trade of organic products in the world into account, it can be clearly seen that it is extremely important for Turkey to grow exports by ensuring the equivalence between the organic farming regulations of Turkey and other foreign countries.

Materials and methods

In this study, both primary and secondary data were used. The primary data that constitute the main material of the study were obtained from the questionnaires conducted with companies exporting organic agricultural products and control and certification bodies in Izmir province. Secondary data used in the research were obtained from the related theses, reports, articles and domestic and foreign sources on the internet sites such as IFOAM, FIBL, Ministry of Food, Agriculture and Livestock (MFAL).

Based on the list obtained from MFAL website, a survey was conducted with 22 firms exporting organic agricultural products in Izmir province. There are leading, but few firms among those Turkey-based firms which export organic products. Besides, eight control and certification bodies authorized by the MFAL and the authorities of importing countries to export organic products were included in the study. These control and certification bodies have first begun and are continuing their operations in Izmir province in Turkey, and their independence and competence have been accredited. While conducting the questionnaire with the control and certification bodies, the general manager or another authorized person was interviewed face-to-face in all bodies, except for one.

In this paper, tables and graphs as well as simple statistical methods such as arithmetic average and percentage calculation were used to analyze data.

Results and discussion

All firms surveyed exporting organic agricultural products have been exporting for 12.50 years on average. It has been determined in the study that the main organic products exported by the firms surveyed are dried figs, raisins and dried apricots (over 50.00%) as well as a wide variety of organic products. In addition, 15 out of the 22 firms surveyed carried out more than 50.00% of total exports of organic agricultural products to a single country. These countries are the USA, Germany, France, Holland and Denmark (Table 1).

Table 1 Surveyed Firms Exports of Organic Farming Products to the US and EU Countries

Countries	50% and more	%	Less than 50%	%	Total number of firms (22)	%
France	2	9.09	15	68.18	17	77.27
Germany	4	18.18	12	54.55	16	72.73

* Since more than one product is exported, the total is more than 100%.

Companies that export organic agricultural products after 2009 cannot formulate an opinion on the EU regulation change because they cannot make a comparison with the previous system. For this reason, as of 2009, 66.66% of the companies exporting organic agricultural products indicated that it is now easier to certify organic products to be exported, and 33.34% indicated that there is not any change. 90% consider that the new arrangement in the EU facilitates quick trade and certification of the products. Since organic production is a controlled production method from the outset, in the previous system companies had to communicate all phases of export including the organic product supplier information to competent authorities in the relevant countries. This process had to be repeated in every export. After the aforementioned process has been removed,

a) the exporting firms should be able to work with the suppliers they wish or work with more suppliers in order not to meet with an obstacle while exporting products in case of changing suppliers,

b) it is now possible to certify more products in order to meet the demands of the EU countries, even if there are a few demands. For these reasons, 50.00% of the companies stated that the new regulation facilitated working with more suppliers, and 40.00% stated that certifying more products got easier.

31.82% of the companies surveyed have and 68.18% have not been certified by a different CB since the year they started organic export. Among the firms that previously worked with a different CB, 42.86% of them changed their CB to receive higher quality certification services, and 57.14% changed their CB due to special reasons such as commercial issues or customer requests. 13.33% of these firms stated that Regulation No 1235/2008 affected the quality of organic products positively, and 86.67% stated that this regulation had no effect on the quality of products. 73.33% of the firms surveyed stated that Regulation No 1235/2008 facilitated the transportation of poultry while exporting organic products, 20.01% said that it did not bring about a change, and one firm said it got more difficult.

Of the firms that think it got easier to access to the market to export organic products, 90.90% stated that the new regulation saves time; 63.63% stated that instead of giving separate import permits to each country desiring to export organic products, the certificates obtained from authorized CBs are valid in the EU countries, which facilitates access to the market. 72.72% of these companies can make sales to meet instant demands, 36.36% can work with more suppliers, and 45.45% can certify more products, so it gets easier to reach the market. As of the year 2009, 13.33% of companies exporting organic agricultural products stated that they had rarely experienced quality loss when they reached foreign countries, while 86.67% stated that there was no quality loss. The two firms stating that quality loss was rarely experienced expressed that removing the EU's import permit process shortened the period, but this did not affect the quality loss because the formalities were completed before the export process. More clearly, these firms are of this opinion because they containerized the goods when they got import permits from the relevant countries before the export took place. The eight surveyed CBs operating in Izmir are all EU-based companies. These CBs have been operating for an average of 14 years domestically and in the EU, and for about 12 years according to US-NOP regulation.

87.50% of the CBs agreed that the concept of 'conformity' is 'the control and certification bodies operate on the basis of the EU directive', while 12.50% participated in this statement partially. Similarly, 87.50% of the CBs agreed that the concept of 'equivalence' is 'the control and certification bodies establish their own standards and operate with the approval of the EU Council', and 12.50% agree with that statement partially. All CBs thinking that the new EU directive facilitates the certification of organic products to be exported have all indicated that this is due to the fact that the amendment to regulation has resulted in less bureaucracy and saved time. 87.50% of the CBs think that the new regulation facilitates the certification of organic products in terms of the companies exporting to our country, and 12.50% think that it does not bring any convenience. 57.14% of the CBs thinking that this regulation brings convenience to the exporting firm reported that the workload of the firms in the certification process decreased because of the decrease of bureaucratic transactions, and 85.71% of the time was saved by shortening the process. They also pointed out that trade is accelerating, giving the exporters a broader supply chain and broader buyer opportunities.

On the other hand; in accordance with the Regulation No 834/2007, in case of a discommodity detected in their bodies operating in other countries, the EU Commission could disauthorize CBs that the organic product firms in Turkey need to work together with to export to the EU. In such a case, the loss of all EU countries' markets is the main problem with the cancellation of the authority of the CB's headquarter with all the organs operating in other countries along. In addition, while the relatively new EU system and the previous system were co-operated, CBs stated that they had gone through a complex and lengthy process in order to have sufficient technical equipment and knowledge in order to become an equivalent institution listed in the Regulation No. 1235/2008. 75% of the CBs participating in the survey did not apply to the EU Commission to be an equivalent company. For this reason, the headquarter of these CBs has to apply to the EU Commission to include the CBs in Turkey. However, applications of all applicants have been accepted. These firms stated that they applied to serve domestically and abroad as a company based in Turkey, to work with more export firms and to increase competitiveness in the sector. These applicants stated that the application process to the EU Council was lengthy and complicated. In addition, 50% of the CBs had some complications / difficulties because the CBs of their suppliers were not be included in the annex to Regulation No 1235/2008, and thus this caused a setback to the export of organic products.

Conclusion

In recent years, some countries such as the EU, the USA and Canada have taken important steps in the development of organic commodity trade in the world, with mutual recognition agreements facilitating the trade of organic products. Yet, the agreements made include the trade of organic agricultural products between developed countries, but have not yet been addressed to developing countries. Mutual agreements made in developed countries ensure that the organic products in these countries can be sold without subjecting them to additional control and certification procedures, which reduces the difficulties in the trade of organic products. As a result, the trade of organic products between these countries is being facilitated and increasing (Jaenicke and Demko, 2015) While legal regulations in Turkey have been implemented effectively in organic agriculture since 1994, it is still necessary to monitor the institutions that control and certify based on foreign standards and collect data, review and fill out the legal gaps in equivalence issues in the existing system in terms of importing organic products and inputs and facilitate the procedures. In addition, considering the EU countries where the organic commodity trade is largely conducted worldwide, it can be said that the Third Country List remains important in the foreign trade of organic agricultural products, despite EU amendments to Law No 834/2007.Turkey, which is now a third country, applied to enter the Third Country List of the EU in 2003 and has completed several phases of

supervision successfully. However, it is not on the list yet. Moreover, Turkey does not have mutual recognition agreements with the US and other countries. For these reasons, Turkey needs to comply with the regulations of its target markets to export organic agriculture products, and the same products are compulsorily subject to multiple certification. Considering the gradual increase in demand for organic products by the USA and the EU, which are important countries for Turkey's organic product export, Turkey holds an important position in terms of a) its compliance with the regulations of these countries, b) its potential of organic agriculture, c) its being a country whose regulations are considered equivalent by these countries based on the growing export especially since 2012. Thus, it is going to be possible for Turkey to increase organic product exports, have an important place in the organic products market in the world, and increase its competitiveness with other countries in terms of varieties of organic agricultural products.

Abstract

This study was carried out in Mersin (Turkey) in 2012-2013. Mersin, a city of Mediterranean Region, has very high potential for viticulture, while the early ripening table grapes are cultivated in the lowlands, late ripening table grapes and raisins grapes cultivation is done widely at highland regions. In this study, it was understood that Yalova İncisi, Tarsus Beyazı, Ergin Çekirdeksizi, Trakya İlkeren and Victoria grape varieties were cultivated at the lowland (≤500 m) and Kişniş, Göğüzüm, Takkara, Dilmit and Tilkikuyruğu grape varieties were cultivated at the highland of the Mersin. Grape growing maturity period in Mersin begins with in the second half of June at lowland (Trakya İlkeren) and ends with at the end of November (Tilkikuyruğu) at highland. The highest yield of grapes per vinestock was determined at Ergin Çekirdeksizi (10.42 kg) at lowland and, on the other hand, in Tilkikuyruğu (16.93 kg) at highland. Varieties' cluster of grapes weights was determined between 318.09 g (Trakya İlkeren) and 410.48 g (Ergin Çekirdeksizi) and a hundred berry weight was found out between 285.0 g (Ergin Çekirdeksizi) and 759.4 g (Victoria) at lowland. However, cluster of grapes weights showed a change between 192.00 (Kişniş) and 446.61g (Tilkikuyruğu) and a hundred berry weight was from 93.6 g (Kişniş) to 651.8 g (Tilkikuyruğu) at highland. TSS contents of varieties differed from 14,8% to 13.1% (except Tarsus Beyazı) at lowland. On the other hand, that showed an alteration between 15.6% and 19.2% at highland.

Keywords: *viticulture, yield, quality, lowland, highland, Mersin.*

Introduction

Turkey ranks the fifth in terms of vineyard areas (435.227 ha) and the sixth in terms of grape production (4.000.000 ton) throughout the world (Anonymous, 2017a). Mersin province, which is located in the Mediterranean Region of Turkey. Summer months are hot and extremely humid, while winter months are warm and rainy. Mersin is one of the exceptional provinces where agricultural production is aimed at three periods; i.e. "early", "mid-season" and "late". Early fruit types and varieties, greenhouse vegetable growing, banana and strawberry production are predominant at the coastal part of the province. Late season fruit and vegetable growing, aimed at exportation, is considerably important in highland areas. Mersin province has suitable climate conditions for viticulture in terms of annual average temperature (19,1°C), effective temperature totals (3150,4 day-degree) and annual amount of precipitation (592,3 mm) (Anonymous, 2017b). Agricultural soil of the province are generally argillaceous and calcareous, with high pH rate.

Mersin province ranks the fourth with 22.148 ha vineyard area and the third with 287.429 tons of grape production throughout Turkey (Anonymous, 2017c). Table (88,8%), dried (6.8%) and wine (4.4%) grapes are grown in the province. Mersin province ranks the second throughout Turkey in table grape growing (255.303 tons). While the amount of table grapes grown per unit area is 800 kg/da in Turkey, this amount is 1400 kg/da for Mersin. It is considered that this increase in production is caused by cultivation techniques such as irrigation, fertilizing, training system and pruning in addition to selection of cultivars. Early

season grape cultivation is prevalent in the lowland parts of the province, while late season cultivation is prevalent in the highlands (Tangolar and Gök Tangolar, 2003).
Grape harvest period of the province is quite long. The length of this period is influenced by selection of cultivars in addition to ecological conditions. Early or late ripening of cultivated variety allows the product to be evaluated more easily and at higher prices.
In this study, cultivars that are widely used in viticulture in vineyard establishments at lowland and highland parts of Mersin province have been determined and yield and quality characteristics of these cultivars have been determined.

Material and Methods

In the study, vineyard establishments in Mersin province were reviewed in two parts; lowland area and highland area. In terms of altitude, 0 to 500 m was accepted as lowland while 501m ≤ was accepted as highland. The number of establishments to be surveyed in Mersin was determined according to simple random sampling method (Yamane, 1967). Accordingly, a total of 297 surveys were conducted throughout Mersin; 125 in lowlands and 172 in highlands.
Top 5 grape cultivars that are most commonly cultivated in lowland and highland viticulture of Mersin province were identified according to the results of the conducted survey. These grape cultivars were used as materials of the study. 10 vineyards with similar characteristics (economical yield age, same type of cultivation) were identified for each cultivar. Each vineyard was accepted to be a repetition. Samples were obtained from a total of 100 vineyards. 10 vine were randomly selected in each vineyard and 2 cluster samples were obtained from each vine. Sampling of each cultivar was made during grape harvest of establishment owners. In order to identify quality characteristics of cultivars; cluster characteristics [cluster weight (g), cluster height (cm), cluster width (cm)], berry characteristics [berry weight (g), berry height (mm), berry width (mm), berry color (L, *a, *b), berry removal force (g)] and must characteristics [TSS (%), pH, acidity (%), TSS/acidity rate] were analyzed (Ergenoğlu, 1985; Lancaster *et al.*, 1997; Tangolar *et al*. 2005). Yield per vine ratio was determined as a result of multiplication of the number of clusters in each vine with average cluster weight for 10 vine in each vineyard.
Average values regarding yield and quality characteristics of cultivars are given in tables together with their standard deviations.

Results and Discussion

Eighteen grape cultivars, which are cultivated in lowland part of Mersin province, were determined according to survey results. It was identified that top five cultivars, which were most commonly cultivated, were; Yalova İncisi (52,56%), Tarsus Beyazı (15,17%), Ergin Çekirdeksizi (8,55%), Trakya İlkeren (6,86%) and Victoria (3,94%).
On the other hand, it was determined that fifty two grape cultivars were cultivated in highland part of Mersin province. It was identified that top five cultivars, which were most commonly cultivated, were Kişniş (16,84%), Göğüzüm (13,61%), Takkara (12,82%), Dilmit (12,56%) and Tilkikuyruğu (10,26%). It was observed that Trakya İlkeren was the earliest ripening cultivar (June26) in Mersin lowland viticulture, and that harvest of Yalova İncisi and Ergin Çekirdeksizi cultivars followed in approximately one week intervals. It was seen that Tarsus Beyazı and Victoria cultivars were harvested in the last week of July. It was determined that the harvest of Takkara and Kişniş cultivars started at the end of August, harvest of Göğüzüm and Dilmit started during the first week of September, while harvest of Tilkikuyruğu started during the first week of November in highland viticulture (Table1)
In our study, our findings regarding ripeness dates of cultivars bore resemblance to the results of Sabır (2008) and Gök Tangolar (2009) regarding Trakya İlkeren and Yalova İncisi; results

of İnal (2000) regarding Takkara; and results of Özdemir and Tangolar (2005) regarding Tarsus Beyazı. However, it was observed that ripeness times of Trakya İlkeren, Yalova İncisi and Ergin Çekirdeksizi cultivars were approximately one week earlier than our findings in the study conducted by İnal (2000) under Alata/Erdemli conditions.

It was identified that yield values of cultivars per vine vary between 6,58 kg (Trakya İlkeren) and 10,42 kg (Ergin Çekirdeksizi) under lowland conditions, and 5,96 kg (Göğüzüm) and 16,93 kg (Tilkikuyruğu) under highland conditions (Table1).

Our findings regarding yield of cultivars per vine were significantly lower than the findings of Sabancı (2009) for Trakya İlkeren and Yalova İncisi cultivars. In our study, yield value determined for Ergin Çekirdeksizi cultivar was similar to the findings of İnal (2000) and Sabancı (2009); while yield values for Tarsus Beyazı, Tilkikuyruğu and Takkara cultivars were higher than the findings of İnal (2000). Tarsus Beyazı and Yalova İncisi cultivars yielded respectively the highest and the lowest values in terms of cluster width in the lowland; while respectively Göğüzüm and Kişniş cultivars yielded the same values in the highland. In terms of cluster weight, the highest and the lowest values were observed on respectively Ergin Çekirdeksizi (410,48 g) and Trakya İlkeren (318,09 g) cultivars in the lowland; in comparison with Tilkikuyruğu (446,61 g) and Kişniş (192,00 g) cultivars in the highland (Table1).

Our findings regarding cluster weights of cultivars bear resemblance to the findings of Sabır (2008) and Gök Tangolar (2009) for Trakya İlkeren, and the findings of İnal (2000) for Ergin Çekirdeksizi and Takkara cultivars. Values identified by Sabır (2008) for Yalova İncisi, Ergin Çekirdeksizi, Tarsus Beyazı and Tilkikuyruğu cultivars; by İnal (2000) as well as Özdemir and Tangolar (2005) for Tarsus Beyazı cultivar; and Kamiloğlu and Polat (2009) for Yalova İncisi and Ergin Çekirdeksizi cultivars were found to be lower than the values that we obtained in our study. It was also seen that cluster weights identified by Gök Tangolar (2009) for Yalova İncisi and İnal (2000) for Trakya İlkeren, Yalova İncisi, Tilkikuyruğu cultivars were higher than our study. While Victoria yielded the highest value and Ergin Çekirdeksizi yielded the lowest value in terms of berry width, berry height and weight of 100 berries among cultivars that are widely cultivated in lowland viticulture; Tilkikuyruğu yielded the highest and Kişniş yielded the lowest values in terms of the same characteristics in highland viticulture (Table 1). Our findings regarding 100 berry weights of cultivars were similar to the findings of Sabır (2008) for Tilkikuyruğu, and Kamiloğlu and Polat (2009) and İnal (2000) for Yalova İncisi and Ergin Çekirdeksizi. Berry weights of Trakya İlkeren and Tarsus Beyazı were found to be higher than the findings of Sabır (2008) and İnal (2000). Furthermore, berry weights of Tilkikuyruğu and Takkara cultivars were also found to be higher than the values determined by İnal (2000). In terms of removal force; while Victoria yielded the highest value (536 g) and Tarsus Beyazı yielded the lowest value (240 g) in the lowland; Tilkikuyruğu and Kişniş cultivars respectively yielded the highest (418 g) and the lowest (121 g) values in the highland (Table1). It was determined that the berry removal force value of Trakya İlkeren cultivar was higher than the findings of Ozer and Kiracı (2002) and similar to the finding of Kamiloglu (2013). However, the value obtained from Yalova Incisi in terms of this characteristic was higher than the findings of Aydın (2009). On the other hand, berry removal force value of Ergin Cekirdeksizi was lower than the findings of Kamiloglu (2013) and the same value of Tarsus Beyazi was similar to the findings of Ergenoglu (1985).

In terms of berry color characteristics of cultivars; L and b* values were found to be the highest in Victoria cultivar and the lowest in Trakya İlkeren cultivar under lowland conditions. A* value was identified to be highest in Trakya İlkeren cultivar and the lowest in Ergin Çekirdeksizi and Victoria cultivars. In terms of color characteristics under highland conditions, L and b* values were found to be the highest in Tilkikuyruğu cultivar, while a value was found to be the highest in Kişniş cultivar. The lowest L, a*, b* values were obtained from respectively Dilmit, Tilkikuyruğu and Takkara cultivars.

Table 1. Harvest date and yield and some quality features for grape cultivars that are widely cultivated in MersinLocation	Cultivar	Harvest date	Yield (kg/vine)	Cluster weight (g)	100 Berry weight (g)	Berry removal force (g)	TSS (%)	pH	Acidity (%)	Maturity index
Lowland	Trakya İlkeren	Jun26	6.58 ± 1.86	318.09 ± 52.01	461.80 ± 37.71	460 ± 52.4	13.4 ± 0.90	3.46 ± 0.11	0.61 ± 0.06	21.76 ± 2.84
	Yalova İncisi	Jul03	7.59 ± 2.27	359.24 ± 52.90	647.80 ± 73.26	363 ± 41.5	13.9 ± 2.02	3.65 ± 0.19	0.36 ± 0.10	38.46 ± 18.72

	Göğüzüm	Sep03	5.96 ± 2.00	312.27 ± 50.35	539.05 ± 40.39	377 ± 37.2	15.6 ± 1.80	3.52 ± 0.14	0.44 ± 0.12	35.37 ± 22.10
	Takkara	Aug29	7.34 ± 1.51	274.98 ± 23.61	397.90 ± 43.80	281 ± 29.0	18.7 ± 1.05	3.32 ± 0.07	0.51 ± 0.06	36.65 ± 4.90
	Kişniş	Aug29	14.14 ± 2.45	192.00 ± 23.42	93.60 ± 18.94	121 ± 32.2	19.2 ± 1.68	3.30 ± 0.12	0.67 ± 0.10	28.75 ± 4.45
	Dilmit	Sep03	11.05 ± 2.52	235.05 ± 38.34	223.20 ± 31.16	139 ± 11.6	18.6 ± 0.88	3.57 ± 0.09	0.48 ± 0.04	38.71 ± 2.93

It was identified in the study that harvest of early-ripening cultivars other than Tarsus Beyazı (19,6%) were started to be harvested at 13-14% TSS content in the lowland. pH level of cultivars varied between 3,05 and 3,79, while their acidity contents varied between 0,29% and 0,61%. Maturity index value was the lowest for Trakya İlkeren cultivar, which was the earliest cultivar to be harvested, and the highest for Tarsus Beyazı and Victoria cultivars, harvest of which started at the end of July. In cultivation under highland conditions, harvest of cultivars other than Göğüzüm (15,6%) starts at 18-19% TSS content. In addition, pH varied between 3,30 and 3,59, acidity varied between 0,35% and 0,67%, and maturity index varied between 28,75 and 52,86 in cultivars cultivated in the highland (Table1).

The findings regarding TSS contents of cultivars were similar to the findings of İnal (2009) and Sabancı (2009) regarding Yalova İncisi; and Sabır (2008) and Özdemir *et al*. (2006) regarding Tilkikuyruğu. It was seen that this characteristic was lower for Trakya İlkeren and Yalova İncisi cultivars than the values obtained by Sabır (2008) and Aydın (2009) from their studies. This value was found to be higher for Tarsus Beyazı than the findings of Özdemir and Tangolar (2005) as well as Sabır (2008). Maturity index values established during our study were identified to be similar to the findings of Kamiloğlu and Polat (2009) regarding Yalova İncisi and Ergin Çekirdeksizi; similar to the findings of Sabancı (2009) regarding Trakya İlkeren; and higher than the findings of Özdemir *et al.* (2006) regarding Tilkikuyruğu.

Conclusion

Yalova İncisi, Tarsus Beyazı, Ergin Çekirdeksizi, Trakya İlkeren, Victoria grape cultivars are widely cultivated in lowland viticulture establishments, while Kişniş, Göğüzüm, Takkara and Tilkikuyruğu grape cultivars are widely cultivated in highland viticulture establishments in Mersin province. Grape harvest starts in the second half of June (Trakya İlkeren) in the lowland and continues until late November (Tilkikuyruğu) in the highland. Table grape cultivation is prevalent in the lowland, while mid- and late-season table grape and raisins (Kişniş, Dilmit) cultivation is prevalent in the highland in Mersin province. Among these cultivars, Ergin Çekirdeksizi is prevalent in the lowland while Tilkikuyruğu is prevalent in the

highland in terms of yield per vine and cluster weight. In terms of berry weight and removal force, Victoria stands out in the lowland while Tilkikuyruğu stands out in the highland.

Abstract

Due to the fact that soils contaminated with heavy metals have features on the intensity and type of contamination (lead, cadmium, mercury, tin, titanium, chromium, etc.) in various regions of Belarus, and plants differ significantly in the ability to accumulate heavy metals, it is necessary to show the effectiveness of sorbents on the basis of calcinated sugar beet production defecate on the example of growing a technical colza. The use of cheap sorbents based on a defecate on contaminated soils can facilitate their return to an agricultural circulation. The method of X-ray fluorescence analysis (XRF) has been used to assess the environmental safety of soils and plant organs, as well as to determine the level of their accumulating capacity. The analysis of the obtained data has shown that the accumulation of cadmium and lead in colza leaves significantly increases on the contaminated soils (by 82%). The levels of the accumulation of manganese, zinc, zirconium, and strontium significantly increase in a phytomass. A decrease in the accumulating capacity (with respect to copper and iron) of colza plants grown on the contaminated soils has been revealed. It has been shown that spreading heat treated defecate to the soil permits reducing the accumulation of arsenic, copper, manganese, and lead by a technical colza phytomass.

Keywords: *environmental safety, X-ray fluorescence analysis, heavy metals, technical colza, sugar beet production defecate*

Introduction

Sugar industry is one of the priority directions of the social and economic development of the Republic of Belarus, providing food security of the country, contributing to the development of agricultural production. More than 450 agricultural enterprises in four regions of the Republic – Brest, Grodno, Minsk, and Mogilev – are engaged in industrial beet growing. There are formed two types of solid wastes in the production of sugar from sugar beet – a pulp and filtrational sediment (defecate). A pulp is used as an additive to livestock feed, so the issue of its utilization is closed. This is not the case with a defecate.

Defecate (the secondary product of sugar beet and raw sugar production) is a product valuable on its chemical and consumer properties. In the earlier period it was removed from sugar factories to filtration fields in the form of a mud suspension and was known as "a filtrational mud". In the conditions of modern advanced technology, it goes out of production in the form of compressed lumps with the mass fraction of dry substances 65% - 70% and has a short, convenient for the producers name "defecate". At the same time according to the TS RB 37602662.630-99, an official name of this waste is "a filtrational sediment". The sediment is destined for liming (neutralization) of acidic soils. The method of application is in accordance with the "Instruction on liming of acid soils of the agricultural lands of the Republic of Belarus", Minsk, 1997.

Because around the world the most recognized scheme for the treatment of sugar solutions from nonsugars and dyes is accepted a scheme through the processes of defecosaturation, the amount of a defecate increases in sugar-producing countries every year. In the Republic of Belarus the volume of a defecate output in all sugar factories has increased significantly and

reached 362 thousand tons per year over the past 4-5 years. At the same time, the use of a defecate in the national economy is limited. 152 thousand tons of a defecate as lime deoxidizing materials were shipped for the agricultural organizations of the Republic; the remaining amount (230 thousand tons, or 60% of the production volume) was exported to the quarries and a small part of it was placed near sugar factories. And the issue of defecate utilization becomes complicated every year with an increase in sugar production. Recently across countries, attempts have been made to use a defecate in various technical sectors: in the production of building materials, fertilizers, in the creation of new types of effective sorbents, etc. Taking into account the uniqueness of defecate composition, the important significance is attached to it as a component of the feed for pets and birds. So it can replace a career fodder chalk. The physical and chemical parameters of a defecate in the form, in which it goes out of production, are suited to the requirements of neither mixed fodder nor agricultural enterprises. High humidity (about 30% - 35 %) and polydisperse composition (from a dust to large clods) prevent organizing the processes of dosing a sediment and its uniform mixing in combined fodder. The same parameters prevent organizing the uniform introduction of a filtrational sediment in deoxidized soils by the method of blowing out from tanks that is now applied everywhere when using a fine dolomite flour.

Currently, only a small proportion of a defecate is used in the agricultural sphere for soil mineralization, however, most of it is stored in industrial sites or filtration fields as unclaimed wastes. According to approximate calculations, more than 120 hectares of land are alienated for the storage of a defecate in industrial sites at each plant. When storing a defecate on landfills, environmental pollution occurs.

As it is known, carbon sorbents are widely used for wastewater treatment. However, they have a number of disadvantages: the need for regeneration and utilization, high cost, the unsustainable use of natural resources (deforestation).

The carbon-containing sorbent obtained from a defecate, of course, may have lower sorption properties compared to generally recognized carbon sorbents. However, despite this, its production and use has a number of advantages: low cost, the conservation of natural resources, no need to regenerate the spent defecate (Gregersen *et al.*, 1999).

Materials and methods

The object of research is a technical colza in the process of growth on heavy metal contaminated soils with the introduction of heat treated sugar beet production defecate as a sorbent. When taken for the analysis, the soil and plants have been brought to an air-dry state. The samples have been crushed and sieved through a sieve with a cell size of 1 mm. The particles, which have not passed through a sieve, have been again ground in a mortar and sieved. The obtained samples have been studied by the method of X-ray fluorescence analysis (XRF). This is one of the many modern physical and chemical methods of measurement. It is widely used for the qualitative, semi-quantitative and quantitative determination of the elemental composition of substances. The XRF method is based on the measurement of energies (wavelengths in wave dispersion spectrometers) and the intensities of spectral lines emitted during secondary X-ray emission. A permissible error is up to 30 %.

The level of the chemical contamination of soil compositions has been found by comparing the content of the gross forms of chemical elements in the contaminated soil with the established in the Republic of Belarus maximum permissible and approximately permissible concentrations (MPC and APC, respectively) (Petukhova and Kuznetsov, 1992).

We have calculated the coefficient of biological accumulation (CBA), which has allowed characterizing the migration ability of heavy metals in the "soil-plant" system at the cultivation of a technical colza on the soils with the introduction of a defecate.

Results and Discussion

Table 1 shows the comparison of the gross concentrations of metals in the colza phytomass, which has been grown during a bench experiment, with their normal content and MPC levels.

Table 1. Concentrations of metals in a colza phytomass in different soil compositions

mg/kg

Element	Soil + solution of cadmium and lead salts	Soil + solution of cadmium and lead salts + heat treated defecate	Normal content (of air and dry mass, mg/kg)	MPC (of air and dry mass, mg/kg)
	Leaf	Leaf		
As	0.44 ± 0.19	trace quantities	0.1-0.5	5.0-20.0
Cd	0.60 ± 0.12	0.62 ± 0.11	0.05-0.2	5.0-10.0
Co	1.84 ± 0.57	18.26 ± 1.62	0.01-0.30	10.0-20.0
Cu	211.57 ± 7.39	74.95 ± 4.13	6.0-15.0	15.0-20.0
Mn	65.72± 5.04	52.02 ± 4.22	15-150	300
Fe	478.41 ± 10.15	557.25 ± 14.78	20-300	750
Pb	18.80 ± 1.88	3.31 ± 0.74	0.1-5.0	10.0-20.0
Sn	1.52 ± 0.31	1.25 ± 0.43	0.2-1.9	1.9
Ti	trace quantities	12.91 ± 4.93	0.15-80	20.0-30.0
Zn	39.95 ± 2.34	31.01 ± 1.94	15-150	150.0-200.0
Zr	7.69 ± 0.57	19.93 ± 0.87	0.06-12	-

The intensity parameter of the biological absorption of elements by vegetation – coefficient of biological accumulation (CBA) – has been calculated, which has allowed characterizing the migration ability of heavy metals in the "soil-plant" system. CBA has been calculated on the basis of data on the gross content of elements in soils and a plant phytomass (Ilyin, 1991)

The coefficient of biological accumulation has been calculated according to the formula

$$CBA = C_{p/} C_{п}$$

where C_p - the concentration of an element in a plant;

$C_п$ - the gross content of an element in the soil.

The value of biological accumulation has been determined according to the gradation (table 2) proposed by A. I. Perelman (Perelman, 1975).

Table 2. Scale of the intensity of element accumulation by the value of CBA (Perelman and Kasimov, 1999)

Value of biological accumulation	Value of CBA
Vigorous accumulation	10–100
Strong accumulation	1–10
Weak accumulation or medium capture	0.1–1.0
Weak capture	0.01–0.1
Very weak capture	0.001–0.01

The CBA of metals for the biomass of a technical colza, when growing in the contaminated soils without sorbents and soils with the application of a defecate, are presented in table 3.

Table 3. Coefficient of biological accumulation of metals in the colza phytomass grown in different soil compositions

Element	Soil + solution of cadmium and lead salts	Soil + solution of cadmium and lead salts + heat treated defecate
	CBA	CBA
As	0.595	0.000
Cd	0.021	0.069
Co	0.034	2.024
Cu	2.813	2.679
Mn	0.165	0.076
Fe	0.049	0.050
Pb	0.523	0.024
Sn	0.025	0.125
Zn	0.889	1.164
Zr	0.037	0.087

According to the data obtained, the series of the biological absorption of metals by a colza phytomass have been constructed.

Soil composition soil + solution of cadmium and lead salts:

Cu (2.813) > Zn (0.889) > As (0.595) > Pb (0.523) > Mn (0.165) > Fe (0.049) > Zr (0.037) > Co (0.034) > Sn (0.025) > Cd (0.021).

Vigorously accumulated metals in the phytomass of colza grown on the contaminated soil without sorbents have not been revealed. Copper accumulates strongly. The elements of a medium capture are as follows: zinc, arsenic, lead, and manganese. The elements of a weak capture are as follows: iron, zirconium, cobalt, tin, and cadmium.

Soil composition soil + solution of cadmium and lead salts + heat treated defecate:

– colza phytomass Cu (2.679) > Co (2.024) >Zn (1.164) > Sn (0.125) > Zr (0.087) > Mn (0.076) > Cd (to 0.069) > Fe (0.050) > Pb (0.024).

Vigorously accumulated metals in the phytomass of colza grown on the contaminated soil with the introduction of a defecate have not been revealed. Copper, cobalt, and zinc accumulate strongly. The element of a medium capture is tin. The elements of a weak capture are as follows: zirconium, manganese, cadmium, iron, and lead.

Thus, when introducing the heat treated defecate of sugar beet production as a sorbent to soil, the intensity of the accumulation of arsenic, copper, manganese, and lead decreases in a technical colza phytomass.

Conclusion

The application of the XRF method is promising in the solution of environmental safety issues. A sorbent on the basis of heat treated sugar beet production defecate permits reducing the intensity of arsenic, copper, manganese, and lead accumulation in a technical colza phytomass.

Consequently, the production of a sorption material from the calcinated defecate is characterized by a number of positive factors:

- decrease in the amount of a large-capacity waste – defecate;
- reduction of the areas of the fertile soil, applied for defecate storage;
- improvement of sanitary and epidemiological indicators of soils in the areas of sugar factories;

- social effect: improvement of the living conditions of the population due to the reduction of an anthropogenic impact on the environment.

Research in this direction is continuing.

ENVIRONMENT PROTECTION AND NATURAL RESOURCES MANAGEMENT

THE AGRO-ECOLOGICAL PRESERVATION OF APRICOT VARIETIES BY THE BIOLOGICAL CURTAINS IN THE BOUKHMISSA AREA, HODNA PLAIN (M'SILA), ALGERIA

Abstract

The varietal potential of the apricot in the agricultural area of Boukhmissa in the arid Hodna plain north of the town of M'sila has five varieties. This plant genetic resource contributes economically, socially and ecologically to the region. The overall protection of this potential is imperative and the biological curtains as an indirect protection is more than necessary. The biological curtains (windbreezes) installed for agronomic and environmental reasons. It consists of one or more rows of trees. The Boukhmissa (M'sila) perimeter, where the fruit plantation with apricot tree is the most important speculation, illustrates this practice well. A diagnosis of the situation in 29 study stations showed that the biological curtains in this area were installed in a subjective and anarchic way within the apricot orchards, the five most replicated varieties in the study area are: Red Louzi, Bullida, Paviot, Tounsi and Polonais. The results obtained at the end of this study are: -The use of conifers is dominant in more than 62% of study stations. -The biological curtains have a relatively young age (less than 20 years), which shows that this agroforestry protection system in this area is recent. - The low porosity of the system (28%) due to the relatively high planting density. -With respect to the height of the wind breezes of our stations, and given the relatively young age in most stations, the height is less than 10 m. - Most of the stations have small biological curtains, which are to say less than 3 meters, is more than 86% of the study stations, because of their composition of a single row of plant species Protection. In order to better exploit the biological curtains (wind breezes), an optimal height of protection, a porosity of 40 to 50%, A minimum width of 03 meters, an orientation perpendicular to the direction of the winds and finally a choice of fast growing, long-lived and multi-use species.

Keywords: *Biological curtains, Diagnosis, Varietal potential, Apricot, Boukhmissa*.

Introduction

Hedgerows and windbreaks have long demonstrated their effectiveness and are effective tools for improving the quality of the environment. Indeed, these structures reduce erosion and soil loss, increase biodiversity, promote better use of mineral elements and water in the soil. However, producers often perceive the establishment of such agroforestry systems as a loss of space, production and consequently a loss of income (Lebel and Deroy, 2007).

Scientific studies have shown that when windbreak trees are well chosen, well located and well maintained, agricultural and forest production increases, biodiversity, landscape quality and living conditions improve, water pollution, soils and air decreases (Labant, 2009). Due to its complex structure, the hedge offers ecological niches and shelters especially during the winter, it is also a relatively undisturbed environment (INRA, 2009).

In Algeria the protection of crops against the wind is indeed all the more necessary as climatic conditions are less favorable to agriculture, such is the case in coastal regions, plateaus and steppe areas (Greco, 1966). The practice of installing shelterbelts in agriculture is relatively recent in Algeria. The area of M'sila, by its agricultural perimeters, offers good examples, in

this case the perimeter of Boukhmissa which justifies this practice especially that it is a perimeter of fruit arboriculture by excellence.
The general objective of this study is a diagnosis of the importance of windbreaks among small agricultural producers of apricot orchards in the area of Boukhmissa (M'sila in Algeria) on the one hand and to see the prospects of rational use windbreaks by farmers in Boukmissa. In our study on wind breezes in this area, where the average size of the farms is relatively small, we first try to establish a statement on these protective and promising elements and secondly to identify the optimal, real and possible prospects in this place.

Materials and Methods

The study area is located in the region of Boukhmissa, it is an agricultural area located north of the town of M'sila in Algeria, its area is 4500 ha (Brahimi, 1992).
The direct observation aimed to identify and characterize agricultural stations or plots with respect to windbreaks: the type of windbreak, its location and the species that compose it. At the end of this inventory, we were able to identify twenty-nine (29) stations throughout the Boukhmissa perimeter. The research was conducted in 2012, The data on the stations and windbreaks used were collected according to a previously established questionnaire, for the owners of the plots, the respondents were the farmers themselves This survey questionnaire aims to collect quantitative and qualitative data on study stations and windbreaks used. Station data: Geographic position (Altitude, latitude, longitude), Exposure, Plot position in relation to River of K'sob (East or West shore), Plot size (m^2), Culture in place (Perennial or annual).
Data on windbreaks used: Type of windbreak (live or inert), Windbreak used (coniferous, hardwood), exposure (orientation of windbreak against wind), age (Young, adult or old), height (high and low), width (thick and thin), length (long and short) and the porosity of the windbreaks (low, medium and high).

Results and Discussion

1-Area

The study stations have variable areas, their classification according to this parameter is indicated in Table 1.

Table 1. Variation of the surface of the study stations.

Area (m^2)		Less than 5000	5000 and over	Total
Stations	Number	20	09	29
	%	68.96	31.04	100

The majority of the studied stations have surface areas lower than 5000 m^2 that is about 69 % of the total of the stations of study. This state shows that the studied stations are small parcels of land in the form of fruit orchard according to the dominant speculation of the zone and which is the fruit growing, in particular the apricot tree as pointed out (Bahlouli*et al.*, 2009). In all stations, one station has an area of 15,000 m^2 and three other stations have 10,000 m^2 each.

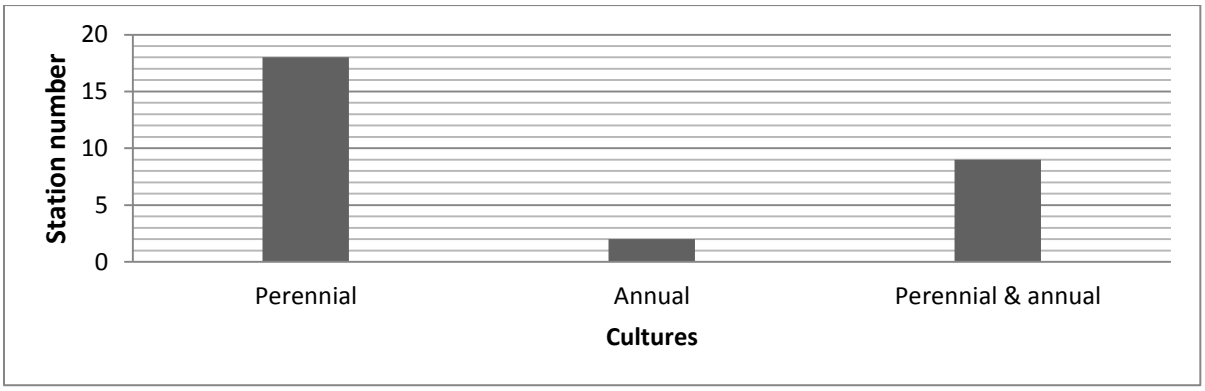
2- Cultures in place

The cultures in place testify to the vocation of the plots (Table 2). Preference is given to perennial crops, with more than 62% of the total number of study stations (Figure 1). These crops adapt to the environment on the one hand and have fairly substantial income for farmers on the other.

Table 2. Cultures in Place of Study Stations

Culture in place		Perennial	Annual	Perennial + annual	Total
Stations	Number	18	02	09	29
	%	62.07	06.89	31.04	100

According to the statistical data of the agricultural services of the area, the most cultivated fruit species are in order of importance: apricot, olive, pomegranate, pear and fig. Apricot has a percentage of 71.75% compared to other perennial species (D.S.A, 2018). For annual crops, there are cereals (wheat, barley, fodder) and market garden crops (onions, garlic, turnips, etc.). As for the other stations, they present mixtures between perennial culture is annual culture.Figure 1.Variation of cultures in place according to the stations.



3- Type of windbreak used

Farmers in the Boukhmissa perimeter use windbreaks to protect their crops. These windbreaks can be either alive or dead (remnants of the size of fruit trees, dead trees, banchages cuts of spontaneous woody species ...). According to this type of windbreak used, the stations surveyed were classified as indicated in Table 3.

Table 3.Number of stations according to the type of windbreak.

Nature of the Windbreak		Alive	Death	Total
Stations	Number	27	2	29
	%	93.10	6.90	100

In the study area, more than 93% of the stations recorded (27 stations), are protected by live windbreaks whether they are woody species such as: Cypress, Aleppo Pine, Casuarina, Atriplex, Tamarix ... or non-woody species such as reed. These types of windbreaks are more effective for crop protection because they create microclimates. For dead windbreaks their use is very low less than 7% of the total windbreaks used. They are used as a barrier for orchards or crop plots against intruders. It is obvious that the use of dead wood causes outbreaks of insects and cryptogams that can cause disease and indirectly disrupt the fall in crop yields.

4- Windbreak species used

The stations were classified according to the species used as windbreaks (Table 4).

Table 4.Number of stations according to windbreak species used.

Windbreak species		Softwoods	Hardwood	Reeds	Total
Stations	Number	17	08	02	27
	%	62,96	29,63	07,41	100

Most stations (17 stations) use softwood species as windbreaks, more than 62% of the total stations. These woody species are evergreen and this is what farmers prefer most for summer and/or winter protection of their plots. The most commonly used species in conifers is the green cypress (Cupressus sempervirens), which is characterized by its longevity, persistent foliage and prominent habit (Photograph 1).

Photo 1. The types of windbreak used in Boukhmissa.

Softwood (Cypress green)-Hardwood (Atriplex)-Reed (Egyptian cane)-Hardwood (Casuarina)

(Zedam A., 2012)

Photo 1. The types of windbreak used in Boukhmissa.

Hardwoods in 08 stations represent 29.63% of the total number. Among the hardwoods used: Atriplex, Myoporum, Acacia cyanophylla, Eucalyptus and Casuarina, which remains the most used. The reed is a grass grass and perennial grass is only present in 02 stations with a percentage of 07.41% of the total recorded.

5- Age of windbreaks used

Depending on the age of windbreak species, a classification could be made only in the live windbreaks (Table 5).

Table 5. Age of windbreaks used

Age (years)		less than 20	20 to 40	40 and over	Total
Stations	Number	14	09	04	27
	%	51.85	32.80	14.81	100

The study stations with the youngest windbreaks are 14 stations or 51.85% of the total, which shows that they are relatively young plantations compared to others and where it has become a practice for the protection of apricot orchards. As for the oldest stations, they are limited to the number of 04 stations or less than 15% of the total.

6- Porosity

6-1- Porosity of the study stations

Table 6. Variation of the porosity of study stations in Boukhmissa.

Porosity class (%)		< 40	40 to 60	>60	Total
Stations	Number	18	09	02	29
	%	62.07	31.03	06.89	100

The majority of low porosity sites dominate the agricultural area of Boukhmissa. Indeed more than 62% of the study stations have this low porosity. According to Vezina (2001), the porosity of a windbreak is effective and is obtained with a porosity close to 40% which corresponds to a moderately dense windbreak. This percentage is present in 31% of the stations surveyed.

According to I.N.R.F (1994), the effectiveness of the windbreak depends mainly on its permeability (porosity).-A windbreak must not be an insurmountable wall; because it

generates swirling phenomena that are very detrimental to crops.- A semi-permeable windbreak (porosity of 40 to 50%) is widely recommended.

6-2- Porosity of the type of species used

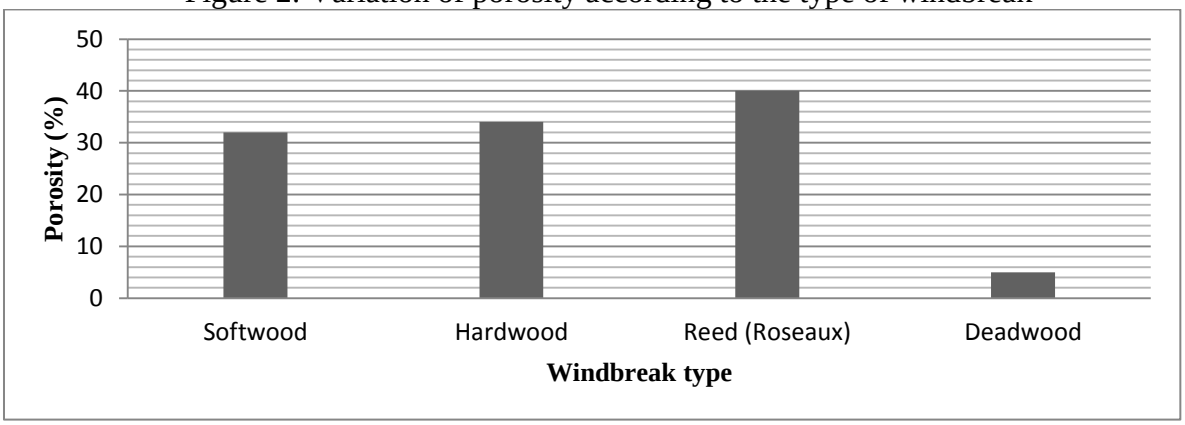
The porosity varies according to the types of windbreaks used where their porosity exceeds 30% whether they are coniferous, deciduous or reeds (Table 7).

Table 7: Porosity of types of windbreak used.

Windbreak used	Softwood	Hardwood	Reed (Roseaux)	Deadwood
Porosity (%)	32	34	40	05

According to Figure 2, the porosity of the planted windbreaks is higher than the dead wood windbreaks which are crammed on the ground, of limited height and sources of disease. For the planted windbreaks, there is a variation according to the species used in a decreasing way "Reed-Hardwood-Softwoods".

Figure 2: Variation of porosity according to the type of windbreak



7- Height

7-1- Height of the study stations

(Parde and Bouchon, 1988) classify trees according to their height in three sizes: first size (> 20m), second size (10 to 20m) and third size (<10m).

Table 8.Number of stations according to the height of windbreaks.

Height class (m)		Less than 10	10-20	Greater than 20	Total
Stations	Number	13	12	04	29
	%	44.83	41.38	13.79	100

The variation in the height of the windbreaks in the study stations shows that a fairly large number of stations have relatively low heights (<10m) where the percentage of these stations is greater than 44%, (Photograph 2).

This can be explained by: - Windbreak plantations are relatively young.

-Non woody species (Reed) and low perennial species such as Atriplex or Myoporrum.

Trees of first magnitude | Trees of second magnitude | Trees of third size

(Zedam A., 2012)

Photo 2.The three types of height of wind breezes observed in Boukhmissa.

7-2- Height of the type of windbreak used

The height of the wind breezes used varies differently (Table 9).

Table 9.Variation of the height according to the types of wind breezes.

Windbreak used		Softwood	Hardwood	Reeds	Deadwood	Total
Stations	Average height (m)	14.37m	5.6m	2.5m	2m	/
	Number	17	08	02	02	29
	%	58.63	27.59	6.89	6.89	100

It is observed that the height of softwoods is the largest with an average of 14.37 m against the other three types where their heights do not exceed 5.60 m. This highly variable difference can be justified by the fact that conifers such as green cypresses are prime trees, unlike deciduous trees such as casuarina, Eucalyptus and acacia or shrubs such as Atriplex, Tamarix and Myoporum. (Figure 3).

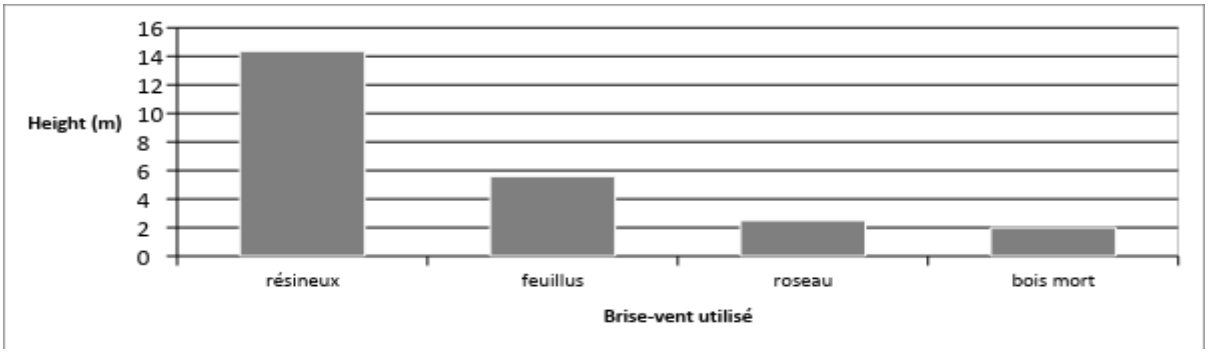


Figure 3.Variation of the height of the windbreaks used.

7-3- Height according to the culture in place

In Table 10 there is a classification of the stations according to the culture in place and the height of the windbreaks.

Table 10.Average height of windbreaks according to crops in place.

Culture in place		Perennial	Annual	Mix	Total
Stations	Average height (m)	11.3	6.5	12.55	/
	Number	18	02	09	29
	%	62.07	06.89	31.04	100

By direct observation on the ground, we notice that most orchards are composed of a single row of windbreaks. According to (Vezina 2001), a row of windbreaks requires less maintenance and takes up less space.

8- Width

(Fortin *et al*., 1999) classify windbreaks by width into: Windbreak at low width (<3m). Windbreak at medium width is effective (3m to 10m). According to this classification, our study stations were classified as follows:

Table 11.Number of stations according to windbreak width.

Windbreak width		< 3m	from 3m to 10m	Total
Stations	Number	25	04	29
	%	86.21	13.79	100

More than 86% of the windbreak width of our stations is not effective. If the thickness of the windbreak increases its permeability decreases but the thickness of the medium width windbreak (3m to 10m) is effective.**9- Length**

The larger the parameter, the more important it is. The ratio of windbreak length to height must be at least 11.5 (Nageli 1953 in Guyot 1989, I.N.R.F 1994 and Vezina 2001). It is a practice in the study area that serves more parcel boundaries or along irrigation canals than for the actual protection of crops. Our stations have been classified according to the length of their shelterbelt (Table 12).

Table 12.Length of the station windbreaks.

Windbreak length	Less than 100m	Greater than or equal to 100m	Total
Number of stations	11	18	29
Percentage (%)	37.93	62.07	100

Stations with a windbreak length greater than or equal to 100m account for more than 62% of the total stations.

10- Orientation

This is the essential factor to consider when setting up a windbreak network. The orientation of the windbreak must be perpendicular to prevailing winds (Nageli 1953 in Guyot 1989, I.N.R.F 1994, Vezina 2001 and Fortin *et al*., 1999). The different orientations of the windbreaks of the study stations are illustrated in groups in Table 13.

Table 13.Number of stations according to the orientation of wind breezes.

Wind Breeze Orientation		North	East	West	North / East	East / South	North / West	South / West	East / West
		A	B	C	D	E	F	G	H
Stations	Number	2	3	4	4	3	4	2	4
	%	6.89	10.34	13.79	13.79	10.34	13.79	6.89	13.79

We noted that 10.34% of stations have windbreaks installed in all four directions. Indeed only two orientations can be justified. It is the directions perpendicular to:
-South -South-East: it is the Siroco, which is a southerly wind or Chehili which causes the drying up of the cultures increases the evaporation and the rise of the temperatures.
- North-North-West: Bahri is a north wind that lowers temperatures and increases the risk of frost. The orientations observed in the study stations of Boukhmissa is concerning these two orientations account respectively 12.92% and 23.26% of the total of the stations. They were installed subjectively and anarchically.

Conclusion

At the end of this work, it is interesting to underline that the objective of our study is first of all on the diagnosis of windbreaks in the agricultural area of Boukhmissa and secondly the release of optimal and real prospects in this environment and this for a good crop protection in place and increased yields. To do this, we conducted a subjective sampling of 29 study stations. The results obtained were analyzed and resulted in the following:
- The majority of the stations (more than 68%) have surface areas of less than 5000m² with a dominance of fruit growing on more than 62% of them and where 27 study stations use breezes live alive.
- The use of coniferous species is dominant in more than 62% of the study stations.
- In general, the windbreaks surveyed are relatively young (less than 20 years old), which proves that the installation of this agro-forestry protection system in this area is recent.
- Overall, the study area has a low porosity with more than 62% because of the relatively high density of planting windbreaks but as for the species used, they have: 32% for conifers, 34% for hardwoods, 40% for reed and only 5% for deadwood.
- Regarding the height of the windbreaks of our stations, and given the relatively young age (20 years old) for most stations, the height is less than 10m where more than 44% of the stations testifies it. For this parameter it is obviously the conifers who hold the most important height. According to the speculation practiced, perennial crops have relatively high windbreaks compared to annual crops, which is justified by the need to protect perennial crops which are the most sensitive to certain types of accidents in the absence of agroforestry systems protection.
- Most of the stations have windbreaks of small width, less than 3 meters, is more than 86% of the study stations, due to their composition of a single row of protective plant species.
- The length of the windbreaks stations seems rather important but this is not sign of plots of large area where this length seems to be justified by its installation much more like boundaries of plots or along the canals and irrigation channels for the actual protection of crops.
- The direction or orientation of the windbreaks observed in Boukhmissa, is concerning these two orientations respectively account for 12.92 % and 23.26 % of the total of the stations. They were installed subjectively and anarchically.
- Choose native species, fast growing, if possible with taproot especially for the case of Boukhmissa which is an irrigated area. A windbreak can only perform its function if it is established according to a judicious plan and is constantly maintained in an optimal state.

As perspectives, for a better exploitation of windbreaks, we have made the following propositions concerning these agroforestry structures:
-A perennial species height of at least 10 m. -A porosity of 40 to 50%.
-Width of 03 meters with spacing between trees from 01 to 02 meters.
-The length must be total to ensure the protection of the parcels.
-The recommended guideline is the installation of tree curtains in the four directions of each plot to ensure better protection and creation of microclimate. If the prevailing winds are decisive, we will proceed with the installation of tree lines perpendicular to their direction.
-Finally, the choice of windbreak species will focus on those adapted to the environment, fast-growing, long-lived and presenting a multi-use.

Abstract

The black bellied sandgrouse (*Pterocles orientalis*, L. 1758) appears to be one of the most adapted species to extreme conditions of arid regions. However, implementing actions to promote in situ conservation based on understanding the behavioral ecology of the black bellied sandgrouse populations. this study was conducted in the south east of Algeria between 2014 and 2015, we sampled water from 20 watering sites of the black bellied sandgrouse, and we conducted water tests on the following parameters: the hydrogen potential pH, conductivity (EC) and the rate of: potassium (K), sodium (Na), copper (Cu) and zinc (Zn). The results show that the variation in pH between 6.17 and 7.61 with an average of 7.19 ± 0.3 (n = 20), while the EC varies between 0.18 and 24.2 mS / cm with an average of 3.73 ± 6.89 mS / cm. Our results show that the concentrations of potassium varies between 1.27 and 93.92 ppm, with an average of 18.61 ± 24.22 ppm, while the changes in sodium concentrations is between 0.13 and 3799.73 ppm, with an average of 668.72 ± 1023.06 ppm . the concentrations of copper vary between 0.12 and 0.24 ppm, with an average of 0.19 ± 0.03 ppm, while the variations in concentrations of zinc is between 0.86 and 1.68 ppm, with an average of 1.31 ± 0.21 ppm. The black bellied sandgrouse uses has no preference, it drinks readily available water, whether fresh or brackish.

Keywords: *black bellied sandgrouse, drinking behavior, salinity, heavy metals, south east of Algeria.*

Introduction

The black bellied sandgrouse (*Pterocles orientalis*, L. 1758) appears to be one of the most adapted species to extreme conditions of arid regions (Thomas and Maclean, 1981; Thomas, 1984; Maclean, 1984, 1985, 1996; Mourer-chauvire, 1993; De Juana, 1998). According to Hüe and Etchécopar (1957), the black bellied sandgrouse frequent daily the watering site. Hence, understanding sandgrouse drinking regime and regularly used water holes is of great conservation importance (Reuven and Piotr, 2011). In arid region birds, this aspect is particularly important because the fixed elements of the landscape are limited mainly to oases, Dayas, chotts and some water points, which is far from negligible. In the region of Biskra, the diversity of landscapes and water resources are important for the metapopulation of Ziban (Farhi and Bellhamra, 2015). Water consumption is increasing. The potential demand is estimated at 150 liters per capita per day. 97% of the water resources in Biskra are underground. This trend can be explained by the fact that urbanization took a large scale in Biskra (twice as much as the old urban fabric). In addition, the population has more than doubled in 20 years. The amazing enthusiasm for agriculture sometimes pioneering spirit that has more than 1.2 million new palm trees were planted. Gardening in plastic greenhouses, doubled and probably will quadruple by 2030 (Gaouar, 2003). The intensive exploitation of land and water could accelerate fragmentation phenomena. In order to lay the foundations for the sustainability of the farming anthropozoic systems, in competition and to improve the ecological connectivity of these sensitive habitats, frequented by a rich and diversified avifauna, it is more than necessary at first to worry about the quality water in watering sites frequented by arid birds. Therefore, in this work, the questioning is how to implement a

reference database on the abilities of the black bellied sandgrouse to use the available waters of different origins.

Material and Methods

This study was conducted in the region of Biskra (34 ° 48 '00 "North and 5 ° 44' 00" East), it is located about 470 km southeast of the capital Algiers, at an average altitude of 125 m and covers an area of approximately 21.671 Km² (Farhi, 2001).,water from 20 watering sites of the black bellied sandgrouse was tested, between november 2014 and October 2015, on the following parameters: the hydrogen potential pH, conductivity (EC), respectively by using a pH meter and a conductivity meter, the rate of: potassium (K), sodium (Na), copper (Cu) and zinc, by using the flame photometer.

Results and Discussion

1. Hydrogen potential (pH) and Conductivity (EC) of sampled sites

The results of the hydrogen potential and conductivity measurements show a variation of the pH between 6.17 and 7.61 with an average of 7.19 ± 0.3 (n = 20), these results show that the samples studied have a pH that is close to neutral. However, the electrical conductivity EC varies between 0.18 and 24.2 ms / cm with an average of 3.73 ± 6.89 ms / cm (n = 20). (figure1)

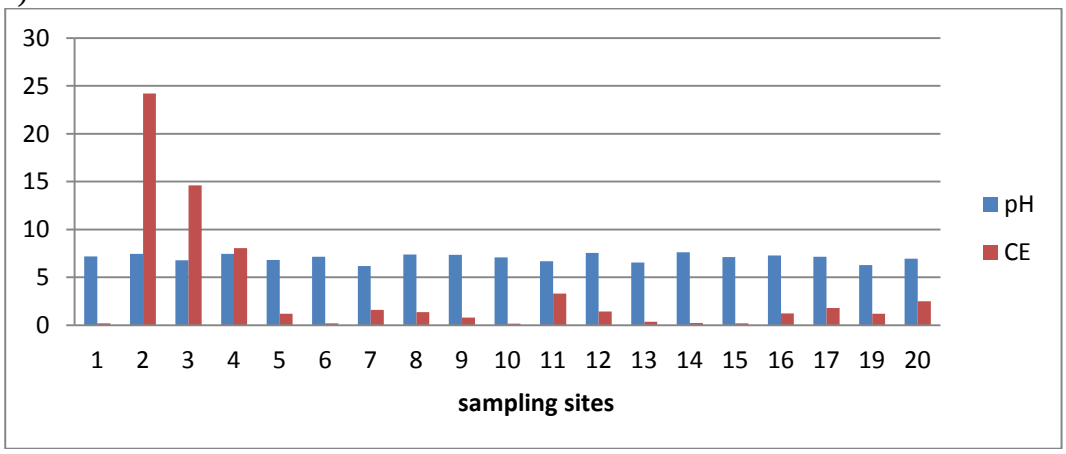

Figure 1: pH and Electrical Conductivity (EC) of Sampled Water

The WHO (2004) standards for pH range from 6.5 to 8.5. Ferns and Hinsley (1995) have shown that the water pH of the watering sites frequented by the black bellied sandgrouse and the pin-tailed sandgrouse in Spain (n = 8) is equal to 7.9 ± 0.1. The pH conditions a large number of physicochemical equilibrium and depends on multiple factors, including the origin of water, agricultural inputs, releases from agglomerations and industries (Tamrabet, 2011). According to Khoul and Touhami (2014) The classification of water as a function of conductivity is as follows: Conductivity equal to 0.05µS / cm: demineralized water; Conductivity from 10 to 80µS / cm: rainwater; Conductivity 80 to 100 µS / cm: low mineralized water Conductivity 300 to 500 µS / cm: moderately mineralized water; Conductivity 1000 to 3000 µS / cm: saline water; Conductivity greater than 3000 µS / cm: sea water. The EC values of our samples are between 1.8us / cm and 242us / cm. This shows that the sampled waters fall into two classes: rainwater and slightly mineralized water (domestic, industrial, and agricultural water). According to Bartholomew and Cade (1963), the role of salt water in the water economy by birds has long intrigued ornithologists, but so far there are only random observations and conclusions drawn from distribution data. However, an examination of the electrolyte metabolism is of particular interest in a survey of land bird water economics. On the one hand, it offers powerful help in understanding the mechanisms

of renal function, and, on the other hand, it can contribute to the understanding of the ecology of desert birds that have access to salt springs and ponds temporary and alkaline. Thomas and Robin (1977) suggest that Moroccan sandgrouse species lack nasal salt glands and appear to be suitable for salt and water conservation. Maclean (1968) noted that the Namaqua Sandgrouse and Burchell's Sandgrouse attend saline springs to drink

2. Concentration of potassium (K) and sodium (Na) at sampled sites

Our results show that potassium (K) concentrations vary between 1.27 and 93.92 ppm, with an average of 18.61 ± 24.22 ppm (n = 20), while the variations of sodium (Na) concentrations are between 0.13 and 3799.73 ppm, with an average of 668.72 ± 1023.06 ppm (n = 20) (figure 2 and 3).

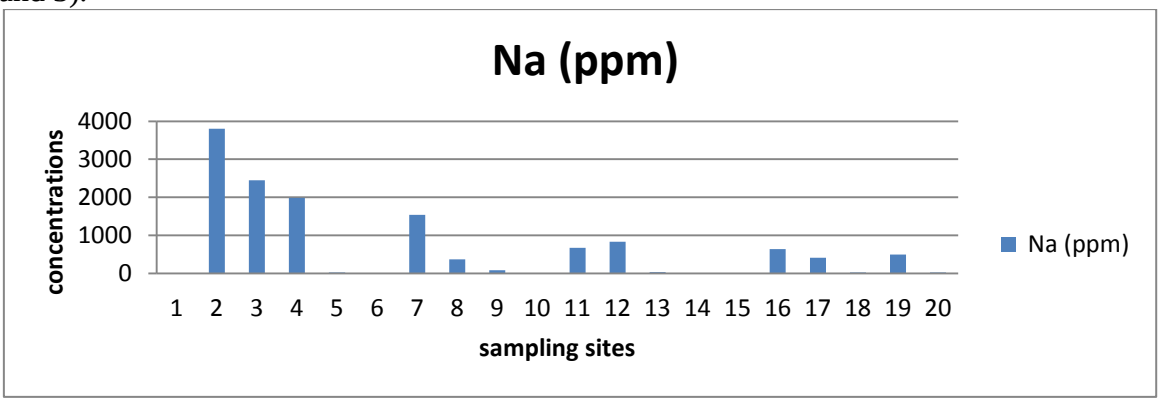

Figure 2: sodium (Na) concentrations of sampled sites

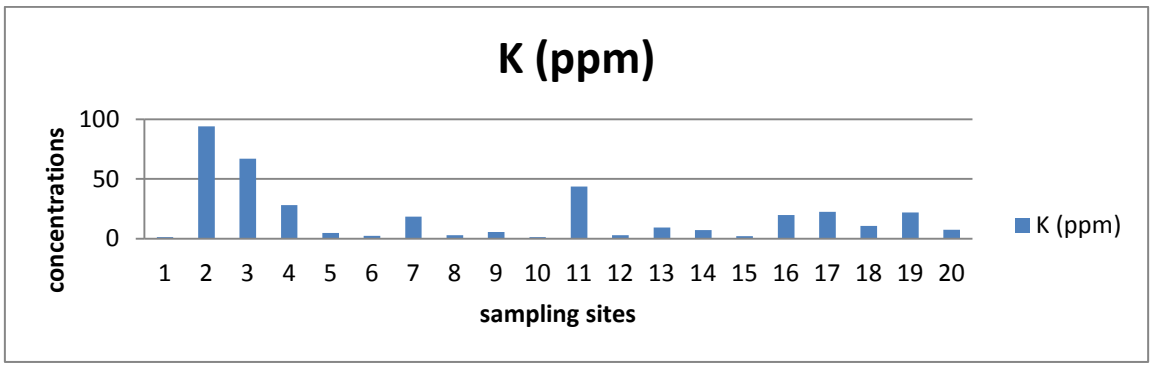

Figure 3: potassium (K) concentrations of sampled sites

In arid regions, not only can water resources be limited, but also saline and / or sodic Thomas and Robin (1977). In the steppes of Morocco, Thomas and Robin (1977) reveal that the concentration of potassium (K) is equal to 10.53 ppm, and the concentration of sodium (Na) is 67.39 ppm in the water of watering sites frequented by the black bellied sandgrouse and the Pin-tailed sandgrouse (n = 1). According to Hinsley (1992) and Ferns and Hinsley (1995), the mean concentration of sodium (Na) in drinking water used by the black bellied sandgrouse and the Pin-tailed sandgrouse in Spain (n = 8) is 120 ± 20 ppm. According to WHO (2003) Sodium ion is ubiquitous in water. Most water supplies contain less than 20 mg of sodium per liter, but in some countries levels may exceed 250 ppm. Saltwater intrusion, mineral deposits, sewage effluents, and salt used in road de-icing can contribute significant amounts of sodium to the water. In addition, water treatment chemicals, such as sodium fluoride, sodium bicarbonate, sodium hypochlorite, together, can cause sodium levels as high as 30 ppm. Domestic water softeners can give levels above 300 ppm. Potassium, much less abundant than sodium, and rarely present in water at levels above 20 mg / l. It does not represent any particular disadvantage although the K one of the possible sources of radioactivity in water (Potelon and Zyman, 1998)

3. Concentration of copper (Cu) and zinc (Zn) at sampled sites

Our results show that copper (Cu) concentrations vary between 0.12 and 0.24 ppm, with an average of 0.19 ± 0.03 ppm (n = 20), while variations in zinc (Zn) concentrations are between 0.86 and 1.68 ppm, with an average of 1.31 ± 0.21 ppm (n = 20)(Figure 4).

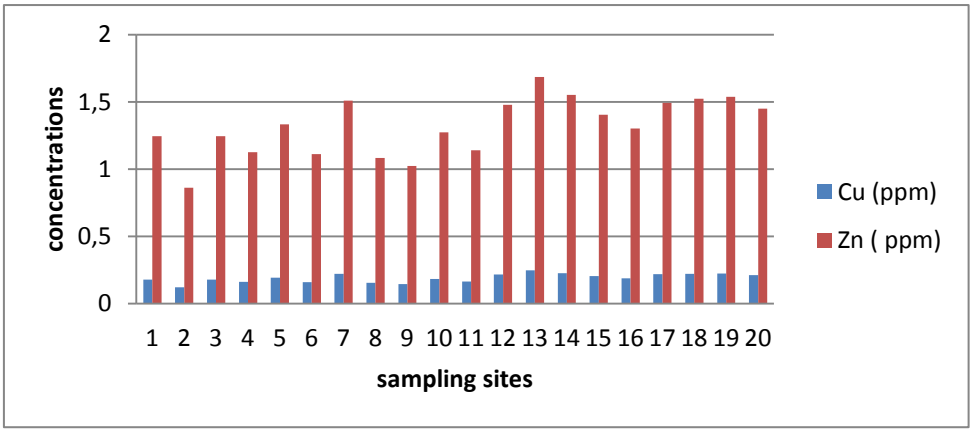

Figure 4: copper (Cu) and zinc (Zn) concentrations of the sampled sites

Loué (1993), suggest that these concentrations are well below the toxicity thresholds recommended for these two heavy metals (2 ppm for each element). However the copper concentration is higher than the norms of WHO (2000) which is of 0.05 ppm, as for the zinc it presents a value lower than norms of WHO which is of 5ppm. According to Nirel and Pasquini (2010), there are two main sources of copper pollution in water: an urban source and an agricultural source. Copper pollution of urban origin is accompanied by pollution in Zn concomitant (roofs, roads ....), which is not the case of copper pollution of agricultural origin. Copper is toxic to animals breeding. The phytotoxicity threshold is reached before that of zootoxicity (Baumont et al, 2004 in Tamrabet, 2011). According to Nys et al (2003), in birds, zinc and copper are physiologically, metabolically and immunologically important, and their toxic levels are much higher than the birds' needs. In captive birds, high doses of Zn may induce a decrease in food consumption that causes a decrease in body weight (Sundaresan et al, 2008)

Conclusion

In the Biskra region, and for several years, agricultural and urban developments as well as climate change have changed the structure of the oasis landscape of the Ziban, which has led to a disequilibrium of anthropozoic pressures, over-exploitation of natural resources and mismanagement of the water resource. The surface waters available for the watering of the birds of the Ziban, including the black bellied sandgrouse, have different origins (rainfall, dams, sewage water (urban, agricultural and industrial) and qualities (physical-chemical parameters). the characterization of the physicochemical quality of this water consumed by the populations of the black bellied sandgrouse, shows that the nature of this water is neutral to slightly acidic and has a wide range of values in terms of salinity and heavy metal content, which makes the black bellied populations, which prove a need for daily watering, subject to numerous physicochemical variations of available surface water.

A SYSTEM OF SENSORS AND ACTUATORS PREVENTING ANIMALS FROM INJURIES DURING THE GRASSLAND HARVESTING

Abstract

During the harvesting process-especially in spring time-animals are in danger of being injured or killed by agricultural machines e.g. mowers cutting and collecting grass. Every year a large number of fawns are killed because their instinct does not allow them to flee from the approaching machines. There are some important reasons to protect fawns: not to contaminate the grass, not to blunt the knives, and last but not least not to kill the very young animals. Several systems for detecting animals in a hayfield are available. They differ in usability, comparativeness, sensor technology, and automation capabilities. Our approach consists of a row of optical sensors mounted in front of a grassland mower. The measuring line corresponds to the total working width of the mower. While the measuring line crosses live animals, they are detected within a time period of 20 ms by means of their certain optical features. The detection signal immediately triggers the hydraulic lifting process of the mower mounted at the tractor. This procedure prevents the injury of the animal up to a tractor speed of 13 km/h. The optical sensor detects the live animal due to its surface reflectance in certain wavelengths. The sensor system also includes an artificial light source to be independent from the ambient light (morning/evening light conditions). Several tests have been carried out in the last few seasons to ensure the reliability of the system.

Keywords: *animal protection, grassland harvesting, optical sensor, hydraulic actuator*.

Introduction

In Central Europe the season of the first cutting of grass and the birth of fawns merge. Fawns are led into the high grassland by their does to hide from small predators so they are hard to see. In addition young fawns do not have a scent. Fawns behavior is lay down - see *Fig. 1 a)* - and wait until their doe appears and being feed-and to not show any reaction to any sound and/or approaching objects. This strategy helps them to survive their first weeks after they are born where they are too slow to flee from predators. However, this instinct also keeps the fawns from fleeing from harvesting machines. Every year approximately 200,000 fawns are killed in Germany and 25,000 in Austria during the harvesting process – see *Fig. 1 b) – [Wagner J.]*.

Fig. 1 – a) Fawn hiding in the grass b) killed fawn by rotating knives of the mower

This injuring and killing shall be avoided: A contamination of the silage with protein can lead to botulism (endangering cows), and to several other deceases. The knives of the harvesting machines will get blunt which leads to a higher energy consumption and a lower quality of the grass. In addition there is a legal obligation for farmers to protect animals during the harvest by law. The following systems are state-of-the-art and are in use to protect fawns:
a) Mowing strategy from the inside to the outside of the meadow. This can easily be performed at no extra cost in time and money. Some wild animals will flee to the outer side of the meadow, but most fawns remain due to their instinct *[Poel, Zehm]*.
b) Setting up scarecrows days before harvesting beside meadows–see *Fig 2 a)*–or at the machines. There are optical (flashing lights), mechanical, and olfactory devices beside meadows which prevent does and/or fawns to enter these areas. Machines are equipped with lines of flashing bars. These devices need to be installed and removed regularly and therefore consuming extra time and money. Their impact is low and they work under sever conditions only *[Schmitt S.] [Green C.]*.
c) Checking the concerning area using hounds and removing the fawns by hand just before the harvest. This is tiring and takes a lot of time. The impact is low because of the effective hiding strategy of fawns.
d) Checking the concerning area using electronic devices before the harvesting process and removing the fawns manually. Several sensor systems are in use: infrared sensors, microwave sensors, ultrasonic devices, GPS-localization. One or a series of sensors is mounted on bars (and carried across the meadow manually–see *Fig. 2 b) [Baumgartner M.]*, by tractor, or by drone–see *Fig. 2 c)*). Found fawns are removed immediately or their GPS-position is captured and handed to the operator to remove the fawn. This method is time consuming and costly. Infrared capturing is available at night/morning only while the ground temperature differs from the body temperature of the fawn *[Schmitt P.] [DLR]*.

Fig. 2 – a) Scarecrows optical/mechanical/olfactory b) manual sensor bars c) sensor on drones

e) Checking the area manually (driver of the mower machine) and stop the machine during the harvesting process. This technique requires the driver to monitor the area ahead of the tractor with full attention and to react quickly enough to prevent an injury. Due to the high operational speed and the large working width this system has a low impact.
f) Checking the area whilst harvesting by means of electronic devices and spare cutting locally. This is our approach and will be described in the following chapter. The system is mounted directly on the mover and needs no addition preparation from the operator during harvesting. There is only need to invest once in sensors and actuators at the mower. The reliability is high. *Fig. 3* shows the complete system attached to the mower.

Fig. 3 – Tractor and mower, with sensor bar attached in front of the mower

Materials and methods

Our approach consists of sensors and actuators on the mowing machine. The system operates online during harvesting process and works for speeds up to 13 km/h. The sensors are mounted about 1.5 m ahead of the knifes. Immediately after detection of a fawn a hydraulic system lifts the mower–see *Fig. 4*. While the tractor (and therefore also the mower) moves further the eventual reached height of the knife prevents the fawn to be touched. There is no interrupt of the harvesting process-no direct stoppage is required. In case of a positive detection of a fawn the operator can remove the animal later on.

Fig. 4 – a) Mower with knife during and b) after the lifting process

Each sensor is equipped with an illumination source and a capturing device. A sensor scans an area with a diameter of smaller than 100 mm at the ground. All sensors are integrated into a special sensor bar which is mounted on the mower about 1200 mm above the ground. To allow a simple handling when the machine is switched to street transport position the sensor bar can be folded. Different near infrared wavelengths are used to detect the fawn and segment against other objects as grass and earth. The sensor works with a sampling rate of 500 Hz. The response time of the connected control unit is about 20 ms and the response time of the hydraulic devices is about 350 ms (which is lifting the knife to about 300 mm above the ground). So the overall response time of the system is largely dependent on the hydraulic lifting process. First tests without artificial illumination showed a significant relation to the ambient light conditions. Consequently in the following tests we integrated an artificial illumination source. It operates with low power in the near infrared spectrum and therefore does not harm eyes of humans and animals.

Results and Discussion

The system passed comprehensive tests under laboratory conditions as well as under real harvesting conditions and has been optimized significantly in the last two years. By means of

models within high grass we developed and proofed the correct sensor reaction. We had enough positive true and nearly no negative false reactions of the system so far for going further: Next season an updated sensor system will be tested in an attempt to increase reliability further and to reduce system costs. One of the actual issues is if too much of high grass obstacles the fawn from above. There is need for a minimum amount of fawn signal getting back to the sensor (reliable signal/noise ratio). We tested different measuring areas per sensor but finally got the optimum with respect to the reliability/economic costly ratio. We know of single other systems than ours in use in Austria and Bavaria by local enthusiasts. But due to the fact that the investment costs are dramatically high and/or the operational costs take money (e.g. about EUR 1000.- per day for lending a drone system) and time prior to the harvesting process (e.g. about 1 h per hectare/10,000 m² meadow) until now the systems failed in essential decrease the killing of fawns. Our system has no operational delay and costs at the harvesting process. There is need in one investment for the sensor bar and the lifting hydraulics. We are on to shorten the investment budget by means of approaching a mass product status.

Conclusion

Seasons of fawn birth and harvesting merge in Central Europe, North America, Australia, and New Zealand. Especially in these regions fawns have to be protected against harvesting machines. Due to their natural instinct of hiding in long grass and staying put when enemies are approaching they are likely to be injured or killed by mowers. For preventing these losses measures have to be taken. Systems for fawn protection are already available on the market. They differ in reliability, investment and operational costs. The shown approach comprises a system of sensors and actuators mounted on mowers. Within our studies and recent tests a high number of positive detections have been achieved. Further developments will lead to reduced investment costs and increased reliability. It shall make the market sensitive for the broad usage of such systems.

A SYSTEM OF OPTICAL/ACOUSTICAL SENSORS/ACTUATORS PREVENTING ACCIDENTS BETWEEN WILD LIFE ANIMALS AND VEHICLES ON ROADS

Kurt NIEL[1*], Roland EXLER[2], Ernst MOSER[3]

Abstract

Roads across free wild landscape pose a permanent danger of accidents in which vehicles collide with wild-life animals. In most cases animals are aware of the sound and visibility of approaching cars. In rare situations, however, either at dawn/sunset or rare traffic, or at specific topologic situations, collisions happen between vehicles and animals. We propose a sensor/actuator system that prevents these collisions by warning animals. This system consists of active electronic components and is operated by solar power. Tests with the previous generation of this device showed a reduction of accidents by 89% and under certain conditions by more than 95%. The system consists of devices that can operate alone or as a group. The device is operated by a microcontroller, it contains optical/acoustic sensors and actuators, a wireless communication facility, and is supported by a power harvesting/storage/control system. One device is 18 cm in height, 9 cm in width and 7 cm in depth, weighs about 400 g and it is mounted on any guide post in the street. One device detects approaching vehicles either by their sound (microphone sensor) or head light (solar cell used as light sensor) and emits a tone of about 4 kHz directing off the street warning the animals. A LED flash light gives an additional optical warning. The tone makes animals observe their environment carefully and keeps them staying several seconds preventing them crossing the street at the same time when a vehicle comes by. A group of nearby devices is connected wireless. They are placed about 30-50 m apart. One can stand in the street and another one 50 m away upwards or downwards remotely from the street for keeping aisles and curved areas safe.

Keywords: *Animal protection, accident prevention, optical sensor, acoustic sensor, energy harvesting*

Introduction

(Nichols A.P. *et al.,* 2014) gives a very broad and fundamental survey of the problem of deer and human behavior at roads, related to the central states of US. There are statistics about size of population with respect to number of accidents, seasonal and hourly occurrences, etc. Their statement corresponds to the observations in Central Europe due to similar landscape and wildlife population (with exceptions). Wild-life animals move for their nutritional support and breeding. They are mostly shy and very sensitive about their surroundings. If they receive an optical or acoustic alarm they stop motion and try to figure out if they are in danger. After a while, which is about 20-30 seconds, they get back from the alarm status and carry on. They know their region and take care about human interaction on places like roads. But they also are aware of timing constraints and make usage of dawn/daylight/night periods. While there is heavy traffic on roads wild-life animals in general avoid these places. But at rare traffic conditions they feel save. If they face a vehicle approaching their instinct allows for an immediate reaction to flee. But this works for vehicle speeds up to approximately 45 mph (70 km/h) on clear areas only. Therefore high speed, rare traffic, winding and/or carved roads or obstacles beside them increases the probability of accidents.

(Meisingset E.I. *et al.*, 2014) checked for deer movement and collisions within a certain area in central Norway 2007-2008. Some of the deer had been equipped with GPS trackers. The 271 detected collisions occurred on major and medium-sized roads only and none at small roads. The identified deer crossings appeared some at main roads, more on medium-sized, but most on small roads. They conclude that speed limits and vegetation clearance had the best impact on avoidance of collisions. (D'Angelo G.J. *et al.*, 2006) evaluated behavior responses of deer to different colors of wildlife warning reflectors. They conclude that these reflectors were ineffective in changing deer behavior such that deer-vehicle collusions might be prevented. Deer reacted accordingly just and short after implementing the reflectors. After theses new situations deer became used to it and ignored the additional light effects. (Riginos C. *et al.*, 2018) tested different road sections in Wyoming, USA, in 2013 and 2014. At each of these sections they compared three different reflector situations: red reflector open, with white and with black canvas. They conclude that the best impact preventing deer crossing ahead a vehicle has white canvas narrow followed by red reflectors. No impact has the black canvas.
Several categories of measures are applied and reduce the amount of accidents by different costs:
a) Inform drivers: warn them at neuralgic sections, aided by speed limits.
b) Control wild-life paths: Erection of secure paths for the animals like tunnels, bridges, corridors, fences, and removal of vegetation from beside road.
c) Warn animals: There are passive (reflective) and active (detection and signaling) devices beside road.
(Huijser M. *et al.*, 2009) developed an in depth cost-benefit analysis of measures for mitigating animal- vehicle collisions. They concentrate on category a) driver warning systems and b) costly road works (bridges, tunnels, fences). Their evaluation relays on the situation in North America and Canada and takes a lot of local statistical data into consideration. (Valitzski S.A. *et al.*, 2009) tested reaction of deer to different sound imissions (frequency, level) originated on approaching vehicles. They conclude, that pure vehicle based whistlers will have nearly no effect in changing the deer behavior. They generally concluded with a weak impact of sound systems, but at the same time they state if the transmitting system is ahead the vehicle and nearby the deer probably there would be a positive reaction.
Within this paper we present a system of advanced sensor/actor modules for warning animals on behalf of appearing vehicles on the road. We designed and built a series of sensors, equipped several desired road sections with them and checked for the accident statistic. These devices are installed on posts besides the road and ahead of shoulders. Regarding the given references they do their signaling nearby the approaching deer with optical (visible light) and acoustical (4 kHz) actuators. This alarm signals are short pulses followed several seconds of pause for not inuring deer too much.

Materials and methods

The system consists of sensors, actuators and communication facilities. It is mounted on guide posts in a series beside the road – see *Fig. 1*. The main objectives of each single device are:

- Detect approaching vehicles by their sound and head light
- Send a single acoustic and optical alarm periodically every 15 seconds while there are vehicles
- Communicate wireless with nearby (30-50 m) devices for handing them the vehicle detection information in advance.

The device is equipped with solar cells and can operate even at low energy input in winter seasons at shadow places. The solar cell additionally works as a brightness sensor detecting the head light of vehicles. A microphone detects the sound. As animals shall be warned a speaker (the microphone works as a speaker as well) sends a 4 kHz tone for 500 ms and a

LED flashes. A transmitter/receiver establishes the wireless communication with nearby devices. A microcontroller operates all sensors and actuators of one device. Low power consumption is achieved by implementing several activation levels/slots depending on daylight/dawn/night conditions. There is a single type only within a housing of 180 x 90 x 70 mm. The weight is 400 g. We concentrate on easy to install and operate, robust, autonomous, and affordable devices. They are now in the third version stage. With respect to the first and second versions improvements in sensitivity, signaling and wireless communication have been carried out. The electronic is completely sealed within a casting resin for being isolated against humid air. By this the system is robust under changing weather conditions like rain during all the year or snow/salt in winter.

Fig. 1 – Devices beside the road and on topological shoulders mounted on guide posts

Results and Discussion

The first version (actuator for optical/acoustical signals but no wireless communication) has been implemented 2003 in Upper Austria. *Tab. 1* shows the reduction of accidents by 89%.

Tab. 1 – Device usage on Upper Austrian roads, accidents without/with first version 2003+; reduction by 89%

Device		*no*			*First version*			
Street \ Year	*2000*	*2001*	*2002*	*2003*	*2004*	*2005*	*2006*	*2007*
B 124	7	5	5	1	6	0	0	0
L 576	1	6	4	1	0	0	0	1
B 38	34	33	33	1	1	0	2	1

L 564	16	11	33	0	2	2	2	3
Total	**71**	**71**	**92**	**4**	**9**	**2**	**5**	**5**
Total		**234**				**25**		

(Böck C., 2017) states that after this first collection of statistical data by the usage of the first version in 2007 there have been 22,349 devices installed at about 480 km of additional roads

in Upper Austria. In total there has been a reduction from 3364 cases per year (2015/16) to 842 cases per year (2016/17) which is a reduction of 75%.
Due to the communication feature at the third version we have been able to support carved roads by means of placing devices 30-50 m away from the road on topological shoulders. Beginning with spring 2017 tests have been carried out by means of this third version especially on carved roads. *Tab. 2* shows the reduction of accidents by 91%.

Tab. 2 – Accidents without/with third version 2017; reduction by 91%

Street \ Device	*no*	*Third version*	*Remark*
B 124 km 27.8	5	0	*Fig. 2 a)*
L 576 km 3.6	4	0	
L 576 km 1.7	6	0	4 m talus, *Fig. 2 b)*
L 579 km 1.6	10	1	5 m talus
B 124 km 2.8	8	2	8 m talus forested
Total	**33**	**3**	

Fig. 2 – Devices on guide posts a) B 124 km 27.8, b) L 576 km 1.7

The platform ahead the shoulders of carved roads – see *Fig. 2 b)* - cannot be reached by the head light and the sound of approaching vehicles. Therefore wild-life animals in that area are not aware of the traffic at the lower road. If they are in a flee condition towards the road they are eventually too fast for stopping. With the devices at top of the shoulder, which are signaled wireless, sound and light alarms reach wild-life animals ahead the shoulder.

Conclusion

The above given results indicate a dramatic reduction of deer-vehicle collisions by the usage of simple to install/operate and affordable devices. Therefore the local government and insurance companies show high interest in providing essential and dangerous sections of roads in Upper Austria. With the gained experience since the first installations in 2003 we are now on to optimize the system in the sounding alarm (frequency and level). Another field of usage of these devices became visible by the implementation under railway system conditions. Negotiations are on the way.

Abstract

This paper has studied invasive weed population of row crops, vineyards, orchards and olive groves in Herzegovina. If the list of weed species is compared to the list of invasive plant species in Bosnia and Herzegovina, it can be seen that 10 species belong to the group of invasive species in BIH. Out of 6 families, 5 families belong to Dicotyledons. The most numerous family is Asteraceae (6 species), and Fabaceae, Rosaceae and Poaceae families are represented by one species each. By analyzing life forms, domination of terophyta and hemicryptophytes can be seen, while phanerophytes and geophytes are represented by one species each. According to the origin, the largest number of species is from America (five types). Analyzing invasive weed species in Herzegovina and their strategies it can be concluded that species with CR strategies and C strategies are dominant. This condition is particularly worrying because C species strategies are more successful in natural and semi-natural vegetation and they negatively effect on native species. The results of this research suggest that it is necessary to conduct further research of C-S-R strategy of invasive species (not only weed species) which will help better understand mechanism and successfulness of their spreading.

Keywords: *weeds, Herzegovina, Grimme CSR plant strategies.*

Introduction

Theory of CSR strategies set by J. P. Grime (Grime, 2002) implies the ability of plant to develop certain strategies of using resources which enable their optimal survival taking into consideration disorder and stress and by adapting to the existing habitat. On the basis of plants adaptability to those two factors, plant can be divided into three basic types: competitors (C), stress tolerators (S) and ruderals (R) and a number of different sub-types.

CSR system is based on the impact of environmental factors on plant life, and the presence of certain strategies can tell us a lot about the condition of the ecosystem. For example, increasing number of C-type species on the habitats can be associated with leaving the anthropogenic habitats maintained, S-type with increased eutrophication and R-type with more common disorders in the habitat (Hodgson et al., 1999). Relating invasiveness to CSR theory, which assumes that plants invest their resources either in the ability to compete, tolerate stress or survive biomass destruction (disturbance), as an adaptive response to the environment (Grime 1977).

Materials and methods

Sampling data

Floristic - phytocoenological research of weed flora and vegetation of vineyards, row crops and orchards were made during three vegetation seasons (2015, 2016, 2017), from spring to late fall. Floristic - phytocoenological surveys were conducted according to the principles and methods of Swiss-French (Zürich-Monpellier) phytocoenological school *Braun Blanquet*'s (1965).

Nomenclature of plant dicots is compliant with the work Flora Europaea (Tutin et al. 1964-1980, 1993) and only partly with Pignatti (1982) and Trinajstić (1975-1986).
Besides the existing one, dicot name recorded by some author earlier can be written in brackets.
Classification of families, species and subspecies in the framework of higher taxonomy categories is mentioned in alphabetical order on the flora list.
Besides the list of species and subspecies, related living forms are also mentioned.
Besides dicot names, flora list contains the living form for every specie in the form of abbreviation according to Horvat (1949) and Pignatti (1982):
P – *Phanerophyta*
Ch – *Chamaephyta*
H – *Hemikryptophyta*
G – *Geophyta*
T – *Terophyta*

The existing data on CSR strategies

The existing data on CSR strategies were taken from internet bases Flora Croatica Database (https://hirc.botanic.hr/fcd/), BioFlor (Klotz et al., 2002) and internal Lookup database for defining CSR strategies (Hodgson et al., 1999). For the species in which CSR strategy was different only in one out of three sources, we took the strategy from the two overlapping sources.

Calculation of the CSR strategy

Method used in this paper for determining CSR strategies was developed by Hodgson et al. (1999). In the period from 1965 to 1987 they conducted a longtime research project, which included field work, laboratory and manipulative experiments. CSR strategies of the bigger number of flora species came out as a result of that research. Using those data as the base, we decided to develop simpler, more transient method for determining CSR strategies. Observing each of three basic categories separately we defined the basic parameters which should be measured for calculating CSR strategy of a certain species. Hodgson et al. (1999) then developed an application in the computer program MS Excel, in which CSR strategy of a certain species is calculated by entering the above mentioned parameters. Table 1 gives an overview of all the mentioned measurable variables, out of which canopy height, flowering start and lateral spread have additional categories such as measurement result or literature data.

Table 1 Description of the variables used in determining of the CSR strategy

Variables Canopy height (mm)	Procedure Plants were measured in the field
Leaf dry matter content (%)	Calculated as the ratio between dry and fresh leaf weight
Flowering period (months in duration)	Data were obtained from literature
Flowering start (six-point classification)	Data were obtained from literature
Lateral spread (six-point classification)	Plants were observed in the field and compared with literature
Leaf dry weight (mg)	Leaves were oven-dried for 48 h/80 °C
Specific leaf area (mm^2 /mg)	Fresh leaves were scanned and scans were processed with ImageJ software to calculate leaf area

The process of assigning CSR strategies to plants (CSR classification) includes measuring a set of traits (Table 1) which can serve as predictors for a specific strategy, and calculating the strategy via previously prepared Excel worksheet (Hodgson et al., 1999).

Results and discussion

Wish for classification of plant species in certain categories regarding their life strategies has existed for long time in the studies of plant species and the reason for that is easier understanding of those organisms. One of such systems was suggested by Grime (1979) in his book *Plant strategies and vegetation processes*. In the book he gave a theory according to which all external factors which limit the amount of the present living and dead plant material in any habitat can be divided into two categories: stress and disorder.

Stress is represented by e.g. lack of water or nutrients which limit the plant production. Disorder is represented by e.g. herbivores, fire, wind, i.e. phenomena which destroy the plant biomass. On the basis of the plant adaptation to those factors Grime made a division into three basic types: competitors (C), stress tolerators (S) and ruderals (R).

Competitiveness implies tendency of the neighboring plants to use the same light quantum, ion of mineral nutrients, water molecule and air volume.

- competitive plants thrive the best in the conditions of low stress and disorder and they are competitive to other species in the habitat, because they are morphologically adapted to use available sources in the best way;
- stress tolerant plants are adjusted to the conditions of high stress, but small disorders and most often they are located in habitats with extreme conditions such as extremely low pH of the soil, small amounts of light, etc.;
- ruderal plants can survive disorder appearance, but not constantly present stress and they are often annual colonizers of the habitat with disorder conditions.

CSR system is based on the influence of the environment factors on flora, thus presence of a certain strategy can tell us many things about the state of ecosystem. For example, increase of C-type species number on the habitat can be connected with leaving the anthropogenically sustainable habitats, of S-type with increased eutrophication and of R-type with more frequent disorders on the habitat (Hodgson et al., 1999). C-type plants are robust perennials with high potential of growth, with fast widening above ground and below ground biomass (Grime, 1979). Taking into consideration those characteristics canopy height, vegetative lateral spread and leaf size were taken for competitiveness variables and roots characteristics were neglected for the purpose of simplicity (Hodgson et al., 1999).

S-type plants are mostly of slow growing, stress tolerant type which vegetate in chronically non-reproductive habitats (Grime, 1979). Taking into consideration that they have long living leaves with high content of nutrients, specific surface, weight and dry mass of the leaf were taken for stress parameters.

R-type species are fast growing and they finish their living cycle fast, they are characterized by the early beginning or extended period of reproduction (Grime, 1979). Beginning and end of flowering were taken for ruderality parameters (Hodgson et al., 1999).

This paper studied invasive weed population of row crops, vineyards, orchards and olive groves in Herzegovina (Municipality of Mostar, Široki Brijeg, Grude, Čitluk, Ljubuški, Stolac, Neum). Comparing the list of weed species to the list of invasive plant species in Bosnia and Herzegovina (Review and conditions of biological and landscape diversity in Bosnia and Herzegovina), it can be seen that 10 species belong to the group of invasive species in BiH. Out of 6 families, 5 families belong to Dicotyledons (Table 2).

Table 2. Invasive species in the weed flora of Herzegovina

Ambrosia artemisiifolia L	*Asteraceae*	T	America	CR
Artemisia vulgare L.	*Asteraceae*	H	America	C/CR
Conyza canadensis (L.) Cronq	*Asteraceae*	T	America	R/CR
Erigeron annuus (L.) Pers.	*Asteraceae*	T	America	CR
Galinsoga parviflora Cav.	*Asteraceae*	T	America	R
Lathyrus tuberosum L.	*Fabaceae*	G	Asia	C
Picris eschioides L.	*Asteraceae*	H	South Europe	CR
Rubus ceasiues L.	*Rosaceae*	P	Europe and Asia	SC
Sorghum halepense (L.) Pers	*Poaceae*	H	Africa and Southeast Asia	C
Urtica dioica L.	*Urticaceae*	H	Europe and Asia	C

The most numerous family is Asteraceae (6 species), and Fabaceae, Rosaceae and Poaceae families are represented by one species each (Figure 1).

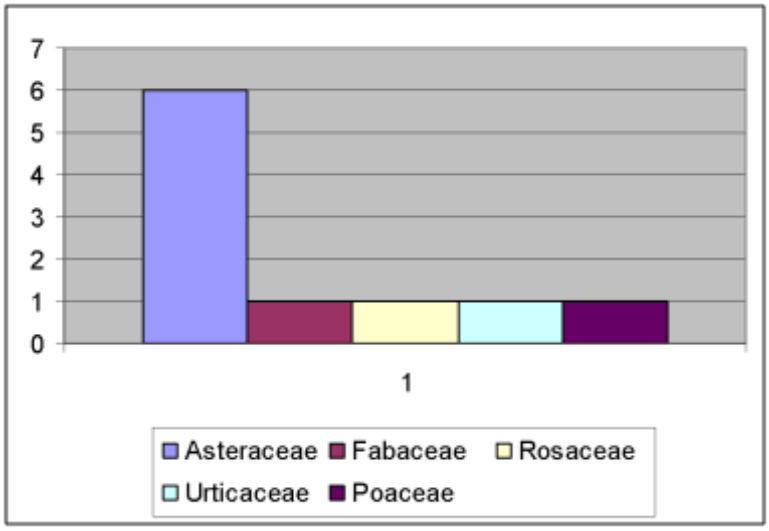

Figure 1. Family representation in the invasive weed flora of Herzegovina

By analyzing life forms (Figure 2) domination of terophita (four types) and hemicryptophytes (four types) can be seen, while phanerophytes and geophytes are represented by one species each.

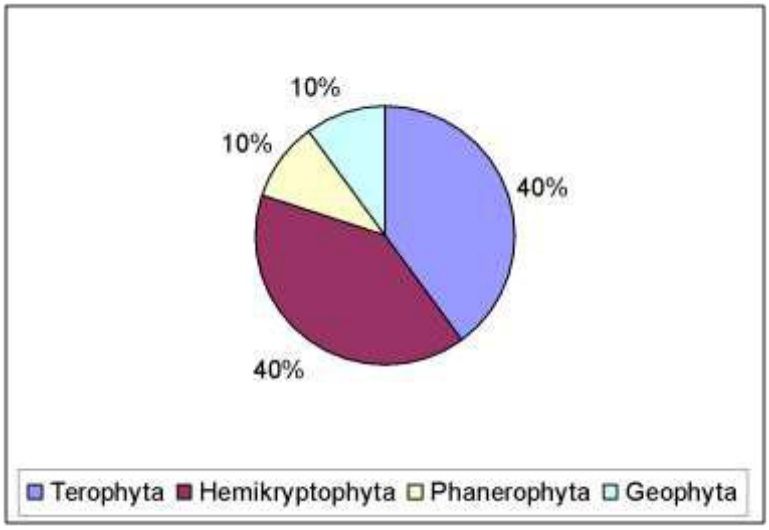

Figure 2. Representation of life forms of the invasive weed flora in Herzegovina

According to the origin the largest number of species is from America (five types), followed by Asia, Europe and Africa. (Figure 3)

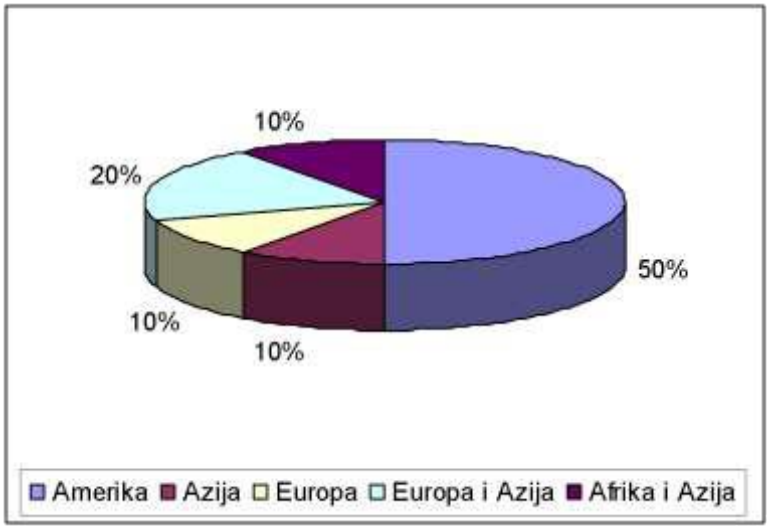

Figure 3. Origin of invasive weed species in Herzegovina

Analyzing invasive weed species in Herzegovina and their strategies (Table 3), it can be concluded that species with CR strategies and C strategies are dominant.

Table 3. Invasive weed species of Herzegovina with their strategies

CR	3	30,00
C/CR	1	10,00
R/CR	1	10,00
R	1	10,00
C	3	30,00
SC	1	10,00
Total	10	100,00

This condition is particularly worrying because C species strategies are more successful in natural and semi-natural vegetation and they negatively effect on native species.

The results of this research suggest that it is necessary to conduct further research of CSR strategy of invasive species (not only weed species) which will help to better understanding of mechanism and successfulness of their spreading. Combining that knowledge with the impact of other factors such as, for instance, the way of their spreading (Vuković et al, 2010.), it will be possible to better understand invasive flora and its adaptation to the environmental conditions which could facilitate the control of its spread.
Taking into consideration that Croatia is very near (border area), the list of weed flora of Herzegovina was compared with the list of invasive species in Croatia (Boršić et al, 2008) (Table 3)

Table 4. Invasive species in feed flora of Herzegovina according to the list from Croatia

Ambrosia artemisiifolia L	*Asteraceae*	T	America
Conyza canadensis (L.) Cronq	*Asteraceae*	T	America
Erigeron annuus (L.) Pers.	*Asteraceae*	T	America
Galinsoga parviflora Cav.	*Asteraceae*	T	America
Sorghum halepense (L.) Pers	*Poaceae*	H	Africa and Southeast Asia
Amaranthus retroflexus L**.**	*Asteraceae*	T	America

Amaranthus retroflexus is the invasive species in Croatia and because of nearness it can be expected it will soon become invasive in Bosnia and Herzegovina too.

Conclusion

Ten invasive weed species with the most numerous family *Asteraceae* were registered on the explored localities in Herzegovina (vineyards, orchards, olive groves and row crops). Regarding life forms of plants domination of terophita can be seen, while regarding origin the biggest number of species are from America. It is important to point out that the most represented strategies in the invasive weed flora of Herzegovina are CR and C strategies and taking into consideration that those C strategies are extremely adaptable, they negatively influence on autochthonous species.
Amaranthus retroflexus L. is especially pointed out on the list of invasive weed species in the Republic of Croatia. It is not invasive in Bosnia and Herzegovina, but it can be expected it will become invasive.

Abstract

The Busko Lake forms a large karstic, surface freshwater accumulation in the southwest of Bosnia and Herzegovina, at the foothills of Dinaric mountains massif. From the scientific standpoint, especially recognisable is the species diversity of freshwater ichthyofauna, while a significant number of endemic fish species that inhabit the underground karst aquifers, by their status, witness the unexpected changes in composition and diversity of ichthyopopulation. The Cetina River basin encompasses surface and underground waters of Glamocko, Kupresko, Suicko, Livanjsko, Duvanjsko and Sinjsko karst fields. The total number of recorded species is 35, with the greatest diversity in the main waterway of the Cetina River (27 species), followed by the waters of Livanjsko field (18 species). More than half the fish species (18 species; 51%) were introduced and are potentially invasive. Out of the 17 native species, five (29%) are stenoendems. The research task represents continuation of a long-term investigation of qualitative and quantitative traits of the Busko Lake ichthyopopulation. The latest, thoroughly defined ichthyological research was conducted during 2007, 2008, and 2009 on the Busko Lake. The rationale of the current research can be found in a marked extinction of many species, specific for a particular ecosystem, which have either completely disappeared or have had their numbers significantly reduced, while there is a simultaneous, gradual increase in numbers of introduced species. These evident changes in qualitative and quantitative profiles indicate that the observed ecosystem has undergone significant changes, the cause of which has yet to be eradicated. Initially, in this paper, it is essential to conduct a survey and ascertain areal of each individual species, determine distribution of endemic species, and establish protection measures.

Keywords: *Busko Lake, freshwater fish biodiversity, endemic species, Bosnia and Herzegovina.*

Introduction

Biodiversity is a defined phenomenon in the living world, stemming from the fact that the process of speciation still, albeit on a slightly smaller scale, exceeds the process of extinction or disappearance of living species. Speciation is a continuous process of geographical spread of populations and their separation due to fragmentation of habitats and the creation of conditions for propagation of species. Biodiversity is often defined as a number, variety and variability of living organisms, and thus a basis for their survival. Commitments placed before humanity relate to the prediction, prevention and eradication of the causes of biodiversity loss by a model of monitoring and identification of negative changes in ecosystems and habitats themselves, thus ensuring the existence of a small number of endemic and endangered species. Some data indicate that the degree of extinction today is 40% higher than normal, representing a moment of crisis, as the loss of biodiversity unfolds rapidly and uncontrollably. The causes of endangerment of certain species and disappearance of biological diversity are twofold: natural causes (natural disasters) and anthropogenic factors, which directly affect the

changes in natural processes and conditions of the environment (habitat loss, uncontrolled catch and exploitation, introduction of foreign species, pollution and destruction of the environment). The chronology of the previous research in the area of the Busko Lake distinguishes important papers, with their true aims directed at determining the level of ichthyofauna diversity in the southwestern Bosnian karst region. In the earliest period of the study of ichthyofauna in Bosnia and Herzegovina, the first more extensive works were written by Austro-Hungarian researchers, among whom are Heckel & Kner (1858), who in their papers give incomplete, yet the first description of a large number of species from the Cyprinidae family in the Busko Lake and the rivers of Livanjsko, Duvanjsko and Sinjsko fields. Ćurčić (1910, 1913, 1916) in the work *National fisheries in Bosnia and Herzegovina* states that by that time nobody had enough studied *"our"* domestic fish, their way of life and the hunting methods. The author connects the existence of the so-called "cavalry fish", to this area, referring to the genus *Paraphoxinus*, or the gait. It is significant because the species of that genus, *Phoxinellus (Paraphoxinus) alepidotus* (Heckel, 1843), inhabit the karst region of Livanjsko and Duvanjsko fields, and, according to Mučibabić *et al*. (1973), it was present in the Busko Lake until recently. Numerous research papers have different methodological approaches to solving ichthyological research problems in the running waters of Duvanjsko and Livanjsko fields, with a note that there are still insufficient current data on diversity of ichthyofauna of the Busko Lake (Karaman, 1923; Protić, 1926, 1927; Taler, 1951, 1954). In the period that followed, in addition to valorising the state of diversity in the area, analyses of cytophysiological characteristics, as well as serological and immunological tests were conducted within a complex approach to problems of biosystematics, which is of crucial phylogenetic-taxonomic importance. Studies of interspecies and intergeneric hybridization among different fish species were also made, thus following the behaviour of natural and artificially created hybrids. This data made a good basis for solution to a problem of using the applied ichthyology results in practice (Vuković 1963, 1966, 1977; Vuković & Kosorić 1970, 1978; Vuković & Ivanović 1971; Aganović *et al.* 1974, etc.). The continuation of cited papers is related to the period after formation of the Busko Lake accumulation and the somewhat modified ecological conditions of habitats in the investigated area (Mučibabić *et al.* 1973; Habeković, *et al.* 1987; Cvijović & Kosorić 1985; etc.). Kosorić *et al.* (1991) present the real possibilities of using water reservoirs in Bosnia and Herzegovina for production of fish, with the research in support of the familiarisation with endemic ichthyofauna in the Busko Lake area. The last twenty years were marked by the individual papers by authors Guzina, 2000; Dumanić, 2004; Bogut *et al.* 2007; Žujo Zekić, 2009; Škrijelj *et al.* 2015 and others. In this paper, the fundamental ichthyological research was conducted and the aims were set to determine the current state of fish populations diversity of the Busko Lake hydroaccumulation. The results are presented through a qualitative structure analysis of investigated ichthyopopulations and their interrelations within the ichthyofauna of the researched area, with a reference to adaptive reactions of endemic species to the apparent changes in the given ecosystem.

Materials and Methods

Researched area, the Busko Lake, or the Busko Mud as it is still sometimes called today, was once a natural creation and a wetland-marsh ecosystem of the Bosnian karst region. Knowing the Dinaric karst characteristics, (vertical jagged relief, the scarcity of the rugged soil, the scarce flora and the richness of carbonate rocks), there is a clear lack of surface watercourses and underground drainage. Therefore, this significant hydrographical centre is also a "monumental" work of nature. The Busko Lake, the third largest in Europe, is in the southeastern part of Livanjsko field, forming a closed feature with the most imposing morphological characteristics (area 60 km^2) for a karstic area (Figure 5).

Figures 1-4. 1. Site L/1 Prisoje – Tomislavgrad; 2. L/2 Golinjevo-Livno; 3. L/3 Podgradina-Kanal-Livno; 4. L/4 Mukišnica-Grabovica (Tomislavgrad); Figure 5. Cartographic presentation of the geographical position of research sites at the Busko Lake (Boškailo, 2018)

The fieldwork part of the ichthyological research of this aquatic area was conducted within the framework of the project titled "*Survey and monitoring of the life communities of the aquatic ecosystem Busko Lake*", during spring - summer season of 2018, through several field trips. For the assessment and analysis of qualitative and quantitative structure of fish populations within the fishing zone Busko Lake, four sites were marked and studied: L/1 Prisoje - the old bridge; L/2 Golinjevo; L/3 Podgradina-Kanal; L/4 Mukišnica - Grabovica (Figures 1-4). The importance of the proper selection of individual fishing sites that differed in terms of depth, wind direction, geographical position, wealth of aquatic vegetation, percentage of exploitation, etc., reflected on the composition and structure of investigated ichthyopopulations in the area. Analysed representative samples of fish populations were obtained by standard catching methods (the "fill" nets with different diameters, the "barracuda" nets, and fishing by electro aggregate). A general annotated description of research sites is presented in Table 1. Systematic determination of fish was made according to Vuković T. & Ivanović B. (1971) and Kottelat M. & Freyhof J. (2007). Diversity indices Shannon-Wiener index (H) (Shannon-Wiener, 1949) and (Bray-Curtis index) were calculated using the BioDiversity Pro software.

Table 1. General notes on sampling sites at the Busko Lake hydroaccummulation area

Number	Site label	Site name	Coordinates	Altitude (m)	Length of nets (m)	Average depth (m)
1.	L/1	Prisoje – old bridge (Tomislavgrad)	*N 43˚41'117"* *EO 17˚04'896"*	702-712 m	200 -250 m	1,50 m

Results and Discussion

Qualitative composition of ichthyopopulations at selected sites at the Busko Lake

Investigating the qualitative structure of fish populations in the Busko Lake, and linking the lake's position with its size and ecological environmental factors, it is evident that composition of ichthyocenosis in these karst watercourses is very diverse and specific. A partially interrupted connection of this hydroaccumulation with karst streams in the Livanjsko and Duvanjsko fields, as well as the centuries-old isolation of this karst basin, formed a specific endemic ichthyofauna. It has been previously known that out of the total of five indigenous fish species that exist in the Busko Lake, the four are endemic, with a very narrow areal. Several fish species were subsequently introduced, due to the curiosity and intentions of local fishing associations to increase the commercial value of the lake. All this however depends and relies on biological characteristics of individual fish species, some of which found more favourable ecological niches in a newly formed ecosystem, while others, unable to adapt, moved to less karstic watercourses or completely disappeared from the area.

During current research, we were guided by the very beginnings of the study of ichthyofauna, where special attention was paid to endemic fish species, known spawning periods, the way of life, the influence of certain weather conditions on behaviour of some fish, seasonal oscillations in abundance of communities, appearance of "cavalry fish", conditions at a catchment site (water level, periods of rain, periods of drought), etc.

The current review of a qualitative composition of ichthyopopulations is far from a positive assessment of the state of biodiversity in an artificially controlled ecosystem. According to current results, which differ from those published by Žujo Zekić (2009), at four sites during the spring-summer season 2018, ten species from five families were identified in the Busko Lake:

Family Cyprinidae Bonaparte, 1840, with species: *Chondrostoma phoxinus* (Hackel, 1843), *Cyprinus carpio* (Linnaeus, 1758), *Carassius gibelio* (Bloch, 1782), *Tinca tinca* (Linnaeus, 1758), *Alburnus arborella* (Bonaparte, 1841), *Scardinius dergle* Heckel & Kner, 1858;

Salmonidae Linnaeus, 1758, with species *Salmo farioides* Linnaeus, 1758 (*Salmo trutta m. lacustris* - lake form);

Siluridae Cuvier, 1816, with species *Silurus glanis* (Linnaeus, 1758);

Percidae Cuvier, 1816/7 with species *Sander lucioperca* (Linnaeus, 1758);

Centrarchidae Berg, L.S. 1958 with species *Lepomis gibbosus* (Linnaeus, 1758).

Having obtained data on the state of species diversity, expressed through the qualitative structure of ichthyopopulations at designated sites, obvious is the absence of endemic species from the Cyprinidae family: *Squalius tenellus* Heckel, 1843, *Aulopyge huegelii* (Heckel, 1842), and the species *Hypophthalmichthys molitrix* (Valenciennes, 1844) and *Pseudorasbora parva* (Temminck & Schlegel, 1846), as well as the species *Ameiurus nebulosus* (Le Sueur, 1819) from the Ameiuridae family. Compared to previous studies, the obtained data point to emergence of unnatural competitive relations among investigated ichthyopopulations, at certain habitats, resulting in a poor estimate of the lake's ecosystem bioproductivity.

Degree of ichthyofauna heterogeneity in the Busko Lake (cluster analysis)

The Bray-Curtis index of diversity represents a measure of the degree of similarity and difference in the structure of one community at different locations (communities of ichthyofauna at catchment sites). The cluster diagram (Diagram 1), composed by a series of linear links, shows the two sets of samples, grouped on the basis of similarity of individual sites in relation to biodiversity of the studied ichthyopopulations of the Busko Lake.

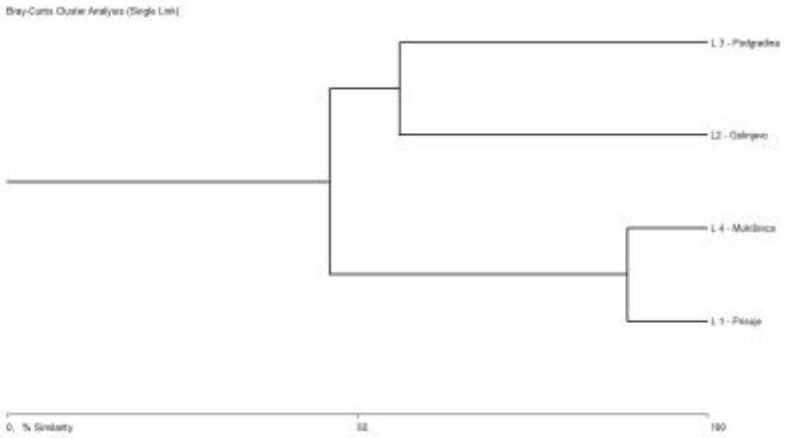

Diagram 1. Bray-Curtis claster analysis of researched sites according to diversity of ichthyopopulations of the Busko Lake

Shannon-Weaver index of diversity

The value of the biodiversity index is a significant indicator of the status and condition of the ecosystem in relation to environmental and anthropogenic impacts, enabling the assessment of the biological diversity of fish communities at the research sites. The Shannon-Weaver diversity index of ichthyofauna is calculated based on determined numerousness and distribution of fish species. It is used in our ichthyological research, and basically measures the order (disorder) within a particular living community. The advantage of this index is that it takes into account the number and equality of species (equal representation). Index values increase with the increase in the number of "special" species, or due to their higher equality, or more even representation in the sample. The results of this test are presented in Diagram 2, with values ranging from 0, for sites containing only one species, up to 1, for sites that have exceptionally high diversity of species.

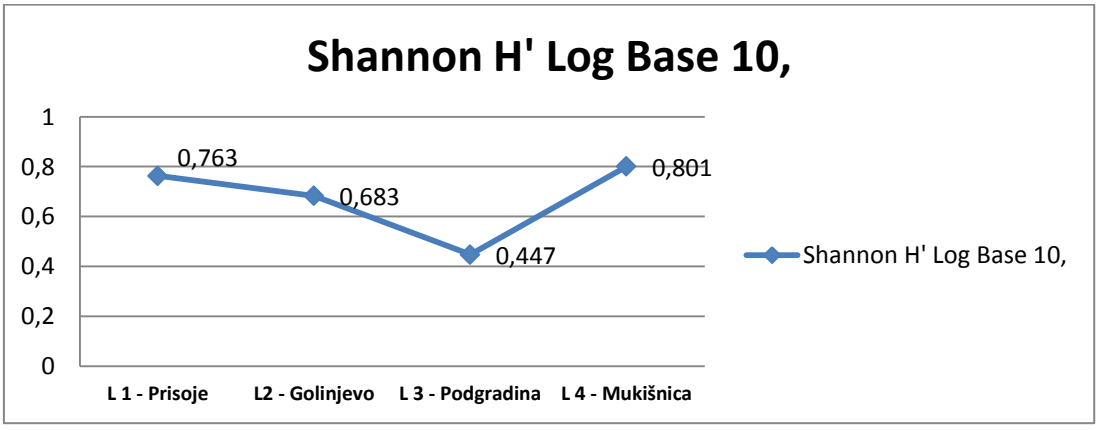

Diagram 2. The Shannon index values for ichthyofauna at researched sites of the Busko Lake

Conclusions

The formation of ichthyofauna of the Busko Lake was especially influenced by a composition of fish communities from the surrounding watercourses, as well as the existing fish fund of the former natural wetland-marsh ecosystem the Busko Mud. Considering that the initial conditions of habitats have been altered, it can be unambiguously concluded that the entire ecosystem has been changed, which is especially noticeable in the composition of ichthyopopulations. This brings into question the survival of certain species. Endemic species of the Busko Lake ichthyofauna appear as indicator organisms, whose absence or health

condition is used to identify a specific type of biocenoses, or as a measuring unit of altered ecological conditions within the hydroaccumulation.
This paper shows a great variation within the observed fish populations as well as individual species, which is conditioned by a series of abiotic environmental factors with an unavoidable anthropogenic effect.

Conclusion

Currently, an interspecific competition is particularly prominent, where in the mutual exploitation of a common natural resource one species has more benefits, thereby reducing its quantity and availability to other species. Hence, the rate of growth, reproduction and survival of the other species are lowered and the species is becoming endangered. Today, this phenomenon has surpassed natural laws. Wherever a human appears as a predominant species, and disrupts the natural relationship of autochthonous species through introduction of "foreign" species, a cascade of events leads to this unbalanced state of the environment. The degree of impact, very seriously undermines the survival of certain endemic species. Considering the basic characteristics that describe the typical cyprinid water, it is clear that the results obtained for the qualitative composition of ichthyopopulations is made up of ten fish species from the five families with the dominance of species from the Cyprinidae family.

Acknowledgement

This scientific research paper is the result of the final implementation of the project entitled "*Survey and monitoring of the life communities of the aquatic ecosystem Busko Lake* ", which was supported by the Environmental Protection Fund of the Federation of Bosnia and Herzegovina, in accordance with the allocation of funds for the implementation of programs, projects and similar activities in the field of environmental protection for 2017 - JP2017. Field work is supported by the company "Voda-Riba-Sport Buško jezero" from Tomislavgrad.

Abstract

From the aspect of biodiversity, in the broadest sense of comprehension, Bosnia and Herzegovina is one of the most unique regions of Europe. One such natural resource is the area of the present-day Tomislavgrad municipality. The special attraction, for botanists, is the aquatic complex of the Busko Lake.The research was conducted during vegetation season in spring 2018, in order to determine diversity and distribution of plant species inhabiting coastal parts of the Busko Lake. Using the Braun-Blanquet method (1964), phytocoenological analysis was performed at selected sites. Lowland forests and shrubs have developed in coastal parts of the lake and its tributaries, the most prominent of which are: *Crataegus monogyna, Rhamnus alpinus ssp. fallax,* while less represented species are*: Cornus sanquinea, Salix alba, S. fragilis* and *Populus nigra.*Tertiary vegetation is also present in the area where anthropogenic impact occurs to a greater or lesser extent. This type of vegetation is located around human settlements, rich in habitats and nitrites, edges of roadsand other similar habitats. The species of this vegetation present at researched sites are: *Senecio vulgaris, Lolium strictum, Poa annua, Sonchus oleraceus, Erigeron canadensis, Fumaria officinalis, Lamium purpureum* and others. Macrophytic vegetation is well developed in the coastal belt and shallow waters, represented by species: *Veronica beccabunga, Glyceria fluitan, Veronica anagallis-aquatica* and others. Many human activities lead to the rapid disappearance of rare and ecologically specialized species as well as the fragmentation of their habitats. Environmental protection guarantees the complete preservation of environmental quality, the preservation of natural communities, the rational use of natural resources and energy in the best way for the environment, as a basic condition for healthy and sustainable development.

Key words: *Buško Lake, phytocoenological analysis, floristic composition of vegetation, anthropogenic factor, sustainable development.*

Introduction

From the aspect of biodiversity, in the broadest sense of comprehension, Bosnia and Herzegovina is one of the most unique regions of Europe. One of such natural resources is the region of Tomislavgrad municipality. Particular significance, from the floristic perspective,have the Vran mountain, Dugo field, karstic Duvanjsko field, the Busko Lake and many others. The Busko Lake is a large surface, karstic aquatic complex in south-western part of Bosnia and Herzegovina at the foothills of Dinaric mountain massives. From the scientific standpoint, especially recognisable is the species diversity of freshwater ichthyofauna in the area, and presence of endemic fish and plant species. The Cetina River basin encompasses surface and underground waters of Glamocko, Kupresko, Suicko, Livanjsko, Duvanjsko and Sinjsko karst fields on the territory of Bosnia and Herzegovina and basins of the Jadro and the Zrnovnica rivers in the Republic of Croatia.

The area of today's Tomislavgrad municipality has been a long-standing point of interest for botanists, considering its geomorphological and climatic heterogeny, and hence floristic and

vegetational heterogeny. The influence of biotic factors, especially anthropogenic, was especially significant for flora and vegetation over time, which engrossed attention of botanists. A significant number (70) of plant families have been identified, which is almost one half (43.5%) of the total number of vascular plant families (161) on the entire territory of Bosnia and Herzegovina. Dominant sunflower families Asteraceae and Cichoriaceae are represented with the largest number of species (47) (Abadžić, 2013). Abundant families are also: Caryophylaceaea, Fabaceae, Poaceae, Lamiacece, Rosaceae, Apiaceae. The analysis of the spectrum of floral elements established their numerousness, and therefore divided them into several basic groups of floral elements, the most common of which are: the Eurasian, the Eurosuboceanic, the Supramediterranean, the Mediterranean, the Subatlantic, the Arctic, the Alpine and Pre-Alpine floral element, as well as the Balkanic, Balkan-Apennine and the Dinaric floral element (Abadžić, 2013).

Material and Methods

Field research was conducted in 2018 during the vegetation season - spring (May-June) in the area of the Busko Lake. The survey covered the coastal part of the Busko Lake at sites: Prisoje (old bridge), Golinjevo, Kanal-Podgradina and Mukisnica where phytocoenological analyses were done. Braun-Blanquet (1964) methodology was used, adapted to the research needs. Most plant species were identified on site, during fieldwork. When it was not possible, the samples were identified in the laboratory. Nomenclature of plant taxa was determined in accordance with Tutin *et al*. (1964-1985), Mucina (1997), Rodwell *et al*. (2002), Šilić (1996), and Hayek (1927-1933). The affiliation to the floral element and life form was assigned according to the databy Oberdorfer (2001).

Results and Discussion

The assessment of vegetation was conducted during May and June 2018 at the Busko Lake. These surveys covered four sites in total: Prisoje (old bridge), Golinjevo, Kanal-Podgradina and Mukišnica (Figure 1). Phytocoenological analyses and identification of plant species were conducted at each site.

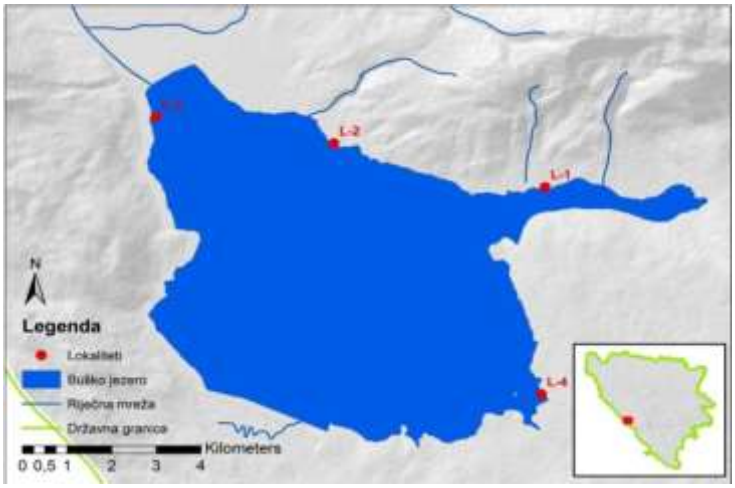

Figure 1. Position of research sites at the Busko Lake

Elements that are directly or indirectly related to determination of the shape and the level of biodiversity are: geological and pedological characteristics, altitude, terrain inclination and the action of anthropogenic factor, manifested through various forms.

Taxonomic analysis

Taxonomic analysis of riparian flora at selected sites of the Busko Lake was performec at the family level. All taxa were sorted into 25 families. Out of 70 taxa identified at selected sites, majority of species were from the family Asteraceae (14), followed by families Poaceae (8), Rosaceae and Fabaceae (7), Ranunculaceae and Scrophulariaceae (3), Polygonaceae and Salicaceae (3), Plantaginaceae and Cyperaceae (2), with all other families represented by one taxon each (Table 1).

Table 1. Taxonomic structure of the most abundant floralfamilies at selected sites

Family	**Number of taxons**	**%**	**Family**	**Number of taxons**	**%**
Asteraceae	14	9,8	Boraginaceae	1	0,7
Poaceae	8	5,6	Campanulaceae	1	0,7
Rosaceae	7	4,9	Clusiaceae	1	0,7
Fabaceae	7	4,9	Convolvulaceae	1	0,7
Ranunculaceae	4	2,8	Cornaceae	1	0,7
Scrophulariaceae	4	2,8	Juncaceae	1	0,7
Polygonaceae	3	2,07	Lamiaceae	1	0,7
Salicaceae	3	2,07	Papaveraceae	1	0,7
Plantaginaceae	2	2.1	Urticaceae	1	0,7
Cyperaceae	2	22,1	Crassulaceae	1	0,7
Apiaceae	2	2,1	Betulaceae	1	0,7
Alismataceae	1	0,7	Potamogetonaceae	1	0,7
Asparagaceae	1	0,7	**Total**	**70**	**100**

Spectar of Life Forms

A range of life forms was determined for the identified plant species at researched sites, amounting to a total of 13, with transitional forms.

Analysis of the structure of hemicryptophytes (H) in the coastal part of the Busko Lake's flora showed that they were represented by a largest number of taxa (39). If we also include hemicryptophytes of transitional forms- H (G), (H) G) i H (Ch), it can be concluded that hemicryptophytes make up a total of 46 species (32,2%). Phanerophyte (P) are the second most numerous life form (10 species), followed by terophya (T) (6) with six plant species and two transitional forms T (H) - (2 species) and T (Ch) - (1 species). A low percentage of hydrophytes (W) (0.16%) can be attributed to a small number of sampling sites, a few field trips and the fact that floral analysis included samples from the coastal part of the lake only. Geophyte (G) were represented by one species and one transitional form G (H), with one species. Similarly, hamephyta (Ch) were represented by two plant species, out of which one was a transitional form Ch (H) (Table 2).

Table 2. Biological spectrum of coastal flora of the Busko Lake

Basic and transitional life forms	**Number of taxa**	**%**	**Total**	**%**
Hemicryptophytes (H)	39	17,94	46	32,2
H (G)	3	1,38		
H (Ch)	3	1,38		
(H) G	1	0,46		
Phanerophyes (P)	10	1	10	7
Terophytes (T)	3	0,18	6	4,2
T (H)	2	0,12		
T (Ch)	1	0,06		
Hydrophytes (W)	4	0,16	4	2,8
Hamephytes (Ch)	1	0,02	2	1,4
Ch (H)	1	0,02		
Geophytes (G)	1	0,02	2	1,4
G (H)	1	0,02		

Spectrum of floral elements

Considering the climatic, geomorphological, pedological and other diversities of the researched area, it was expected that vascular floral species present in the area would show a significant diversity of floral elements, which was found to be 37. The most numerous floral elementsare: nine eurassubozean-smed, four omed-kont, followed by three species each of euras-smed-med, euraskont-smed, euras-smed, smed-euras, no-euras and osmed. Finally, other floral elements were represented by two or one species (Table 3).

Table 3. Spectrum of floral elementsof coastal flora of the Busko Lake(N – number of species)

Vascular flora in Bosnia and Herzegovina is rich in endemic plant species, hence it was no surprise to note the presence of a Dinaric endem *Chouardia litardierei (Breistr.)* Speta (syn. *Scilla protensis* W& K). The macrophytic vegetation in the coastal belt and shallow waters was represented by *Veronica beccabunga, Glyceria fluitans*. In the Busko Lake itself, aquatic plants rooted in muddy substrates were present, such as *Potamogeton perfoliatus, Polygonum amphibium f. natans.*

Influence of pollution on flora and vegetation

The Busko Lake is an area rich in natural beauty, however we also have to take into consideration a significant influence of an anthropogenic factor, which has created various problems on the lake due to human ignorance. Most human activities lead to the rapid disappearance of rare and ecologically specialized species as well as the fragmentation of their habitats. General long-term preventive measures against biotic and non-biotic agents, which could endanger the stability of the lake and its environment, will be based on water management that takes into account natural processes, as well as the maintenance and appropriate improvements of biodiversity conservation. Fundamental biological resources, including the Busko Lake, must be effectively preserved, without further internal fragmentation, significant reduction in size or degradation through development and construction, in order to preserve the natural resources and ecosystem processes that depend on them. Environmental protection guarantees the complete preservation of environmental quality, the preservation of natural communities, the rational use of natural resources and energy in the best way for the environment, as a basic condition for healthy and sustainable development.

Conclusions

The research results that included sampling sites: Prisoje (old bridge), Golinjevo, the channel - Podgradina and Mukišnica on the Busko Lake, indicate that 70 taxa were identified within 25 families. The total spectrum of life forms in the researched area is 13 with transitional forms, while the spectrum of floral elements is 37.

These findings point to the need to organize additional comprehensive field research on parts of the Busko Lake area, which to date have been partially or almost never explored. These activities would certainly lead to new knowledge that would to a great extent update the present understanding of the biodiversity of flora in the Busko Lake area.

Acknowledgements

This paper presents the original data obtained through field research during implementation of the project: Survey and monitoring of the life communities of the aquatic ecosystem Busko Lake, financed by the Environmental Protection Fund of Federation of Bosnia and Herzegovina.

TREATMENT OF FILTERS ON SANITARY LANDFILL

Obrenija KALAMANDA*, Vlatka ĐURAŠINOVIĆ, Svetlana TOPIĆ

University of Business Studies, Faculty of Ecology, Banja Luka, Bosnia and Herzegovina
*Corresponding author: obrenija2009@hotmail.com

Abstract

Sanitary landfills are specific places where municipal waste disposal is carried out using sanitary landfilling technology. Biochemical, physico-chemical and geological processes in aerobic and anaerobic conditions take place at sanitary landfills. Anaerobic decomposition of waste matter in the body of the landfill occurs at temperatures of 35-55 ° C and passes through several transformation phases to the final mineralization. In the body of the landfill a very high degree of pollution is formed, which together with the formed gases make the main emission factors of the harmful substances in the environment. The filtrate in the body of the landfill should be collected by the appropriate drainage system, which is lying on a waterproof natural or artificially formed substrate that protects the groundwater. Purification of the landfill filtrate is done by various methods, most often in combination of several types of technological procedures. The aim of the paper is to determine the quality of the filtered filtrate from Bosnia and Herzegovina, at the Ramici landfill that is released into the water stream. The tests were carried out in January, April, September and December 2016. In order to determine the quality of the filtered filter, the determined parameters are: temperature, pH value, electrical conductivity, HPK, BOD, total phosphorus, nitrates, sulfates, chlorides, heavy metals (manganese, iron, lead, etc) and toxicity test Daphnia Magna Straus. The obtained data have been processed and analyzed in accordance with the legal requirements set out in the Regulation on limit values for wastewaters discharged into surface waters (Official Gazette of the Republic of Srpska (Bosnia and Herzegovina) no. 44/01).

Key words: *landfill filtration, treatment, sanitary landfill*

Introduction

Waste materials are substances or objects that arise during the production, service or other activities, objects excluded from use, those which are not for further use and must be discarded. In order to solve the problem of waste materials, there are various functional elements that are grouped into the waste management system, which works in the direction of optimizing such a system, minimizing costs and achieving the maximum effect on environmental protection (Kalambura, Racz, Toth, 2017). Waste management includes the prevention of waste generation, waste reduction and its hazardous characteristics, waste treatment, waste management planning and control, waste transportation, the establishment of a system for operation, closure and maintenance of waste treatment facilities after closure and monitoring. In order to establish a sustainable waste management system, it is important to look at all waste management options. Common technical and technological solutions for the treatment of certain types of waste include procedures for the avoidance and utilization of waste, recycling, treatment by mechanical, biological, thermal and chemical processes and final disposal by landfilling or export. Each of these technologies has its advantages and disadvantages, but everything must meet environmental conditions and must not endanger human health. Only proper treatment of waste materials can create a healthy environment, as a basis for a healthy life. Landfilling of municipal waste is the simplest and cheapest waste management process. The main goal of waste disposal is the long-term sustainable disposal of waste with the aim of protecting the environment and human health (Vujić, 2009). Municipal waste landfilling involves the use of a sanitary technological process that takes place in a

well-preserved location, in accordance with environmental conditions related to the protection of environmental components. The sanitary landfill is a specific construction facility where heterogeneous municipal waste is disposed of in a controlled manner, containing various fermentation and inert components. The deposited waste matter is transformed to the final mineralization by various processes that take place in optional aerobic-anaerobic or anaerobic conditions. As a result of physical-chemical and biochemical processes, carbohydrates, proteins, fats, amino acids, glucose, methanol, methane, carbon dioxide, ammonia, hydrogen and sulfur are formed. In contact with organic matter in the body of the landfill and products of its decay of infiltrated atmospheric precipitation, it builds an extremely high pollution filtrate, which makes the main emissions of harmful substances into the environment together with landfill gas.

The amount of landfill filtrate is difficult to determine. The maximum quantity of landfill filtrates ranges up to 50% of the average rainfall in the landfill area. It is affected by the slope of the site of the landfill site, the quality and type of covering material, the height of the landfill and other. The filtrate in the body of the landfill is collected through a drainage system that lies on a watertight substrate and is discharged into the collection lagoon located near the body of the landfill. The depot filtrate from the collecting lagoon is considered to be the most complex source of pollution in nature, so it is the obligation to be purified before releasing it into a natural recipient (Marković, Milanović, 2016).

Knowing the negative impact of the landfill on natural recipients, the aim of the paper is to determine the quality of the filtered filtrate from the Ramici landfill at Bosnia and Herzegovina that is released into the water stream. The tests were carried out in January, April, September and December 2016. In order to determine the quality of the purified filter, the parameters were determined: temperature, pH value, electrical conductivity, HPK, BPK5, ammonia content, total phosphorus, nitrates, nitrates, sulfates, chlorides, heavy metals (manganese, iron, lead, etc.) and toxicity test Daphnia Magna Straus. The obtained data have been processed and analyzed in accordance with the legal requirements set out in the Regulation on limit values for wastewaters discharged into surface waters (Official Gazette of the Republic of Srpska (Bosnia and Herzegovina) no. 44/01).

The basic hypothesis of the research is that the landfill filtrate after the purification meets the conditions prescribed by the Regulation on the discharge of sewage into surface waters (Official Gazette of the Republic of Srpska (Bosnia and Herzegovina) no. 44/01).

Material and Methods

The waste disposal site in Ramici near Banja Luka is located in the north-western part of the city, at the location of Crkvine (Kalamanda, Vujcic, Delić-Jović, 2015). With all its natural elements, the site of the Ramici landfill is under the influence of anthropogenic degradation. Existing degradation is reflected through the pollution of surface and ground waters, air and soil. Environmental pollution and problems that arise are associated with pollution of surface and groundwater. Treatment of landfill filtrates at sanitary landfills is a very complex task. In order to be released into natural recipients, the criteria for wastewater condition the application of different treatment processes (Jahić, 2006). Since 2014, the landfilled (discharge) water collected at the Ramici landfill has been purified by the reverse osmosis process. When purified, it is discharged into the water stream. In order to determine the quality of treated purified water at the exit of the purification plant, water quality is determined before they are discharged into the watercourse. The quality control of purified landfill water was carried out according to the methodology prescribed in the Regulation on the conditions for discharging wastewaters into surface waters (Official Gazette of the Republic of Srpska (Bosnia and Herzegovina) no. 44/01). For the purpose of the research,

purified landfill water was sampled at the exit from the purification plant, in January, April, September and December 2016, as shown in Image 1.

Results and Discussion

Based on the parameters of purified landfill filtrates that are discharged into surface water, the obtained results are shown in Table 1.

Table 1. Results of the parameters of purified landfill water that is discharged into surface waters (January, April, September, December 2016)

Parametar	**Unit**	**Research method**	**Limit value**	**Sample I (January)**	**Sample II (April)**	**Sample III (Septembar)**	**Sample IV (Decembar)**

By analyzing the data from Table 1. it can be seen that the parameters of purified landfill water, from which the harmful substances have been removed or reduced to the level acceptable for natural recipients, have been determined. The obtained results are compared with the limit values of the parameters according to the Regulation (Official Gazette of the Republic of Srpska (Bosnia and Herzegovina) no. 44/01). Purified water for research purposes was sampled in different periods of 2016 (January, April, September and December). At the sampling point, the following were directly determined: the wastewater temperature was from 14.9 - 22.0°C, which is within the limits of the allowed values, the pH value is from 6.87 - 7.39, the allowed values are up to 9.0. Suspended solids in all tested samples were significantly lower than the maximum allowed concentrations and ranged from 1.6 to 5.0 g/m^3 and allowed 35. The obtained data for electrolytic conductivity showed the lowest value in January 427 μS/cm , and the highest value in April 481 μS/cm.

Imhoff's soluble substances in all tested samples amounted to < 0.2 ml/l, which is lower than the limit values (0.5 ml/l). Biological Consumption of Oxygen (BOD_5) is a basic indicator that serves as an indicator of the presumed impact of wastewater on natural recipients in which the content of dissolved oxygen decreases (Jahić, 2004). The obtained values for BOD_5 in the tested samples ranged from 1.0 g O_2/m^3 in September to 4.6 gO_2/m^3 in January, which is significantly lower than the allowed values (25 gO_2/m^3) compared with the indicators from the Regulation. Analyzing the obtained data for chemical consumption of oxygen (HPK) of the tested samples, it can be concluded that the lowest values were in September 9.36 gO_2/m^3, and the maximum in January was 28.6 gO_2/m^3, which is negligible compared to the indicators from the Regulation 125 gO_2/m^3). The determined values for BOD_5 and HPK in the tested samples were within the limits of the permitted values according to the Regulation, based on which it can be concluded that the content of organic matter in the waters is reduced by the treatment of landfill waters. The content of ammonia in the tested samples ranged from 2.13

g/m^3 in January to 8.7 g/m^3 in September. The values obtained for the content of ammonia, nitrate and nitrite nitrogen in all tested samples are within the permissible limits of the Regulation. Total Kjeldahl nitrogen in tested samples ranged from 3.25 g/m^3 in January to 14.8 g/m^3 in December, which is within the prescribed limits (15 g/m^3). The content of total phosphorus, sulphate and chloride in all tested samples is significantly lower than the prescribed values. The Daphnia magna Straus toxicity test was 84.4% in December, and in January it had the highest value of 86.2% of wastewater diluted, from which it can be seen that the samples were tested within the limits of the allowed (> 50% dilution wastewater). The obtained data for the content of heavy metals (iron, chrome, lead, zinc, manganese) in all tested samples are significantly lower compared to the values prescribed by the Regulation, from which it can be concluded that the content of inorganic as well as organic matter in the tested samples is significantly reduced by the treatment of landfill water.

Conclusion

- At the sampling point, the following were directly determined: the temperature of the waste water was from 14.9 to 22.0° C, which is within the limits of the allowed values, the pH value is from 6.87 to 7.39, the allowed values are up to 9, 0.
- Suspended solids in all tested samples are significantly lower than the maximum allowed concentrations and ranged from 1.6 - 5.0 g/m^3, with 35 allowed.
- Biological consumption of oxygen (BOD_5) in the tested samples ranged from 1.0 gO_2/m^3 in September to 4.6 gO_2/m^3 in January, which is significantly lower than the allowed values (25 gO_2/m^3 in comparison with the indicators from the Regulation)).
- Data for the chemical consumption of oxygen (HPK) of the tested samples of the lowest values in September were 9.36 gO_2/m^3, and the maximum in January was 28.6 gO_2/m^3, which is negligible compared to the indicators from the Regulation (125 gO_2/m^3) . The obtained values for BOD_5 and HPK in the tested samples are within the limits of the allowed values according to the Regulation, based on which it can be concluded that the content of organic matter in the waters is reduced by the treatment of landfill waters.
- The content of ammonia in the tested samples ranged from 2.13 g/m^3 in January to 8.7 g/m^3 in September.
- The values obtained for the content of ammonia, nitrate and nitrite nitrogen in all tested samples are within the permissible limits of the Regulation.
- Total Kjeldahl nitrogen in tested samples ranged from 3.25 g/m^3 in January to 14.8 g/m^3 in December, which is within the prescribed limits (15 g/m^3).
- The total phosphorus, sulphate and chloride content in all tested samples is significantly lower than the prescribed values.
- The Daphnia magna Straus toxicity test was 84.4% in December, and in January it had the highest value of 86.2% of wastewater diluted, from which it can be seen that samples were tested within the limits of the allowed (> 50% dilution wastewater).
- The obtained data for the content of heavy metals (iron, chrome, lead, zinc, manganese) in all tested samples are significantly lower in relation to the values prescribed by the Regulation, from which it can be concluded that the content of inorganic as well as organic matter in the samples tested is significantly reduced by treatment landfill sites at the Ramici landfill.

Abstract

The opening of landfills in our country, as a result of production and consumption, is spontaneous and unprofessional, without taking into account hazardous processes of waste degradation in landfills, or dangerous and harmful matters that are continuously released in form of gases, and in particular of filtrate, causes significant pollution, mostly contaminating river flows and groundwater and other environmental media. One of the most important project tasks in the construction and exploitation of the landfill is the controlled management of the landfill and precipitation waters through the construction of a system that allows separate collection, treatment and discharge of these waters into natural watercourses. Treatment of leachate/leachate filtrate includes purification or non-neutralization of the harmful effect. Raw landfill leachate cannot be discharged into the recipient without prior treatment, due to its exceptional pollution ability. Reverse osmosis, as a membrane technique for filtering leachate filtrate, has been increasingly used to separate and filter organic and inorganic matter from the filtrate. The principle of the process is very simple. The aim of this paper is to examine the fact that the landfill filtrates are among the most problematic types of wastewater, viewed from the aspect of toxicity, and selection of appropriate techniques for their purification.

Keywords: *filters, pollution, reverse osmosis, purification, cleaner technologies*

Introduction

Environmental problems can be individual and local, but their negative impact is manifested and become visible globally. Therefore, in the concept of environmental management and action, the basic motto is: "Think globally, act locally". If we are talking about environmental problems, we can say that they are numerous and objectively difficult to solve. The responsibility for this falls on a man who, in view of his great scientific and technical power and ecological awareness, can protect nature, destroy it or further "create" it in a state of dynamic equilibrium. Naturally, this depends on the character of direction and a new scale of values in the processes of industrialism, post-industrialism, urbanization and adequate design of new technologies. Protection of the natural environment must become an organic part of the overall development projection. Humanity enters the new century and the third millennium with great ecological problems. One of the major problems is large quantities of waste, of various origin and contents in three aggregate states. Disposal and termination of waste is becoming a growing and increasingly general global problem, but also a local problem at the same time. Although located at the very bottom of the waste management hierarchy, landfilling is the most common method of waste management in both European and Pan-European countries. Generally speaking, there is a small degree of separation of different types of municipal waste at the site of production, and the production of waste and landfilling is one of the major problems of our civilization. During life of a landfill, special attention should be paid to the accompanying phenomena occurring on landfills in the form of unpleasant odours, rodents, insects, gases as well as leachate, and their impact on the environment. In particular, attention should be paid to water, both surface and underground, being under the greatest impact of potential pollution from landfills. Sewage waters are

loaded with matters of inorganic, organic and microbiological origin and are even 5 to 10 times more polluted than municipal wastewater. If natural watercourses are directly mixed with landfill waters that have not been previously purified, contamination poses danger for human and animal health. The same happens if soil or groundwater is contaminated by untreated landfill waters. One of the basic problems of waste management at landfills in practice is the problem of collecting and treatment of leachate (filtrate). The intensity of their production, and therefore the quantities, basically depends on a number of factors: age of landfill, types of waste, climatic factors and the like.

Material and Methods

For the purpose of this research paper, intensive research was conducted regarding the most efficient and economically most cost-effective solution for purification of leachate (filtrate), both from the aspect of the quality and quantity of treated leachate, and surface water quality in which the purified filtrates are directly released.

For research to bear results, regular monitoring of the water being purified has been undertaken, including sampling and testing of wastewater for the purpose of quality control, determining total wastewater load expressed in equivalent number of inhabitants, and determining efficiency of the wastewater treatment plant operation.

One of the most important project tasks in the construction and exploitation of the landfill is the controlled management of the landfill and precipitation waters through the construction of a system that allows separate collection, treatment and discharge of these waters into natural watercourses. In order to determine the quality of the leachate, the analytical method examines the following parameters: colour, temperature, electrical conductivity, haze, pH, ammonium nitrate, nitrates, nitrites, chlorides, sulphates, chemical oxygen consumption, biochemical oxygen demand, cadmium, iron, lead, zinc, consumption of $KMnO_4$, suspended matter, washed residue 105°C, dissolved oxygen, ortho-phosphates. Sanitary microbiological parameters examined during the study are: number of colonies of aerobic organotrophs at 22°C, total coliforms, faecal coliforms and faecal streptococci.(6)

As the landfill filtrate is the largest pollutant, its adequate management improves the quality of the environment and its protection. Landfill filtrates are among the most problematic types of wastewater, viewed from the aspect of toxicity and selection of appropriate techniques for their purification. The composition and quantity of leachate depends exclusively on the age and characteristics of the landfill itself.

The amount of landfill gas is unpredictable; it is difficult to determine it. According to some research, the maximum quantity of leachate is between 20-50% of the average amount of precipitation in the area of the landfill. However, science says it is more realistic to go with 5-15% of annual precipitation, due to the loss of a large part of the liquid by evaporation and in the process of anaerobic degradation of organic matter.

Results and Discussion

Treatment of leachate (filtrate) is considered to be purification or neutralization of the adverse effect. Raw landfill leachate cannot be discharged into the recipient without prior treatment, due to its exceptional pollution ability.

The selection of the leachate treatment process depends on the place for final disposal of the contaminated filtrate, which can be:

- Recirculation to the body of the landfill
- Biological purification in natural conditions (irrigation fields, soil filtration, biological lagoons and oxidation channels)
- Purification in artificial conditions in small plants through biological, thermal, physical, chemical and physical-chemical processes

- Discharge to city sewage, with prior treatment.

What kind of processing will be selected depends on the specific location of the landfill, conditions of its substrate, and quantity and quality of the treated leachate.

All of these processes can completely or only partially purify the leachate, most often biological or chemical impurities remain.

The efficacy of water purification using biological, thermal, physical, chemical and physio-chemical processes is presented in Table 1, based on elimination of parameters from the treated leachate: HPK, BPK_5, AOX (aromatic organic halogenate), NH_4 (N) and salts.(10)

Table no. 1. Benefits of applying different methods for filtering

Parameter / **Procedure**	**HPK**	**BPK_5**	**AOX**	**NH_4(N)**	**Salts**

*Source: Author's elaboration based on the laboratory analysis

Based on Table 1. it can be noticed that from all analysed leachate purification procedures, membrane technique is distinguished in particular, as part of the physical chemical process for purification of leachate, as the most efficient solution for removing mentioned parameters from the leachate.

Purification of leachate is carried out by using one or combination of several methods. Which method or combination is selected for leachate purification depends on the following criteria:

- Types and concentrations of filtrate matter
- Requirements regarding water purification degree
- Quantity of filtrate
- Conditions for disposal of residues after purification
- Other objective possibilities.

Leachate treatment costs range from 11 to 60 euros per tonne of waste and must be included in the cost of waste treatment.

For the purpose of research, as a support to presentation of leachate membrane filtration, a landfill in Ramici was visited, where leachate is purified through reverse osmosis since 2015.

Remediation and expansion of the Ramici landfill takes into account composition and quantity of the leachate, the landfill location, and it is clearly determined that the leachate is purified through reverse osmosis, all in order to meet requirements of the Ordinance on the conditions for discharging wastewaters into surface waters.

Reverse osmosis, as a membrane technique in leachate purification, has been increasingly used to separate and filter organic and inorganic matter from leachate. The principle of the process is very simple. The basic component in this process is the semipermeable membrane on which surface all changes occur. The product, clean water, passes through the membrane under pressure, while the mixture components or the concentrated solution are retained. Degree of water purification, capacity, economy and purpose of the plant depends on the quality of the membrane and operating pressure of the plant.

Basic problems when designing and constructing a reverse osmosis plant are provision of membranes that need to withstand high pressure differences and retain the proper permeability, and adequate quality of the reverse osmosis module in terms of hermetic seal and durability. The main advantage of this plant over adsorption and ion exchange plants is its

durability, without regeneration or replacement of the membrane module. High operating pressures (up to 16 bar) must be provided for efficient operation of the plant.
Reverse osmotic membranes (RO modules) are made of cellulose acetate, polyamide and other materials. The reverse osmosis block uses semi-permeable membranes, permeators and large pressure difference for moving water through the membrane, in order to achieve improvement in chemical, microbiological and endotoxicological quality of water.(9)
Reverse osmosis includes processes of solution separation where, under external hydrostatic pressure, greater than the equilibrium of osmotic pressure of the solution, the solvent is forced to flow in direction of the solute (A) → pure solvent (B) through the semi-permeable membrane, which separates solute and solvent. The direction of this flow is contrary to the direction of solvent flow which would be achieved with the classical osmosis, under the same conditions, from an area of high chemical potential to an area of low chemical potential, i.e. in direction the solvent (B) → solute (A), and based on this distinctly visible differences comes the name of this separation process - "reverse osmosis".(3)
In practical application of reverse osmotic module, this process is implemented in a way that water enters the membrane under pressure, the water molecules and limited amount of salts (permeat) pass through the semi-permeable membrane while the soluble salts are not allowed to pass and are discharged from the membrane and as flow with increased concentration of salt (concentrate) goes into a central sewage drain.
In the processing of the filtrate, the reverse osmosis found a great application for a variety of reasons:

- Meets requirements for the output concentration of heavy metals and aromatic organic halides (AOX)
- Meets requirements for HPK = 200 mg / l and 75% reduction of this parameter
- In case of direct discharge, no water management fee is charged
- Required area and space for the plant are relatively small compared to other procedures
- Simple shutdown and easy restart of the plant, which gives reverse osmosis great variability in capacity change
- Modular design gives light and quick upgrades
- The return of the concentrate to the landfill is generally granted for economic reasons
- 70% of the device is based on the principle of "disc tubes" or on the principle of a pipe barrier
- The plant can be installed in the container at the place of work, and only requires the foundation and power connection
- The plant can be easily disassembled and moved to another location, without significant investments
- The technology in this plant allows a pressure of 150 bar, and the concentrate management only takes 12% of the total quantity of treated water,
- The reversed osmosis process removes monovalent ions, multi-ion ions, insoluble particles, pyrogenic matter, and 99% organic matter.

In addition to the above-mentioned advantages, it is necessary to list measures to be adhered to when using the reverse osmosis plant, including:

- The filtrate tanks must be properly sized so that the leachate can be released into the surface waters after purification
- Due to the limited capacity of the permeable membrane surface it is not possible to increase hydraulic load short-term, as with conventional devices
- A well-trained and trained workforce is required
- It is necessary to have enough vital spare parts, because of the sensitivity to "work interruption"

- Design should be done specifically according to request for quality and quantity of water for processing with adequate cost estimate
- Problems in the plant can arise due to the development of microbial biomass on membranes, poorly chosen location of waste water suction, wrong selection of membrane material in terms of chemical and biological stability, poor concentration of concentrate and poor maintenance of devices, especially measuring instruments.

Conclusions

Reverse osmosis, as a membrane technique in the treatment of leachate (filtrates), also known as hyper filtration, is one of the more perfect filtration processes that eliminates even the tiniest particles from the filtrate. It is used to purify the filtrate by removing inorganic minerals, salts and other impurities in order to improve the quality of the filtrate through odour, taste, colour, etc., all for the purpose of protecting the recipients in which the filtrates are released.

In the treatment of the filtrate, the reverse osmosis found a wide application, with number of advantages and disadvantages. As the progress of each technology follows the economic aspect of the product, it is to be expected that the improved quality of the membrane and membrane filtration filters will improve already high purification rate, and a greater number of installations will reduce price of membrane models, as the economic aspect is the only limiting factor for the use of reverse osmosis in purification of the filtrate at the landfills.

LIFE CYCLE ASSESSMENT (LCA) AS A TOOL TO DETERMINE THE IMPACT OF PRODUCTION AND FOOD CONSUMPTION ON ENVIRONMENT

Vlatka ĐURAŠINOVIĆ *, Obrenija KALAMANDA, Svetlana TOPIĆ

University of Business Studies, Bosnia and Herzegovina
Corresponding author: vlatka1007@hotmail.com

Abstract

Clean environment is a priority in maintaining a healthy life. Food, as well, is an essential part of our lives and its constant production is highly required. However, the effects of food production and consumption often cause environmental degradation in the three crucial media which include water, air and land. Developing cleaner technology or cleaner production is more and more needed, yet it can still be considered counterproductive for industrial and economic development, as the positive effect of clean technology is not achieved in the short term and its implementation leads to higher costs. The method that is used for evaluation of a particular product and its environmental impact is called *Life Cycle Assessment* (LCA). The LCA technique monitors the entire life cycle of the product, starting from the analysis of the raw material, its transformation to the final product, emissions that are involved in the overall process, to the final disposal scenarios. With this tool it is identified each phase of the product's life cycle, with all the *inputs*, i.e. resources, materials and energy and *outputs*, i.e. emissions into water, air and solid waste that are implemented in all the processes. Given all phases and processes, the LCA tool uses all identified data in performing the *environmental impact assessment.* The aim of this paper is to look at the possibilities of setting up the LCA technique in order to reduce the impact of food production and consumption on the environment.

Key words: *Clean technology, clean production, LCA (Life Cycle Assessment)*

Introduction

A clean and healthy environment is a precondition for quality living and the survival of living beings. Food, as well, is an essential part of our lives and its constant production is necessary. Starting from this fact, we are facing one of the major problems of nowadays - the impact of food production and consumption on the environment, through the amount of waste, as the by product represents incremental harm at both the local and global level. Tremendous growth in waste coming from the food industry sector represents the ecological, economic and social problem of all of us. Increasing concern of society about the impacts that the food production and consumption has on the environment have contributed to the ever growing increase in environmental awareness in the last decade. However, the lack of knowledge is still prevailing in many parts of the world, especially in developing countries, where the environmental awareness is still not at a satisfactory level. Waste from food production and consumption is a product that no longer has usable value. However, waste is generated daily in all industries. Increasing amounts of waste lead to degradation of the environment and disruption of human health, both in developed and developing countries. Determining the characteristics of waste from the food industry is a prerequisite for deciding on its management and disposal. In our region, landfills continue to be the most common form of the final destination of waste. Integrated waste management from the food industry should be based on a concept that aims at reducing waste generation. In particular, integrated waste management focuses on waste minimization through the use of biodegradable raw materials and reduction of unneeded packagings, but also on the establishment of a system in a way that is safe for the environment, while taking into account the economic and social aspects.

The paper evaluates a method that is used for evaluation of a particular product and its environmental impact, called *Life Cycle Assessment* (LCA). The LCA technique monitors the entire life cycle of the product, starting from the analysis of the raw material, its transformation to the final product, emissions that are involved in the overall process, to the final disposal scenarios. With this tool it is identified each phase of the product's life cycle, with all the *inputs*, e.g. resources, materials and energy and *outputs*, e.g. emissions into water, air and solid waste that are implemented in all the processes (Stevanovic, 2011). Given all phases and processes, the LCA tool uses all identified data in performing the *environmental impact assessment.* The main aim of the paper is to analyze and explore the possibility of establishing LCA to determine the impact of production and consumption of food on the environment. The paper discusses the theoretical frameworks for the establishment of the LCA, taking into account the available literature in this field.

Material and method

Various methods and research techniques are used within this study, particularly the analysis and synthesis of collected data from literature research, as well as their processing. Objectivity and reliability of the information makes the work credible and give it importance in scientific research. By analyzing local and foreign literature and other sources, the analysis and synthesis of collected data is carried out through theoretical part. In addition to the literature, theoretical and expert contributions, studies of international institutions in the field of ecology and environment are used in the paper. As previously established, the main focus is set to the use of LCA method for calculation of environmental impact caused by the food production and consumption.

Life Cycle Assessment involves the analysis and monitoring of the life cycle of a particular product, both through the product's decomposition and through its environmental impact. This cradle-to-grave approach, as it is often called, considers all the life stages of the product from the raw materials to the final disposal, and are characterized as inputs and outputs of the process. The input includes resources, materials and energy utilization, while the output refers to emissions into water, air and solid waste. These processes are used to assess the impact of products on the environment.

According to LCA standard ISO 14040 (ISO, 2006a), the LCA consists of four consecutive phases, which are:

- Definition of goal and scope: Defining study parameters
- Inventory analysis: Evaluation of inventory inputs and outputs from all processes that form part of the life cycle of the product
- Impact assessment: Use of inventory analysis results to define environmental profiles and resource consumption for the production system
- Interpretation: An analysis of the impact and resource utilization profile according to the defined objective and extent of the study, including the sensitivity analysis of the key elements of the assessment.

The production LCA is used in assessing the impact of productive activities and the use of a particular product on the environment, but it neglects the intermediate waste generation and treats this phase as the output of the product system. For this reason, the LCA for waste management, which regulates the impact of a product that no longer has a usable value (waste) on the environment, is herein defined.

The European Union predicts that LCA in the future will become an important tool for supporting decision-making in all aspects of waste management (EU Commission, 2005). The need for finding this type of tool appeared in the 1980s, as consumers began to seek information about the impact of the products to their environment. Life cycle application in the environmental product and process analysis led to a new discipline, Life Cycle

Assessment (LCA). This approach has since been widely applied in industry to reduce the burden from the production, use and disposal of many products on the environment. Over the past decade, LCA has also been applied in waste management, providing a new insight into the environmental aspects of waste management. In addition to monitoring the impact of products and production on the environment and human health, the LCA system can also monitor the consumption of resources.

The importance of this technique is more and more evident due to increasing pollution in the process of production and consumption, increasing quantities of waste, loss of useful components from waste, and ever increasing exploitation and consumption of natural resources.

Results and discussion

Clean (or cleaner) technologies and waste prevention offer some parallels. Both have access to the life cycle and both aim at avoiding pollution at the source. However, while the waste prevention focuses only on waste and the prevention of waste generation, clean technology considers all types of environmental impacts. Thus, waste prevention can be considered as part of clean technology. An example is pure organic solvents technology (Clift and Longley, 1995). Although pure technology and pure production are often used synonymously, these two approaches may vary. Pure technology is an approach that goes beyond clean production. Clean production is focused on the production of goods and services with minimal environmental impact according to current technological and economic borders. Priority in clean technology is reflected in preserving and protecting the environment, which often implies higher costs. That is precisely why the development of clean technology and clean production can be considered counterproductive for industrial and economic development. This is certainly true in the case of capital costs, but large investments in new production methods can result in lower operational costs and total savings in long term. However, incremental changes are often easier to implement and have less associated risks of radical changes (Murphy and Gouldson, 2000). Regulations can help overcome such short-term barriers that prevent movement toward clean technology (Murphy and Gouldson, 2000). According to the United Nations Environment Program (UNEP) of the Clean Production Program: "Clean production is a continuous application of an integrated preventive environmental strategy to processes of products and services in order to increase overall efficiency and reduce the risk to people and the environment. processes used in any industry, products, and services in the society " (UNEP, 2001). World-wide successful companies have recognized the importance of this business segment and are showing an increasing interest in carrying out activities that prevent environmental damage. Activities within companies focusing on "green" products and environmental product orientations are of paramount importance and gain greater competitiveness on the market. The purpose of reducing the impact of food production and consumption on the environment is to recognize, assess and minimize the negative impact on the environment. It is a long-lasting and complex process, and requires a systematic review of the environmental impacts, human health and biodiversity security. Summarizing the LCA technique in everyday production, we conclude that the LCA allows monitoring of the impact on air and water, as well as the transition of pollutants from one phase to another, or between these three environmental media. It also prevents the negative impact of production and consumption on biogeochemical cycles and brings to a greater importance of the environmental protection through various technologies and services, as well as improving economic opportunities through projects. Harmonization of needs and possibilities, seriousness and responsibility in planning, and persistence in realization of projects, strategies and action programs must be systematic and done with high interest. The results and progress in this sphere are weak, slow, unattractive, without high awareness,

solidarity and support of both the population and the authorities. Still, some proposals of potential measures are visible in emerging projects, plans and programs done by various environmental organisations. Such initiatives should contribute to lowering the shortcomings mostly related to subjective weaknesses, human omissions, ignorance and lack of coordination in the governance structure. Mistakes and omissions with harmful, dangerous, poisonous substances can have unimaginable consequences at the moment, in the short term, on the long run, but also on a permanent basis.

Conclusion

The empirical part of the paper opened some questions and problems of the management function in this field, mainly with regard to the interdisciplinary nature of the ecological sphere. In functional terms, it is necessary to engage numerous teams in the fields of natural, technical, medical and social sciences, i.e biology, ecology, chemistry, economics, law, medicine. The organization of the administration, especially the sector of economic or production activity, is specifically rationally structured and rounded up according to the subject of activity. From the theoretical and empirical part of the research it can be concluded that there is a discrepancy between the knowledge about problems, planned activities and normative approaches on one side and the real financial and technical-technological possibilities of the local and wider community to realize these and other ideas of pure production and consumption, on the other side. When it comes to the waste management, it can be noted that there had been a great shift from the industrial society, when the economy was characterized by mass production and greater responsibility of businesses and cities for their waste, to nowadays when most of these are still absent. The favorable circumstance of support of EU funds is in favor of equipping companies to master the technological process of production of a range of new products for the market, which would make them self-sustaining and profitable in the competition. This can primarily refer to the production of disposable packaging in the food, chemical, textile and construction industries.

PRINCIPAL COMPONENT ANALYSIS (PCA) IN ASSESSMENT OF THE LANDSCAPE IN HERZEGOVINA REGION (BOSNIA AND HERZEGOVINA)

Zrinka KNEZOVIĆ*, Katica ARAR, Elma SEFO, Ana MANDIĆ

Faculty of Agriculture and Food Technology, University of Mostar, Bosnia and Herzegovina
*Corresponding author: zrinka.knezovic@aptf.sum.ba

Abstract

The aim of the research was to reduce a large number of attributes in subjective visual assessment of landscapes. Determination of the significance of the main traits in landscape assessment is important for better understanding of the observer and intensifying of landscape changes. Numerous traits influence landscape perception but some of them can overlap. The question is if they can be grouped into components. We have studied which attributes are important for respondents to value landscapes. Principle component analysis (PCA) was done, and the Kaiser criteria was used to determine how many meaningful components should be retained for the interpretation. The presented methodology was applied to the real data obtained from the questionnaire on a sample of students attending the University of Mostar (Bosnia and Herzegovina). Statistical package SPSS 16.0. was used. The statistical analysis of nine variables showed four relevant main components that should be used for more precise decision-making and improvement of landscape development. The first PC could be named component of environmental and biological value, with traits: environmental value 0.872, biodiversity preservation 0.902 and biogeographic position 0.727 (correlation coefficients). The second PC is spatial and developmental component, and it emphasizes the importance of traits: rural development 0.848, spatial planning 0.838 and technological value 0.752. The third PC component is sociological value with traits of the same name 0.937. The fourth PC cultural tourism with traits: cultural heritage 0.944 and development of tourism 0.677.
Interpretation of data through principal components shows some hidden connections and interrelations of data.

Key words: *PCA analysis, landscape, components, traits.*

Introduction

Landscape means geographical area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors (UNESCO, 2005). Landscape management means action, from a perspective of sustainable development, to ensure the regular upkeep of a landscape. Landscape planning means strong forward-looking action to enhance, restore or create landscapes. When planning and designing public green areas, landscape architect should also give consideration to social needs of the users concerned. Inadequate landscape maintenance may reduce the natural visual quality (Noralizawati *et al.*, 2012). Over time people attach emotional meaning to "place", which can result in a particular attachment to green areas, and can be manifested at a real and symbolic level (Low and Altman, 1992). The visual and aesthetic characteristics of place are one of the most important environmental perception factors (Pereković *et al.*, 2007). Aesthetics of place is important for its "branding" (Miškić-Domislić *et al.*, 2013). According to the subjective paradigm, the quality of landscape can be estimated only by "the eyes of the beholder" (Lothian, 1999). The paper explores the subjective perception of landscape, emphasizes the traits of an object as well as the meaning attached to it by the subject (Crosgrove, 1984). Numerous traits influence the determinants of landscape identity. Knowledge of these traits may significantly influence the intensification of landscape changes acceptable to population.

The main objectives of the PCA are to reduce and analyze the linear correlations of a larger number of multivariately distributed, mutually correlated variables with the aim of obtaining a smaller number of components, new variables, mutually uncorrelated with minimum loss of information. (Orlić, 2012). The maximum number of new variables that can be formed is equal to the number of original variables, and the new variables are uncorrelated among themselves (Sharma, 1996). Many authors argue that PCA is only a specific form of factor analysis (FA) occurring when the decision on the analysis method is made: from the total variance, or the sum of variances of all variables, as is the case in PCA, or only from the part of total variance that is common to all variables, like in FA (Hair *et al.*, 1995). The reason for this is the fact that PCA is found as an option of FA in the statistical package SP SS and STATISTICA. However, the aim of PCA is to create new variables that explain the maximum amount of total variance in data by forming new components (Pecina, 2006). The need to reduce the number of traits is apparent when assessing the main traits.
The objective of this paper is to show the reduction of traits to a smaller number, through implementation of the statistical method of principal component analysis (PCA) and the necessary steps to be followed. PCA is one of the simplest and most popular methods of multivariate statistics used in almost all scientific disciplines.

Material and Methods

The data were collected by the survey method on a sample of students of the University of Mostar (Bosnia and Herzegovina) in 2016. The survey used a questionnaire consisting of questions related to traits determining the value of landscape. The quality of the questionnaire was tested by a pilot study. Data on landscape characteristics were evaluated on the sample of 100 randomly selected students attending the University of Mostar. After this, the final version of the questionnaire was drawn up and the survey was conducted on a new group of respondents with 30 study groups, for nine traits: KA1 environmental value; KA2 rural development; KA3 spatial planning; KA4 technological value; KA5 cultural heritage; KA6 tourism development; KA7 social value; KA8 biodiversity preservation and KA9 biogeographic position. The results of the conducted survey were analyzed using principal component analysis (PCA) (Hotelling, 1936). PCA was processed on the basis of a correlation matrix in the statistical package SP SS 16. After calculating the correlation matrix for all observed traits, principal components are obtained based on correlation coefficients between the variables were extracted. Examination of the Correlation matrix confirmed the suitability of the data for conducting further analysis. Kaiser-Meyer-Olkin (KMO) test measures the sampling adequacy, or whether the data fit into factors. It is obtained as the ratio of sums of squares of correlation coefficients of all the variables in the analysis (except those between themselves which are all equal to 1) to the same sum of squares plus squares of the partial correlation coefficients of each variable *i* with each variable *j* while excluding other variables:

$$KMO = \frac{\sum\sum_{i \neq j} r^2{}_{ij}}{\sum\sum_{i \neq j} r_{ij}{}^2 + \sum\sum a^2{}_{ij}},$$

where r^2_{ij}, ($i \neq j$) is the square of the off-diagonal element of the correlation matrix (square of the coefficient of correlation between the i^{th} and the j^{th} variable), and a^2_{ij} ($i \neq j$) square of the off-diagonal element of the anti-image correlation matrix (the square of the coefficient of partial correlation between the i^{th} and the j^{th} variable). The KMO ranges in a closed interval from 0 to 1. If the KMO value of the measure is less than 0.5, the correlation matrix is not suitable for factor analysis. Except that the KMO value can be calculated for the entire matrix, it can also be calculated for individual variables. Initial results and given eigenvalues,

percentages and cumulative variance percentages for each individual factor were obtained. Eigenvalues of a certain factor are equal to the sum of squares of factor loads by all variables for that factor. Eigenvalue factors greater than one are selected. The percentage of explained variance of each individual factor is calculated on the basis of its eigenvalue of that factor, or as the ratio of the eigenvalue to the sum of eigenvalues multiplied by one hundred. The sum of eigenvalues is equal to the sum of initial communalities. On the main diagonal of the correlation matrix that is analyzed unities are used for initial communalities, the sum of initial communalities is equal to the number of variables. When the eigenvalue of a given factor is divided by the sum of eigenvalues, or with the number of variables and multiplied by one hundred, the percentage of total variance of that factor will be obtained. Using the criterion of the percentage of explained variance, extraction of factors should continue until the extracted factors explain at least 95% of the total variance. The number of factors can also be determined based on Cattell's scree plot. When making a decision, both criteria are usually combined. After determining the number of factors, it is necessary to determine the matrix of factor structure of the extracted factors that contains factor loads. Factor loads show the importance of each variable for the individual factor. The communality (h_i^2) of a variable shows how many variances of that variable are explained by common factors. The factors are then rotated in order to maximize the connection between variables and some of the factors. An orthogonal rotation is performed, and the number of factors is determined. Varimax rotation is more successful in achieving the principle of simple structure than others. After rotating the factor, it is also necessary to determine the factor matrix on which factor interpretation and identification of attributes that have high loads for the same factor are based. The sum of squares of factor loads of a given variable is equal to the communality of that variable. In orthogonal factor rotation, the sum of squares of factor loads for each individual variable after rotation must be equal to the sum of square factor loads before the factor rotation was conducted:

$$\sum_{j=1}^{m} \lambda_{ij}^{\ 2} = \sum_{j=1}^{m} \lambda^{*}_{ij}^{\ 2}, \quad i=1, 2,\ldots,p,$$

Where λ_{ij} is the factor load of the variable i and the common factor j before the factor rotation, and λ^{*}_{ij} is the factor load of the variable i and the common factor j after the factor rotation. It is usual to name components and show the importance of components in prediction of the original variable. After clarification, reliability of the questionnaire is also analyzed. The questionnaire reliability measurement shows the suitability of the measuring instrument and shows that the same measurement indicators would be obtained by its use in repeated measurements. One of the models is the Cronbach α coefficient, which measures the internal consistency of a particular component and the total value. A higher value indicates greater reliability, or shows that the attributes of the same component measure the same occurrence. A value greater than 0.60 indicates an acceptable level of reliability in research.

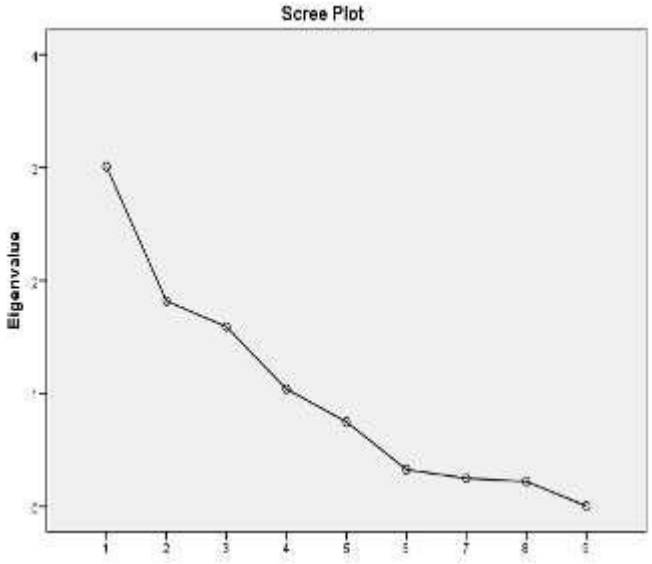
Results and Discussion

The correlation matrix between the variables showed a high degree of correlation, as well as suitability of data for analysis and possible application of PCA. Sample adequacy and test of sphericity were analyzed. KMO was 0.7 and showed that data fit well, and Bartlett's test of sphericity was statistically significant 0.000.

Table 1. Eigenvalue and variability of non-rooted values of principal components

Principal components			
	Eigenvalues	% of Variance	Cumulative %
1	3.008	33.417	33.417
2	1.817	20.187	53.604
3	1.590	17.663	71.266
4	1.039	11.542	82.809
5	0.749	8.320	91.129
6	0.326	3.623	94.752
7	0.248	2.756	97.508
8	0.220	2.450	99.958
9	0.004	0.042	100.000

Table 1 shows that 33.42% of variance is attributed to the first principal component, and even four principal components are needed to cover 83% of variations. Values of Latent roots – Eigenvalues were lower than one after the fourth PC: With those four PC approximately 83% of total variance was explained. Scree plot can also be used to establish the number of components for analysis, or the point at which the curve tends to straighten. When making a decision, both criteria are usually combined. Graph 1 shows that the curve tends to straighten after the component no. 4, for which the eigenvalue is also less than 1.



Graph 1. Component number – Cattell's scree plot

It was not enough to stay at the level of finding PC. Certain traits have a high coefficient of correlation with only one PC. Some have lower correlation level with more PC and next PC have facilitated the need for principal components rotation (Ivanković, 1988). In this way we had clearer distribution of particular traits inside of them, and traits were more closely tied to particular principal components (Table 2).

Table 2 gives the structure matrix data after the Varimax rotation is performed, and shows the coefficients of correlation of individual traits with extracted components.

Table 2. Rotated Component Matrix

	Principal Components			
	1	2	3	4
KA1	0.872	-0.146	-0.097	-0.367
KA2	-0.253	0.848	-0.302	-0.089
KA3	0.183	0.838	-0.301	-0.132
KA4	0.145	0.752	0.003	0.179
KA5	0.047	0.060	-0.064	0.944
KA6	0.366	0.128	0.452	0.677
KA7	0.097	-0.031	0.937	0.017
KA8	0.902	0.055	0.175	0.070
KA9	0.727	-0.018	-0.360	-0.160

Assigning a name to each component shows its importance in the prediction of each original variable. The first PC (KA: 1, 8, 9) could be named component of environmental and biological value, and it contains traits: environmental value = 0.872, biodiversity preservation = 0.902 and biogeographic position = 0.727. Biodiversity preservation has the highest loads in this component. The importance of biodiversity as an important development factor was also adreees by Munić (2010). The second PC (KA: 2, 3, 4) could be named spatial and developmental component and it stresses the importance of traits: rural development = 0.848, spatial planning = 0.838 and technological value = 0.752. The variable rural development has the highest coefficient and load with this component. The third PC (KA: 7) component is sociological value with traits of the same name = 0.937.

The fourth PC (KA: 5, 6) could be named cultural tourism and it is characterized by traits: cultural heritage = 0.944 and development of tourism = 0.677. The importance of these traits was also described by Pavlović (2000) and Bejtović (2008). The Cronbach alpha coefficient measures the reliability of grouping reduced attributes into common components. Traits within the components have satisfactory correlation measures, which confirms the reliability of the survey: PC1 Cronbach $\alpha = 0.85$; PC 2 Cronbach $\alpha = 0.63$; PC3 Cronbach $\alpha = 0.73$; PC4 Cronbach $\alpha = 0.65$. The total value of this coefficient was 0.90 and represents an acceptable level of reliability in the survey, and reliability of the used questionnaire and the possibility of its use as a measuring instrument in a repeated survey.

Conclusion

Based on collected data and application of the principal component analysis (PCA) method, the conducted studies reduced a larger number of traits to a smaller number of components formed on the basis of common traits. The four components were named: environmental and biological value, spatial and developmental, sociological value, and cultural tourism. Interpretation of data through principal components shows some hidden connections and interrelations of data. The obtained results will be used in further studies aimed at measuring the quality and development of landscape. Knowledge of identified traits may significantly influence the intensification of landscape changes acceptable to population.

WASTEWATER GOVERNANCE IN URBAN TERRITORY – CHALLENGES TO THE CIRCULAR ECONOMY IN BULGARIA

Angel SAROV

Institute of Agricultural Economics, Sofia, Bulgaria
*Corresponding author: angelsarov@abv.bg

Abstract

The uncontrolled growth of the cities and urban population has led to need to sustainable governance of natural resources and the waste. One the most important of these resources is water, which becomes a scarce commodity because of its use not only by the households, but also by the industry. In this regard, wastewater recycling is an essential element of the circular economy. Wastewater treatment is a process where extra resources are extracted - remain biogas and sand, sludge and purified water respectively. Generally, the resulting biogas is used for heat and electricity, the sand in the construction, and the purified water is discharged into hydro-basins. In practice, there are several options for utilizing sludge. These are known for improving agricultural or non-agricultural soils. Apart from agriculture, sludge is also used in forestry, reclamation of disturbed terrain - mines and eroded areas, fuel, and construction technologies. The aim of this paper is to analyse the benefits or threats for the society and the economy, as a result of the wastewater governance in urban territory, at the same time, paying attention to the environmental challenges arising from the circular economy. Does the circular economy harm the environment and society?

Keywords: *sustainable governance, circular economy, natural resources, wastewater recycling, Bulgaria*

Introduction

The continued and uncontrolled growth of the cities and urban population has led to the need of sustainable governance of the natural resources and the waste. The goal of the sustainable governance is to reduce consumption and save raw materials, water and energy, thereby contributing to the conservation of resources. During the last decade, economic, social and environmental factors were adopted as key elements of sustainability. In recent years, governance has become the fourth pillar of the sustainability. Linking these concepts and involving the circular economy as the fifth pillar is a challenge of sustainability in the search for new theories and paradigms.

Circular economy models can be divided into two groups. The first one encourages the reuse of resources through recycling, processing, etc. The second one turns old goods into new resources. Knowledge about the essence and objectives of the circular economy is increasingly being applied in the industry. Although the idea of a circular economy is a relatively new concept, it raises fears and scepticism not only in society, but also among the scientific community. The concerns about resource reuse, greenhouse gas emissions, ethics and safety have changed the research approaches. Demonstrating the benefits (or not) of the circular economy will contribute to policy coordination in line with sustainability perceptions and approaches in building business models. When assessing sustainability, a specific historical moment and the specific socio-economic, institutional and natural environment are taken into account (Bashev, 2016). However, this does not automatically guarantee that the same indicators will be reported in future periods. There are contradictions in the business that are related to balancing environmental and economic interests. They involve difficulties in reconciling the objectives of "economic growth" with those of "sustainable governance" and "sustainable development" as indicators for environmental assessment. The main problems

arise from the fact that society and the economy are interrelated. In this case, the question in front of the corporate governance is how to report economic growth that does not damage, but preserves the environment.

The aim of this paper is to analyse the benefits or threats for the society and the economy, as a result of the wastewater governance in urban territory. At the same time, paying attention of the environmental challenges arising from the circular economy. A review is made of the available information on the various aspects of applicability of wastewater sludge in the purification plants. Answers have been searched also for topical issues related to the impact on soil fertility, plant production quality, human and animal health. Opportunities are being explored to exploit this by-product in other systems that do not harm the environment.

The recovery of wastewater sludge is not only a corporate problem. Bearing in mind that wastewater treatment plants and wastewater safety are strategic directions for the benefit of society, the use of sludge should be a national policy with a direct government commitment.

Material and Methods

The paper is based on an extended review of primary and secondary data. The application of wastewater sludge to farmland in EU member-states corresponds Directive 86/278/EU "Environmental Protection Directive". It strongly prohibits the use of sludge from sewage treatment plants in the agriculture, provided that specific requirements are not met. According to European Union laws, sludge from urban wastewater treatment plants is not dangerous when properly managed. Provided that certain requirements are met, they should not pose a risk to the environment or human health, or even to the contrary they can bring benefits. In fact, the EU has a very precise and clear regulation on the requirements for the treatment of sludge, namely: Directive 91/156/EU "Waste Base Directive"; Directive 94/3/ EU according to which sludge from sewage treatment plants is excluded from the category of hazardous waste; Directive 99/31/EU on landfill; Directive 2000/60/EU establishing a framework for Community actions in the field of water policy.

In Bulgaria these issues are regulated in harmony with the European Law on Agricultural Land Protection, Art. 6, paragraph 1, item 3 (SG, No. 35, 1996); Waste Management Act (WAS), (SG, issue 53, 2012); Ordinance on the Procedure and Method for Utilization of Waste Waters by Their Use in Agriculture (Decree of the Council of Ministers No. 330/2004, SG, No. 121, 2014, amended SG No. 20/2011) and others. But strategies and "sustainable practices" that respond to emerging problems in certain countries are not always relevant to others (Bashev, H., 2016).

According to the Ordinance on the Procedure and Method of Utilization of Sludges from Wastewater Treatment by Their Use in Agriculture (promulgated in State Gazette No. 63 of 12 August 2016), it is necessary to take samples from each batch of the following 22 indicators: Dry substance; Total Organic Carbon; Active Reaction - pH (H_2O); Total Kjeldahl Nitrogen; Ammonium and nitrate nitrogen; Phosphorus - extractable and exchange forms, recalculated as P_2O_5; Potassium - extractable and exchange form, recalculated as K_2O; Calcium - exchange forms; Magnesium - exchange forms; Water-soluble sulphates, recalculated as sulphur; Copper; Nickel; Lead; Zinc; Mercury; Chromium; Arsenic; Escherichia coli; Salmonella spp.; Clostridium perfringens; Viable helminth eggs. However, the legislation does not automatically lead to a greater safety.

Results and Discussion

As one of the most important resources, water becomes a scarce commodity because of its use not only by households but also by industry. In this respect, the wastewater recycling is in support of the circular economy. Wastewater treatment is a process in which some extra resources are extracted. Primary, secondary and tertiary purification is expected to separate

biogas and sand, sludge and purified water respectively. Typically, the resulting biogas is used as heat and electricity, sand in the construction, and purified water is discharged into hydro-basins.

The wastewater sludge, also called bio-equipment, is a by-product of wastewater treatment processes. The sludge characteristics depend on the quality of the sewerage network and the type of treatment processes that is used. Practically, there are several options for utilizing (or disposing) sludge. These are the known practices for improving agricultural or non-agricultural soils. Apart from agriculture, sludge is also used in the forestry, re-cultivation of disturbed terrain - mines and eroded areas. Newer options are - power, fuel, construction recovery, new technologies and sludge disposal in special protected landfills.

Wastewater sludge contains organic and nonorganic nutrients that can replace the naturally occurring soil fertilizer, known to the public. The presence of potential toxic metals often limits their use.

The questions are as follows:

• Are the physical, chemical and biological properties of the soil changing, when using sludge in agriculture?

• Is the yield of crops in changed soils higher than in the natural ones?

• What changes occur in soil fertility due to the application of excessive sludge levels over many years?

• Are really sludge contributing to the circular economy or are they an environmental problem?

Will the answers to these questions help to assess the sustainable governance of by-products from wastewater and what are the benefits to the circular economy? It is a fact that plants differ in their ability to absorb from the soil the metals and nutrients, extracted from the sludge. Agriculture is known as one of the most important sectors of economy, which requires the development of a separate model for its sustainable development.

According Milieu Ltd (2010) data, the total sludge in the EU-27 is over 10.1 million tonnes of dry matter, and in 2017 the expectations are to reach over 15 million tonnes (EU-28). About 40% of this amount is used in the agriculture. In different European countries the percentage varies. In Denmark, France, Ireland, Spain and the UK - over half of the sludge is used in agriculture. At three - they are not recycled in the agriculture, and in others less than 5% of the total sludge production is used. Since 1995, the amount of land-filled sludge in the EU has continued to grow. However, in some Member States restrictions have been registered, even stopping the use of sludge in agriculture (such as Switzerland and the Netherlands). Due to the increased public concern about the safety and health of humans and animals in areas such as Flanders in Belgium, Bavaria in Germany and parts of Austria, they have phased out this activity. Some member-states already burn the sludge and the residual ash is deposited. For example, more than 70% of the sludge is burned in Flanders (Belgium), in the Netherlands - 60%, Austria, Denmark and Germany - 40%. This naturally generates side environmental problems. Activities for the recovery of sludge for electricity and heat are increasingly being promoted. In the world's scientific literature, the topic occurs to be quite up-to-date. There are researches on the beneficial impact and possible risk of sludge application in the soil (Singh and Agrawa, 2010). They argue that wastewater sludge in the agriculture provides benefits, as a substitute for chemical fertilizers. The sediment also provides other plant macronutrients, such as potassium and sulphur, copper and zinc. Other researchers point to damages in terms of climate change and greenhouse gas emissions from the sewer. It was found that the carbon from the sludge used in the agriculture would be isolated in the soil. However, this is not entirely scientifically substantiated. As regards to the air pollution, although reducing the use of chemical fertilizer by replacing sewage sludge, the nitrogen oxide emissions associated with this fertilizer of not less than 20% of the nitrogen in the degraded sludge is considered to

be readily available for plants. The condition, structural properties and retention of soil moisture as a result of sludge are also well studied.

In Bulgaria (Marinova and Tsolova, 2005); Baykov, Popova, Zaharinov, Marinova-Garvanska, Kaleva, Kirov, (2013); Popova, Zaharinov, Gentcheva, Pejtchinova, Marinova-Garvanska, Baykov (2017) have extensive research experience and a long list of publications related to the topic. In this area, however, it engenders discussion in the scientific community and practitioners. The publications on the topic are related to the benefits of sludge for agriculture, as a fertilizer for soil fertility and soil structure. Zaharinov (2011) affirms that sludge from "humification products" does not cause "serious" ecosystem damage. It is claimed that "the use of sludge in the agriculture is a cost-effective and environmentally friendly method". Other authors (Dermendzhieva, 2017) have shown that due to the content of "excessive amounts of certain biogenic elements and heavy metals, or pathogenic microorganisms and invasive forms of parasites, they are dangerous to the environment, human health and animal wellbeing". In other words, "there is a risk of microbiological contamination of soils using sludge" (Dermendzhieva, 2017).

The differences of concepts of the benefits and disadvantages of land-use utilization in the agriculture once again suggest that the issue is under-studied and incomplete, raising doubts about the benefits to nature and human health. This reinforces the topicality of the subject, moreover, because (all the more so that) the problem is not only regional or national to the ecological balance but also global. The sludge contains components that can be reused as well as dangerous elements, such as heavy metals.

The sustainable governance of sludge has several basic aspects - legal, techno-economic and informational. They are all interrelated. To account the impact of all factors, they should be analyzed in a relationship, not individually or in isolation.

Some questions arise as follows: Are these indicators sufficient to ensure any safety for humans and animals? Or if the norms of one (or a certain part of it) are above the allowable, what will be the fate of the generated sludge?

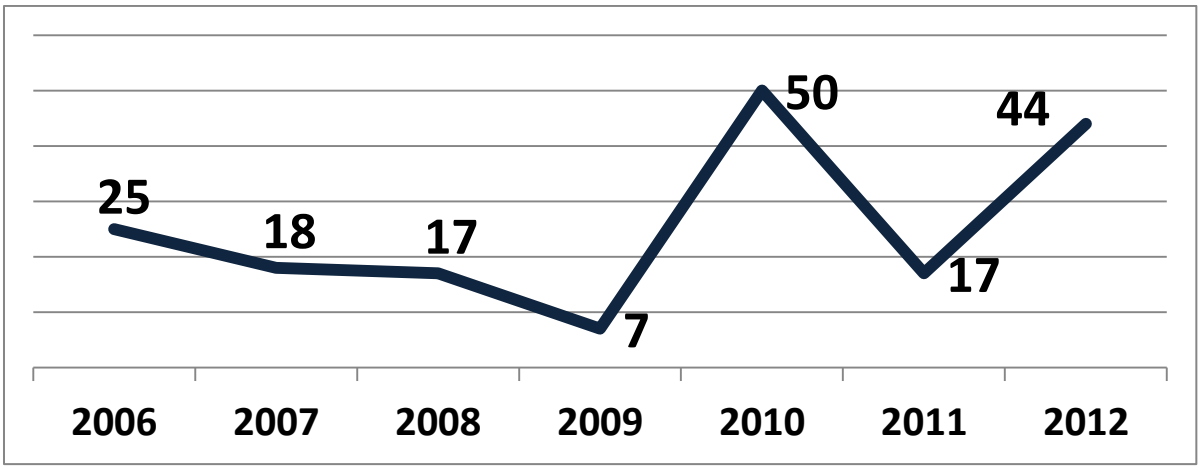
Bulgaria is obliged to implement the statutory provisions of the European Urban Wastewater Treatment Directive (91/271 / EU) on secondary treatment for all urban agglomerations of over 2,000 inhabitants. This means that nearly 90% of the country's population will be covered by the sewerage system. The population will probably continue to move more towards the cities, which will surpass these 90%. As a result, the amount of generated sludge will increase almost twice. Bulgaria has not yet changed the old practices of sludge management (landfilling and recovery in agriculture). They cannot be used in the future, not only because of the risk prevention requirements, but also because of the expected increasing amounts of sludge. The challenges for all stakeholders are growing, and we are all affected by the consequences of "greening" and "green economy" policies. Sludge treatment is the bigger challenge compared to wastewater treatment. Unlike wastewater that after discharge is naturally discharged into water, sewage is collected in a treatment plant, additional costs are generated while being transferred to agriculture, etc. A minimum of 6 months of drying time is required, which reduces the unpleasant odour. However, "sludge remains an environmental problem in terms of their generation, storage and exploitation" (Zaharinov, 2011). According to the legislation, periodic health and environmental expertise and test of stabilized sludge must be carried out.

Are approaches in the circular economy safe for people and nature?

According to the Bulgarian legislation, "sludge is not allowed to be used on meadows, pastures or areas fed with fodder crops if they are used for grazing or the feed is harvested within less than 45 days after the sludge is used; soils on which fruit, vegetable crops and vines are grown, with the exception of fruit trees; soils intended for growing of fruit, vegetables and other crops, which are in direct contact with the soil and consumed in a raw

state for a period of 10 months before and during harvesting; coastal floodplains, riverbeds and protective dykes". The data (Figure 1) show instability / lack of sustainability with regard to the number of permits for the utilization of sludge in agriculture during the period 2006-2012. Naturally, this is an indicator of uncertainty and mistrust among farmers about the quality of sludge, as a humus soil enhancer and about the safety for human and animal health. The practitioners, specialists and researchers interpret differently the conditions and factors for sustainability of agriculture.

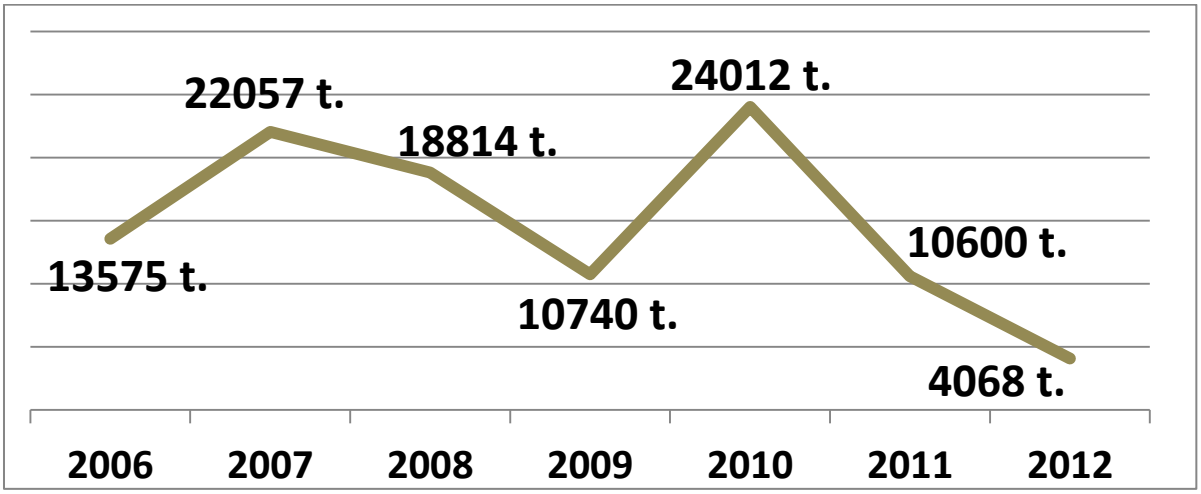
Figure 1. Permits for the utilization of sludge in the agriculture during the period 2006-2012 in Bulgaria



Source: MAF, BSA (2013)

Even more volatile is the emerging picture of the utilization of sludge in agriculture for the period 2006-2012, that has given the constantly increasing amount of sludge from the treatment of waste water. There has been a serious decline in recent years.

Figure 2. Sludge utilization in the agriculture in the period 2006-2012 in Bulgaria, tons



Source: MAF, BSA (2013)

Bulgaria currently operates whit 89 urban wastewater treatment plants, 50 of which are newly built or expanded with European funds from the period 2007 - 2013. The completion of eight treatment plants with funds from the new period and the construction of nine new ones under

the so-called Early Projects under the Operational Program "Environment" will be completed. Thus, sludge will increase simultaneously with the construction of water infrastructure. According to information from the Environment and Water Ministry, 44% of sludge in 2015 is recycled and recovered. This share should grow further in future. By the end of 2016, recycling should reach 55%. 60% by the end of 2018 and 65% by the end of 2020. Energy recovery should reach 10% by the end of 2016. 20% by the end of 2018, and 35% by the end of 2020. Solving a single problem often leads to another one. Sometimes it is more appropriate to rethink and make a reassessment of carefully the opportunities for removing pollution at regional level. Making a hasty decision can cause a global ecosystem crisis and it could have unforeseen consequences.
Another questions arise again:

- Are there any substances contained in sludge that are not monitored but are potentially dangerous for use in agriculture?
- Is the physical-mechanical composition of the soil impaired?
- Is biodiversity in the soil impaired?
- Is the soil poisoned by sludge utilization?

When assessing the sustainable governance of natural resources, it must be known that water, soil and climate are interconnected. This requires that the research should be directed not only to sediments but also to the mixture resulting from the sludge-soil interaction, or how to change the physical-mechanical, chemical and biological properties of agricultural land. In analyzing the physical properties of the soil, the soil-water-climate relationship should be measured. The presence of sludge changes the ability of the soil to retain water, permeability and porosity, which are indicative of its good status. The reducing of organisms, especially earthworms, is an indicator of changes and imbalances. They can be an indicator of sustainability, because their population is heavily dependent on soil contamination. The assessment of the impact of sludge is not only associated with changes in the physical-mechanical, chemical and biological properties of the soil. An economic analysis of plant productivity with purely economic indicators is needed. This means a comparative analysis of the yields obtained with and without sludge in agricultural land.
For these reasons, which are as unexplored factors, farmers are still sceptical about the opportunities about sludge recovery. However, they can prove to be very beneficial for improving the biological properties of the soil.
With regard to chemical changes, the soil must be neither acidic nor alkaline. The most important thing for plants is to have enough nutrients due to the presence of organic matter

Conclusions

The concept of sustainable resource governance includes regulating of consumption, saving raw materials, water and energy to help the protection the environmental. However, following these policies often provokes business contradictions, which are related to the balancing of environmental and economic interests. They involve difficulties in reconciling objectives. Challenges for all stakeholders are growing; we are all affected by the consequences of "economic growth" and "green economy" policies. Therefore, the recovery of sewage sludge with regard to sustainable consumption and production patterns is a challenge in any of science and practice. In support of these opportunities, the EC envisages the signing of two papers for innovations. Legislative barriers to electronic mobility and recycling of batteries will be examined; the other will address regulatory barriers to sustainable wastewater treatment using innovative bio-reactor technology for anaerobic membranes. The Horizon 2020 program envisages investing EUR 650 million in the Industry 2020 in the circular economy. It provides an opportunity to demonstrate the economic and environmental

compatibility of a circular economy approach and at the same time gives impetus to EU re-industrialization. There is a need for a networking concept, which is also supported by funding opportunities for various circular economy projects. The benefits to society will be related to a greener urban environment, conservation of natural resources, economic efficiency, reduction of carbon footprint, Business to Business solutions.

Abstract

The current research is focused on the landscape ecological preconditions and the restricting role of the rice-growing environment in Bulgaria. The analysis of landscape ecological conditions is a fundamental step in characterizing of specific features of rice production as agro-economic activity. The specific research focuses on the relationship between the agro-environmental requirements of rice crops and the specific landscape ecological conditions in the Pazardzhik-Plovdiv field. The specific combination of the main natural components in this part of Bulgaria is a major factor for the development of rice production since the second half of the 14th century. The favorable climatic, hydrological and soil conditions in the Pazardzhik-Plovdiv field determine the process of growing rice crops as the main one in the agrarian profile of this part of Bulgaria. The natural combination of landscape forming factors, interrelationships and interactions between them, predetermines the existence and functioning of specific hydromorphic landscapes, typical of the lowland territories located around the Maritsa River and its tributaries. On the other hand, the specificities of the anthropogenic workload of these landscapes in historical and geographic aspect are a major factor in the development of anthropogenised rice field agricultural landscape. These agricultural landscapes are characterized by a qualitatively new spatial-temporal structure, functioning and development, which are determined by the restricting role of the natural environment. From landscape ecological point of view, the main focus of rice growing in the Pazardzhik-Plovdiv field is the existence of such specific agricultural landscapes, typical for this part of Bulgaria only.

Keywords: *agriculture, anthropogenic activity, landscape components, landscapes, rice producing.*

Introduction

Rice culture is introduced in the Bulgarian lands in the middle of the 14th century. "In the second half of the 19th century around Plovdiv and Pazardzhik large farms for the cultivation of rice on the rivers have formed" (Gramatikov, 2006). The rice becomes a major culture in the agrarian profile of the Bulgarian economy. The rice is one of the main food sources for realization the population's living on these lands from the middle Ages to the present day. At the various stages of development of the Bulgarian economy and social relations, the rice produced on the Bulgarian lands has occupied an essential place in the product export, either of the Ottoman Empire, or of Bulgaria after the Liberation. Pazardzhik-Plovdiv field categorically stands out as the main rice-producing region in the country. Although in the past attempts have been done to grow rice and in other parts of Bulgaria, Pazardzhik-Plovdiv field, both historically and nowadays, is the only region in the country available with appropriate natural conditions for the development of this sub-branch of the crop breeding. The agro-ecological resource potential of the landscapes is the main factor for the development of one or another agricultural production. The landscape concept allows the differentiation of the natural environment of interconnected and interacting natural systems. In turn, "the formation of the system integrity of the landscapes is conditioned by the interaction and the functional

dependencies between the constituent geocomponents – rocks, air, water, plants, animals, soils " (Borisova, 2013). That is why it is necessary to analyze the individual landscape-forming components, involved in landscape differentiation and their complex specific expression defining their role as a suitable recipient of the rice crop. From point of view of the rice production and the requirements of the rice crops, as well as in the meaning of the differentiation of rice paddy anthropogenic landscapes (hydromorphous), the main focus of the research is on the soil presence and the hydro-climatic preconditions for the landscape genesis. The main purpose of the publication is to argue and justify the suitability of the landscapes, occupying certain areas in Pazardzhik-Plovdiv field, for cultivation of rice, in the light of the landscape-ecological approach. The present study analyzes the landscape-ecological conditions for the cultivation of rice within the scope of the investigated area. A comparison is done between the agro-ecological requirements of the rice as an agricultural crop and the natural factors determining the landscape features. The role of the anthropogenic factor in the differentiation of the rice agro-landscapes is analyzed. The study is based on the complex landscape approach, which find expression in the complex analysis of the regularly interconnected and interacting natural components.

Object of research is the field appearance of the naturally occurring landscape-forming components in combination with the anthropogenic activity within the scope of the studied region.

Subject of research is the processes of correlation between the limiting role of the environment, the vegetation requirements of the rice and the activity of the anthropogenic factor in the range of the rice production in Bulgaria

The main tasks, that this study puts forward, are the following:

- Clarification of the vegetation requirements of the rice crop.
- Analysis of the natural factors and the anthropogenic activity regarding their role in differentiating the landscapes formed under rice crop within the scope of the investigated territory.
- Comparison between the vegetation requirements of the rice crop and the suitability of the landscapes in Pazardzhik-Plovdiv field for rice cultivation.

Materials and Methods

The present research is based on the landscape-ecological approach, which in combination with the comparative and statistical method provides opportunity for a complex analysis of the natural environment. In the present study, we maintain the view that the landscape is "objective existence of a dynamic system limited in the space, evolving over time, but at the same time possessing the dialectical unity of its constituent material components: rocks, air, waters, soils, plants and animals, along with the anthropogenic impact on them " (Petrov, 1990).

„The implementation of landscape-ecological research is a complicated complex of predefined and planned activities, grouped in stages. The aim is to get a maximum accurate notion of the relationships and interactions existing in landscape diversity and using the results for solving scientific and practical-applied tasks (Nam, 2013).

Results and Discussion

Agro-ecological requirements of the rice crop

The agro-ecological requirements of the rice crop, in general, demonstrate a high degree of pretense that is established in the first attempts to cultivate it several millennia before the New Age in the limits of Southeast Asia. According to Milev and others (1973) „favorable conditions for obtaining constant and sustainable high average yields of rice are: high temperature with no sudden fluctuations, dry, warm and sunny weather without winds, rains

and cold waves, especially after sowing, during blooming and ripening, without frequent and significant differences in daytime temperature, flat terrain, soils with impermeable under-fallow layer, and presence of water source, providing sufficient irrigation water in time".

Of course, the different varieties of rice react differently to the conditions of the environment in which they grow. For the cultivation of rice a certain permanent water layer is needed, in which the plant to develop. This aqueous layer regulates the soil moisture and maintains it in a certain state, whereby appropriate conditions for the development of the rice are created. Sowing the rice seeds is done on dry soil - without the presence of water layer, and in other cases seedlings are being planted in the already prepared area. In the specific area of research, the rice field is poured into water layer, which has a certain depth. According to Kitanov (1986) this layer is usually 10-15 cm thick. The presence of such a layer prevents the rice plantations from weeds. In addition, the water layer in rice paddy has a great thermal effect in mitigating the abrupt 24-hour temperature fluctuations to which the rice is quite sensitive, especially in adverse weather conditions (Katsarov and Milev, 1966). At the same time, the height of this water layer should not be too great, providing the opportunity to establish suitable conditions for plant development. „The amount of water supplied greatly affects the duration of the vegetation period" (Tenova and others, 1999). The water layer in the rice paddy also influences the humidity of the ground air layer. This indicator, especially in the flowering period, should be 60% -70%. At lower air humidity levels, the leaves of the rice wither. Of particular importance are the mechanical and physical composition of the soils on which the rice grows. To maintain a constant quantity and level of the water layer, it is necessary that the soil, in which the rice is planted, to be medium sandy-loam. Alluvial soils in the river valleys are also very suitable for rice growing. The water layer is difficult to infiltrate in soils when they have relatively higher clay content. In this way a balance of the height of the water layer of the rice fields is ensured and there is no need for constant and intensive supply of new water quantities.

Precipitations are of great importance for the cultivation of the rice. It can also be grown in areas with a drier climate. Of essential importance in this case is to ensure the water layer in the rice paddy and to maintain a certain level and quantity of the water for the proper development of the plants. The provision and maintenance of the water layer in the rice fields is achieved through a system of irrigation channels which accumulate river waters or groundwaters extracted to the surface. The rice absorbs negligible amounts of water directly from precipitations. The main source of hydro masses in the biogeocycle of rice landscapes is the water infiltrated into the soil, permeated directly from the upper water layer. It is this water that is absorbed by plants and plays a vital role in their development.

From the point of view of the irrigation conditions, the relief is very important. The lowland territories with slightly inclined terrain and the low degree of fragmentation provide the most suitable conditions for rice growing.

From the climatic elements, the water temperature for irrigation, air temperature, soil temperature, solar radiation values and the relative humidity of the air are of greatest importance for rice growing. It has already been specified that rainfalls does not have a direct importance on rice cultivation. However, the amount of rainfalls, even if indirectly, has an impact on the feeding of the water sources necessary for the irrigation of the rice. „The most favorable temperature for rapid and intensive germination is 25-30 ° C. The temperature of the soil and the temperature of the ground air layer depend on the temperature of the irrigation water. The most suitable water temperature for all phases of the vegetation is 22-25ºC." (Katsarov and Milev, 1966). Similar air and water temperatures are characteristic for lowland territories located in the lowland hypsometric belt from 0 m to 200 m.

Landscape-ecological conditions

The conditions of the natural environment are the main factor for rice cultivation in the Pazardzhik-Plovdiv field. It is the only well-established and proven in time rice-growing region in Bulgaria. The contemporary landscapes of Pazardzhik-Plovdiv field are regular combination of interconnected and interacting, specific for this region of the country, natural components. In this sense the analysis of the landscape-forming factors is fundamental in clarifying the specifics of the rice landscapes. The favorable hydro-climatic and soil conditions in the Pazardzhik-Plovdiv field are a logical prerequisite for the development of rice production in this part of the country. From the point of view of the landscape concept and the system approach, the interrelations and interactions of the main natural components in the Pazardzhik-Plovdiv area determine the existence on large areas of the specific hydromorphic landscapes, systemically functioning under the conditions of the Transitional Climate in combination with lowland relief and low drainage module. After certain anthropogenic interference, the landscapes in question undergo transformations in their horizontal and vertical structure and functioning and become hydromorphic agro-landscapes of rice fields. The new system state of landscapes enables the anthropogenic factor to simplify, to homogenize the horizontal landscape structure on a significant area.

Regarding the relief features of the territory, Pazardzhik-Plovdiv area is characterized by a small slope and a very slight fragmentation of the relief. This favors gravitational transport from water basins within the southern foothills of the mountain Sushtinska Sredna gora of great quantities of water at significant distances through canal systems without complicating the technological process. The insignificant incline of the lowland (near Maritsa River) stimulates the naturally accumulation and retention of large quantities of water in the range of the hydromorphic agro-landscapes. On the other hand, the incline of the relief proves to be sufficient to carry out measures for planned or emergency drilling of the mentioned agro-landscapes.

One of the main requirements for rice growing is the temperature of the air during the vegetation period, which is required to be in the range of 25°C - 30°C. Table 1 presents the data on the average monthly maximum air temperatures for three meteorological stations located in Pazardzhik-Plovdiv field.

Table 1. Average monthly maximum of the air temperature (in °C)_station Plovdiv, st. Pazardzhik and st. Ivaylo(according to the Climatic guidebook of P.R. Bulgaria. (1983)

Station	**January**	**February**	**March**	**April**	**May**	**June**	**July**	**August**	**September**	**October**	**November**	**December**	**per year**
Plovdiv	3,6	7,0	11,8	18,5	23,6	27,6	30,3	30,2	26,0	19,4	12,1	6,1	18,0
Pazardzhik	4,1	7,0	11,8	18,8	23,5	27,3	30,3	30,2	25,9	18,8	12,1	6,5	18,0
Ivaylo	4,0	7,2	11,7	18,8	23,2	27,1	29,9	29,7	25,6	19,2	12,2	6,5	17,9

It is clear from the table 1 information that during the vegetation period starting in May-June and ending in September, air temperatures above 25°C are registered, which fact complements and confirms the landscape-ecological prerequisites for the suitability of the hydromorphic landscapes in the concerned rice growing area.

In addition, the 24-hour temperature amplitudes during the rice vegetation period are characterized by low values. For Plovdiv station, they range from 12.8°C in May to 14.3°C in September. For Pazardjik station they range from 13.3°C in May to 14.9°C in September. For Ivaylo station they range from 13.4°C in May to 14.7°C in September. The relatively small value of the 24-hour temperature amplitudes favors the development of rice crop.
The data in regard to the other important indicator - air humidity, is presented in Table 2.

Table 2. The monthly and annual average relative humidity (in %)_station Plovdiv, st. Pazardzhik and st. Ivaylo (according to the Climatic guidebook of P.R. Bulgaria. (1979)

Station	**January**	**February**	**March**	**April**	**May**	**June**	**July**	**August**	**September**	**October**	**November**	**December**	**per year**
Plovdiv	84	81	74	68	69	67	62	62	69	77	84	86	73
Pazardzhik	81	77	73	67	69	67	62	62	68	77	82	83	72
Ivaylo	83	78	75	68	66	58	60	60	65	75	81	82	71

The registered air humidity values during the growing season of the rice crop, namely in the range above 60% -70%, satisfy its requirements regarding this element of the climatic component. Main source of water for rice production in the Pazardzhik-Plovdiv area is Maritsa River and its tributaries Topolnitsa river, Luda Yana river, Potoka river, Pyasuchnik river and Stryama river. The average annual water quantity of Maritsa river at Pazardzhik amounts to about 17.5 m³ / sec, which makes an annual average value of the river runoff of about 550 million m³ (Hydrological guidebook of the rivers in P.R. Bulgaria, 1957). The runoff of Luda Yana River is 3.60 m³ / s at village of Sbor, of Topolnitza River - 10 m³ / sec at village of Lesichovo, of Pyasuchnik River - 2.3 m³ / sec at village of Lyuben, of Stryama river - 8,56 m³/sec at Manole village. The large water reserves of surface water in the field create a prerequisite for securing the necessary quantities of water for the rice production. Through a well-structured system of irrigation channels, water is transported from the rivers directly to the rice field. In the period after the Second World War, hundreds of kilometers of irrigation canals were built in Pazardzhik-Plovdiv field, incorporated in irrigation systems. The main irrigation systems used for irrigation of the rice crops are the irrigation systems „Karabunar", „Topolnitsa", „Aleko-Potoka", "Aleko-Pazardzhik", „Plovdiv" and „Stryama-Chirpan". All of these irrigation systems use the surface waters of Maritza River and its tributaries, but also collect waters, using special technologies, from Belmeken-Sestrimo Cascade, from Topolnitsa dam, Pyasuchnik dam and from some smaller local dams. Accumulated and transported water masses provide direct access to irrigation water for the rice crops almost all year round. The construction of such irrigation facilities allows the accumulation of water that can be used for the purpose even in periods when small amounts of rainfall are observed and consequently reduced the river flow, especially during the summer months.
An important factor for the development of the rice production in the country is the supply of large quantities of groundwater through a network of drilling wells. In pliocene sediments significant amounts of ground water are accumulated, and the powerful alluvial deposits over them prove to be a major source of groundwater. The physico-mechanical composition in the vertical structure of the sediments facilitates their ability to infiltrate and accumulate water masses both from surface water runoff and from atmospheric precipitation. In the

Hydrological guidebook of the rivers in P.R. Bulgaria (1957) it is stated that the depth of the level of the ground water between Topolnitsa river and Pyasuchnik river, for example, ranges from 1 m by the terrace of Maritsa River (low flooded river terrace) and of its tributaries - up to 20 m depth in the water catchment areas between rivers within the lowland. Shallow groundwater reserves create a prerequisite for more intense water exchange between the surface waters and the groundwaters. Thus, the soil and sediment water abundance is characterized by high indices, which is undoubtedly a positive factor for the cultivation of rice. „Among all the structures and basins in our country the alluvial deposits in Pazardzhik-Plovdiv field are characterized by the highest water abundance" (Antonov and Danchev, 1980). The state of the hydrocomponent is the consecutive beneficial landscape-ecological prerequisite for the existence of the rice crops in this part of the country.

The soils on which the rice is grown in Pazardzhik-Plovdiv field are mostly mantle (alluvial), but in some places it enters in the area where the Vertisols are distributed. The alluvial soils (Fluvisols) are distributed in the river terraces of Maritza River and its tributaries Topolnitsa river, Luda Yana river, Potoka river, Pyasuchnik river and Stryama river.

The alluvial soils (Fluvisols) are formed upon alluvial deposits and in the conditions of constant humidification. Their humus horizon has a width of 10-70 cm. Under it, usually with a sharply transition, follow river deposits with different mechanical composition. Their physical clay content fluctuates from 10% to 60%. They are loose with good aeration, high water permeability and average moisture capacity (according to Penin, 2007). These basic characteristics of the alluvial soils (Fluvisols) satisfy the agro-soil requirements of the rice. They favor the intensive flow of moisture turnover in the landscapes, the regulation of the water balance between surface and groundwaters. The alluvial soils (Fluvisols) retain the water quantities required for plants and are a major generator of mineral substances and water necessary for the growth and development of the rice.

The Vertisols occupy the low parts of Pazardzhik-Plovdiv field. They extend over young Pliocene and Quaternary deposits. Contain significant amounts of clay - from 50% to 75%. The relatively higher clay content creates conditions for formation of an original barrier which makes to be difficult for the water masses to infiltrate intensively through the soil profile and to fall into the underground runoff. In this way the soil profile saturates with water. This favors the soil moisture and allows the rice plants to absorb the required water quantity from the waters accumulated in the soil.

Conclusion

Pazardzhik-Plovdiv field is a major rice-producing region not only in Bulgaria, but also on the Balkan Peninsula. The suitability of the contemporary landscapes in the rice growing area is confirmed by the analysis of the landscape-forming factors, the specific landscape-ecological conditions and the limiting landscape-ecological requirements of the rice crops. The large-scale presence of hydromorphic landscapes and the evolutionary assumed interrelations and interactions at system level in vertical and lateral plan, predetermine the establishment of large areas with rice fields in this part of Bulgaria. Despite the crisis in the rice producing sector over the past 29 years, there is now an increase in the areas, planted with rice. During the period 2011-2017 the yield of rice in Republic of Bulgaria is slightly more than 70,000 tons from 12,000 ha. It is necessary to bear in mind, that undesirable consequences of the long-term and monocultural use are recorded. A. Velchev (2011) points out, that „the agricultural utilization of the territories leads to a reduction of the pedo-masses, while the meliorations carried out - to decrease the ecological potential" (Velchev and others, 2011). We agree with such an ascertainment and we would add that in terms of rice cultivation, the negative consequences are not limited to depletion of the soil profile and salinisation, but also to long-term changes at microclimatic level, starting of eutrophication processes, formation of

an environment for breeding of various stinging insects - possible carriers of disease-causing organisms, and etc. That is why a strict annual complex and component analysis of the hydromorphic landscapes occupied with rice crops is necessary, to reduce the risk of the occurrence of different in intensity and range environmental problems.

SOIL AND AIR TEMPERATURE DURING THE SOWING PERIOD OF SPRING CROPS IN THE REGION OF SOUTHERN BULGARIA

Veska GEORGIEVA, Nadezhda SHOPOVA*, Valentin KAZANDJIEV

National Institute of Meteorology and Hydrology, Bulgarian Academy of Sciences, Sofia, Bulgaria
*Corresponding author: nadia.shopova@meteo.bg

Abstract

The whole ranges of spring crops are traditionally cultivated in Bulgaria. Over the last thirty years, temperature and precipitation have been studied in Eastern Europe and, in particular, in Southern Bulgaria, with changes in both the average values of meteorological elements and their frequency and extreme event. Rainfalls are irregularly distributed and sometimes are heavy. In the same time droughts are intense and prolonged. These changes influence basic agrometeorological indices and are the subject of a study in detail. High temperatures start very early in the spring, they last long in the summer and negatively affect the growth, development and productivity of plants. All these make the cultivation of spring crops in some regions of South Bulgaria risky. To a great extent, the influence of anthropogenic factors is limited or minimized. However, the correct sowing time is a passive method for avoiding adverse meteorological effects. Initially, the plants begin their development in the soil and in this respect the conditions of heat and humidity in the layers of 2 cm to 20 cm during the sowing and germination period are of scientific interest. There is dependence between air temperature and soil, which is particularly strong during the spring period. The aim of the present study is to analyze the relation between air and soil temperature during the spring period paying attention to using and predicting the sowing time of spring crops in the southern Bulgaria area at the beginning of the 21st century.

Keywords: *spring crops, air temperature, emergence, soil temperature, sowing period*

Introduction

In southern Bulgaria, the cultivation of spring crops in recent years is risky. In the last 30 years is registered strengthening of extreme weather events (Alexandrov, V., 2011, Bocheva,L., 2012). Summer precipitations during the last century show a decreasing tendency in the lowlands of Bulgaria (Koleva E., et al., 2008) and a winter increase in southern Bulgaria (Alexandrov, V., 2006, Kazandjiev V., et al., 2008, Moteva, M.,et al., 2009). The average monthly, maximum and minimum temperatures in South Bulgaria were increased during the spring, autumn and summer (Georgieva at al, 2017).The amount of precipitation in the period from October to March is increasing (Georgieva at al, 2017). These trends of temperature change and rainfall lead to a change in agro-climatic resources (Eitzinger J., et al., 2008). Nowadays in few areas of the country, there are favorable conditions for cultivation of crops (Moteva et al, 2016). Summer droughts are a common occurrence and often coincide with the critical humidity periods of spring crop development. In this sense optimally selected period of sowing is essential for obtaining optimum yield and liability method at minimal cost to mitigate the adverse effects of the weather character. On the other hand the period of sowing depends largely on the development and productivity of crops from year to year. In this respect, the object of the study is the relationship between soil and air temperature during the spring season in major agricultural regions of southern Bulgaria in the period between 1986-2015. The results show the decade values of the two parameters and the correlation between them in the spring, during the sowing and start growth of some early, medium early and warm-loving crops? The analysis is valuable for predicting and optimizing the sowing time of early, medium early and late spring crops in the area.

Material and Methods

Data on average daily air temperature (˚C) and the soil temperature of 0.05 m; 0.10 m; 0.20 m from weather and agrometeorological stations - Plovdiv, Pazardzhik, Chirpan, Kurdzhali, Kazanluk, Yambol, Sadievo, Sadovo, Karnobat from the network of National Institute of Meteorology and Hydrology (NIMH) in the region of Southern Bulgaria are used. Daily data of soil temperature which is measured at 7, 14 and 21 hours local time in March, April and May are used. The average values are being calculated as the arithmetic mean of the three periods. The decade values of the two indicators have been calculated, analyzed and a correlation has been found between them. The agrometeorological stations are located on the main soil types for the South Bulgaria according to the classifications of FAO (Food and Agriculture Organization of the United Nations***)*** and *Koynov* et al. (1998) - alluvial-deluvial meadow (Plovdiv, Kazanlak); cinnamonic forest soils (Pazardzik, Sadievo) and Vertisols (Yambol, Chirpan and Karnobat). The coefficient of temperature conductivity about the area of the Thracian Lowland are published by Marinova, T., 1993; Doneva et al., 2001. The coefficients for the area are very small in the range between $3.0*10^{-7}m^{2}.s^{-1}$ and $5.6*10^{-7}m^{2}.s^{-1}$. Long term phenological data for the sowing and germination period in the three groups of spring such as sunflower, beans and peanuts from the archive of the Agrometeorology Department to NIMH are used. The dates of sowing (D_1), germination (D_2) and the interphase period ($D_{(2-1)}$) were analyzed in Julian days.The data are collected from the agrometeorological network of the section according to the NIMH methodologies and in accordance with the international standards of the World Meteorological Organization (WMO, 1975 and 1984). Air and soil temperature data are compared with sowing and germination of basic spring crop. The graphic presentation of the figures is visualized with Microsoft Excel. Regression and correlation analysis was used in data processing. Statistical software "Statgraphics" has been used. The study period ranged between 1986 and 2015.

Results and discussion

Soil temperature and air temperature are formed by components that are highly variable and depend on the location, seasons and physical characteristics of the soil. Warming and cooling is also a result of the physical properties of the environment. In the spring, soil humidity is the highest, the air temperature is of small amplitude and there is no permanent snow cover in the area. All this smooths the differences. It is therefore logical to seek relationship between both parameters during the months of March, April and May. In the same period is the sowing of the early, middle early and warm-hearted spring cultures. Optimally selected date favors jointly germination Very early seeding and long standing in the soil can lead to seed rot; roots and young plants. Late sowing reduces interphase periods and displaces reproductive phases to hot and dry summer. Since the middle of the last century in our country has begun the search for a connection between the air temperature and that of different depths in the soil (Stanev et all., 1965; Gurova et al., 1975). The relationship between the two temperatures is also discussed by a number of scientists outside of our country (Daolan Zheng 1993; Langholz. H., 1989). The ability to use longer and up-to-date data ranges, and their viewing by months, makes it possible to obtain dependencies with greater accuracy. Decade data is a sustainable, widely used agrometeorological indicator. At the same time the temperature of the soil is measured in climatic points, but in the synoptic stations measurement is only on the air temperature. Good correlation allows determining the soil temperature indirectly, by the measured and predicted air temperature. This helps farmers to start preparing for sowing and also doing it on time. The duration of the vegetation season for the different groups of spring crops is determined by the continuous retention of air temperatures above 2.5°C, 5°C, 7.5°C, 10°C, 12.5°C and 15°C. Given the observed increase in air temperatures and the earlier occurrence of a sustained transition above the biological threshold of spring crops and the

increasing number of droughts of varying intensity, predicting the times of reaching optimal sowing soil temperatures will allow the growing season of crops so as to limit the adverse effects. When sowing the seeds are laid at a depth of up to 0.10 m. The surface soil layer (0.5 m; 0.10 m) begins to warm up in March and its temperature becomes higher than that of deeper soil layers and that of the air (Figure 4-12). In the first ten days of March the temperature of the soil and air rise above 5°C, with the exception of Kazanluk which is the coldest place and Karnobat, where these values are close but not higher than 5°C. The two parameters considered during the second ten days of March are about 7.5°C. The air temperature rises above 10°C in April. There is a slight difference in the average values of the temperature and one-level temperature for the second and third decades of April at all stations. The values are about 12.5°C and for Plovdiv, Sadovo and Pazardzhik about 15°C. The temperatures are rising faster in the first decade of May when the soil temperature reaches 15°C and at the end of the period the temperature of the air in Kazanlak, Chirpan and Karnobat also reaches these values. The data shows that the soil temperature corresponds to the requirements for sowing of early spring crops in the first ten days of March; the middle-aged ones in the last of March and the first of April, and the warm-loving-in the middle of the second ten-day period and the third ten-day period in April. The final results show a positive deviation compared to the period 1961-1990 in both parameters (Fig. 25-26). In search of dependence Information is divided by decades, months and stations. The results show a strong, positive, correlational relationship with all stations and all soil types (St (0.05m-0.20m) = a*AT2m +b). The statistical evaluation of the regression model is shown in Table 1. Since the P-value in the ANOVA table is less than 0.01, there is a statistically significant relationship between the variables at the 99 % confidence level. According to the data, the sunflower produced in southern Bulgaria in recent years is about 25% of the total for the country. There is also an increased interest in growing protein crops. From the early spring crops in the area are cultivated peas, pheasant, and chickpeas as conditions allow (see fig. 4-12) the sowing to be held very early in spring at the end of February, early March. They do not suffer from the negative temperatures that are possible within the period. Early crops are sown after a stable transition of air temperature at 2.5°C to 5°C. As a perspective and drought-resistant culture, we have looked at data on chickpeas. Analysis shows that chickpeas sowing is from the end of February to the beginning of April, the average date in July days is D1 = 79, the earliest D1 = 57, the latest D1 = 96. The duration of the interphase period is on average D2-D1 = 14 days. The average date of germination is D2 = 93 days, the earliest D2 = 71 and later D2 = 107. The length of the vegetation period is average D7-D1 = 100 days and yields about 108 kg / dca. A comparison of the data shows that favorable conditions for sowing chickpeas are formed from 48 to 58 days, around the earliest date, and which is about 30 days earlier than the massive surveys we are watching. At a transition above 5°C and up to 7.5°C the conditions favor sunflower sowing. We pay special attention to it because in recent years it has grown in the region. Good conditions for sowing sunflower are observed during the third ten days of March in Kazanlak and Karnobat and at the end of the second in the other stations. However, sowing occurs on average on D1 = 139 days. Germination starts D2 = 155 and has an average duration of D2-D1 = 16 days. The vegetation period (D7-D1) continues 100 days. From the warm-loving crops we have analyzed the phenological evolution of peanuts, beans. For them, good sowing times are observed at a steady average temperature above 12.5°C or from 97 to 113 days. When sowing at the end of March, the plants will spring up after the average spring frost dates. The peanuts are mainly sown in the Sadovo and Plovdiv regions and on average on D1 = 121 days. The plants germinate at D2 = 136 as D2-D1 = 14; D6-D1 = 133, yield 232 kg /dca.

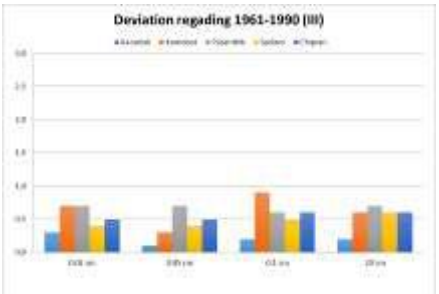
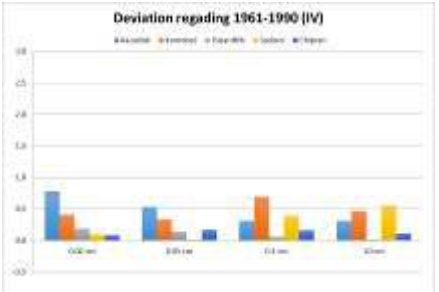
Fig.25 -26 Deviation of soil temperature regarding 1960-1990 III, IV





Conclusions

Correlations between decade values of soil temperature (0.05m;0.10m;0.20m) and air temperature ($St_{(0.05m-0.20m)} = a*AT_{2m} + b$, $p<0.01$) have been established. These dependencies can be used to assess the temperature conditions during the sowing period only based on the air temperature data. The average decade values of air temperature and soil temperature for the period 1986-2015 were calculated. Both indicators show an increase over the period 1961-1990 in the watched stations. In the same period phenological data show delayed sowings of a vast majority of observed crop. This shows that farmers do not strictly monitor agro-meteorological forecasts and are not ready on time. They omit favorable conditions that affect productivity. The relationship between science and practice needs to be improved.The authors believe that in the early sowing periods, the conditions of plant growth will be improved during the growing season, especially in critical development stages.

POTENTIAL OF CALENDULA OFFICINALIS FOR PHYTOREMEDIATION OF SOILS CONTAMINATED WITH HEAVY METALS

Violina ANGELOVA*, Maria ICHTJAROVA

Agricultural University of Plovdiv, Plovdiv, Bulgaria
*Corresponding author: vileriz@abv.bg

Abstract

A field study was conducted to evaluate the efficacy of Calendula officinalis for phytoremediation of contaminated soils. The experiment was performed on an agricultural fields contaminated by the Non-Ferrous-Metal Works near Plovdiv, Bulgaria. The content of heavy metals in different parts of Calendula officinalis (roots, stems, leaves and flowers) was determined by ICP. The essential oil of the Calendula officinalis was obtained by steam distillation in laboratory conditions and was analyzed for heavy metals and its chemical composition was determined. Calendula officinalis is a plant which is tolerant to heavy metals and can be grown on contaminated soils. Based on the obtained results and using the most common criteria, Calendula officinalis can be classified as Pb hyperaccumulator and Cd, and Zn accumulators, therefore, this plant has suitable potential for the phytoremediation of heavy metal contaminated soils. Favorable is also the fact that heavy metals do not influence the development of the Calendula officinalis, as well as on the quality and quantity of the essential oil. For oil obtained from the processing of Calendula officinalis flowers grown on highly contaminated soils, its key odour-determining ingredients meet the quality requirements of the European Pharmacopoeia Calendula officinalis oil and/or have values that are close to the limits of the standard. The ability to process the calendula flowers in oil and its use in perfumery makes it extremely suitable for phytoremediation of heavy metal contaminated soils.

Keywords: *Calendula officinalis, Heavy metals, Phytoremediation*

Introduction

Environmental pollution with heavy metals is a global problem, and therefore the development of phytoremediation technologies for plant-based clean-up of contaminated soils is therefore a significant interest. Aromatic and medicinal plants have shown to uptake and accumulate toxic heavy metals from polluted areas, and could be used as biomonitors or accumulators of pollutants (Abu Darwish *et al.*, 2009, Angelova, 2012).

Calendula officinalis L. is an aromatic herb that belongs to the Asteraceae family. Also known as pot marigold or marigold. It originates from the Mediterranean (Gazim *et al*., 2008). While the biennial plant is found in a wild state in southern, eastern and central Europe (Van Wyk and Wink, 2004), the annual plant is cultivated. Calendula is grown for decorative and medical purposes (Ramos *et al*., 1988, Muuse *et al*., 1992) and finds application in the pharmaceutical and cosmetic industries. Teas, tinctures and creams made from this herb are used for healing purposes (Re *et al*., 2009). Studies have shown that extracts of C. officinalis have antioxidant (Albulescu *et al*., 2004, Fonseca et al, 2010) and antibacterial (Iauk *et al*., 2003) properties. The compounds found in essential oils of C. Officinalis have biological activity, for example, α-muurolene has antifungal activity, β-caryophyllene has anti-inflammatory, antibiotic and antioxidant activity (Legault *et al*., 2007).

Insufficient is the information available on the potential of *Calendula officinalis L.* for accumulation of heavy metals and its potential for use for phytoremediation. The studies connected with growing the pot marigold on polluted soils are too limited. There is evidence that *Calendula officinalis L.* can grow on soils containing large amounts of Cd and Pb without

suffering from phytotoxicity and is able to tolerate high concentrations of heavy metals (Liu *et al*., 2008). This gave us the grounds to carry out a comparative research, which to allow us to determine the quantities and the centers of accumulation of Pb, Zn and Cd in the vegetative organs of pot marigold, the quality of the oil, as well as the possibilities to use the plant for phytoremediation of heavy metal contaminated soils.

Material and Methods

The experiment was performed on an agricultural fields contaminated by Zn, Pb and Cd, situated at different distances (0.5, and 15.0 km) from the source of pollution, the NFMW (Non-ferrous metal plant) near Plovdiv, Bulgaria.

Characteristics of soils are shown in Table 1. The soils were neutral to slightly calcaric, with moderate content of organic matter and essential nutrients (N, P and K). The psedo-total content of Zn, Pb and Cd is high and exceeds the maximum permissible concentrations (MPC) in 1 (from 0.5 km from the NFMW) (Table 1).

Table 1. Characterization of the soils

Parameter	pH	EC, dS/m	Organic C,%	N Kjeldal,%	P, mg/kg	K, mg/kg	Pb, mg/kg	Zn, mg/kg	Cd, mg/kg
Soil 1 (S1) 0,5 km	7,4	0,15	2,2	0,34	625,6	6960	2509,1	2423,9	64,3
Soil 2 (S2) 15 km	7,5	0,15	1,54	0,12	387,3	6780	49,4	172,7	1

MPC (pH 6.0-7.4) – Pb -100 mg/kg, Cd-2.0 mg.kg, Zn-320 mg/kg
MPC (pH >7.4) – Pb – 120 mg/kg, Cd – 3.0 mg/kg, Zn -400 mg/kg

The test plant was pot marigold. Plant samples were taken immediately after harvesting and the contents of Pb, Zn and Cd in their different parts - roots, stems, leaves and flowers - was determined. The essential oil of the pot marigold was obtained by steam distillation in laboratory conditions which was analyzed for heavy metals and its chemical composition was determined.

The concentrations of contents of heavy metals in different parts of pot marigold (roots, stems, leaves, flowers), and oils were determined by the method of the microwave mineralization.Total content of heavy metals in soils was determined in accordance with ISO 11466. The mobilisable heavy metals contents in soils, considered as a "potentially bioavailable metal fraction", were extracted by a solution of DTPA (ISO 14870). The quantitative measurements were carried out with inductively coupled plasma emission spectrometry (ICP) (Jobin Yvon Emission - JY 38 S, France).

Statistical analyses were conducted with Statistica v. 7.0.

Results and Discussion

The results presented in Tables 1 and 2 show that in the soil samples S1 (taken from the area situated at the distance of 0.5 km from NFMW), the reported values for Pb were exceeding MPC approved for Bulgaria and reached to 2509.1 mg/kg. In the area located at a distance of 15 km, the contents of Pb significantly reduce to 49.4 mg/kg. Similar results were obtained for Cd and Zn. The results for the mobile forms of the metals extracted by DTPA show that the mobile forms of Cd in the contaminated soils are the most significant portion of its total content and reached to 57,2%, followed by Pb with 33,8 % and Zn with 9,8%.

In the soil located at a distance of 15km from NFMW the mobile forms of Cd are the most significant part of its total content and reach up to 70%, followed by Pb - 43.5% and Zn - 22.5%.

Table 2. DTPA-extractable Pb, Zn and Cd (mg/kg) in soils sampled from NFMW

*DTPA -extractable / total content

Figure 1 presents the results obtained for the content of heavy metals in the vegetative organs of pot marigold. Most of them (Pb, Cd and Zn) are accumulated in the aboveground parts of the pot marigold (the leaves). By moving the source of contamination away, there is a clear tendency of reduction of the heavy metal content in pot marigold's vegetative organs. The content of Pb in the roots of pot marigold grown at 0.5 km from NFMW reaches up to 228.4 mg/kg, Zn - 126.4 mg/kg, Cd - 36.6 mg/kg. The obtained values obtained for the heavy metals (Cd, Pb and Zn) in the roots are much higher than the values considered by plants by Liphadzi and Kirkham (2005) as toxic for the plants (0.1 mg/kg Cd, 30 mg/kg Pb, 100 mg/kg Zn,).

It is known that calendula forms a bearded root system, 20 cm long tap root and numerous thin, secondary roots. Probably this is the reason why calendula accumulates heavy metals in the roots.

The movement of heavy metals and their accumulation in the vegetative organs of pot marigold is specific to the individual elements. A significant accumulation of Pb is found in the leaves and stems of the pot marigold. The content of this element reaches up to 54.1 mg/kg in stems, and 1506.8 mg/kg in leaves of the pot marigold grown at a distance of 0.5 km from NFMW. The content of Cd in the stems and leaves of the pot marigold reaches up to 39.4 mg/kg and 45.5 mg/kg, respectively, values considered to be toxic to plants (Kabata-Pendias, 2001). The content of Zn in the stems and leaves of the pot marigold reaches up to 214.6 mg/kg, and 604.9 mg/kg, as these values are also higher than the critical values for plants - 100-400 mg/kg.

The results obtained show that significant quantities of Pb are accumulated in the leaves of pot marigold. This is probably due to the anatomical and morphological features of the crop. Its greater accumulation in the leaves is probably due to the fact that they are covered with hairs, which favour the retention of heavy metal aerosols.

The content of heavy metals in the stems and leaves of the pot marigold grown at 15 km from NFMW are significant lower. Increased concentrations of heavy metals in leaves of pot marigold grown at 0.5 km from NFMW are largely due to aerosol contamination.The heavy metal content in the above-ground mass of pot marigold is higher than that in the root system, which is consistent with the results of other authors. Dwivedi and Dey (2002) found that the Pb content in medical plants ranged from 2.624 mg/kg to 32.757 mg/kg, and cadmium from 0.056 mg/kg to 0.419 mg/kg. They found that the content of heavy metals (Pb and Cd) in medical plants was higher in the leaves than in the stems or roots, and the lowest values were found in the seeds. It has been found that with the increase of the concentration of metals in the soil the ability of accumulation of metals in calendula increases.

The heavy metal content in flowers is significantly lower compared to the root system and the above-ground mass of the plants. The Pb and Zn content in the flowers of pot marigold grown at a distance of 0.5 km from the NFMW reaches 419.4 mg/kg and 308.9 mg/kg, respectively, and Cd - to 33.3 mg/kg. Probably a portion of the accumulated heavy metals in the flower of the pot marigold is due to the aerosol pollution.

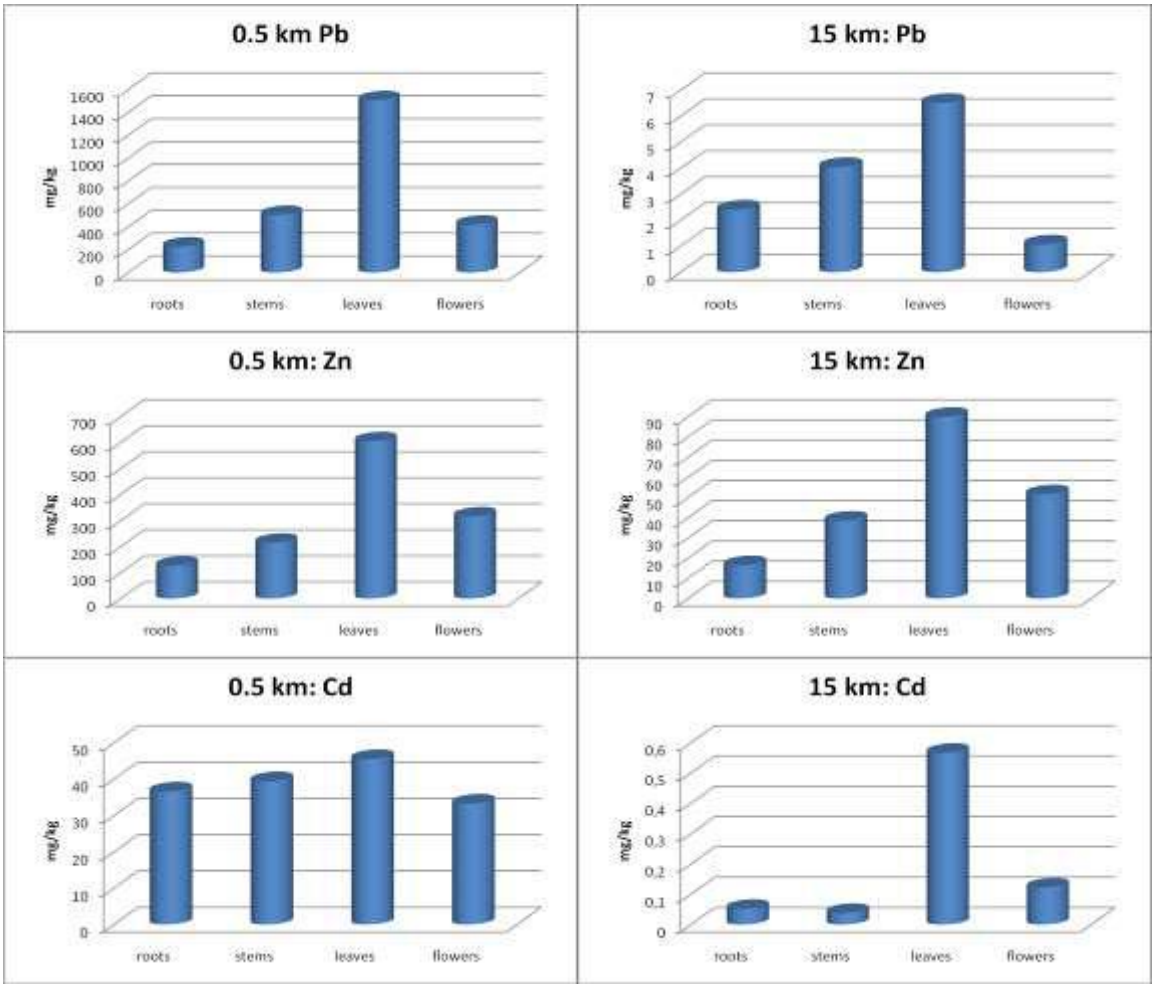

Fig.1. Content of heavy metals (mg/kg) in pot marigold

The content of Pb in flowers of pot marigold grown at a distance of 15 km from NFMW reaches 1.1 mg/kg, Zn – 51.6 mg/kg, Cd - 0.13 mg/kg

The heavy metal content in the essential oil from pot marigold was also determined. The results obtained show that the majority of the heavy metals contained in the flowers of the pot marigold do not pass into the oil during the distillation, therefore their content in the oil are much lower. Pb content in the essential oil of pot marigold reaches up to 0.22 mg kg, Zn up to 0.57 mg/kg, while the content of Cd is below the limits of the quantitative measurement of the method used. Significantly lower are the content of heavy metals in the essential oil of pot marigold grown at a distance of 15 km from NFMW - 0,14 mg/kg Pb and 0,10 mg/kg Zn. The results obtained show that the content of heavy metals in the essential oils is much lower compared to the flowers of pot marigold, and the amounts of Pb, Zn and Cd in the oil of pot marigold are lower than the accepted maximum values and meet the requirements of an environmentally friendly product. The results are confirm the ones established by Angelova et al. (2015), who found that the heavy metal content in the essential oil of lavender is very low and is not affected by the level of soil contamination with heavy metals.

To be able to give a categorical answer to the question what are the abilities of the pot marigold to extract heavy metals from the soil and to assess the potential of pot marigold for phytoextraction, the translocation factor (TF) and bioconcentration factors (BCFroots and BCF shoots) were calculated.

The BCFroots is the ratio of heavy metal content in plant roots to soil content. BCF values can be used as an indicator to assess the ability of plants to accumulate heavy metals

depending on the content of metals in the soil. They vary depending on the concentration and type of heavy metals, the ability of the plants to accumulate, the physiological characteristics of the plants and the environmental factors. The values from 1 to 10 are considered to be high, 0.1-1 are low and 0.01-0.1 are very low (Li et al., 2007). The results we obtained show that this coefficient reaches 0.27 at Pb, 0.53 at Zn and 0.99 at Cd (Table 3).

The bioconcentration coefficient BCFshoots is defined as the ratio between the metal concentration in the above-ground mass of the plant and in the soil and is a measure of the plant's ability to digest and move the metals to the above-ground mass that can easily be collected. In hyperaccumulators, the enrichment factor is higher than 1 and in some cases may reach 50-100 (McGrath and Zhao, 2003). The results obtained by us show that, with respect to Pb, the bioconcentration factor of above-ground mass for calendula grown at 0.5 km reaches 2.4, for Zn up to 3.5 and for cadmium up to 2.3 (Table 3).

Translocation factor (TF) gives information on the ability of plants to uptake heavy metals through the roots and to translocate them to the above-ground mass (leaves) (Liu et al., 2010). Hyperaccumulators usually contain less heavy metals in the roots than in the above-ground mass. (Baker et al., 1994). This specific criterion for hyperaccumulators can reach values > 1, indicating that the content of heavy metals in the above-ground mass is higher than that in the underground parts (roots). The results we obtained show that the TF values for Pb reach 8.8 and 4.4, indicating that a significant amount of Pb is moving to the above-ground parts of calendula. Similar results are obtained for Cd. TF values for Zn reach up to 6.5 (0.5 km), up to 7.8 (1 km) (Table 3). Similar results are obtained for Cd. TF values for Cd range from 2.3 to 11.7.

Table 3. Translocation (TF) and bioconcentration factor (BCF) factors in pot marigold

Element	TF		BCF root		BCF shoot	
	0.5 km	15 km	0.5 km	15 km	0.5 km	15 km
Pb	8.8	4.4	0.27	0.11	2.4	0.49
Cd	2.3	11.7	0.99	0.07	2.3	0.86
Zn	6.5	7.8	0.53	0.42	3.5	3.3

BCFroots=[Metal]roots/[Available metal]soil, TF=[Metal]shoots/[Metal]roots), BCFshoots=[Metal]shoots /[Available metal]soils

The distribution of heavy metals in the organs of the pot marigold has a selective character, it is specific for the individual elements (Fig.2).

There is a distinct feature in the accumulation of heavy metals in the vegetative organs of the pot marigold. The pot marigold accumulates heavy metals through its root system, but a very small portion of the heavy metals are retained by the roots, and most of them translocate and accumulate in the above-ground parts (stems, leaves).

Our results strongly suggest that pot marigold is a crop which is tolerant to heavy metals and can be grown in contaminated soil. The pot marigold may be referred to the group of hyperaccumulators of Pb, and to the accumulators of Zn and Cd, and therefore, it can be successfully used for phytoremediation of soils contaminated with Pb, Cd and Zn.

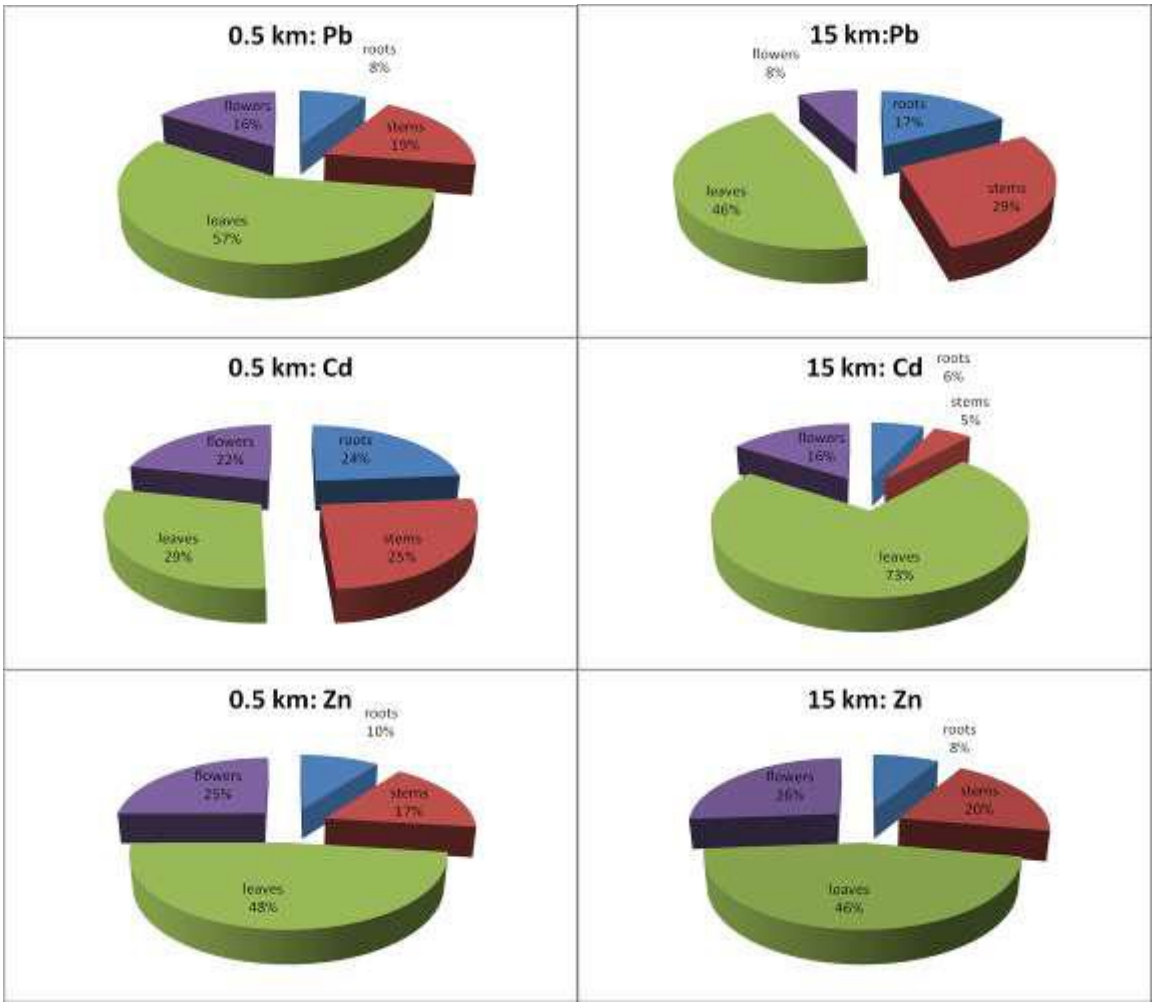

Fig. 2. Distribution of heavy metals in pot marigold

Calendula essential oil was obtained by steam distillation in laboratory conditions. Essential oils samples in hexane (1:1000) were analyzed on Agilent 7890A Gas Chromatography system equipped with FID detector and Agilent 5975C mass spectrometer. The compounds were identified on the basis of literature data and estimated Kovat′s (retention) indices that were determined using a mixture of homologous series of normal alkanes (C8-C40) analyzed under Automated Mass Spectral Deconvolution and Identification System (AMDIS) conditions. Confirmation was made by comparing the mass spectra of the components present in the EOs with the reference spectra obtained from NIST'08 and Adams mass spectra libraries. Quantification of the essential oils components was performed using the normalization method of the GC/FID peak areas without any correction factors.

According to the literature, various monoterpenes and sesquiterpenes are contained in the oil. The major components (> 1.0%) identified in the oil from comtaminated soils (S1) are δ-Cadinene (22,088,) epi-α-Muurolol (18,187), α-Cadinol (14,519), γ-Cadinene (8,943). α-Muurolene (4,739), α-Cadinene (3,912), β-Ionone (3,286), Ledene (2,475), γ-Muurolene (2,392), β-Oplopenone (1,811), 1-epi-Cubenol (1,675), Geranylacetone (1,628), Geranylacetone (1,628), α-Calacorene (1,407), Viridiflorol (1,393), Ledol (1,324), α-Humulene (1,241). Traces of minor components (in the range <1.0 and> 0.10%) 1,10-di-epi-Cubenol (1,002), Cadalene (0,923), α-pinene (0,892), α-Copaene (0,877), β-caryophyllene (0,755), α-Copaen-4-ol (0,735), Caryophyllene oxide (0,616), α-thujene (0,319) have been identified in oils from comtaminated soils (S1).

There are no significant composition differences between oils obtained from areas located at different distances from NFMW - Plovdiv, which have varying degrees of pollution.
According to Chalchat et al. (1991) the volatile fraction obtained from Calendula officinalis flowers were included α-cubebene, α-copaene, β-cubebene, α-gurjunene, β-cariophyllene, α-ionone, α-humulene, γ-muurolene, β-ionone, α-muuronele, γ-cadinene, δ-cadinene and α-cadinene. The oil is rich in α-cadinene, α-cadinol, t-muurolol, limonene, and 1,8-cineol and p-cymene (Okoh et al., 2007).
Calendula essential oils vary in composition (Miguel et al., 2004, Danielski et al., 2006) for the different countries. The variation between the individual results for the chemical composition of the oil may be due to the conditions of cultivation, genetic factors, varietal peculiarities and other factors. The composition of the soil, temperature and atmospheric conditions during the growth and development of plants, which influence the composition of secondary metabolites in plants, determines the different plant haemotypes. As α-Cadinol has the highest content of alcohols, this indicates that the oil we studied belongs to α-cadinol chemotype.
An important point in the study is to trace whether heavy metals affect the quality of essential oil. Pot marigold oil is used in a wide range of perfumery, pharmacy and medical products and must have guaranteed indicators of cleanliness and harmlessness, i.e. to meet pharmacopoeial requirements. This means that it must not contain heavy metals and/or contains traces of metals and there must not be any change in its composition.
The data show that the cultivation of pot marigold on heavy metal contaminated soils does not negatively affect the composition of the oil. Heavy metals in the soil have a negligible impact on yield (data not provided) and do not affect the quality of the oil.
The results we obtained show that heavy metals do not affect the development of pot marigold as well as the quality and quantity of the oils it produces. The ability to process the calendula flowers in oil and its use in perfumery makes it extremely suitable for phytoremediation of heavy metal contaminated soils.

Conclusions

Based on the obtained results the following conclusions can be made:

1. There is a clear distinction in the accumulation of heavy metals in vegetative organs of pot marigold. Pot marigold accumulates heavy metals through its root system, but a very small part of the heavy metals are retained by the roots and most of them move and are accumulated in the above-ground parts (stems, leaves and flowers).
2. The quantities of Pb, Cd and Zn in the oil of pot marigold grown 0.5 km from the NFMW, were lower than the accepted Maximum permissible concentrations, and meet the requirements of an environmentally friendly product.
3. Pot marigold is a crop that is tolerant to heavy metals, it can be attributed to hyperaccumulators of Pb and accumulators of Cd and Zn and can be successfully used in phytoremediation of heavy metal polluted soils. Processing of flowers to oil and the use of the obtained oil in perfumery will significantly reduce the cost of phytoremediation.
4. Heavy metal soil contamination has no significant effect on the essential oil composition.

SUSTAINABILITY OF THE CONSTRUCTED WETLANDS FOR WASTEWATER TREATMENT USING RENEWABLE ENERGY SOURCES

Bojan ĐURIN[1*], Lucija PLANTAK[2], Lucija NAĐ[1]

[1]Faculty of Geotechnical Engineering, University of Zagreb, Varaždin, Croatia

Abstract

Constructed wetlands for the wastewater treatment represent not only effective facility for the removing of contamination, but they also fit good into the environment. Natural and artificial swamps, lakes or accumulations are usually used for these purposes. Despite of their positive characteristics for purification of the wastewater, there is a need for the electric energy, which is in the most cases used for the re-pumping of the wastewater, cleaning of the grid on the entrance in constructed wetland, re-pumping of the purified wastewater, heating during the winter period, illumination and safety reasons. There are many renewable energy sources, which may be used for such purposes. Availability, with accent on intensity and duration of the renewable energy sources depends mostly on the climate characteristics of the observed location in the world. This research will explore which of the renewable energy sources can be used for the production of the electric energy for the constructed wetlands for wastewater treatment, where the primary orientation would be achieving of the systematic sustainability of such constructed wetlands from the energy and hydraulic aspects. For the purpose of the research, there is an intention to present model, which will take into the account all situations, which could happen during procedure of the wastewater treatment. During the operational work of the constructed wetlands, there is a possibility for a surplus of a produced electric energy, which can be used for different purposes or to be sold into existing electric energy grid.

Keywords: S*ustainability, Wetlands, Wastewater treatment, Renewable energy sources.*

Introduction

Constructed wetlands for wastewater treatment (WWT) are well known technology, which is widely used in rural as well as in urban areas. During past decades, technology of wastewater treatment, by using of the constructed wetlands, was continuously improving (Badhe et. al, 2014, Chen et. al, 2014, Harrington and Scholz, 2010, Wu et. al, 2013). As a matter of fact, constructed wetlands for WWT, in their basic form do not require any energy for their operational work, but despite of this, just minor improvement of existing wastewater treatment process should include at least a small portion of the energy. For example, this is re-pumping of the wastewater, cleaning of the grid on the entrance of wastewater in wetland (pre-treatment procedures), illumination and safety reasons.

Nowadays, sustainability of every hydro-technical system is not persisted only from economical view; i.e. by cost-benefit analysis. Providing of such a task should be accomplished by taking into the account technological, social and maybe the most important one-ecological criteria. On the other hand, especially from the engineering point of view, hydraulic and energy balance of the system must be rounded into integral whole by satisfying both mentioned aspects. Biggest accent of this paper is using and production of the renewable energy sources (RES) with regards on the constructed wetlands for the WWT. Most important reason for this is possible neatness of particular RES and their applicability for including them as energy sources. Not of all RES are suitable for this usage. Next reason is the fact that RES

are the only possible energy source for the location outside of the cities, on the islands or allocated areas. Both of this will be examined within this paper.

Theoretical background

Constructed wetlands are engineered wetlands that have been designed and constructed to mimic the natural processes involving wetland vegetation, soils and the associated microbial assemblages to assist in treating wastewaters involving physical, chemical and biological mechanisms to remove pollution (Vymazal et. al, 2006). Constructed wetlands at the beginning were used mainly for treating domestic and municipal wastewater but now their application expanded for treating industrial, agricultural wastewater, polluted rivers and lakes as well for treating collected precipitation from highways and city roads. Within the constructed wetlands, biological processes such as microbial metabolic activity and plant uptake as well as physic-chemical processes such as sedimentation, adsorption and precipitation at the water-sediment, root-sediment and plant-water interfaces are always taking place.

Constructed wetland systems are classified into two general types (Wetlands International-Malaysia Office, 2003): the Horizontal Flow Systems and the Vertical Flow Systems, which are fed intermittently and drains vertically through the bed via a network of drainage pipes, Figure 1.

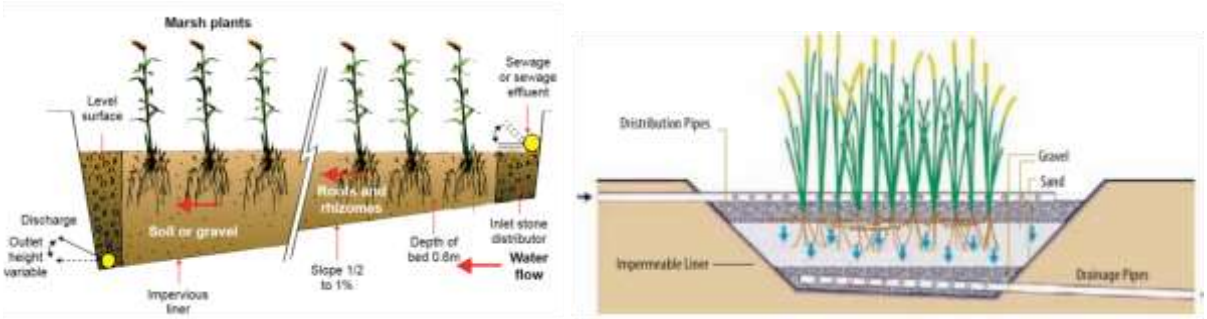

Figure 1. Horizontal and Vertical Flow Systems ((UN-HABITTAT, 2008; Wetlands International-Malaysia Office, 2003)

In Horizontal Flow System wastewater is fed at the inlet and flows horizontally through the bed to the outlet and has two general types: Surface Flow and Sub-surface Flow systems (Wetlands International-Malaysia Office, 2003). In Europe, Horizontal Flow Systems are widely used concept of constructed wetlands (Vymazal et. al, 2006).

Usually, the Common Reed (lat. Phragmites karka) and Cattail (lat. Typha angustifolia) are used for WWT because they have a large biomass both above (leaves) and below (underground stem and roots) the surface of the substrate (Wetland International-Malaysia Office, 2003). Plants in constructed wetlands stabilise the surface of the beds, slow down the water flow and increases water transparency, but most important is that they provide a huge surface area for attachment and growth of microbes. Microbes have the most important function in wastewater treatment. They use the organic substance in wastewater as a source of food and transform it into energy and biomass. Also, the choice of substrate is important and determined in terms of their hydraulic permeability and their capacity to absorb nutrients and pollutants. A mixture of organic clay soils, sand, gravels and crushed stones could be used to provide support for plant growth (Wetland International-Malaysia Office, 2003).

Sustainable model of the constructed wetlands for wastewater treatment

Not only hydro-technical, but also every observed system has so called ''black-box'' with input and output. Same situation is for the constructed wetlands for the WWT, Figure 2.

Figure 2. Main concept of the sustainable model of the constructed wetlands for wastewater treatment

Obvious intension is to minimize energy input E_{Input} and to maximize produced energy, E_{Output}. Wastewater input, W_{Input}, should be in prescribed range of the flow, which is defined by the designers of the constructed wastewater plant. Purified wastewater output, W_{Output}, usually does not have prescribed flow range, because this amount is connected with the W_{Input}. Also, energy and water losses exist in constructed wetlands, but for the practical cases they are usually neglected.

Wastewater (hydraulic) input

Depending on the type of the wastewater, there are many pre-treatment facilities which should be provided before wastewater enters the wetland for WWT. Rainwater, industrial wastewater and settlement wastewater define pre-treatment facilities. Due to the scope and purpose of this paper, further discussion and researching will be focused on the precipitation wastewater. For the precipitation wastewater, there is only need for the protection grid because of large floating and scattered particle, eventually a sedimentary basin due to the grease collected from the highways, roads, sidewalks and pavements. Regarding character of the rainwater/precipitation, inflow regime into the wetland is of the stochastic nature and depends on the climate characteristics of the observed area, Figure 3.

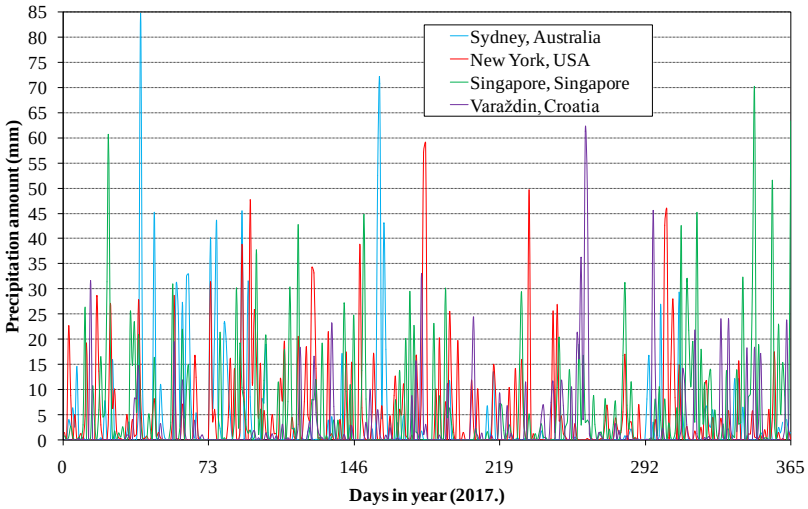

Figure 3. Daily precipitation regimes (modified from Australian Government, 2018.; CNYWeather, 2017; Meteorological Service Singapore, 2017.; MHSC, 2017)

Energy input

Renewable energy would be used as a primary energy source, which will be converted into the electric energy (mostly) and into the heat energy. Electric energy would be used for the re-pumping of the wastewater, cleaning of the grid on the entrance of wastewater in wetland (pre-treatment procedures), re-pumping of the purified wastewater, illumination and safety reasons. Heat energy can be used for heating up during the cold/winter period of the year, especially in the case of snow precipitation.

Solar energy is widely used energy source all around the world in form of the solar photovoltaic (PV) energy and solar thermal (ST) energy. Figure 4. presents daily and yearly insolation regimes for some locations in the world (PVGIS, 2018).

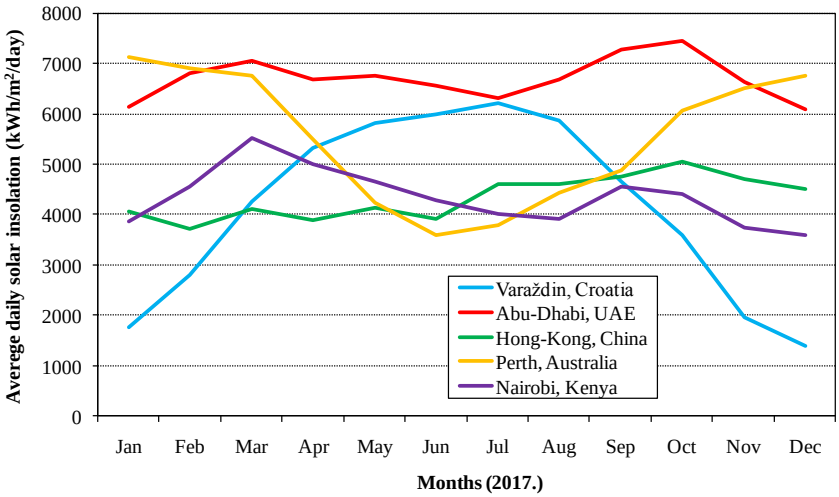

Figure 4. Daily and yearly insolation regimes for some locations in the world

Wind energy also can be used for the producing of electric energy for the already mentioned purposes in constructed wetland for WWT. Wind is a global and local energy source, available at numerous locations with different energy potential (Margeta & Đurin, 2017). Figure 5. presents potential for the production of energy from wind turbines.

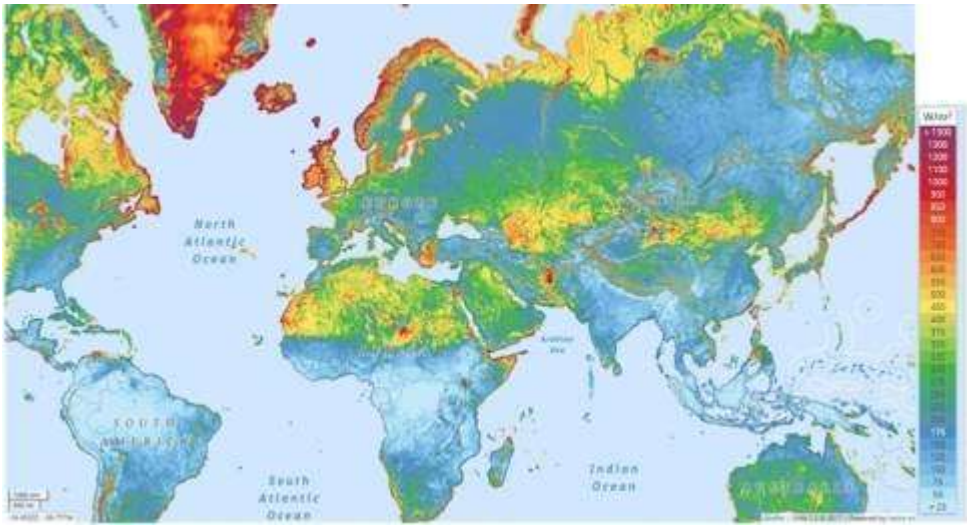

Figure 5. World wind power density (modified from Global Wind Atlas, 2018)

Hydro-electric energy is a classic and economically advantageous source of green energy, but is not often available locally or in the cities (Margeta & Đurin, 2017). Figure 6. shows world map of potential for hydro-generated electricity (Zhou et al., 2015).

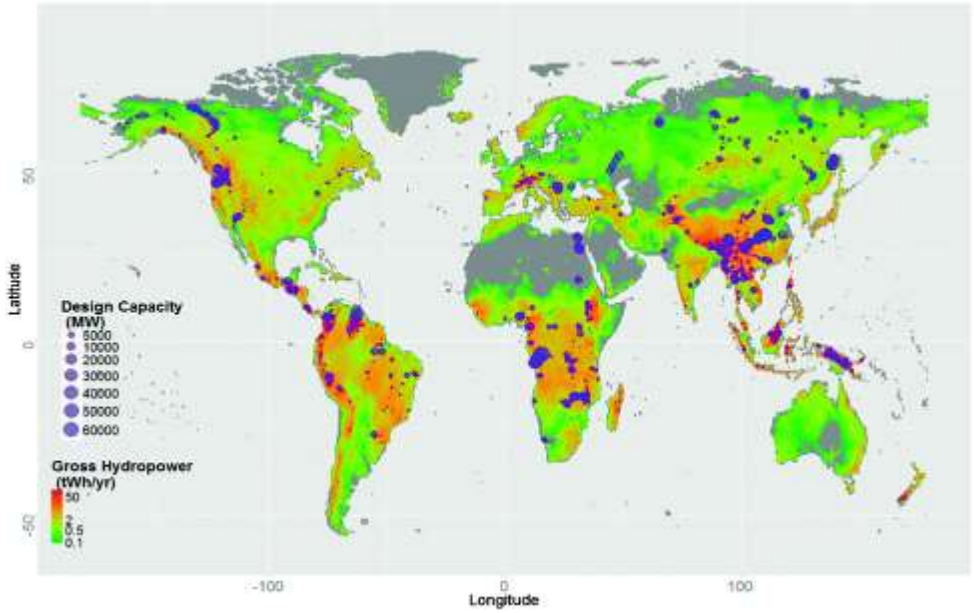

Figure 6. Map of global potential for hydro-generated electricity

Biomass includes any organic matter that is available on renewable or recurring basis; it can be derived from gaseous, solid or liquid biomass. Biomass includes energy crops and trees, agriculture crop residuals, animal manures and other organic waste materials, as well as sludge from wastewater treatment plants (Margeta & Đurin, 2017).

Geothermal energy is obtained from the Earth's internal heat and can be used for generating steam to run steam turbines and electricity generators. A prerequisite for the installation of this energy source is the existence of favourable geothermal conditions near or in the cities (Margeta & Đurin, 2017).

Results and Discussion

Solar photovoltaic (PV) energy for constructed wetlands could be used when the insolation is appropriate for usage. During the intensive precipitation or cloudiness, PV energy cannot be used. But, after ending of the precipitation period, especially after cloudburst, when the rain wastewater inflows are the biggest, using of this kind of energy has full justification. Solar thermal (ST) energy can be used for the purpose of heating during the winter period and snow melting in closer area of the constructed wetlands for the providing of the extended duration of the wastewater treatment, especially when temperatures are under 0 °C. Interruptions of the wind energy production are therefore possible and their characteristics are high unpredictability of occurrence and duration (Margeta & Đurin, 2017). Hydro-energy is very useful energy source for the constructed wetlands for the wastewater treatment plants, because most of such plants are located near rivers and watercourses because of the purified wastewater discharge. Despite seasonal water flow and level changes, purified water in most of the cases generates constant flow at a lesser or greater extent. Biomass is a proven technology as well as its economy. Unfortunately, there are many of locations where this energy is not available in required quantity, i.e. it is not sufficient to satisfy all energy needs of constructed wetlands (Margeta & Đurin, 2017). Particular amount of biomass could be produced by constructed wetland itself (mud, sludge, surplus of the plants, etc.) in a form of an internal energy. Unfortunately, this amount is not satisfying required need for energy within wetland. Geothermal energy is not available at most of the locations near constructed wetlands. Thereby, this energy is not appropriate for such usage.

Conclusions

The course of the conducted discussion show that solar photovoltaic (PV) energy and hydro-energy are most suitable renewable energy sources for the constructed wetlands. As a matter of fact, mutual combination of these two energy sources is very promising for the most locations in the world. In most of the cases, i.e. locations in the world, during summer period, river and watercourses has the smallest flow. Parallel with this period, insolation has the biggest intensity and duration. Therefore, these two sources are covering each other and produce almost constant and continued flow of energy. This paper presents justified and reasoned itemization for the providing sustainability of the constructed wetlands. Further researching will be continued in form of the real case study for the several different locations in the world, considering climate, energy and hydraulic factors.

Abstract

The aim of this study was to evaluate the greenhouse gas emissions based on energy consumption in the saffron and wheat fields in Khorasan Razavi Province, Iran. For this purpose, the information needed was collected from the saffron fields (43 growers) during the 8 years of growing this crop and irrigated wheat production (65 growers) within 1 year by designing and completing a questionnaire through face-to-face conversations. The results revealed that the total and average annual energy consumptions in the saffron fields were 304.60 and 38.08 GJ/ha, respectively, while the total energy consumed in the wheat fields was 43.10 GJ/ha. The total and annual energy efficiencies based on saffron stigma yields were 0.002 and 0.003, respectively, while energy use efficiency and productivity of the wheat fields were calculated to be 1.95 and 0.16, respectively. The total emissions of greenhouse gases over 8 years of saffron growing season were 33099.1 kg of equivalent carbon dioxide per hectare (kg CO_2-eq ha^{-1}) and 1125.4 (kg CO_2-eq) per kilogram of the stigma. Also, the total emissions of greenhouse gases produced in the irrigated wheat fields 3408.2 (kg CO_2-eq ha^{-1}) and 0.81 (kg CO_2-eq) per kilogram of seed. From among the inputs of saffron fields, electricity (68.20%) and manure (28.80%) accounted for the highest shares in greenhouse gas emissions, respectively, so that the amounts of greenhouse gas emissions were 22574.4 and 9531.4 (kg CO_2-eq ha^{-1}), respectively, whereas in the fields of irrigated wheat production, electricity (88.5%) and nitrogen (4.2) had the largest shares in their emissions. Although organic fertilizers were from renewable energy sources, the greenhouse gas emitted from them allocated a high amount because of their immense consumption in the saffron fields.

Keywords: *Climate change; Greenhouse gases; Direct energy; Renewable energy; Energy efficiency.*

Introduction

The increased and intensive use of energy resources causes environmental problems (Alluvione et al., 2011). It was estimated that agriculture contributes 52–84% of world's combined anthropogenic methane and nitrous oxide emissions in the world. Due to its large area and increasingly intensive management, agricultural lands have a significant negative impact on the Earth's carbon and nitrogen cycles. From among agricultural crops, saffron (*Crocus sativus*) is a plant that has been able to withstand the water scarcity problems of the mentioned areas with its own special characteristics, these areas and encourage farmers with a sustainable benefit since having a very high economic efficiency. With regard to saffron being as an export product and saffron market competition in the global level, the need for more research in this area is becoming increasingly tangible (Kafi et al., 2002).

Saffron as a renewable source plays an important role in the sustainable economic development of the country and is considered as a strategic product for regions lacking talent and agricultural facilities like Khorasan Razavi and South Khorasan Provinces. Little water requirement, possibility of exploitation of 5-7 years at one planting time, a long shelf life, ease of transport, lack of need for heavy and sophisticated machinery, ability to employ the

labor force during the harvest season, irrigation during non-critical times for water needs of other plants, and increases of food, industrial, and pharmaceutical consumptions have led to the enhancement and rapid development of saffron cultivation (Dadkhah et al., 2003).
Currently, world annual production of saffron is about 300 tons and Iran has the first rank in the world by producing 282 tons of saffron per year, which is more than 94% of global production (FAO, 2014; Ministry of Agriculture-Jahad. 2016). Through better management practices, such as selection the suitable crop in rotation, organic and sustainable farming, and efficient use of inputs, agriculture has tremendous potential to reduce the atmospheric concentration of GHGs and sequester carbon in the soil (Fares, et al. 2017).
Therefore, increasing and extension of saffron cultivation are in the region and given the fact that Iran has the most important role in the production of saffron in the world and since this product can be in good standing in rotation with wheat, this study aimed to accurately assess the amount and type of consumptive inputs in the fields of saffron and irrigated wheat productions, as well as determine the amount of greenhouse gas emissions and the share of each of the inputs in the production of these gases during various saffron and irrigated wheat production processes in Khorasan Razavi province as one of the most important producing provinces of most crops in the country.

Materials and methods

General information of the study place:

In this study, the information about saffron and irrigated wheat in Khorasan Razavi Province was collected from the Ministry of Agriculture (Ministry of Agriculture, 2006-2015). Khorasan Razavi province are located in the east of Iran, within 56° 19′ and 61° 16′ north latitude and 33° 52′ and 37° 42′ east longitude. After initial data collection, all the agricultural activities such as cultivation, yield and production of saffron and wheat, land preparation, seeding levels, the amount of irrigation water, fertilizers and pesticides, and manpower required during nearly 8 years of growth and development stages of wheat and saffron were identified. Then, the information on all the inputs and outputs was separately extracted through face-to-face discussions with farmers in the area and according to the designed questionnaires.
To complete the questionnaires, a simple random sampling method was used among saffron and wheat farmers. This method is in fact the simplest sampling approach and the results are reliable and generalizable to the entire community with the observance of sampling principles. The number of samples was calculated according to the equation 1 (Yamane, 1967).

$$n=\frac{n\times s^2\times t^2}{(N-1)d^2+(s^2\times t^2)} \qquad (1)$$

In this formula, n is the number of samples required and N is the total number of the target population. S^2 is the estimation variance of the study traits in the community. Assuming the normality of the desired trait, t was obtained from Student's t table at a confidence level of 95% and d was the acceptable error whose value at the confidence level of 95% was 5%. Based on the above equation, the numbers of samples required to complete the questionnaire for saffron and irrigated wheat were obtained to be 43 and 65 farmers, respectively.

Calculation of the amounts of greenhouse gas emissions:

Greenhouse gas emissions resulting from energy consumption in the production of inputs and different operations were calculated by multiplying at carbon dioxide equivalents at the amount of energy used and the amounts of greenhouse gas emissions resulting from different activities in the fields of saffron and irrigated wheat were computed in the form of carbon dioxide equivalent per surface unit (kg of equivalent carbon dioxide per hectare)
By dividing the amount of greenhouse gases in kilograms of carbon dioxide equivalent per hectare on the production amounts of saffron stigma and irrigated wheat seeds in kilograms

per hectare, greenhouse gas emissions for producing a kilogram of saffron stigma and irrigated wheat seeds or in other words, the equivalent weight (kilogram of carbon dioxide per kilogram of saffron and irrigated wheat grain) were obtained. Similarly, by dividing the amounts of greenhouse gases in kilograms of carbon dioxide per hectare on the amount of energy input and dividing the amounts of greenhouse gases on energy output in GJ, the equivalent global warming in kilogram of carbon dioxide/GJ used energy and the energy produced (kilogram of equivalent carbon dioxide/GJ) were achieved.

Results and Discussion

Energy indices:

The total energy input in the saffron fields during the 8 years of its growing season was 287.82 GJ ha^{-1} and the average annual amount of energy input was 35.98 GJ ha^{-1}. It was while in the fields of irrigated wheat production, the total energy input of 43.1 GJ ha^{-1} was calculated (Table 4). In the fields of saffron production, the highest and the lowest energy inputs were 104.09 and 23.27 GJ ha^{-1} related to the first and third years of production, respectively. Of the main reason for the higher energy consumption in the first year of saffron production compared to the other years was the high amount of used seeds (about 4130 kg ha^{-1} with the energy equivalent of 61.83 GJ ha^{-1}) (Table 1). Bakhtiari1 et al. (2015) reported that in five years of saffron production cycle in Khorasan Razavi and south Khorasan region in Iran, the overall input and output energy use were to be 163,912.09 and 184,868.28 MJ ha^{-1}, respectively. But Mohammadzadeh et al. (2017) demonstrated that overall input and output energy use for five years cycle of saffron was 25,144 GJ ha MJ ha^{-1} and 154,755 MJ ha^{-1} in Azerbayjan province in Iran.

The total energy input during the 8 years of saffron growing season was reckoned 175.23 GJ ha^{-1} with an average annual of 21.90 GJ ha^{-1} (Table 1). The amounts of energy available in the saffron stigma, straw and stubble, and bulb were 0.57, 149.03, and 25.63 GJ/ha during the 8 years of its growing season, respectively, and the average annual energies for the stigma and straw and stubble were calculated 0.07 and 18.63 GJ ha^{-1}, respectively (Table 4). The variation trend of the amounts of energy outputs of the saffron fields during the 8 years of growing season was proportionate to the changes in its production rate. Also, the total energy output of the irrigated wheat during the growing season was 88.44 GJ ha^{-1} (Table 1). In the irrigated wheat fields, the energy amounts of grain and straw and stubble were 62.48 and 21.97 GJ ha^{-1}, respectively. Also, Ghorbani et al. (2011) estimated the total energy output of irrigated wheat fields to be 65336.3 MJ ha^{-1}.

The results of this research demonstrated that saffron energy use efficiencies during the 8 years of its growing season based on the yields of stigma and stigma plus straw and stubble were 0.02 and 14.3, respectively (Table 1). The average annual energy use efficiencies of the saffron fields based on the yields of stigma and stigma plus straw and stubble and corm were 0.003 and 1.8, respectively, while the energy use efficiency in the irrigated wheat fields was 1.95.

Also, during the years of saffron production, the maximum and minimum energy use efficiencies based on stigma yield were related to the 5^{th} and 1^{st} years, respectively, and highest and lowest energy use efficiencies based on the yields of stigma plus straw and stubble and corm were observed in the 8^{th} and 1^{st} years of production, respectively. The higher energy use efficiency in the 8^{th} year was due to the addition of corm yield in calculating the energy use efficiency (Table 1). By examining the energy consumed in the production of irrigated and rain-fed wheat in the city of Saveh, Iran, Safa and Tabatabaeefar (2002) reported energy use efficiencies in the irrigated and rain-fed wheat fields to be 1.17 and 0.99, respectively.

Table 1. Total energy inputs and energy indicators for Saffron and irrigated wheat farms.

	Year (Saffron)										Wheat
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**Total**	**Average**	
Total energy input (GJ ha^{-1})	105.7	25.7	25.4	34.6	26.6	30.5	28.6	27.4	304.6	38.1	43.10
Total energy output (GJ ha^{-1})	11.7	15.1	19.6	23.2	24.4	22.3	17.0	272.6	405.9	50.7	84.44
Net energy (GJ ha^{-1})	9.1	1.7	1.3	1.5	1.1	1.4	1.7	0.1	17.8	2.2	41.34
Energy Use Efficiency $_{(Total)}$	0.11	0.59	0.77	0.67	0.92	0.73	0.60	9.94	14.3	1.8	1.95
EUE$_{(based\ on\ stigma\ yield)}$	0.00006	0.002	0.003	0.003	0.005	0.003	0.002	0.001	0.02	0.003	-

Additionally, the total renewable and non-renewable energies for the saffron fields were 131.9 and 172.7 GJ ha^{-1}, respectively, and the average annual energies were 16.5 and 21.6 GJ ha^{-1}, respectively (Table 5). The share of renewable energies in the saffron fields was lower compared to non-renewable energies (Figure 1). The amounts of renewable and non-renewable energies were 43.3% and 56.7% of the total used energy, respectively. Also, in the irrigated wheat fields, the total renewable and non-renewable energies were 8.4 and 34.71 GJ ha^{-1}, respectively (Table 1).

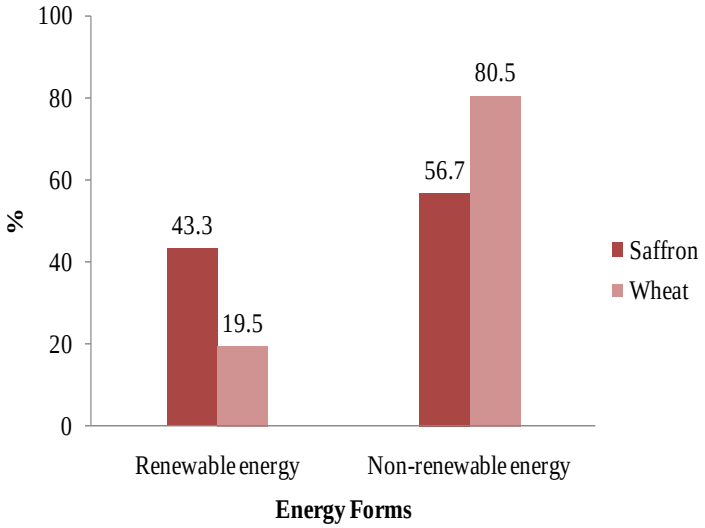

Figure 1. The share of renewable and non-renewable energies in saffron and wheat farms during 8 years production.

Greenhouse gas emissions:

The results of this study showed that during the 8 years of saffron growing season, greenhouse gas emission was 33099.1 kg of equivalent carbon dioxide per hectare and the average annual greenhouse gas emission from the fields of saffron production was 4137.4 kg of equivalent carbon dioxide per hectare (Table 2). During the years of saffron production, the highest and lowest greenhouse gas emissions were observed in the 1st year (70160 kg CO_2-eq ha^{-1}) and 3rd year (2728.9 kg CO_2-eq ha^{-1}), respectively. It seemed that more uses of inputs, especially chemical fertilizers and fossil fuels for soil preparation were of the main reasons for higher levels of greenhouse gas emissions in the first year compared to the other years. The results also revealed that during 1 year of the irrigated wheat production, about 3408.2 kg CO_2-eq ha^{-1} (Table 2). Rajabi et al. (2012) showed that the global warming potential value of

wheat production varied between 268 and 923 kg of equivalent carbon dioxide per hectare. In another study,. Despite the fact that organic fertilizers were from renewable energy sources.
The results of this investigation also revealed that during the 8 years of saffron growing season, the amount of greenhouse gas emissions was 1125.4 kg of equivalent carbon dioxide per a kilogram of stigma, while for producing every kilogram of wheat seeds, 0.81 kg of carbon dioxide was emitted into the atmosphere (Table 2). During the years of saffron production, the highest and lowest amounts of greenhouse gas emissions per stigma production related respectively to the 1st year (22632.4 kg of equivalent carbon dioxide per a kilogram of stigma) and 5th year (401.5 kg of carbon dioxide per a kilogram of stigma), respectively (Table 2). These differences were due to the low production of saffron stigmas in the first year on the one hand and high energy consumption in the same year on the other hand. It was the completely opposite for the fifth year. Rajabi et al. (2012) also reported the global warming potential value of wheat production ranged between 103.8 and 271.5 kg of equivalent carbon dioxide per ton of grain.
Furthermore, during the 8 years of saffron growing season, 108.7 and 188.9 kg of equivalent carbon dioxide were produced per a GJ energy input and output, respectively, while in the irrigated wheat fields, these amounts were 79.1 and 38.5 kg of equivalent carbon dioxide, respectively (Table 2). During the years of saffron production, the highest and lowest amounts of greenhouse gas emissions related to the 4th year (157.9 kg of equivalent carbon dioxide per a GJ of energy input) and 1st year (66.4 kg of equivalent carbon dioxide per a GJ of energy input), respectively (Table 2).
In addition, within the different years, the highest and lowest amounts of greenhouse gas emissions related to the 1st year (601.5 kg of equivalent carbon dioxide per a GJ of energy output) and 8th year (83.8 kg of equivalent carbon dioxide per a GJ of energy output), respectively (Table 2).

Table 2. The greenhouse gases emission in different bases for Saffron and irrigated wheat farms.

	Year (Saffron)									
Parameters	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**Total**	**Wheat**
per unit area (kg CO_2-eq ha^{-1})	7016.0	2869.4	2728.9	5468.7	2850.5	4586.4	4066.4	3512.6	33099.1	3408.2
per unit weight (kg CO_2-eq kg^{-1})	22632.4	1147.8	649.7	994.3	401.5	899.3	1270.8	2341.8	1125.4	0.81
per unit energy input (kg CO_2-eq GJ^{-1})	66.4	111.6	107.4	157.9	107.1	150.2	142.2	128.1	108.7	79.1
per unit energy output (kg CO_2-eq GJ^{-1})	601.5	190.0	139.3	235.9	116.6	205.7	238.6	83.8	188.9	38.5

Conclusion

On basis of the studied results, because of saffron growers in this region are cultivated and manage saffron as modern (conventional) agriculture therefore in view of CO_2 emission saffron production is not reasonable case for cultivation in this region (4137.4 kgCO_2-eq ha^{-1}) compared to irrigated wheat (3408.2 kgCO_2-eq ha^{-1}) per year. But in another study in west of Iran has shown that saffron production with 646.24 kgCO2-eq ha^{-1} had the lowest GHG emissions amongst the studied crops (Mohammadzadeh et al. 2017). In fact saffron

cultivation in Khorasan Razavi is a high input production system, because farmers use all kind of chemical inputs and fossil fuel in the agricultural practices, so it is not an efficient system in term of energy use and CO_2 emission. But in other part of Iran, saffron is a new crop in their crop rotation, so farmers manage their farms as subsistence (traditional) agriculture. In these fields farmers apply renewable energies and reduce application of chemical inputs. Thus type of farm management severely affect on greenhouse gas emission in saffron and irrigated wheat production systems.

Abstract

The European Landscape Convention 2000 has given new inputs to landscape research and action especially by inviting the parties in its article 6-C to identify its own landscapes throughout its territory, to analyze their characteristics, dynamics and the pressures that modify them to eventually study their transformations. Therefore, it enhances the importance of the Landscape Observatory as a tool in each country. Despite its small area (10452 km²), Lebanon has a large variety of landscapes. However, it faces several natural and anthropogenic pressures stressed by the nonexistence of a national landscape law. Beirut Northern Suburb, *North Metn* is one of the most affected districts. Its 51 localities are distributed from the coastline to the highest mountains representing different Lebanese geographical characteristics in only 2.5% of the national surface. The current research aimed to explore the landscape transformations within the case study area. The research theoretical base included a comparative study of the landscape Observatory's methodologies around the world. By taking into consideration the national context, the Landscape Observatory was applied by using the Landscape Indicators, the visual monitoring system, field visits, public participatory, road books containing social, cultural and natural information of each locality occurred with aerial maps study (2005 till 2017). The results showed that 45% of the landscape mutated from natural landscapes to urban/industrial/rural landscapes, while 55% of the urban landscape became even denser specially by losing most of the green areas. Hence, the Landscape Observatory is important as an analyzing tool to manage, restore and protect the landscapes.

Keywords: *Landscape, Landscape Observatory, North Metn, Lebanon.*

Introduction

The Landscape Observatory, initiated in the face of rapid and profound changes in the landscape, aims to monitor the evolution of landscapes and territories as stated in the articles of the European landscape convention. This convention defines the landscape as it "refers to a part of territory as perceived by the people, whose character is the result of the action of natural and / or human factors and their interrelations." (Europeen convention 2000). Mankind has shown throughout the decades a lot of effects on the landscape whether positive or negative. Effected landscapes by anthropogenic factors are called: "cultural landscapes" that differs by their social, ecological and spiritual dimension; some are related to specific land-use techniques that maintain biodiversity, others associated in the minds of people with beliefs, artistic and customary practices, witness an exceptional spiritual relationship between man and nature. (Unesco New Delhi, 2012) In Lebanon (10452km²), 70% of the territory is mountainous and its wide seaboard over the Mediterranean presents a wide variety of landscape. The casa of North Metn has a surface of 265 km². Its geographical characteristics represent a smaller scale of the same geographical characteristics of Lebanon. It is one of the busiest most effected casas in Lebanon, where it contains 51 region. These features made the minorities of the region over the centuries, to find refuge which enriched its cultural

landscape. Unfortunately, in addition to the global stress caused by the climate change these landscapes are facing all kind of natural and human threats stressed by the nonexistence of a national landscape law, which leads us to the following problematic: "How will the landscape observatory be a baseline and tool for studying these developments, especially based on landscape indicators? According to which methodology can we master the evolution of these landscapes?" (Ireland Heritage Council, 2010)

In order to apply the landscape observatory methodology in Lebanon, were there is no landscape law, two specific comparisons were made between 10 different landscape observatories: First comparison was a study of identification of the landscape in different Landscape Observatories while the second one was related to methodologies followed or created in Landscape Observatories around the world. It shows that every landscape is defined by its role and objective to the country and the methodology used based on the objective they want to achieve. After this analysis, strength and weakness points helped create a new methodology to follow in our site of study, based on two large systems: Visual monitoring Landscape System and the Landscape Indicators. The methodology followed is applied in Lebanon, in the casa of North Metn. A list of factors of changing the landscape of North Metn were studied in details such as: the effect of rapid urbanization, self-reliance and centralization, the increase of random quarries, the effect of fast road construction, the destruction of the seafront, the decrease of green spaces, rivers and wet landmarks disappearance and dumps. These factors were taken into consideration to study the evolution of the region especially while going through the history books and pictures in the municipalities. Moreover, what helped the most was an essential factor in every Landscape Observatory study which is: the public participatory. Surveys and dialogues with the public added to the analysis important issues and factors on social dimensions to study further more. Following these basics led to the qualification and quantification of the landscape of the casa of North Metn. The objective of this paper, therefore, was to study the transformation of North Metn and assure a future scenario for these changes if actions of protection and restoration were not made.

Materials and methods

Visual Monitoring system (VMS) and landscape indicators as said before were the basic of this methodology. The VMS helps comparing new pictures of a landscape to old pictures of the same landscape from the same angle taking into consideration the monitoring of physico-spatial and visual component besides the sociocultural component of the landscape. In addition to understanding the difference between the three different kinds of transformation: disappearance, mutation and persistence. (CPEUM, 2007)

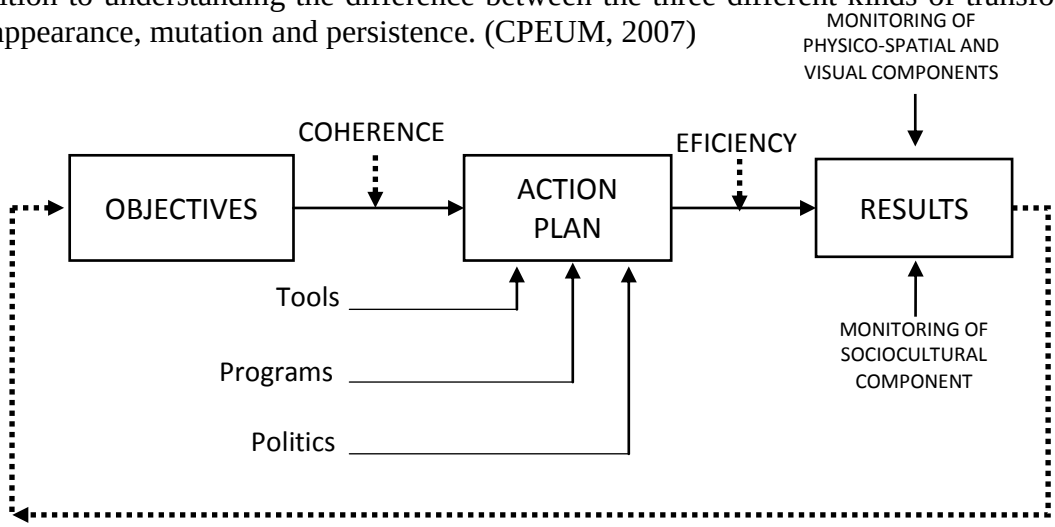

Figure 8: Model for Monitoring Landscape
Source: (CPEUM, 2007)

The "Landscape Indicators", (Joan Nogué, 2005) which present the largest parts of studies in the LO of Catalonia, are key factors for a good monitoring of the state of the landscape in Catalonia and during the application of landscape policies, at all levels. The Landscape Observatory proposes a list of landscape indicators based on economic, social and environmental points of view that will help in the measurement and analysis of the evolution of the landscape of Catalonia following the principles of sustainable development. The indicators began by being simple parameters that represent all the complexity of the landscape. These parameters indicate the current landscape situation and are used as data to define the use of sustainable soil. Due to their importance especially in the field of agriculture by studying the effects of changes, these are defined as "Landscape Indicators." "An indicator is a way to reduce a large amount of data to its simplest form, retaining an essential meaning for the questions that are asked about this data."(OttWascher, 1978)"Indicators show changes over time for each criterion and demonstrate progress towards its specific goal. " (MCPFE 1998). Landscape indicators are either qualitative or quantitative. The indicators are: Landscape Transformation, Landscape Diversity, Landscape Fragmentation, Economic Value of Landscape, Landscape Knowledge, Landscape Sociability, Landscape and Communication, Landscape Satisfaction, Application of Protective Law Instruments, planning and landscape management, public and private action in the field of conservation. The range of studies made was 20 years: 2005-2017: throughout these years, effects were noticeable quickly specially after the war, where the effects of urbanization and mass destruction of green areas has finally occurred. In order to understand further more these transformation, field visits were a must: circuits were chosen based on the existing types of landscape along the way. The Belgaum-Hainaut landscape observatory committee has created and followed a "road book" "contains all the technical information necessary for this: the roadmap (geographical coordinates, technical information of the aircraft, etc.), a location diagram of the point of view, a photograph locating the foot of the camera in its context, a location map." (OP, 2008) And in parallel, questions for the survey has occurred to ask while the field visit. And of course, the table of comparison between the old pictures and new ones with the municipalities' outcome were taken into consideration as well. Each landscape has its own road book due to their showing difference. During these field visits, it was noticeable that some of the old compositions of the landscape are no longer available which adds more value to the study. Programs were used at the end to analyze the survey results, in order to have a better perspective of people's thoughts and satisfaction of landscape. And other programs were used to summarize the results of the study on the maps such as AutoCAD and GIS.

Results and discussion

After applying this methodology, North Metn landscape was classified accordingly: the Littoral and the hills of the littoral, the middle mountains and the high mountains. And each type of landscape transformed quickly according to the comparison between old and new maps: the littoral landscape is known utterly for its high and quick urbanization where the difference in the map of 2001 and the map of 2010 shows a disappearance and a decrease in the green areas while the urbanized areas has grown much more, on the other hand comparing this to the 2016 map shows how urbanization is becoming saturated and the green areas are being demolished. As for the middle mountains landscape transformation, the comparison between maps from 2005 and 2017 shows a big disappearance of green spaces where industries and urban landscape started showing. On the other hand, even the mountainous landscape shows a 60% of green areas while only 35% has concrete and other urban forms and 5% of it are arid as the map of 2005 shows but the green areas decrease by 10% in 2016. In North Metn casa, studies and research show that it handled all kind of transformations

differently with 55% persistence, 40% mutation and 5% disappearance in the past 10 -15 years.

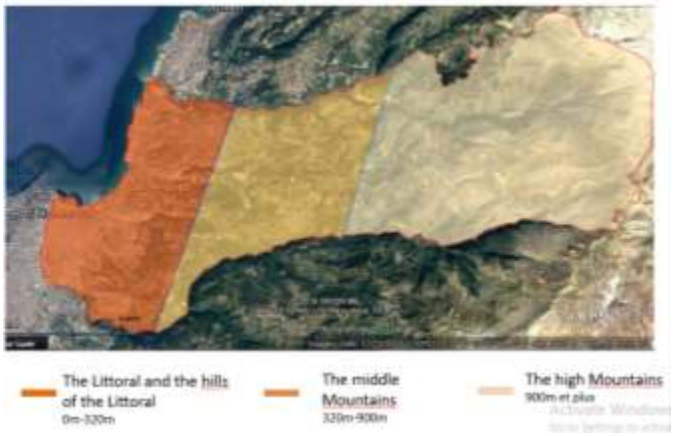

Figure 2: Qualification of the landscape of North Metn

Mainly what persisted are all the urban areas that are saturated with no place left for change or modification, 40% mutated from green areas to urban landscapes, or from a certain urban landscape to an industrial one … However, the 5% that disappeared are mainly the green landscapes that could never become reforested again because they are destroyed by concrete invasion and industries and rural houses. A map showing the frequent transformation in the landscape of North Metn during the last 10 years was a result of these researches as well. The map shows as well future transformations, where buildings and compounds are being constructed throughout these areas. This study helped in creating a future scenario of the future transformations as seen in the figure 4 below.

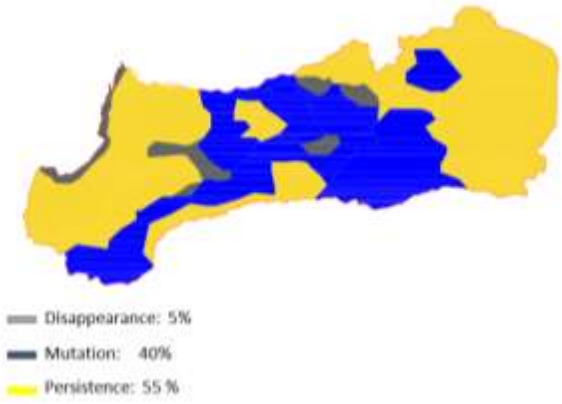

Figure 3: Map showing different types of landscape transformations in North Metn

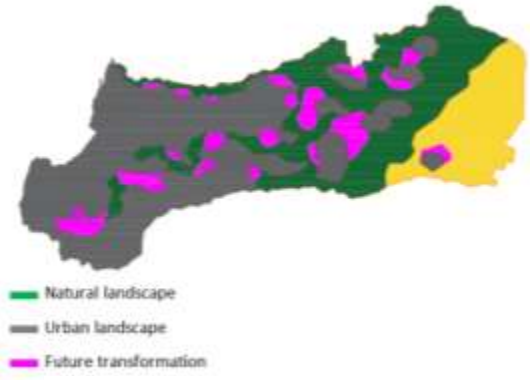

Figure 4: Map showing a scenario of future transformation (next 10 years)

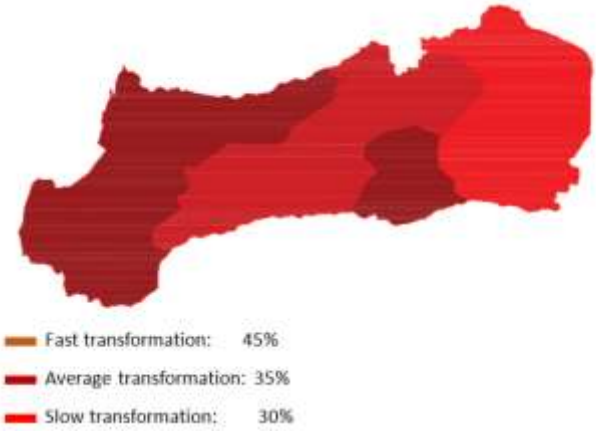

Figure 5: Map showing the frequency of landscape transformation in North Metn during the last 10 years

These transformations were studied on a smaller scale on every field visit, results of mutation and fast transformations throughout the last 10 years are shocking. Some patrimonial features has disappeared, greenery is decreasing, forests are becoming smaller and urbanization is finding its way through the mountains. These results were filed in the road books and helped summarizing the vision of transformation.

Conclusion

Concerns about the setting and the quality of life, as well as the awareness of the environmental impasse in which we find ourselves, have brought the landscape to the fore. The landscape was considered here as an object of observation, but also as an observation tool: the landscape as entrance to the territory. This article's objective was to develop a landscape observatory at the Metn Nord housing estate to finally raise awareness of the importance of landscape, interaction between the landscape and the observer, as well as accomplishing a goal of following the evolution of the landscape and making it a tool for territorial and landscape action, integrating all the populations, the leaders, the elected officials, associations following an organized participatory approach. In their participatory version, landscape observatories appear to be a good compromise between the analysis of the material nature of landscapes: diagnosis, photography, field studies and their subjective dimension: interviews, inquiry, social demand; and contribute to the emergence of a prospective reflection of the management of territories and landscapes. As far as photography is concerned, this research made it possible to become aware of both the interest and the danger it represented. It seems relatively easy to let photography "guide" an observatory of the landscape, to photograph landscapes perceived as representative and to be limited to follow their evolutions. However, photography should be seen as a tool and should not be the only framework for analysis.

VARIETY AND STATE RESEARCH OF ENERGY PLANTS IN LITHUANIA

Antanina STANKEVIČIENĖ

Kaunas Botanical Garden of Vytautas Magnus University, Kaunas, Lithuania
*Corresponding author: antanina.stankeviciene@vdu.lt

Abstract

Article presents the review of introduction studies on energy plants (variety and state of plants) cultivated at the collection at Kaunas Botanical Garden of Vytautas Magnus University. Collection was formed of 72 samples of plants: 40 genus, 53 species, 33 cultivars, 1 varietes, 3 hybrids. Plants are grown separately depending on their life form – woody plants, perennial herbaceous plants, annual (biennial) plants and introduced plants. Also non-infectious diseases (necrosis, dry branches), fungal disease agents (7 genus, 10 species), pests (2 genus and species) are described.

Keywords: *energy plants, state, variety, Kaunas Botanical Garden of Vytautas Magnus University*

Introduction

Lithuania is in a cool temperate climate zone with moderate summer temperatures and moderate cold winters. The average temperature in July reaches about 17 °C, in winter – apie -5 °C. Therefore, the country needs a lot of energy resourses.

The decreasing imported non-renewable natural resources (coal, oil, gas, ect.) should be replaced with indigenous, renewable ones. One of the most important prerequisites for sustainable development is the rational use of natural resources. Plants can be used for energy purposes: woody plants (*Salix* L., *Populus* L. ir kt.) or tall in hight large-stem non-woody herbaceous plants (*Miscanthus* Andersson, *Silphium* L., *Napaea hermaphrodita* L., *Solanaceae*, *Helianthus annuus* L., *Cannabis sativa* L.) (Jakienė *et al*., 2013; Kryževičienė *et al*., 2005; Makarevičienė and Sendžikienė, 2013). For energy purposes could also be used straw, sodder grain plants, also specially grown *Brassica napus* L. ssp. *napus*, x *Triticosecale* spp. Wittm (Jasinskas and Liubarskis, 2005). Most of these plants are easily propagated, easy to maintain, non-sensitive to soil, fast growing, resistant to adverse biotic and abiotic factors (Jeviė, Lunaèek *et al*., 2000; Jasinskas *et al*., 2008; Jasinskas, 2009; Lewandowski *et al*, 2000, 2003). There are 80 species of energy plants calculated in the world that can be used to generate energy (Bassam, 2012). The biomass of woody plants produces heat, electric power, biofuels; sugar (sugar beet), starch (*Solanom tuberosum* L., grain) – bioethanol; vegetable oil (from *Brassica napus*, *Linum* L., *Glycine* Willd, *Solanum tuberosum*, *etc*.) – biodiesel; *Zea mays* L. – biogass (Jakienė *et al*., 2013; Makarevičienė and Sendžikienė, 2013).

Plantation of energy plants are raised in Europe and studies are carried out on most popular, grown for energy purposes plants (*Miscanthus*, *Panicum* L., *Phragmites australis* (Cav.) Trin. ex Steud., *Typhoides arundinacea* (L.) Moench, etc.), biogas stations generating biomass are being built (Lewandowski *et al*., 2003. Wright, 1990). For the energy needs 35 species of herbaceous plants were investigated in the United States.

Researches of energy plants in Lithuania were started in 2000 in Lithuanian University of Agriculture. Investigations were carried out on the possibilities of the cultivation and usage perennial crops as biofuel, also explored options of herbaceous plants for energy efficiency (Kryževičienė *et. al.,* 2005). During 2007–2009 at the testing base there was investigated *Salix viminalis* L. for the technology purposes of fuel preparation. From 2007 in Lithuanian Research Centre for Agriculture and Forestry scientific project '*The development of new renewable energy sources by formating plantations of short-growing forest plants and*

herbaceous (imprted and native) plants'. The cultivation and use of energy plants for energy purposes in Europe has a tendency to grow. It is an opportunity to use unused, less fertile, rehabilitated areas or territories located on roads and other contaminated air objects.
During 2012–2014 at the Kaunas Botanical Garden of Vytautas Magnus University in the framework of the Public Information and Environmental Education means project "School of green ideas" (No VP3-1.4-AM-09-K-02-001) a collection of energy plants was created.
Aim of work: evaluate the variety and state of energy plants cultivated in Kaunas Botanical garden of Vytautas Magnus Uviversity (Lithuania).

Material and Methods

Research object – energy plants, grown at the area of 60 ares at Kaunas Botanical Garden of Vytautas Magnus Uviversity (Lithuania). The plants were planted in 2012–2014. These plants are grown at separate areas according to their life forms: woody plants, perennial herbaous plants, annual (biennial) plants and introducated plants.
The variety of plants is described on the basis of the taxonomic-analytical method, placing them according to the dependence on the higher taxonomic rank according to A. Takhtajan phylogenetic system (1987). *Pathogens* were identified visually (according to disease symptoms and morphological signs of pathogens – fungi, using lupus) and using descriptors (Grigaliūnaitė, 1997; Minkevičius and Ignatavičiūtė, 1993; Sinclair and Lyon, 2005). Pests are described by (Pileckis *et al*., 1968). The intensity of non-infetious and infectious diseases and pests abundance asssessed on a scale of 0–4 grades, in July – August (0 grades – up to 10 % of assimilated area is damaged, 1 grade – 11–30 %, 2 grades – 31–60 %, 3 grades – 61–80 %, 4 grades – 81–100 %). Plant Latin names are used accroding to *www.Tropicos.org*. Fungi teleomorphic taxons of fungi disease agents are described by the database „*Index fungorum*' (http://www.indexfungorum); pests – according to „*Fauna Europeae*" (http://www.fauna-eu.org/).

Results and Discussion

In 2012–2014 at the collection of energy plants were planted 72 plant samples. Plants belong 1 division, 2 classes, 5 subclasses, 15 families, 40 genus, 53 species, 3 subspecies, 33 cultivars, 1 variety and 3 hybrids (Table 1). The collection is the richest in Lithuania. Plants in the collection are planted in separate areas according to the form of life: woody (short rotation), herbaceous perennials, introduced herbaceous, annual (biennial) plants.
Plants of different life forms are grown at a separate areas: woody (of short rotation) – 15 samples belongint to 6 genus, 11 species, 7 cultivars, 3 hybrids, perennial herbaceous plants (14 samples – 13 genus, 12 species, 4 cultivars), introduced herbaceous plants (18 samples – 10 genus, 15 species, 3 cultivars, 1 hybrid), annual (biennial) – 22 samples: 16 genus, 12 species, 2 subscpecies, 12 cultivars, 1 variety. Poacea family plants compose a larger amount in numbers among the collection plants (14 genus, 16 species, 12 cultivars) (Table 1).

Plant state investigation is relevant to plant introduction. During the research period 18% of plants were injured by 2 species of non-infectious diseases (necrosis, dry branches); 8 genus, 11 species of fungal disease agents and 2 genus and species of pests (Table 2).
The greatest variety of violations was on *Populus* x *euramericana*. They were injured by necrosi by 1 grade, rust – (*Melampsora larini-populina*) – 3 grades and by pests of two species: moth (*Lirhocolletis populifoliella*) and leaf beetle (*Phyllodecta vulgatissima*) by 1 grade each. Most strongly injured were *Salix matsudana* 'Tortuosa' and *Salix purpurea* 'Gracilis'. 'Tortuosa' genus rees were injured by mildew (*Erysiphe adunca*) and scab (*Venturia saliciperda*) by 3 grades of each and noticed single injuries of rust (*Melampsora caprearum*). 'Gracilis' genus trees were noticed to have large amount of dry branches (3 grades), rust (*Melampsora caprearum*) injuries of 3 grades and scab (*Venturia saliciperda*) by 1 grade. Another 7 plant species were damaged by one pathogen and plants of two species had injuries of physiological origin – necrosis. Mildew was noticed to be of the stongest violation: mildew *Helianthus tuberosus* (*Plasmopara halstedii*) (4 grades), *Lupinus angustifolius – Erysiphe trifolii* (3 grades) and *Lupinus polyphyllus – Erysiphe trifolii* (2 grades), *Helianthus annus* – (*Plasmopara halstedii*) and *Fagopyrum esculentum* – (*Erysiphe communis* f. *fagopyri*) – by 1 grade each.

Table 2. State of plant grown at the collection of energy plants at Kaunas botanical Garden of Vytautas Magnus university, 2018.

Hosts plants	Disease, pest	*Agents – injury grade*
Althea officinalis	Rust	*Puccinia* malvacearum Bertero ex Mont. – 0
Beta vulgaris subsp. *vulgaris* var. *altissima* Doll 'Ernestina'	Leaf spot	*Ramularia betae* Rostr. – 1
Fagopyrum esculentum Moench.	Mildew	*Erysiphe communis* f. *fagopyri* Jacz. – 1
Helianthus annus		*Plasmopara halstedii* (Farl.) Berl. & De Toni – 1
Helianthus tuberosus		*P. halstedii* (Farl.) Berl. & De Toni – 4
Lupinus angustifolius		*Erysiphe trifolii* Grev. – 3
Lupinus polyphyllus		*E. trifolii* Grev. – 2
Galega orientalis Gale	Physiological injuries	Necrosis – 1
Reynoutria sachalinensis		Necrosis – 1
Populus x *euramericana*		Necrosis: – 1
	Rust	*Melampsora larini-populina* Kleb. in Zeitsch.) – 3
	Pest, moth	*Lirhocolletis populifoliella* Tr.). – 1
	Pest, leaf beetle	*Phyllodecta vulgatissima* (L.) – 1
Rosa chinensis	Physiological injures	Necrosis – 1
	Rose black spot disease	*Diplocarpon rosae* F.A. Wolf – 0
Salix purpurea L. 'Gracilis'	Physiological injures	Dry branches – 3
	Rust	*Melampsora caprearum* Thüm – 3
	Scab	*Venturia saliciperda* Nüesch – 1
Salix matsudana 'Tortuosa'	Mildew	*Erysiphe adunca* (Wallr.) Fr. – 3
	Scab	*Venturia saliciperda* Nüesch – 3
	Rust	*Melampsora caprearum* Thüm – 0

During the research there were detected two species and genus of pests that injured *Populus* x *euramericana* by intensity of 1 grade: poplar moth (*Lirhocolletis populifoliella*) and leath beetle (*Phyllodecta vulgatissima*). The detected injuries are common on mentioned plants in Lithuania. Injuries has no significant influence on plant state, exluding hawks, they have freezed out.

Conclusions

In Kaunas Botanical Garden of Vytautas Magnus University (Lithuania) the energy plant exposition was established. Exposition consists of 72 plant samples, they taxonomically belong to: 1 divisio, 2 classes, 5 subclasses, 15 families, 40 genus, 53 species, 3 subspecies, 33 cultivars, 1 variete and 3 hybrids.

Assessing the state of the plant was found 18% of plants to be injured by disease of non-infectious origin: necrosis – 1 grades, dry branches – 3 grades; 0–3 grades – 8 genus, 11 species of fungal disease agents and 1 grade – 2 genus and species of pests.

The largest variety of injuries were detected on *Populus* x *euramericana*: necrosis (1 grade), rust – (*Melampsora larini-populina*) – 3 grades and by 1 grade of pests of 2 species and genus (*Lirhocolletis populifoliella*, *Phyllodecta vulgatissima*).

Mildew was of the strongest violation: *Helianthus tuberosus* – *Plasmopara halstedii* (4 grades), *Lupinus angustifolius* – *Erysiphe trifolii* (3 grades), *Lupinus polyphyllus* – *Erysiphe trifolii* (2 grades), *Helianthus annus* – (*Plasmopara halstedii*) ir *Fagopyrum esculentum* – (*Erysiphe communis* f. *fagopyri*) – 1 grade each.

Abstract

Aquaculture, just like any other economic activity, has effects on environment. This can be seen through the eutrophication and quality decrease of surrounding surface waters, due to being polluted by waste. One of the main advantages of recirculating aquaculture systems (RAS) is the absence of dispersed waste, i.e. the possibility to produce concentrated waste and thus simplify the decontamination process. This paper presents a review of RAS waste characteristics, global practices and tendencies of waste decontamination and their potential reuse, as well as recommendations, based on waste characteristics gathered through an analysis in an aquaculture farm. Sludge, produced in RAS, as well as the generated pollution, depends on the volume of feed. The main parameters, determining waste pollution – organic pollution index and dissolved nitrogen and phosphorus compounds - were measured in the analysed farm. The following results were obtained: biologic oxygen usage, showing the pollution of waste with organic material, was 106 mg/l, ammonium nitrogen concentration was 29 mg/l. This was significantly higher than 12 mg/l, found in literature. However, because the water pH index in the system oscillated between 6.27 and 6.7, in 23^0C water temperature; non-dissolved ammonium part was only 0.2%. Nitrite values were from 0.38 to 0.69 mg/, measured RAS phosphate values oscillated between 12 and 14 mg/l, which would correspond to phosphorus concentration of 3.9 – 4.6 mg/l. After determining the volume of sludge, produced in the RAS, relevant techniques for sludge reuse were suggested. The main features of these techniques are that they are eco-friendly, prevent pollution of surface water, are able to create added value and increase the profit of the company.

Keywords: *aquaculture sludge, environmental protection, recirculating aquaculture system, pollution, sludge reuse.*

Introduction

Water saving and concentrated and thus better manageable effluents are primary reasons talking in favour of recirculating aquaculture systems (RAS). Though aquaculture effluents have economic potential which is expressed primarily through nutrients and energetic capacity it contains, their reuse is rarely considered due to lack of site specific research on investment and absence of well-established and viable appropriate technologies. RAS gives possibility to obtain reasonably concentrated effluent flow compared to other production systems in terms of relatively small flow and higher amount of solids, which could be concentrated for further treatment and reuse. Significance of the reuse options is not only for seeking economic benefits but also important for aquaculture sector in regards of EU water protection and green circular economy policy. There are number of big international collaboration projects funded by EC which were called to tackle various aspects of aquaculture sustainability issues as well as aquaculture waste management and reuse: SUSTAINAQUA (Integrated approach for a sustainable and healthy freshwater aquaculture) https://cordis.europa.eu/project/rcn/84683_en.html; AQUAETREAT (Improvement and innovation of aquaculture effluent treatment Technology)

https://cordis.europa.eu/result/rcn/47777_en.html; INAPRO (Sustainable food production through aquaponics) https://cordis.europa.eu/result/rcn/203873_en.html; BIFFIO (Cooperation between the aquaculture and agriculture sectors with the intent to use animal manure and fish faeces for sustainable production and utilization of renewable energy and recovered nutrients) https://cordis.europa.eu/result/rcn/204311_en.html; BIOALGAESORB (Enabling European SMEs to remediate wastes, reduce GHG emissions and produce biofuels via microalgae cultivation) https://cordis.europa.eu/result/rcn/153864_en.html.
In spite of findings and new knowledge generation, these collaborative research point out that there is still room for increase knowledge on various aspects of reuse and bioconversion of aquaculture effluents.

Materials and Methods

The primary aim of the work was the help for decision making procedure on expanding the African catfish RAS owned by rural energy generating and distributing company JSC "Baisogalos bioenergija" in central Lithuania. We have performed extended review of literature on possibility of beneficial reuse of RAS effluents and sludge and evaluated RAS sludge characteristics on site. The company's aquaculture business was launched there as additional income source taking benefits of cheaper energy for heating water for warm water species like African catfish *(Clarias gariepinus)*. The capacity of the farm production is 20 tons/year appeared not to be sufficient to allow establishment on the market, so now feasibility study is carried on for to increase the production tenfold. For this reason, company is looking for possibility to reuse farm effluents and sludge in viable way. The farm consists of 112 m^3 fish rearing space and water treatment unit – mechanical drum filter, trickling biological filter and UV water sterilization unit. Water retention time in the system – 1 hour, water refreshment rate 200 l/kg feed, fish rearing density – up to 400 kg/m^3. The farm effluent analysis was performed and research papers review was made which suggests closer look on various options of beneficial reuse of aquaculture effluents. Possible options of reuse according to literature review include land application as nutrient rich irrigation for various crops; aquaponics; composting and biogas production.

Results and Discussion

Research on JSC 'Baisogalos bioenergija' farm was performed between October 2017 and March 2018. Main wastewater parameters of interest, namely, biochemical oxygen demand (BOD) and nutrients (nitrogen and phosphorus) were measured. Mechanical drum filter operated more than half of time (51%) thus suggesting that there was many suspended solids in RAS water. Literature states for normally one-third total time of operation but it refers to RAS with lower production densities. African catfish tolerates lower water quality so this is the option to use less sophisticated and zero-energy suspended solids filtration system like lamella sedimentation which according to reviewed data can produce equally good effluent if viable design is available for RAS flow rate. This was suggested when biotechnology for raising African catfish was being developed in the Netherlands somewhat forty years ago.
Measured BOD mean rate was found to be 106 mg/l. Effluent settling for two hours removed more than half (53%) BOD leaving its value at 50 mg/l. This point out that half of organic pollution could be removed from effluents with sludge. Nitrogen compounds ammonia nitrogen, nitrite nitrogen and nitrate nitrogen that are crucial for RAS functioning were monitored. Mean value of ammonia nitrogen was equal to 29 mg/l and was higher than can be found in literature (12 mg/l), but the RAS water was slightly acidic with pH value ranging from 6.27 to 6.7 and this helped to fix undissociated part of ammonia which is extremely toxic to fish on safe level. Water temperature being 23^0C, calculated undissociated ammonia ranged from 0.0576 mg/l to 0,144 mg/l and was well below reported in literature value of 0.34

mg/l which hinders growth of the African catfish. Water pH values found on farm are more suitable for plant growth in aquaponics, but biofiltration process is impeded under such conditions. Another toxic to fish nitrogen compound – nitrites – value was found to be 0.38 mg/l and was below the level of few mg/l which reported in literature as safe level for warmwater fish growth. Nitrates measured were between 33 mg/l to 45 mg. Nitrates value depends on water refreshment rate and they are not of great in RAS per se, because they are toxic to fish in high concentrations when reach several hundred mg/l. Nitrogen compounds concentrations in settled water did not differ thus suggesting most of nitrogen being dissolved in RAS water. Phosphorus and its compounds were found do not affect fish growth even at concentrations as high as 52 mg/l (Van Bussel et al., 2013), but it is the major component promoting fresh water eutrophication. Measured phosphate values ranged from 12 mg/l to 14 mg/l which give phosphorus concentration 3.9–4.6 mg/l. Settled water phosphate concentration slightly diminished to 11 mg/l. Further we discuss only reuse of aquaculture effluents with possibility to obtain added value. These options were already mentioned, so let's have closer look at them.

Land application/irrigation

Dry aquaculture sludge nutrient content is comparable to livestock or poultry manure with nitrogen content of 3-9 % and phosphorus 1-4% with lower content of potassium (up to 0.3%). Plants can't use nutrients from organic compounds that are why sludge must be stabilized. It must be kept in mind that when sludge is being disinfected by adding lime for raise pH value up to 12 and kill pathogens it becomes alkaline with high amount of calcium (up to 15%). Normally, aquaculture effluents and sludge is not suspected to contain harmful substances like heavy metals, hazardous materials etc. so it can be used for edible crops fertilization by irrigation for cost effective and sustainable cultivation. There are some reports on research of RAS effluent usage for irrigation. Grassland irrigation in Chile with brackish water RAS effluents with various application rates (30/60/90 t/ha) demonstrated positive effect, but showed the need of potassium addition (Teuber, 2005), but same done with potatoes (50/100/200 t/ha) did not give any additional value (Teuber, 2007). Another research (Brod et all, 2017) revealed that aquaculture sludge application will have the effect only if there are deficiencies of the nutrients in the soil and we need it to raise to optimal level. One more research (Danaher, 2015) demonstrated aquaculture sludge with nutrient content N:P:K = 11:3:1 was beneficial when using as addition to growing substrate up to 25%, because higher content hinder plant roof oxygenation and raises salts content.

Aquaponics

Effective aquaponics system functioning is a challenge because fish and plant need for water chemical parameters are not exactly the same with do not to mention in such system present microorganisms with their own requirements. According to research reports for every m^2 of planting there is need for nutrients from 100 g of fodder with over all plant to fish growing surface being 8:1 and recalculating to volumes this relationship should be 2:1. Fish growing in RAS generates carbon dioxide which must be striped and on the other hand is very beneficial for plant growth – when it doubles the crops increase is 30%. (Rakocsy et al., 2006). Most critical water parameter is pH value, when it drops below 7.5 biofiltration efficiency diminishes this follows with ammonia removal decrease, but on the other hand when pH > 7.0 some nutrients and microelements of interest (PO_4, Mg, Fe, Mn, Ca) form non-soluble compounds which are not accessible for plants. Calcium is main deficient element for plants in RAS water which need supplementation, the other two, namely, potassium and iron can be deficient under certain conditions. Effective aquaponics system states for fish as only additional not commercially important production and source of nutrients. Now on research

agenda is decoupled aquaponics systems (for example, EU funded project INAPRO) which shows promising results.

Composting/vermicomposting

Though RAS produces relatively concentrated effluents compared to other aquaculture production methods, but they are still too diluted (up to 0,5% dry content) to be economically viable to transport to remote sites. To obtain more concentrated sludge few methods are in (primarily demo) use. These are (1) additional concentration in secondary belt filters with further settling and (2) concentration in geotextile bags. These methods allow to obtain sludge concentration in range of 8-12 % dry content. This allows to more versatile use of the sludge or even transport it on the distant sites. Sludge, stabilized in mesophilic conditions is suitable for worm growing (vermicomposting). Warmwater RAS has optimal temperature of 25^0C all year round, worms also tolerate wet substrate with 83-91% humidity (Mishra, 2003). Research revealed worms can process 0.16 – 0.63 kg/m^2 RAS sludge (dry matter) during 2-5 days when continuously provided sludge dry content is 3.5%. After four weeks worm mass grew up by 489%, survival rate was 96% (Yeo and Binkowsky, 2010). Laboratory trials gave excellent results when aquaculture sludge was mixed with cardboard in relation 92:8 with optimal mixture carbon to nitrogen ratio being 25:1 and sludge being properly dewatered.

Biogas production

Energetic capacity of the fodder used on the farm is 20.3 MJ/kg which theoretically equals to 80% of coal and 45% of petrol energy amount. When feed conversion ratio of 1.2, 5% of feed wastage and 75% of feed assimilation we have that farm producing 100 t/year will loss with effluents energy equal to 640 GJ or 177 kW, which is sufficient for yearly supply of 10 households. Anaerobic sludge stabilization is quite complex biochemical process with reduces sludge volume by tenfold and generates biogas consisting mainly of methane and carbon dioxide (Mirzoyan and Gross, 2010). Aquaculture sludge is suitable for biogas generation which was proved by research carried out by different researchers during their laboratory trials: trout RAS sludge with 2% dry matter which is 80% biodegradable at 25^0C yielded 0,4 m^3/kg biogas with 80% of methane (Lanari and Franci, 1998); salmon RAS concentrated sludge with dry matter 6-12%, temperature 35^0C gave 0,28 m^3/kg dry matter biogas with 44-54% methane, stabilized sludge yielded 3.4 – 6.8 kg/t nitrogen and 1.2 – 2.4 kg/t phosphorus. The need for additional stabilization was founded due to high rate of biodegradable fatty acids (Gebauer ir Eikebrokk, 2006). Biogas generation from RAS sludge is a new domain primarily because of lack of sufficiently big production based on RAS. Good example is EU funded BiFFiO project trying to incorporate RAS sludge together with livestock manure to generate biogas and produce fertilizer. Experiments were carried in RAS with production capacity of 1000 tonnes with the yield of methane of 194 l/kg sludge dry matter which is comparable with results obtained from household effluents. RAS under consideration produces 200 tonnes of sludge (dry matter) with potential to produce of 400.000 m^3 methane which is equivalent of 40 000 litres of diesel fuel and which supposed to satisfy 8% of RAS energetic requirements. Besides process produces stabilised sludge with nitrogen content of 4 g/kg sludge and phosphorus content of 0.8 g/kg. One more interesting example comes from Germany, where local 34 kW cogeneration power plants was based on biogas from aquaponics system sludge and plant residuals with addition of food residuals with relationship 1:1:1. For the purpose of such power plant which need 81 m^3 was estimated to have 47 t/year RAS, 860 m^2 aquaponics grow field and 252 kg/daily dry mass food residuals. Overall conclusion states that RAS sludge solely is not viable for viable biogas production due to the need of tremendous production volume. Industrial biogas generator suppliers specify to have 50 000 t/year

substrate feed to the reactor. For this reason now only small minority of livestock waste is involved in biogas generation. Norway practice states for 2.4% only (Del Campo et al., 2010).

Estimations for hypothetical 100 t/year production African catfish farm

One more RAS advantage – intensive, stable, season independent production. Effectively working RAS must always be loaded to near its maximum capacity and this state for stable predictable effluent flow. For Hypothetical 100 t/year African catfish farm some estimations can be calculated:

- at maximum load with selling every four weeks of 7.7 tonnes with standing crop of 30 tonnes in basins. Basins volume 160 m^3;
- with assumed no fluctuations in system loading and feed conversion ratio of 1.2 we can calculate 120 tonnes of fodder per yearly production cycle or 330 kg/day;
- assuming 0.3 kg sludge dry weight per kg feed we have 100 kg sludge daily or 36 tonnes yearly;
- nutrients based on fodder used on farm with 42% protein, 0.9% phosphorus and assumed 40% assimilation, excretion can be calculated as nitrogen 13.3 kg daily or 4856 kg per year, phosphorus 1.8 kg and 650 kg;
- if we assume that sludge concentration is done up to 8%, we have sludge amount of 1.25 m^3 daily or 456 m^3 yearly with supernatant amounts daily 14.4 m^3 and yearly 5250 m^3;
- is to be noted that according to situation actual situation on farm with refreshing rate 200 l/kg feed the effluent amount will quadruple to 20 000 m^3 yearly;
- according our estimations 3300 m^2 area for aquaponics crop will be supported by the system;
- biogas production according to various reports in literature will be from 18 to 40 m^3 daily;
- vermicomposting volume will be 40 m^3 – say, 100 m^2 bed with 40 cm deep;
- composting area needed will be 125 m^2.

Conclusions

We have gathered data from African catfish RAS farm. This species is known and actually appeared to be extremely sturdy so we have large degree of freedom in approach to any integrated effluent treating system stability while doing research. We are convinced that this is good basis for some near market research or demo projects to refine possibilities for coupling RAS with some chosen innovative wastewater reuse system. All these system couplings still lack either reliable real life or even literature based reports. This is obvious because there is no consistency in raising either marine or freshwater, cold or warmwater species, different farm management and different farm environmental setting.

Actually there are two challenges – one to seek for best available technology, which do not solve the problem because after comes the other, namely, one has to make it flexible and adapt it to local situation. This is the real challenge for creative specialists. This is not boring and one has always space for individual judgements and can always withstand industrial "turn-key" solutions.

All interested in reuse aquaculture effluents are warmly welcomed for collaboration in the projects we can set on some particular topic and investigating possible suitable technologies.

CHANGES IN NUTRIENTS IN THE DOTNUVELE AND SMILGA STREAMS

Stefanija MISEVIČIENĖ*, Aurelija RUDZIANSKAITĖ

Water Resources Engineering Institute. Aleksandras Stulginskis University. Lithuania

Abstract

Due to the intensifying agricultural activity, the leaching of nitrogen and phosphorus compounds from the soil to water has been increasing each year. According to the data of Helsinki Commission, the largest river in Lithuania – Nemunas, which Nevezis flows into, is considered to be one of the nutrient suppliers to the Baltic Sea. The tributaries of the Nevezis River - Smilga and Dotnuvele, collect the water saturated with nutrients from agricultural land, thus degrading the quality of the water of Nevezis, Nemunas and the Baltic Sea. Research data from 2013-2017 has shown that the average N_{total} and NO_3-N concentrations in Dotnuvele and Smilga streams' water in March (12.6 mg l^{-1}, 11 mg l^{-1} as well as 8.5 mg l^{-1} and 8.7 mg l^{-1}, respectively), May (11 mg l^{-1}, 9.1 mg l^{-1} as well as 5.4 mg l^{-1} and 4.6 mg l^{-1}, respectively), and November (4.5 mg l^{-1}, 8.7 mg l^{-1} as well as 3.5 mg l^{-1} and 7.4 mg l^{-1}, respectively) mostly corresponded to a very bad and poor ecological status, and only in August they corresponded to a good and very good water ecological status (2.4 mg l^{-1}, 3.2 mg l^{-1} as well as 1.1 mg l^{-1} and 1.3 mg l^{-1}, respectively). P_{total} and PO_4-P concentrations in the researched streams' water were usually low (0.04 – 0.08 mg l^{-1} and 0.02 – 0.05 mg l^{-1} in Dotnuvele, 0.03 – 0.08 mg l^{-1} and 0.01 – 0.03 mg l^{-1} in Smilga, respectively) and corresponded to a very good ecological status of water bodies, except in August, when the water quality in Dotnuvele was found to be average (0.19 and 0.14 mg l^{-1}).

Keywords: *Concentration, Ecological status, Nitrogen, Phosphorus.*

Introduction

The ecological status of rivers' water usually deteriorates due to the diffuse pollution. caused by intensive agriculture; the concentrated pollution, which is the urban rain as well as the industrial and production wastewater pollution; due to international pollution, which includes the pollution load coming from neighbouring countries; as well as the historical pollution, caused by long-term pollution. In recent years, a declining trend in rivers' water pollution has been observed. The surface water bodies' monitoring data, which is carried out in Lithuania according to the 2011-2017 State Environmental Monitoring Programme, has shown that 49% of Lithuanian rivers meet good or very good ecological status. In the eastern, south-eastern and western regions of Lithuania, where human activity is less intense, 53-65% of all water bodies correspond to very good and good ecological status. Bigger issues in surface water bodies have been identified in intensive agricultural areas, i.e. northern, central and southwestern Lithuania, where 50 to 79% of water bodies do not meet the requirements of good ecological status (National, 2016).

Nevezis is a contaminated river, because 74% of surface water bodies in its sub-basin do not meet good ecological status (National, 2016). The pollution of the Nevezis River is greatly influenced by its tributaries, which flow through the fertile soils of the Middle Lithuanian Lowland collecting nutrients; thus, degrading water quality. Studies in the Nordic and Baltic countries have shown that the trends of nitrogen concentrations have been decreasing mostly in Denmark and Sweden, while they have been increasing in the Baltic States (Stalnacke et al., 2014). The largest of the four Nevezis tributaries in Kedainiai town is the Smilga and Dotnuvele streams. The sources of concentrated pollution in their basins are the urban wastewater treatment plants, rainwater cleaning equipment and JSC Kedainiai Canning

Factory. Not all inhabited houses are connected to the central sewage system, and part of the surface water flows from the town straight into the stream. Sewage flows into the Dotnuvele and Smilga streams from various settlements which are situated in their basins.

Dotnuvele and Smilga streams, flowing in the Kedainiai town territory, were very polluted from the Soviet military airfield and two fuel bases. However, in 2009 – 2012, by implementing the environmental measure, "The management of historically polluted territories", the water and banks of the streams were cleaned from harmful substances. It was hypothesised that after cleaning up these contaminated sections of streams, the water quality would improve. After that, the maintenance of cleaned water bodies and streams' water monitoring was carried out for five years. The purpose of the research is to investigate the changes of nitrogen and its compounds in the Dotnuvele and Smilga streams, depending on meteorological factors.

Materials and Methods

Dotnuvele and Smilga streams, flowing through Kedainiai town, are the right tributaries of Nevezis river. Even though Smilga stream is almost twice shorter (32 km) than Dotnuvele (60.9 km), its basin is almost the same (208.8 km^2) to Dotnuvele's (192.7 km^2).

The cleaning of 1.95 km length of Dotnuvele stream (measured from the mouth of the stream) as well as restoration of 10 m width of coastal strip was completed in 2012. In 2013, 1.98 km length of Smilga stream and 2 ha of coastal land was cleaned, and 5157 m^3 of sludge removed.

Water samples were taken from the mouths of Dotnuvele and Smilga streams four times a year (2013 – 2017) – in March, May, August, and November months. Chemical analysis, according to the methodology described in literature (Unified, 1994), was done by Aleksandras Stulginskis University Chemical Analytical Laboratory of Water Resources Engineering Institute.

In the samples total nitrogen (N_{total}) was determined by applying the spectrometric method, by mineralizing with potassium persulphate, P_{total} was determined by spectrometric method after mineralization with potassium persulphate, nitrate nitrogen (NO_3-N) – by spectrometric with phenol sulfonic acid, phosphorus residue (PO_4-P) – by spectrometric with ammonium molibdate and ascorbic acid. The colorimetric analysis was performed using 'FIA star 5012 system' analyser.

Surface water bodies quality currently is assessed according to 'The Surface Water Bodies State Evaluation Methodology' approved by the Minister of Environment of the Republic of Lithuania (Surface, 2010). According to this methodology, the ecological state of rivers is divided into 5 classes from a very good state, when N_{total}<2, NO_3-N<1.30, P_{total}<0.1. PO_4-P<0.05 to a poor state, when N_{total}>12, NO_3-N>10.0, P_{total}>0.47, PO_4-P>0.4 mg l^{-1}.

Mathematical and statistical analysis of the data was performed using the computer program MS Excel 2010 and Statistica v.5.

Results and Discussion

The highest amount of nitrogen and its compounds is found in the rivers of central Lithuania, where the most intensive agricultural activities are being developed. However, nitrogen compounds are almost always present in the surface water bodies, even those that are not affected by anthropogenic pollution. This means, that their formation is influenced not only by human activity but also by natural factors (Tumas, 2003; Šileika, 2012).

The research has shown that in summer, nitrate concentrations in both Dotnuvele and Smilga streams, are lower compared to the spring and autumn. In summer – the third quarter of the year, the water quality in both rivers was very good: in Dotnuvele 1.1 mg l^{-1}, in Smilga – 1.3 mg l^{-1}, which means, that these concentrations were 7.7 times in Dotnuvele and 6.7 times in

Smilga lower than in the I quarter of the year (Figure 1). This was influenced by an intensive assimilation of aquatic vegetation.

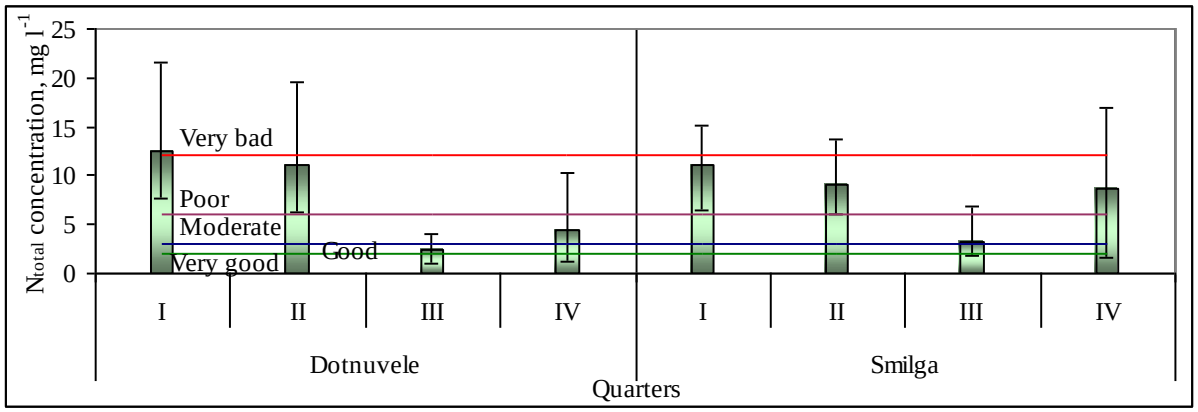

Figure 1. NO_3-N concentrations change in streams' water

During the autumn period (November), intensive autumn rain washes large amount of organic and inorganic fertilizers out into streams and rivers. In addition, plants and algae begin to decompose in the rivers, which increases the nitrate concentration in the water. The average concentration of NO_3-N in Dotnuvele in the fourth quarter was 3.5 mg l^{-1}, while in Smilga - 7.4 mg l^{-1} and they corresponded to the average and poor water ecological status. At the end of the cold season (March), the nitrate concentration in the ecosystems is the highest and corresponds to the poor ecological status of the streams: in Dotnuvele - 8.5 mg l^{-1}, in Smilga - 8.7 mg l^{-1}. Thus, the season of the year affects the nitrate inflow into the water bodies (Kutra and Berankienė, 2006; Stankevičienė, 2012). Over time, there are periods in which nitrate concentrations may depend not only on river runoff but also on other factors: plant vegetation, winter conditions, soil freezing depth, snow cover (Povilaitis, 2003; Lintern et al., 2018). According to Šileika (2012), "comparison of N and P concentrations in the Nevezis River and in the Graisupis Stream revealed that in the Nevezis River N concentrations were lower by 15.4% and P concentrations were higher by 52.2% than those in the Graisupis where non-point pollution prevails".

The highest nitrogen concentrations were observed in the Graisupis stream in the middle Lithuanian lowland, where more intensive agricultural activity occurs (Povilaitis et al., 2014). "The highest monthly N concentration in the Graisupis Stream was registered in December and November – 9.4 and 12.7 mg l^{-1} respectively" (Šileika et al., 2010). Higher N_{total} concentrations were determined in areas with intensive agricultural activity or in soils having a small number of clay particles. Also, water quality of the streams is affected by high fertilisation rates both of mineral fertilizer and manure (Stalnacke et al., 2014).

To determine the trends in eutrophication. it is very important to analyse the change in total nitrogen in rivers' water. In Figure 2, it can be seen, that the higher concentrations of this indicator as well as nitrate nitrogen, were determined during the cold season or at the beginning of vegetation – at that time the status of water of both streams was in a very bad or poor ecological condition: in Dotnuvele – 12.6 mg l^{-1} and 11.0 mg l^{-1}, and in Smilga – 11.0 mg l^{-1} and 9.1 mg l^{-1}.

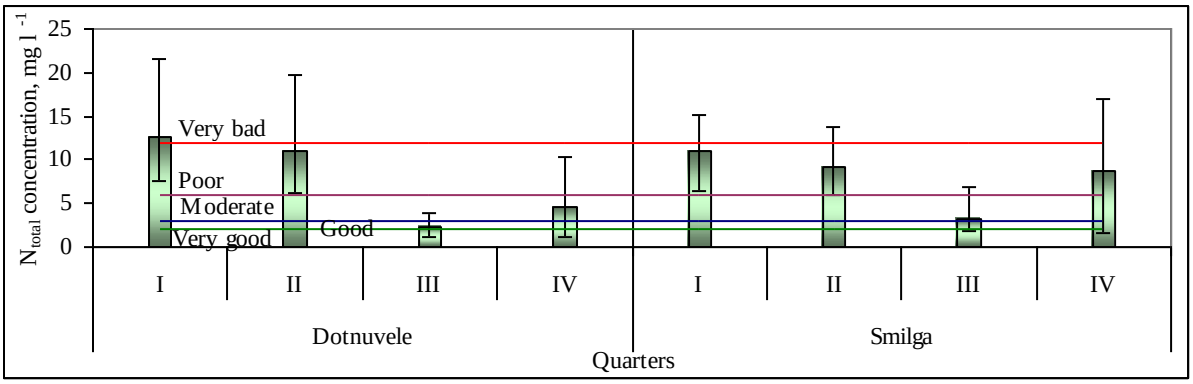

Figure 2. N_{total} concentrations change in streams' water

Dotnuvele and Smilga streams' water receives biogenic matters from agricultural lands, as increased concentrations of these elements were observed mostly in spring, when, during the snow melt, water with dissolved nutrients reached these streams by drainage.

In the spring, agricultural fields still have a very poor vegetation cover, which is able to absorb only a part of the dissolved nitrogen and the other part of it flows into the streams via drainage. The smallest N_{total} as well as NO_3-N concentrations were found in the August samples; as nitrogen is used to mature crop yields, the amount of it flowing into the streams is very small.

In the fourth quarter of the year, N_{total} concentrations are rising again due to the autumn rain, which dissolves nitrogen; as the plant cover is often scarce in this period, it is therefore unable to absorb all of the nitrogen.

The changes in concentrations of PO_4-P and P_{total} in the Dotnuvele and Smilga streams are completely opposite to the changes in nitrogen concentrations. The lowest concentrations of these indicators were observed in the I, II and III quarters of the year and corresponded to the very good ecological status of these streams. They were the highest in the third quarter of the year. The average concentrations of PO_4-P and P_{total} were found to be 0.14 mg $l^{-1}$and 0.19 mg l^{-1}, respectively in Dotnuvele, and corresponded to a poor condition of the water bodies. In the Smilga Stream, water status, according to both of the indicators, was found to be very good (0.04 mg l^{-1} and 0.06 mg l^{-1}), but the deviations from the average showed that in some years the water status in this stream deteriorated to an average ecological status (Figure 3, 4).

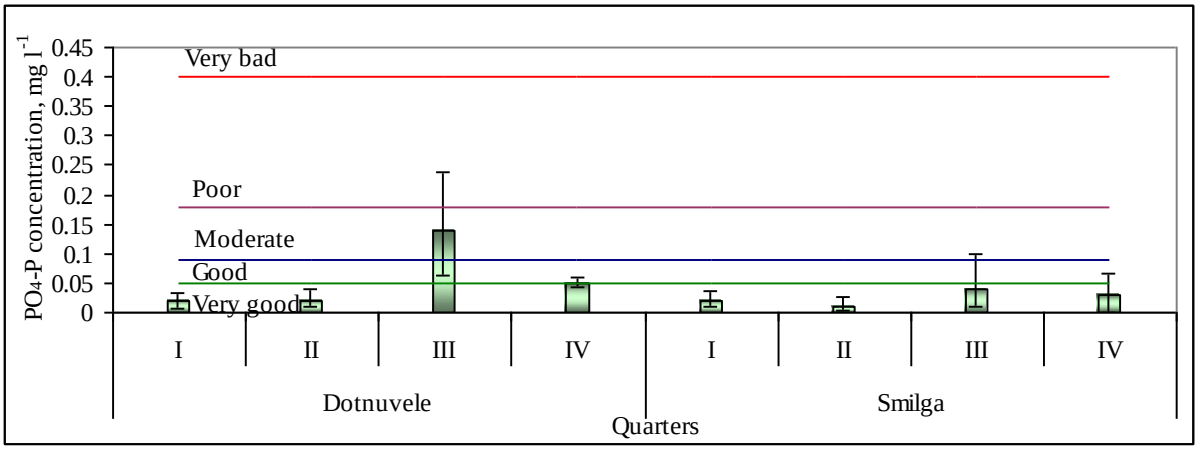

Figure 3. PO_4 – P concentrations change in streams' water

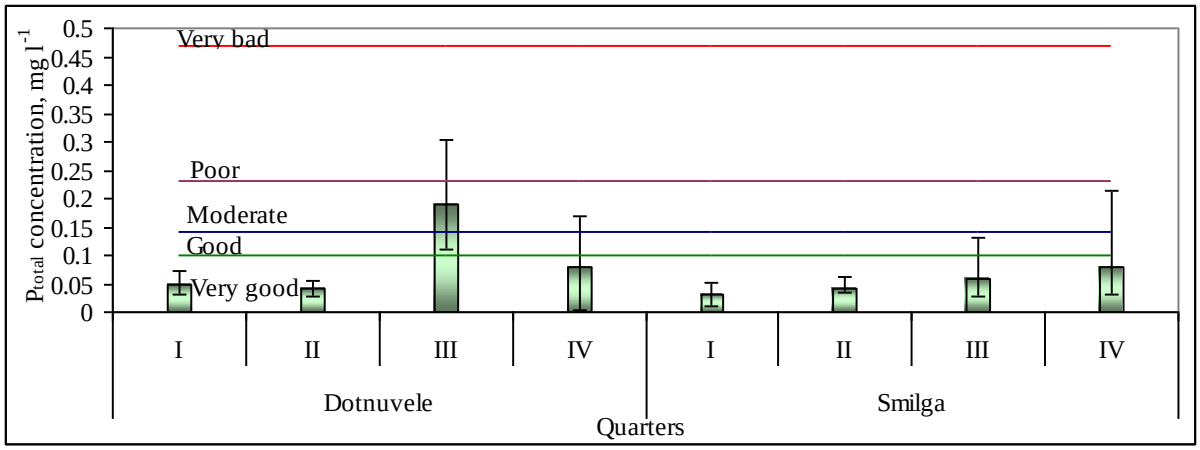

Figure 4. P_{total} concentrations change in streams' water

Due to meteorological conditions, the water speed in streams slows down significantly and the water temperature increases in August. In addition, a dam is located near the mouths of the Dotnuvele Stream, where sediments are deposited. Thus, secondary pollution from sludge accumulated in the streams could have had an effect (Howell, 2010).

On average 6.9 mm, 70.5 mm and 16.7 mm more precipitation than the climate normals has fallen in the I, III, and IV quarter of the year. The average air temperature was higher than the climate normals in every quarter of the year: I - 1.0 °C, II – 0.4 °C, III – 0.6 °C, IV - 1.5 °C (Table 1).

Table 1. Meteorological conditions of 2013-2017 study periods

Year	Quarters				Per year
	I	II	III	IV	
Precipitation, mm					
2013	87.0	142.2	224.5	112.5	566.2
2014	96.7	167.6	207.1	124.9	596.2
2015	125.9	128.2	129.2	119.8	503.1
2016	151.5	144.2	246.1	207.3	749.2
2017	78.2	123.7	440.6	204.1	846.6
Climate normals, mm	101	149	179	137	566
Average air temperature, °C					
2013	-4.5	13.1	16.4	5.0	7.5
2014	-0.2	12.1	16.9	2.9	7.9
2015	1.3	11.2	17.0	4.4	8.5
2016	-1.5	13.1	16.6	2.5	7.7
2017	-0.4	11.3	15.8	4.1	7.7
Climate normals, mm	-2.0	11.8	15.9	2.3	7.0

The statistical analysis of the data shows the relationship between the concentrations of the analysed biogenic substances in the streams' water and the meteorological conditions (Table 2).

Table 2. The influence of meteorological factors to the change in concentrations of nutrients in streams' water

N_{total}	$z=13.6174-0.4095x_1-0.9015x_2$	0.54	40	7.64	0.0017	-0.51	-0.37
PO_4-P	$z=-0.0051+0.0034x_1+0.0042x_2$	0.45	40	4.64	0.0159	0.45	0.18
P_{total}	$z=0.0055+0.0045x_1+0.0128x_2$	0.52	40	6.86	0.0029	0.46	0.41

Note: z – concentration of indices; x_1 – water temperature ˚C; x_2 - precipitation amount mm; $F_{theor.95\%} = 3.3$; relationship is significant when $F_{theor.95\%} < F_{fact.}$

Meteorological factors influenced the increase of nitrogen and phosphorus concentrations in the researched streams' water: NO_3-N, N_{total}, PO_4-P and P_{total} respectively (r = 0.67), (r = 0.54), (r = 0.45) and (r = 0.52). Data analysis has shown, that concentrations of nitrates and total nitrogen were strongly influenced by the streams' water temperature: the lower it was, the higher amounts of the analysed indicators were found in the streams' water, respectively (r = -0.66) and (r = -0.51). This is confirmed by studies carried out by Tripolskaja (1995), which showed that nitrification processes are taking place even at low positive temperatures, which results in additional nitrate reserves in the soil. However, the autumn – winter period is very favourable for nitrogen leaching, because during this period the soil is bald and the precipitation is not too low. When the temperature is positive, though not high, mineralization processes in the soil are more intense, resulting in an increase in the amount of nitrogen that is washed into drainage, and via drainage it flows into the rivers (Clein and Schimel, 1995; McMahon et al., 2009).

In the third quarter of the year (2013 – 2017), the streams' water average temperature was high (in Dotnuvele - 21.6 °C, in Smilga - 20.5 °C), which affected the increase in the PO_4-P and P_{total} concentrations in streams' water, respectively (r = 0.45) and (r = 0.46). As claimed by Lintern et al. (2018), that the season of the year and the temperature have an impact on the fluctuation of nutrients in the streams' water.

Conclusions

When Dotnuvele and Smilga streams flow through the agricultural fields, they collect drainage water saturated with nutrients. In the winter, spring and autumn seasons, the ecological status of the streams according to N_{total} and NO_3-N concentrations are found to be poor or very bad. The smallest concentrations of these indicators in the analysed streams were determined in summer and corresponded to a good and very good ecological status of water and were due to the intensive assimilation of aquatic vegetation. The phosphates and total phosphorus levels in the winter and spring seasons were low, therefore the streams' water corresponded to a very good status of water bodies. However, in summer, due to the high temperature of the water. the increase in these indicators has been observed, therefore the ecological status of the water in Dotnuvele has been set to moderate.

Abstract

Lithuanian-Poland border is a special territory, which belonged to Grand Duchy of Lithuania for 300 years long. Only in the 20th century state borders separated this territory. Still 20-30 km from the border on both sides the bigger part of inhabitants are Lithuanians. Decorative and medical plants were inventoried in 16 farmsteads (8 on each side) in Lithuania and Poland. The aim of this research was to assess how well the traditions of Lithuanian old traditional gardens were kept for around one hundred years in territories separated by state border. Altogether 95 species, now classified as traditional Lithuanian gardens plants, were found. These plants have been grown in flower gardens in Lithuanian villages from old times. 83 species of these plants grew on Lithuanian side of the border and 76 species on Polish side. There are no records telling when flower gardens have been established from in Lithuanian rural homesteads, but it is thought that it was done around 15th-16th centuries. According to their growth time plants were divided into three groups: 1) plants which were grown from 15–16 centuries – 14 species of such in Lithuania grown plants and 16 species in Poland; 2) from 17–18 centuries – 12 species in Lithuania and 13 species in Poland; 3) from 19–20 century – it was found 57 species in Lithuania and 47 species in Poland.

Keywords: *Lithuania-Poland border, traditional Lithuanian gardens; decorative and medical plants and herbs.*

Introduction

Flower garden is a traditionally formed usually is fenced composition of traditional assortment plants (Martynėnaitė, 2010). In Lithuanian villages flower gardens appear around 15th-16th centuries. Decorative, medicinal plants and herbs introduced from monasteries, rectories and manor parks spread around gardens in villages. Homesteads management has intensified after cancellation of serfdom in 1861. It is impossible to identify exact species, which were grown in Lithuanian gardens also to detect time when it was started to grow them. There are no remaining plants grown in monasteries gardens lists but there are some manor gardens descriptions from XVI century. First specific knowledges about plants spread in gardens were found in work about the flora of Grand Duchy of Lithuania by S. B. Jundzila in 1791 (Gudžinskas, 2010). More data from 19th century is in notes by J. Jundzila, S. B. Gorskis and J. A. Pabrėža in Vilnius University herbar. Flower gardens in the current territory of Lithuania and Punsk surroundings were most thoroughly explored by G. Žumbakienė (2016). For a long time, the variety of species grown in flower garden was not big. At first useful plants were grown such as: medicinal or flavoring plants, herbs, plants used for coloring or parasite-repelling or repulsive plants, plants used for religious rites. Only in the 19th century at the beginning of 20th century more attention was paid for aesthetic plants qualities such as: pleasant smell, beautiful flower blossoms or leaves. All times assortment of plants changed: one were liked more than the others, more ornate plants changed less ornate plants. Not many species were kept in flower gardens for couple of hundreds of years. This is why it is interesting to find traditional old plants growing next to newly spread plants in Lithuanian flower gardens.

It was interesting to compare the growing traditions and the variety of species grown in villages in both sides of the Lithuania-Poland border.
Lithuanian–Poland border is a special territory, which belonged to Grand Duchy of Lithuania for 300 years. Only in the 20th century state borders separated this territory. In Poland where there was no collectivization, lots of Lithuanian rural homesteads remained together with traditionally flower gardens. In Lithuania lots of bigger old homesteads were destroyed but flowers were loved and gardens with traditional plants were established in newer times. 20-30 km from the border on both sides the bigger part of inhabitants still are Lithuanians (Žemaitis, 2017). The object of present paper is to assess how traditional Lithuanian flower gardens at the Lithuania-Poland border.

Material and Methods

Decorative and medical plants were inventoried in 16 farmsteads (8 on each side) in Lithuania and in Poland. It was chosen the farmsteads 20 km from national border – Punsk Gmina in Poland and Marijampolė and Alytus County in Lithuania. Geographical position and altitude of every farmstead was detected.
Plants were inventoried only in such flower gardens which had around 50% of traditional/old gardens plants (which grew in Lithuania from 15th to 20th centuries).
Plants were observed three times during their vegetarian period (May, August and September). During observation plants were identified by species. We described plants based on plants description guides (Snarskis, 1968; Vilkonis, 2001; Botanica, 2006). They were assigned to medicinal plants or herbs according to literature sources (Dagytė, Penkauskienė, 1978; Smaliukas et al., 1992; Ragažinskienė et al., 2005; Gudžinskas and Balvočiūtė, 2007; Budnikas and Obelevičius, 2015). Collected data were compared to literature sources about all Lithuanian traditional flower gardens especially in Dzūkija and Suvalkija (Andriušytė et al., 2008; Kačinskaitė et al., 2008; Pabrėža, 2009; Gudžinskas, 2010; Žumbakienė, 2016) and according to these authors assigned to traditional Lithuanian gardens plants.

Results and Discussion

Altogether 95 species, now classified as traditional Lithuanian gardens plants, were found in 2017. These plants have been grown in flower gardens in Lithuanian villages from old times. Eighty three species of these plants grew on Lithuanian side of the border and seventy six species on Polish side. According to the date of plants planting in Lithuanian gardens, which were specified in literature sources (Pabrėža, 2009; Gudžinskas, 2010; Žumbakienė, 2016) we analyzed todays plants assortment at such specific territory as Lithuania-Poland border. Geographically friendly areas almost one hundred years belonged to a different country could have had different flower garden growing traditions. Although there are no exact data about the beginning of flower gardens in Lithuania's villages it is thought that first decorative and medicinal plants could have been grown in farmsteads next to dwelling houses from around 15th-16th centuries (Gudžinskas, 2010; Žumbakienė, 2016). Everywhere they spread from the nearest monasteries and manor houses later from one farmstead to another.

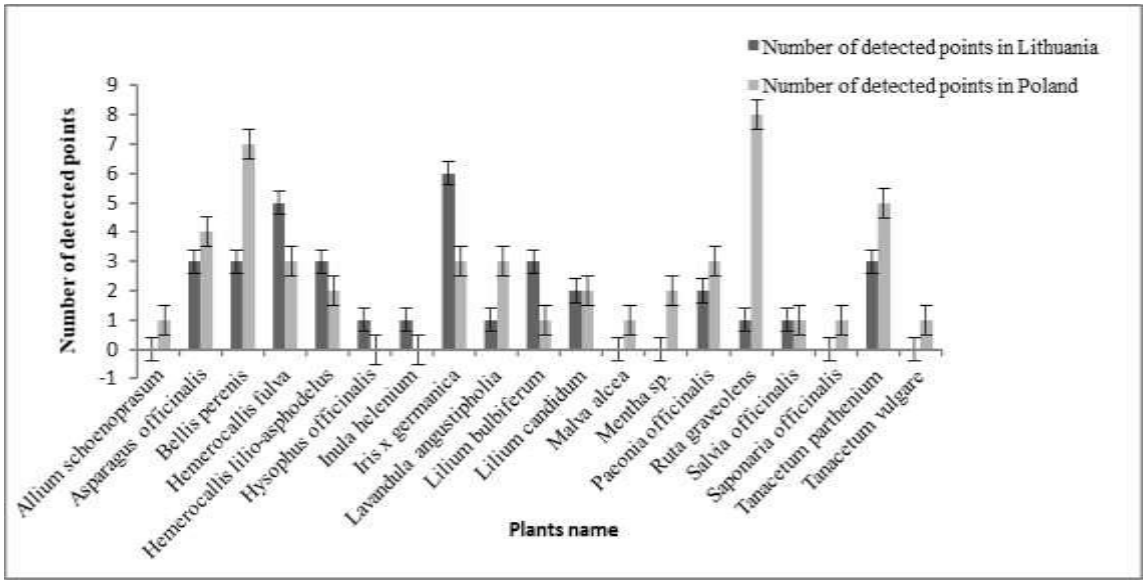

Fig. 1. Plants which were grown from 15-16 centuries in Lithuanian flower gardens in farmsteads at Lithuania-Polish border in 2017.

The variety of oldest plants is not big most of these plants are used for medicines or food (Fig. 1). Exceptions are *Hemerocallis* spp. and *Lilium* spp., which were very respected and spread together with Christianity (Gudžinskas, 2010). In Poland in one of the farmsteads *Hemerocallis fulva* (L.) L. var. *kwanso* Regel was grown. It's a long time introduced full-fledged plant, which is rarely grown now. A little elder species (16 species) are grown on Poland side (14 species in Lithuania). *Ruta graveolens* L. and *Bellis perenis* L. are grown almost in all farmsteads in Poland and less on Lithuania's side. Most of these plants grown in old Lithuania's flower gardens are not being grown everywhere now usually separate species in 1-2 farmsteads. Also, most of the plants which were grown couple of hundred years later are modest, mostly medicines, fragrant. Brighter blossoms or fruits have: *Tulipa gesneriana* L., *Dianthus barbatus* L., *Physalis alkekengi* L., *Calendula officinalis* L.

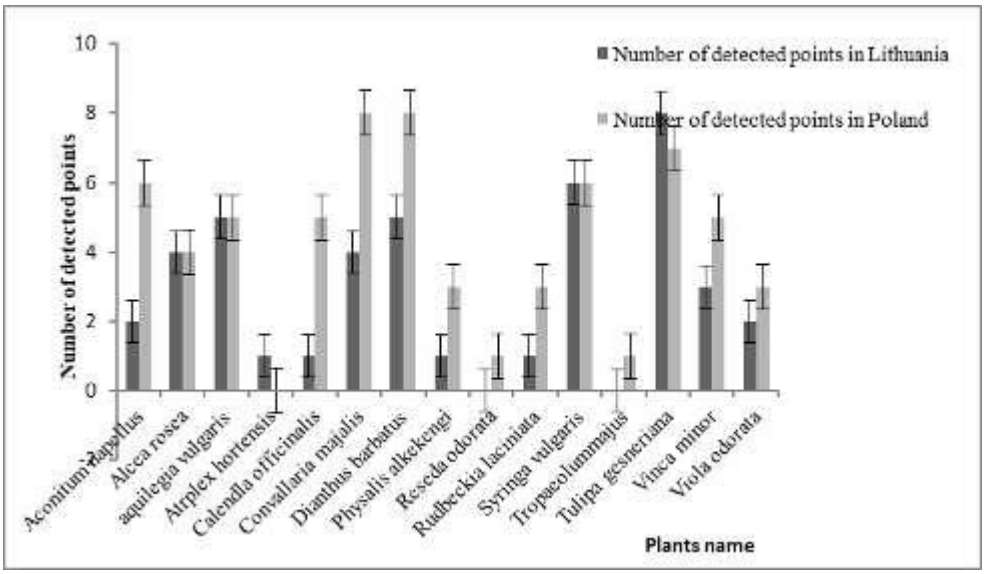

Fig. 2. Plants which were grown from 17-18 centuries in Lithuanian flower gardens in farmsteads at Lithuania-Polish border in 2017.

From those, which grew from 17-18 centuries, it was detected 13 species in Poland and 12 species in Lithuania now. *Aconitum napelus* L., *Convallaria majalis* L. grow almost in all farmsteads in Poland and in Lithuania - *Aquilegia vulgaris* L., *Syringa vulgaris* L. (Fig. 2).

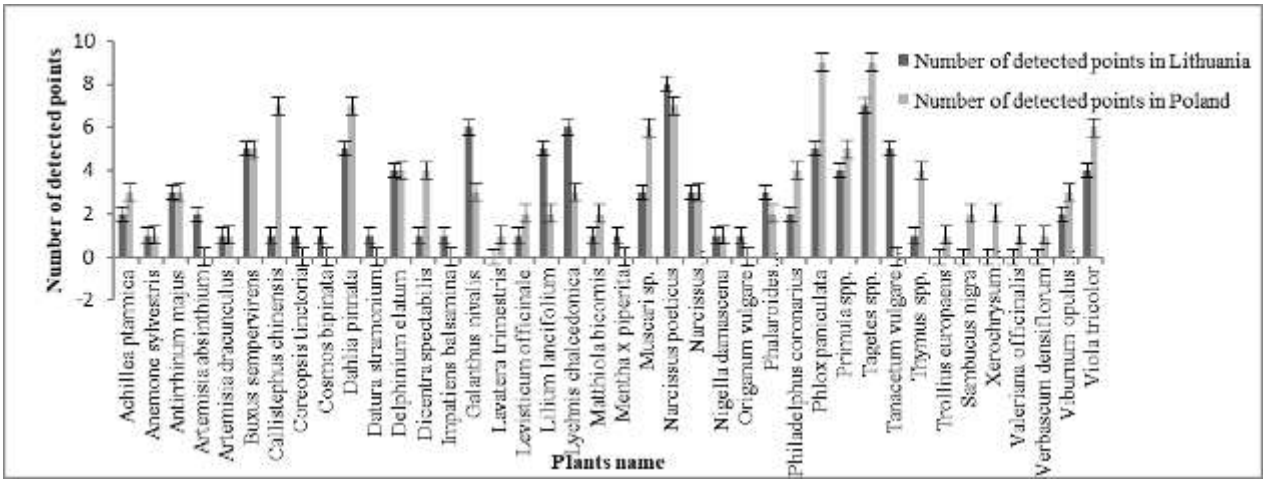

Fig. 3. Plants which were grown from 19 centuries in Lithuanian flower gardens in farmsteads at Lithuania-Polish border in 2017

During 19th century the variety of plants species got bigger in Lithuania's flower gardens (Fig. 3). Annual plants were planted next to already popular perennial plants. Until now these annual plants are grown at the Lithuanian-Polish border: *Antirrhinum majus* L., *Callistephus chinensis* (L.) Nees, *Coreopsis tinctoria* Nutt, *Cosmos bipinnatus* Cav., *Impatiens balsamina* L., *Lavatera trimestris* L., *Mattiola bicornis* (Sibth. et Sm.) DC, *Tagetes* spp., *Tropaeolum majus* L., *Xerochrysum bracteatum* (Vent.) Tzvelev and bulbous plants: *Galantthus nivalis* L., *Muscari* spp., *Narcissus* spp. are grown too. At the end of 19th century *Dahlia pinnata* start growing which widespread in 20th century. More and more plants are grown for their look and not for the use. Most of these plant species are still popular. Now other cultivars especially annual and bulb plants are grown but tradition remain in growing same species plants.

In the beginning of the 20th century Lithuanian flower gardens became more and more flowery, flowers which require more caretaking are grown: *Gladiolus* x *hibridus* Van Houtte, *Rosa* spp., *Primula* spp., *Hosta* spp. and *Paeonia lactiflora* Pall. cultivars. All these plants still grow at the Lithuania-Polish border. In Poland almost every flower garden has *Paeonia lactiflora*, various species and cultivars of *Primula*, couple of species and many cultivars of *Symphyotrichum* spp. (Fig. 4). These flowers also grow on Lithuanian side of the border but not so often.

On both sides of the border farmsteads are trim with lots of flowers but during last decades especially after the war different conditions had influence on farmsteads management in Lithuania and Poland.

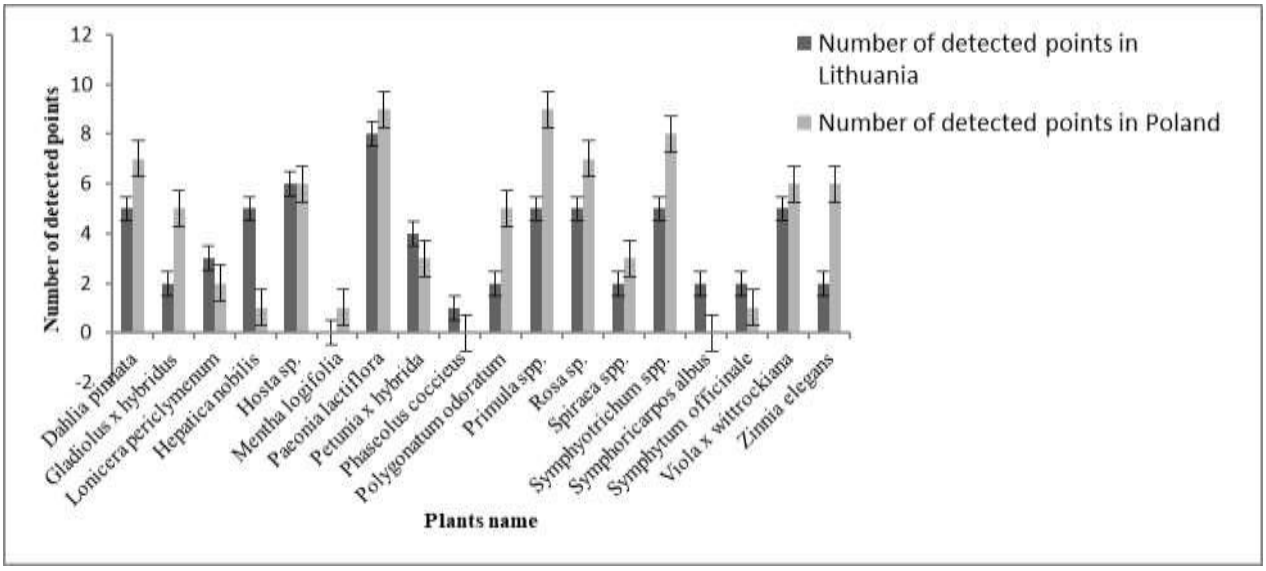

Fig. 4. Plants which were grown from the first half of the20 century in Lithuanian flower gardens in farmsteads at Lithuania-Polish border in 2017

In Punsk Gmina remain many old farmsteads which were established by ancestors of todays owners. These farmsteads are big and young people live in them. On Lithuanian side of the border after collectivization old and rich farmsteads did not remain. Many of current inhabitants are worthy age. Although farmsteads are under care their future is unclear. Lithuanians living on the Polish side of the border kept not only Lithuanian language but also Lithuanian traditions. It was harder to do that in Lithuania. During the last 100-120 years there were many events in Lithuania which influenced economic, political and cultural counties life. Also these events influenced the survival of traditional rural ethno cultural domain. Only some places kept ethnic architecture even less places kept traditional plantations characteristic to ethnographic regions (Misius, 2015). On both sides of the border owners of flower gardens spoke with love about their plants if the plants were medicinal or herbs people knew their uses. Usually people used folk names for the plants. In Poland they usually used Polish names. Traditional interwar mono-farm rural landscape lost its traditional peculiarity when it was changed into collective farmland landscape. Today for other reasons (globalization, destruction of granges system) but ethnic cultural heritage is still vanishing in Lithuanian villages. Together with ethnical architecture are disappearing the unique plantings, traditions of farmsteads landscaping and regional peculiarities (Misius, 2010; 2015).

Conclusions

2017 we inventoried 95 species of traditional Lithuanian flower gardens plants in rural gardens at the Lithuania-Polish border. On both sides of the border was detected similar number of species: 83 plant species on Lithuanian side and 76 species on Polish side. Half of all decorative and herbs/medicinal plants grown in 9 farmsteads on Lithuanian side of the border and 9 farmsteads on Polish side are traditional Lithuanian flower gardens plants which started growing in Lithuania from 15 to 20 centuries. Most of the plants in farmsteads at Lithuania-Polish border were starting to grow and spread in Lithuania in 19-20 centuries. These plants are still popular in flower gardens. Only newer cultivars of annual and bulbous plants species are grown.

ENVIRONMENTAL USE OF WATER IN MEXICO

Aurelio REYES RAMÍREZ[1], Erasmo VELÁZQUEZ CIGARROA[2]*

[1]Irrigation Department, Chapingo Autonomous University, Mexico
[2]Department of Rural Sociology, Chapingo Autonomous University, Mexico
*Corresponding autor: erasmo.vcigarroa@gmail.com

Abstract

Mexico is located between 12° and 32° north latitude and 84° and 121° west longitude, in the world's tropical deserts area. With almost 2 million km^2, a third of its total surface lies in the desert and semidesert areas. Desert areas are characterized by: rainfall volume lower than 500 mm/year (in the northernmost parts of the country this is less than 200 mm/year), extensive hours of sunlight, real evaporation and evotranspiration (1500 mm/year); around 80 % of Mexico's population lives in desert areas, although 57 % of the total population lives in the meridional part of the country, a semidesert area, with rainfall volume ranging between 400 and 500 mm/year. The focus of the present analysis is on the geographic characteristics of the region in terms of water, lack of education and environmental awareness of its inhabitants, as well as the erratic government policies of neoliberal governments that keep the country in a chronic state of poverty, broken-down agricultural fields, unequal distribution of wealth, reasons that make groups of people live in extreme poverty. The methodological process used in the project was research-action, because, as members of society, we are part of the problem. Besides reviewing literature, informal surveys were carried out among the people involved, municipal authorities, school principals and teachers from the elementary and high school levels. The result is an educational proposal and a personal alternative to collect rain water.

Keywords: *shortage, arid areas, environmental education, chronic poverty*.

Introduction

Mexico has never had abundant water. It has always been a dry county. Why do people choose not to get involved with an issue that affects everyone? Why is the government expected to solve everything without any engagement from the citizens? It could very well be that Mexican culture has been thus developed: to ask and obey. The administrations that this country has had, following the Mexican revolution, are a clear example that officials in turn only have particular interests, acting always for their own benefit, forgetting about the citizens and the people who are always asking for handouts to make ends meet at the short-term, but not the long-term; such an issue is water supply. Government programs around water have not solved the problem, sometimes due to incapacity, others due to lack of knowledge, or just because it is convenient to keep capitalism running, a sistema that, through globalization, has caused that the State's functions are overrun, reinforcing interdependence for this political and economic system (Gómez, 2008).

In view of the above, it is important that people engage in shortage issues during dry seasons, analyze the government proposals aimed at diminishing the problem, and do not grow indifferent to such crisis. The objective of the current study is to analyze data about rainfall in Mexico to create strategies for the sustainable use of water, and to find a way that makes people engage in the solution to a problem that affects everyone.

Materials and methods

Methodology for the current research consisted of reviewing documents and data generated by Mexican government agencies such as the Secretariat of Environment and Natural Resources (SEMARNAT), National Water Comission (CONAGUA), and the Official Mexican Standards (NOM) 04, 05, 06, 07, 08, 09, 010, 011, published in the Federal Official Gazette (DOF, 2013). Through this data, the intention is to show to the people the relevance of water and also show them way for them to participate in the solution to the water shortage problem that affects several regions in this country; to bring them together through observing the water shortage matter and use of water in agricultural, livestock-related, industrial, household and urban activities. Data gathering in diverse social groups (housewives, farmers, municipal authorities, teachers, children) was conducted through participant observation (Spradley 1980), while attempting to identify the views on the water issue in its daily use, the shared responsibility that they acknowledge in the actions they take, the way they could participate in solving the problem, and the degree of commitment shown. A qualitative analysis of observed data was conducted as well as an inductive-deductive method to conclude the analysis and establish alternate proposals (Hernández *et al*., 2003).

The method of active investigation was adopted because of the researchers' involvement with the problem and its solution; they are acting for changes to take place around them. (Bisquerra, 1996). Work was carried out mainly in the states of Mexico (Tezoyuca, Acolman, Teotihuacán), Guanajuato (Dr. Mora), Michoacán (Zinapécuaro, Maravatio), central regions in the country, and also in the Peninsula of Baja California Norte (San Quintín, Ojo de Liebre, Ensenada), places where participant observation was performed as well as informal interviews with municipal authorities, farmers, water users, and elementary education principals, with whom data was gathered to conduct the research and analyze proposals.

Results and discusion

Regular rainfall in the country from 1981-2010 was around 740 millimeters. Normal values, according to the World Meteorological Organization (WMO), correspond to the average measures calculated for a uniform and relatively long period, which has to span at least 30 years of data gathering, which is considered as a minimum representative climate period (CONAGUA, 2016).

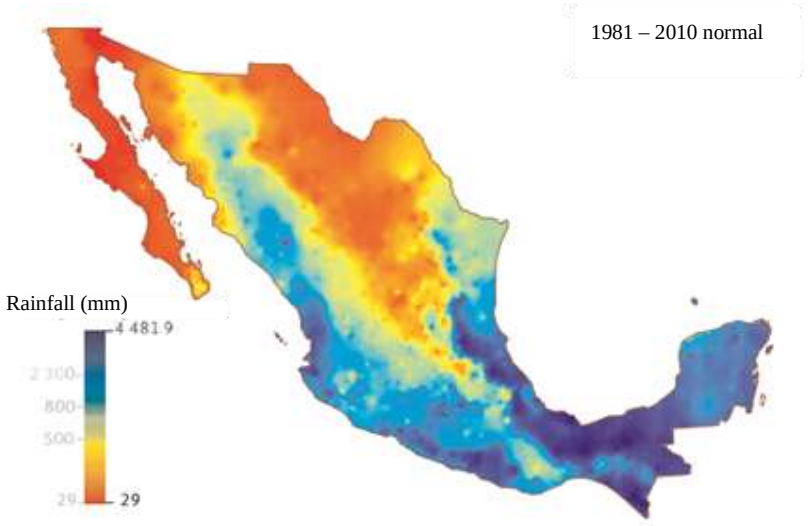

Image 1.- Map that represents the pluvial precipitation index in Mexico. Source: Elaborated by CONAGUA (2016, p. 35)

Tetumo (1993) registered that in Mexico, average yearly rainfall is 780 mm, equal to 1, 538.59 km^2, deposited in 1, 972, 447 km^2 and distributed as follows: 2/3 in the south of the

country, 1/3 in the north of the country, concentrated from the month of June to October. In the Mexican territory, because of its geography and climate, two large availability areas stand out, the first of them encompasses the south and southwest while the second encompasses the north, center and northeast of the country. Natural availability in the former is seven times greater than in the rest of the country. In the north and central areas, 77 % of the population is located, 85 % of the Gross National Product (GNP) is generated, and only 32 % of the average natural availability is at hand.

Surface-water Hydrology

The surface runoff value for the national territory, according to the first result obtained by the National Hydrologic Plan, was 410, 021 million m^3, and represents 27 % of the surface runoff volume. The largest runoff volume occurs in the south of the country, through the Grijalva and Usumacinta rivers, while in the Peninsula of Baja California runoff is around 1 %. In the rivers of the country, runoff approximately amounts to 410 km^3 each year, including water coming from other countries and excluding water going outside the country. Around 87 % of runoff occurs in the main 39 rivers listed below and whose basins occupy 58 % of the Mexican continental surface (CONAGUA, 2016).

Groundwater hydrology

For the purpose of water management, the country was divided into 653 aquifers, on January 31, 2013. Water availability in 188 aquifers was published in the DOF (2013). From these aquifers, 66 % of groundwater used in the country is extracted, and 79 % of underground water recharge is collected in them. From the 70s onwards, the number of overexploited aquifers has increased substantially, from 32 in 1975 to 36 in 1981, 80 in 1985, 97 in 2001, 102 in 2003, 104 in 2004 y 126 in 2010. From them, around 60 % of groundwater is extracted for all kinds of use (CONAGUA 2016). In the DOF of December 5, 2001 (DOF, 2013), 653 aquifers were published. The splitting of the Sonoita-Puerto Peñasco aquifer is not official; however, occasionally it is used for technical purposes. There are 17 aquifers with issues of salt water filtering in the states of Baja California, Baja California Sur, Colima, Sonora and Veracruz. Among them are Maneadero y San Quintín in Baja California, Santo Domingo in Baja California Sur; Caborca, Costa de Hermosillo y San José de Guaymas in Sonora.

Water distribution across Mexico in not balanced. In the current circumstances, large urban areas, climate change, and the lack of recycling and reutilization policies for water are making matters worse. According to Magaña (2006), by the year 2020, around 60 % of the world's population will live in cities, generating greater challenges for water supply. By the year 2050, it is likely that at least one in each four people will live in countries affected by chronic or recurrent fresh water shortages. Several hypothetical scenarios have been proposed based on the latest studies conducted by some agencies of the United Nations (UN) about population, and according to the worst possible scenario, almost 7000 million people in 60 countries might suffer from water shortages by the year 2050. According to the most optimistic scenario, less than 2000 million people in 48 countries will suffer from water shortages by the same decade.

Mexico's location on earth that makes it more vulnerable to climate change. Droughts are another major threat for the planet. Even though droughts are part of the weather's natural variability, growing demand for water has led them to turn into a serious danger for society, mainly hydrological and agricultural droughts in developing countries. The Mexican water sector needs to reformulate its strategies on development while trying to reach a balance between consumption, environmental demands, flooding control, as well as costs and benefits of climate variability in water-dependent sectors, such as the tourism, health and recreation industries.

Water availability is already low. The amount of water that people use in a given country does not depend only on minimum needs and on how much water is available for use, but also on the level of economic development and degree of urbanization.
On a global scale, out of the three common categories for the use of fresh water — or agricultural, industrial and household use (personal, familiar and municipal) — agriculture domains.
According to data from (CONAGUA, 2016), around 75 % of the water used in Mexico is for agricultural ends. Household use takes up to 14 %, while the remaining 11 % is for industrial use, *i.e.*, industry in Mexico has a relatively low consumption level according to international standards. In as far as the world becomes predominantly urbanized, agriculture grows more dependent on irrigation. According to the National Institute of Geography and Statistics (INEGI) and the National Water Commission (CONAGUA, 2016), in Mexico water consumption is distributed as follows:

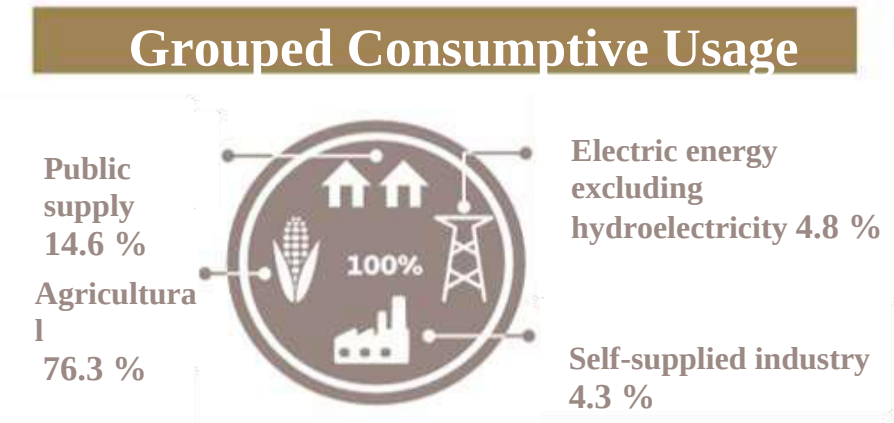

Image 2. Representation of water consumption in Mexico. Source: Elaborated by CONAGUA (2016, p. 69)

Among the many variables that will affect water availability in the country and that depend entirely on our choices are:

- Population
- GNP growth by sector and region
- Efficiency in the use of water
- Water consumption *per capita*
- Food demand
- Agricultura efficiency, both seasonal and irrigational
- Food imports
- Regional water extraction
- Tax regulations

Among the variables that are beyond our reach but that will affect our water availability are:

- Changes in temperature and rainfall
- Geological accidents
- Other natural causes

Official Political Tendencies

Through administrative and financial reforms and also by modifying policies and techniques about water management, authorities are trying to guarantee the provided services and preserve the environment.

Their goals include:

- Foster the efficient use of water in agricultural production
- Foster a greater coverage and quality of fresh water services, sewage and sanitation
- Achieve an integral and sustainable management of water in basins and aquifers
- Promote the technical, administrative and financial development of the water sector
- Consolidate engagement from users and organized society members in water management and foster proper use practices
- Diminish risks and attend the effects of floods and draughts

Their scheme for sectorial water management attempts to head on to a decentralized, integrated management that partakes in water resources, implementing crossed policies that consider concepts such as planification and territorial ordering on the scale of hydrographic basins (Wolfe, 2014).

Proposals at the household and personal level.

To acknowledge that water is not perennial, that it is depleting, not so much due to the water from the hydrologic cycle having been reduced, but rather because of heavy human pollution, which makes it take longer to recover water after it has been returned to nature in such a state. To employ mechanisms that decrease consumption, employ reductive devices in toilets' water tanks of six liters in two phases, one of low consumption and another of full consumption, as needed. These are not expensive. A toilet of this kind is around $ 50.00 USD. Employ water-saving shower heads, reduce time spent taking baths, shaving, brushing teeth, washing face, cars and doing dishes. To build water tanks and rain water containers. It is estimated that a water tank with a 20 000-liter capacity is around $ 1, 500.00 USD; water can also otherwise be collected in polyvinyl chloride (PVC) cisterns. Cisterns with a 10, 000-liter capacity are around $500.00 USD each. The aim is to use collected water for basic needs, which generally would otherwise go down the urban drainage system. This kind of water is very suitable for irrigation, laundry, and personal hygiene purposes. To recycle water, that water used in daily baths, in doing laundry, etc., is very convenient for later use in watering gardens, and if it follows an aerobic cleaning process it can be reutilized for doing further laundry and other household activities. To dramatically diminish the use of running water that fundamentally comes from underground deposits, from where great amounts of energy are needed to extract and use it. Conversely, to minimize residual water and provide less to a society that should also be capable of cleaning it before giving it back to nature. For a family of five members, it was proven that a decrease in running water consumption of 60 % was achieved by collecting rain water with a 20, 000-liter capacity tank, and it was enough to use through a five-month dry season. Once rain season arrived, the tank was re-filled to keep using that water. It was ascertained that only during a month of the year was it necessary to rely on running water to satisfy basic needs.

Conclusions

In terms of the geographical characteristics of the country, it is concluded that Mexico has never had enough water to sustain agricultural development, because the especial distribution of the territory is uneven. Where the best soil is to be found, there is not enough water on the surface or underground water, and where there are abundant water resources, there are not enough areas for extensive agricultural development, nor well developed soil. It is necessary to educate people about the water crisis, to raise awareness through constant advertisement campaigns, to implement the issue of water at the basis of environmental education, to

influence the youth to create in them life-long habits that care for water, to design and foster strategies that help in recovering residual water — in Mexico little water is recovered — not only with treatment plants or by irrigating fields with that same raw water, to design different collectors for graywater and sewage water. The former can be reutilized directly in gardens and for producing food. Sewage water, after being treated, can be reutilized or injected into aquifers. In agricultural production, simple flood irrigation must stop. Its efficiency in terms of conduction as well as in beneficial applications is low. The government must foster and provide the small-scale producer with economical support. Transitioning from traditional irrigation practices to advanced irrigation technology would yield more earnings, since water consumption is reduced by 30 % in comparison with traditional irrigation. Small-scale producers must also be provided with permanent technical support. It is necessary to return to proper water management for agricultural use in all related activities: it is not enough with coating irrigation canals; to guarantee that plots will yield 90 % efficiency and that growing crops will do the same with at least 70 % of direct application. If no action is undertaken for the sake of water in agriculture, which uses it the most, problems will become each time less manageable and more insurmountable.

Abstract

Research training on environmental sciences, in relation to climate change, is an issue that requires immediate attention. Around the world there is but a few researchers on environmental issues for every 100, 000 inhabitants. In Mexico, particularly in public universities, researchers working on the topic barely make up 0.9% of every 1000 inhabitants of the economically active population and, due to the neoliberal government that has ruled over this country, no medium-term improvement to the current situation is foreseen. Considering the circumstances, the present study addresses the case of research training in one of the most important state universities in Mexico: The Autonomous University of the State of Mexico (UAEMEX), regarding in particular the general experience in the Master's and Doctoral Degrees on Environmental Sciences Program. Through documentary research, a review of all theses developed during an eight-year period was carried out, using as indicators the lines of investigation that were developed, the number of theses presented each year, the type of study that was conducted in each of those papers, and the research techniques that were employed. The relevance of these programs in terms of research training in the field of environmental issues was analyzed , as well as its accomplishments, bringing it all to a conclusion with suggestions that may guide and improve the processes of research training on environmental issues related to climate change, in which the relevance of the epistemological construction of knowledge of environmental science with a holistic perspective is emphasized.

Key words: *knowledge generation, environmental research, environmental science, climate change.*

Introduction

The Master's and Doctoral Degrees on Environmental Sciences Program (PMDCA) of the Autonomous University of the State of Mexico (UAEMEX) was established in 2003 with the aim of specializing professionals to contribute in taking care of the environmental problems that the country faces in general and in particular in the State of Mexico (UAEMEX, 2003). It is housed in the School of Chemistry and emerged as a multi-and interdisciplinary effort that four other Schools of the University partake in: Geography, Engineering, Urban Planning, and Tourism. It is worth mentioning that most of the University's academic output is concentrated in this program (School of Chemistry, 2013).

One of the functions of any University's educational programs in postgraduate studies is to generate knowledge through the development of scientific research. The PMDCA does not possess a full research program; this is probably because all professors linked to the program belong to Academic Groups and, even then, some of them research environmental issues. Research conducted thus far belongs to the theses that alumni present to graduate; the lines of investigation followed in them are established by alumni or their lecturers. The objective of the current study consists in exploring the scope of the PMDCA in relation to the researchers

training in environmental field , its successes, as well as its problematics in generating new interdisciplinary environmental knowledge, with the overall aim of improving their processes in the researchers training and their medium and long-term achievements.

Materials and methods

With the aim of reflecting on the direction that the PMDCA is taking and the type of knowledge that it has been generating in a little bit over ten years since its creation, the research projects carried out by the alumni of the program in a period spanning from September 1, 2005 to April 13, 2013 were reviewed and analyzed in the present study. At that moment, the total number of theses registered in the program was 100, 78 of which corresponded to the master's degree graduated students and 22 to the doctorate degree graduated students. According to Sierra (2001), research can be divided into basic and applied. The first refers to the amount of possessed knowledge of the studied phenomenon, whereas the second implies the control, restructuring and transformation of the same. The following study lies in the basic investigation type due to the intention of only conducting an analysis on PMDCA research that is reflected in the postgraduate theses and developed in a determined time frame, with the overall aim of providing data relevant to the improvement of the PMDCA.

In an initial stage, through a deductive and quantitative approach to the results (Hernández et al., 2003; Pick and López, 2002; López, 1972), it was decided not to consider only the quantitative information, for which purpose a second stage of qualitative orientation was begun to find out the theorical quality and epistemological relevance of each thesis in generating new knowledge (Rojas, 1999; Victorina, 2015) in order to have a deeper knowledge of the outcomes. The assumption is made here that each of the 100 research papers are focused on understanding environmental processes and issues. The different fields belonging to each research were identified, as well as its objectives, considered topics, applied methods and techniques, as well as the methodic focus of each paper.

Results and discussion

The directors of the program insist that the purpose of the research that is conducted is to create comprehensive knowledge focused on understanding environmental processes. If it is to be considered that most of the analyzed theses address the environmental concern from both the natural sciences and social sciences perspectives, and that each, on a different depth level, refer to biophysical, social, cultural and political processes, it could be asserted that the aim of the program is met. However, a quantitative-type analysis of conducted research leads to a different conclusion. With the objective of carrying it out, all conducted research was grouped with basis on their covered topics. It was determined that the 100 theses refer to 11 topics or lines of generation and application of knowledge (formerly known as investigation lines): I. Climate Change; II. Pollution; III. Health Damage; IV. Sustainable Development; V. Environmental Management; VI. Environmental Impact; VII. Environmental Regulation; VIII. Hazardous Waste; IX. Environmental Risk; X. Environmental Technology; XI. Environmental Epistemology.

From those 12 lines of generation and application of knowledge, the most studied one was *Environmental Technology* (47 theses), followed by *Environmental Impact* (10) and *Environmental Regulation* (9). The least studied categories were *Environmental Risk, Climate Change, Health Damage, and Environmental Epistemology*, none of which caught the attention of more than three postgraduate students. If it were to be added to these results the fact that little research considers social concerns as components in environmental issues, the necessary conclusion is that the program is more apt to train in the technological than the social aspects.

Upon reviewing each of the covered topics, it was found that most research refers to problems related to chemical science, specifically, to problems about pollution. Such a tendency is considered natural since the program is housed in the School of Chemistry; it is due to this that most students and research are associated to this field of knowledge. What is striking is that those who have been trained in this field almost exclusively conduct studies on pollution; it is a tendency that seems to suggest that their view on environmental issues is rather limited, as they identify their involvement only in terms of such problems.

Additionally, aspects related to the graduation process were also reviewed. It was found that obtaining a degree is tightly adjusted to the compliance with criteria established by the authorities now in charge of postgraduate studies. It is clear without a doubt that emphasis has been made on keeping a level of efficiency superior to 80 percent; in such sense, this began two years after the start of the program, *i.e.*, in 2005. The years 2012 and 2011 stand out as the ones with greater output (22 and 19 respectively), and 2010 and 2005 as those with the least output (6 and 5).

Notwithstanding the erratic behaviour observed in the graduation process, which cannot be described as having established its own rhythm, and the dormant possibility that the program might disappear from the registry of the National Council for Science and Technology's (CONACYT) excellence programs (Román, 2018), the observed degree of compliance has thus far allowed it to be kept in the registry (CONACYT, 2015). The program's directors main concern in that sense is completely evident and is fundamentally due to how, in the current circumstances, budget availability is constrained by compliance with established parameters which are, to their fullest extent, quantitative in nature (Figure 1).

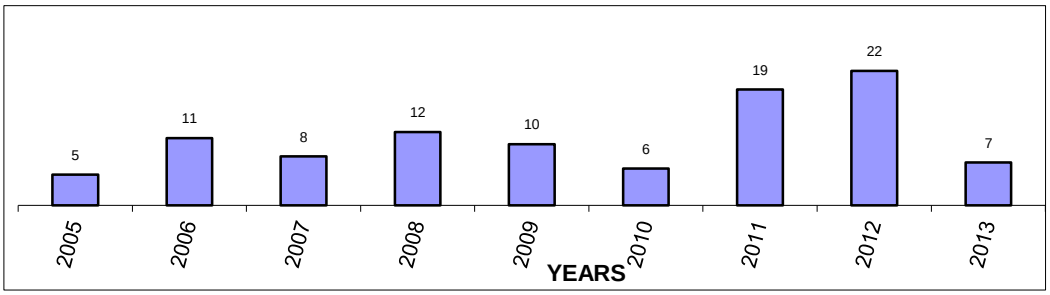

Figure 1. Master's and doctorate theses published yearly. Source: Elaborated by the authors.

The above goes to show how the program's directors have focused all their attention on fulfilling goals, which in turn causes other aspects of the program to fall into neglect, mainly those regarding knowledge production and environmental know-how (Leff, 1998). It is possible that for this reason most research carried out throughout the first 10 years of the program does not meet the understanding-explanatory level, which should otherwise be its primary characteristic since research conducted by postgraduate students is being dealt with; above all, theses corresponding to the doctorate degree should not leave any doubts in this regard. Nevertheless, only 15% of theses meet the alluded level of abstraction.

It can be said that generation of new knowledge is low, not only because little research meets the explanatory level, but also because the number of theses that meet the correlational level (39%) is still regarded as low, *i.e.*, the analysis of statistical relations with more than one variable, also because, for a postgraduate program, it is estimated that a very high amount of research remains at the descriptive (37%), exploratory (5%) and confirmatory (4%) levels (Figure 2)Another factor that allows for considering the generation of new knowledge as low is that related to the techniques used in conducted research. In most cases these are desk studies (42%), where data or information generated by other studies is used to conduct

laboratory simulations and replicate previously conducted experiments. This means that there is no direct investigation of environmental issues on any of its components or manifestations. However, it is fair to acknowledge that a tendency to conduct experimental research is observed (29%), where independent data is generated. Another tendency that is increasing in frequency is to carry out surveys (19%). The former is due to how, as has been said, a great number of master's degree students comes from the School of Chemistry itself, and they are used to experimental studies, which also explains the concentration of research conducted in that field of knowledge. The latter is subjected to how, inside the program, the belief is firm that environmental studies are not complete unless they reach a social knowledge of the issues at hand; the positive aspect of such conviction contradicts itself with the fact that social studies are being understood as the carrying out of little surveys, which blurs the purpose of including them when it comes to environmental studies.

A positive signal is that research that includes field work reaches up to 10%. This is a sign that the student's confronting of environmental reality is gaining preference, which allows to predict a substantial, medium term change. The globalization phenomenon, as part of capitalism, and its effects on education make up for a very extensive topic, which can be observed and analyzed from different perspectives. Currently, it is important to understand what is taking place in terms of both educational and environmental science studies issues, all of this within the global framework and its links to society (Velázquez, 2017). Let it be duly noted that the environmental problems which an increasing number of urban and rural communities go through because of the development of the neoliberal capitalist model do not play a part or are covered at all in the educational and research activities that are conducted (Figure 3).

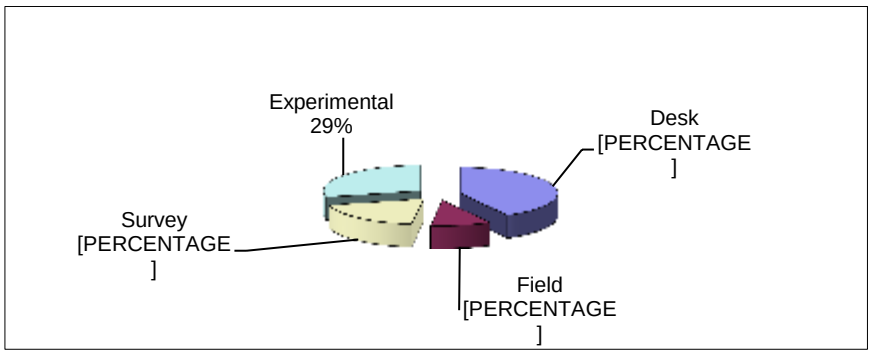

Figure 2. Theses according to study type. Source: Elaborated by the authors.

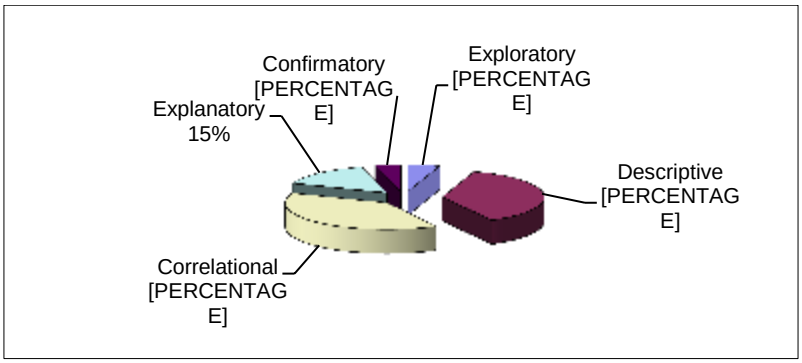

Figure 3. Theses according to used approach. Source: Elaborated by the authors.

Given that most research is technical in nature, studies that use a quantitative-type approach are predominant (59%), above those that offer a qualitative approach (9%). However, it is interesting to observe that a great amount of research is multimodal, or at least has a mixed

approach; *i.e.,* it uses both approaches (32%), so that it can be asserted that the program is moving forward in constructing environmental knowledge whenever both approaches are used (Table 1).

Table 1. Types of study according to approach

Approach		
Qualitative	Quantitative	Multimodal
9	59	32
TOTAL 100		

Conclusions

It is evident that the research that is conducted in the PMDCA focuses its attention on aspects related to environmental technology, such as: technology implementation, studies on damages to health arising from chemical pollution, water, soil and air pollution, while topics like climate change, environmental management, impact, risk and services as well as studies on environmental epistemology and ecological regulation are under-researched. It is a technical focus research rather than social. Such tendency matches studies conducted at a national level for this branch of knowledge.

Likewise, it is acknowledged that what is conducted within the PMDCA is primarily desk research since data or information generated in other studies is used to replicate experiments. The proportion of papers that stem from a direct approach to the studied phenomenon is low. Additionally, quantitative-approach research is being preferred, in which measuring data is what matters most. However, it is of the utmost importance to observe that there is a tendency to modify the referred trend. The propensity for specialized studies has not allowed for moving forward to a holistic view on environmental issues. To this it should be added that the desired level of knowledge has not yet reached the explanatory level that ought to belong to the advanced studies that the program alludes to. Studies historic in nature and with an interpretative approach are conspicuously absent or amount to only a few when all are considered. Although with limited relevance and faithfulness to its own objectives, it can be said that the PMDCA is contributing to the construction of environmental sciences in the state; more specifically, it contributes to the development of environmental chemistry, even though contributions are circumscribed to the field of environmental pollution. But little to no contribution is being made to the construction of environmental science as a whole; this is due to how, up until now, it has not been considered that environmental problems, more than just being technical or social ones, also represent problems in the construction of knowledge. An epistemological shift in the teaching and researching activities of the PMDCA is necessary and urgent.

Abstract

This paper discusses the impact of climate changes on vegetable farmers in Gaza Strip. The objective of this study is to highlight the awareness of vegetable growers in different regions about the concept and elements of climate changes and how these changes effect on different types of vegetables in terms of growth rates, productivity and change of shape and color. Also, the objective of this study also is to highlight the impact of climate changes on the consumption quantity of water needed for vegetables growth. To achieve these objectives, the study relied on descriptive comparative analytical approach for various data collected from its primary sources through distribution of a questionnaire form to 104 farmers in the northern, central and southern Gaza Strip. This study has a lot of results, but the most important result is the existence of sufficient knowledge among the category of vegetable growers in Gaza Strip of the concepts and dimensions of climate changes, as 79.8% of them have sufficient knowledge of the concept and the dimensions of these changes. Also the results indicate that 96.2% of the vegetable growers have been affected by climate changes during the last period, 41.3% of them believe that the impact of these changes has been significant on the volume of agricultural productivity and on the quantity of water consumed for agriculture, 65.4% of them note that the climate changes have led to increasing in water consumption for agriculture. The results also indicate that 53.8% of vegetable growers believe that the wrong agricultural practices, as burning agricultural waste and excessive use of fertilizers and chemical pesticides have direct impact of climate changes, The study recommends the needed for facing the climate changes from vegetable growers by enhancing the concept of dealing with climate changes for these category of farmers and using new technologies to overcome these changes such as regular pressure irrigation techniques and water harvesting techniques.

Keywords: *climate change, vegetable farmers, pesticides, water harvesting, water consumption*

Introduction

Agricultural sector is one of the most important productive sectors in Palestine, it's contributing in leading the process of economic development because of its important role in enhancing food security and manpower. Also agricultural sector has an important role in contributing Palestine economic growth process over the past years, where it was the biggest economic sector in contributing Palestinian GDP with ratio 32% in 1993 which declined to be 5.6% during 2016 (Oumar, H. Qaoud, H (2016).

The observer of the general decline cause in agricultural sector in Palestine realize that this decline has a group of reasons which reflected on the productivity of this sector, perhaps the most important these reasons is the general political situation in Palestine represented by Israel occupation for the Palestinian territories which hinder any development in this sector. However, there are other reasons and factors caused this decline related to the general climate changes in the Middle East, which affected on Palestine in general and Gaza Strip in particular. The most important changes were temperature changes, wind, rain distribution and humidity, which have been associated with a change in agriculture times and type of

agricultural product, the productivity rate was reduced to more than 60% in most agricultural crops.

Materials and methods

First: Study Problem

Because of the importance of agricultural sector in achieving food security of the population specifically in Gaza Strip and the existence climate changes represented by sharp difference in temperature, humidity, rain distribution and wind, which directly reflected on the productivity of farmers in Gaza Strip especially vegetable farmers. The statistics indicates that 43% of farmers affected from high humidity levels and 45.3% of farmers negatively affected from rain intensity, 59.3% of them severely damaged from high temperature rate and high droughts and 50% of them negatively affected as a result of the intensity of wind during the last ten years in Gaza Strip. Therefore, the problem of the study can be formulated in the following main question:

What are the most important climate changes which have been affected on vegetable farmers in Gaza Strip?

A number of sub-questions are branched from this question:

1. Is there an impact from the changes of rates and distribution of rain on vegetable farmers in Gaza Strip?
2. Is there any effect from temperature changes on vegetable farmers in Gaza Strip?
3. Is there an impact from wind intensity changes and trends on vegetable farmers in Gaza Strip?

Second: Objectives of the Study

The main objectives of this study are as the following:

1. Identify farmers' awareness of climate changes and its different dimensions.
2. Identify the impact of climate changes on agricultural sector, both plant and animal.
3. Determining the relationship between climate changes and agricultural practices in Gaza Strip.
4. Identify the effect of climate changes on vegetable crops compared with fruit trees.

Methodology

First: Data collection methodology: Researchers depended on two tools for data collection, the first tool was the questionnaire which used to evaluate the impact of climate on a targeted group of vegetable farmers in Gaza Strip governorates specifically in Beit Hanoun - Gaza Valley - Deir Al Balah - Qarara - Abasan - Khuza'a - Rafah, while the second tool which used was the focus groups, 10 workshops were organized and 120 farmers were interviewed which chosen randomly to fill out the study questionnaire to clarify the impact of climate changes on them in terms of damages and it's economic dimensions.

Climate change in the Gaza Strip

Climate change is one of the most important global phenomena closely related to the agricultural sector in the world. These changes are related to a range of factors affecting the productivity of field crops and vegetables in general and in the Gaza Strip in particular. These elements are temperature, drought, The amount of rain and its various distributions, the rates humidity and wind , where these elements are the most important effects facing vegetable growers in the Gaza Strip because of the negative effects on the productivity of the agricultural sector of vegetables in Gaza Strip(Earth & Human Center for Researches and Studies,2018,P.5).Where the agricultural sector in general suffers from a range of negative effects of these changes and specifically during the past ten years, where the sharpness of climate change was concentrated in the lack of rain and high temperatures and drought, which reflected the effects on productivity in the agricultural sector where the productivity of seeds and vegetables decreased by 28.7% as a direct result of these changes and the inability of

farmers in Gaza Strip to adapt of these changes due to lack of advanced technologies that can be used in this process, which include water harvesting techniques, irrigation by regular pressure or the use of improved seed varieties adapted of this changed (Applied Research Institute Jerusalem, ARIJ, 2018, p. 19).

The reality of vegetable growing in Gaza Strip

Gaza Strip is characterized by the production of a variety of vegetables that meet the needs of the population of the Gaza Strip in a relative manner, where the production of tomatoes, potatoes and sweet pepper all colors, basil, mint, green onions, cucumber, spices and other types of vegetables and the total area cultivated in the Gaza Strip (400%), distributed over 330 thousand tons of vegetables and 70 thousand tons of fruits, including olives and citrus. The percentage of self-sufficiency in the production of vegetables in the Gaza Strip is 98%. Only a few crops are imported from vegetables at certain intervals According to the needs of the residents of the Gaza Strip (Al-Sakka, 2015).

With regard to the value of the Gaza Strip's production of vegetables, its value fluctuated in relation to a range of economic and political variables experienced by the Gaza Strip, where the maximum value of vegetables production in 2007 amounted to 199014 thousand dollars. This value was taken down in 2008-2010 by the Israeli war which In which agricultural land was affected by this war, which resulted in extensive destruction of the agricultural infrastructure, which led to a decline in the volume of vegetables production in the Gaza Strip, but the value of vegetable production was stabilized by the reconstruction projects that are called after the end The Israeli war for the rehabilitation of agricultural land, which averaged 115,200 thousand dollars during the years 2011-2015(Shawa, 2017, p. 27) .

The contribution of vegetables to the size of the plant production was related to the general economic and political variables, which were reflected in the size of the agricultural production of the agricultural sector as a whole in the Gaza Strip, where the maximum contribution of vegetables to the size of plant production in 2007 was 72.7%. Witnessed by the Gaza Strip, but stabilized at an average rate of 52% during the period 2008-2015.

The farmers in the Gaza Strip face many difficulties and challenges, the most important of which is the weakness of the infrastructure needed to grow vegetables in the Gaza Strip and the shortage of water needed for agriculture and the low quality due to the high salinity rates due to the increasing consumption of the reservoir that does not meet the needs of the population, and the lack of water in the Gaza Strip. The researcher interviewed Engineer. Wael Thabet, Palestinian MOA (4 July 2018)

Second: Systematic Analysis of Data:

Researchers used comparative descriptive analytical method as it's the most appropriate method for this study. This method used to study the demographic variables of the target areas, in addition to the different vegetable group which cultivated in Gaza Strip and farmers' culture about climate changes and how to deal with it, SPSS program has been used for data analysis and access to the targeted results. Al grad, K.M (2009).

Analysis and discussion the results of study:

Section One: personal information

In the framework of monitoring the attitudes and opinions of vegetable farmers regarding to the impact of climate changes on crops, the focus was on the most agricultural areas in Gaza Strip which contribute effectively to provide food security for the population in Gaza Strip. Central governorates of Gaza Strip was 43% from the total targeted respondents because it's the largest agricultural governorates in the strip, followed by southern governorates of Gaza Strip by 36% and finally the northern governorates of Gaza Strip by 21%. Rural women in the target group was 10% of the sample size, while male farmers was 90% of the total size of this category. The poor representation of rural women is due to the nature of agricultural holdings in Gaza Strip, where most of these holdings are for men, also the nature of

agricultural work is dominated by men in Gaza Strip, In addition, most of workers in vegetable category within the target group are more than 40 years, followed by the age group from 35 to less than 40 years, and the lowest age groups working in vegetable cultivation field are under the age of 25, which clearly indicates the weakness participation of young groups in agricultural work, this may be due to the fact that the nature of vegetable cultivation requires years of experience in agricultural work and heading the youth towards services jobs more than productive works which requires a high level of mental and intellectual effort. It is important to note here that the most of these workers are holding the General Secondary Education Certificate with ratio 33.7%, followed by the university graduates with ratio 21.2% and the ratio of intermediate certificate holders were close to the primary education certificate holders (20.2% and 19.2%, respectively) and finally the percentage of illiterate vegetable workers represented only 5.8%, These figures indicate that the cultivation of vegetables requires medium level of education which concentrated in general secondary school certificate holders, also the concentrate of workers in this category is due to the high unemployment rate among university graduates in Gaza Strip by 46% in Gaza Strip which led a large group of high school graduates, especially the children of farmers, to work with their family members because getting work has a priority more than university education because of lack of horizon for university graduates to provide jobs after graduation, also the orientation of university graduates to work in the agricultural sector has become limited because of their desire to work in comfortable jobs, especially in services sector, which justifies the low percentage of university graduates which working in vegetable growing field by 21.2% and may be most of those worker concentrated in agricultural colleges graduates.

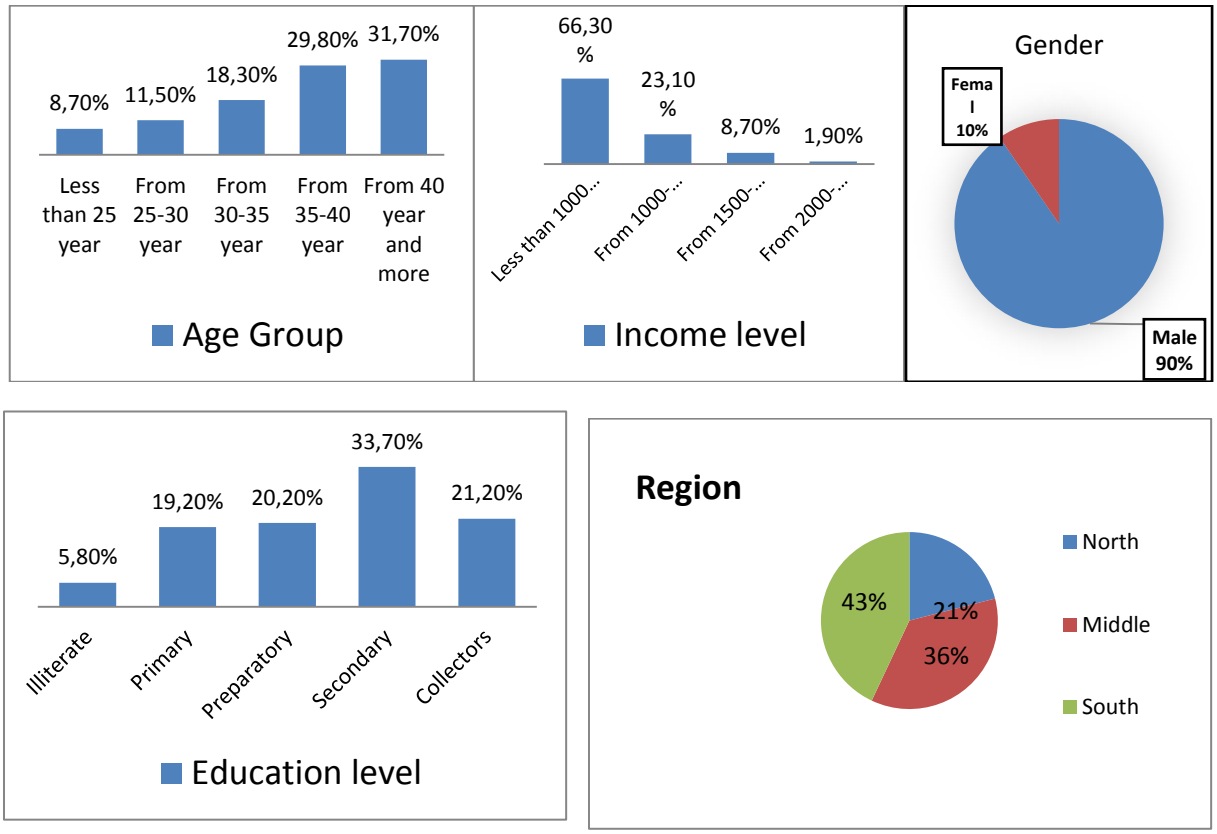

Figure (1) shows the personal information of the targeted group in the study

First: Awareness of climatic changes for vegetable farmers in Gaza Strip

In the framework of monitoring the awareness of vegetable farmers in Gaza Strip about the concepts of climate changes in its different dimensions, the results showed that most of vegetable farmers have a general awareness of the concepts of climate changes in Gaza Strip, as 80.8% of them heard about the concepts of these changes, the awareness of these changes differed between them according to their understanding of these changes, as most of these farmers believe that the concept of climate change is limited in the changes in the weather in terms of water level change as expressed by 93% of them, while 92.3% of them see that the concepts of climate change are limited in the changes in weather in terms of drought and storms, 90.4% believe that change in rain seasons represent the concept of climate changes, and 81.7% believe that temperature changes mainly represent the concept of climate changes, It is important to note here that the lowest percentage of vegetable farmers believe that all the dimensions like rain, heat and wind, combined to represent the concept of climate changes, which is expressed by 20.2% of vegetable growers. Hence, the awareness of vegetable farmers of the concepts of climate changes varies from farmer to farmer according to the effect these changes from region to region, but the final result showed the awareness of the concepts of climate changes between vegetable growers in Gaza Strip with differ in the awareness of the dimensions of these changes according to the impact of each dimension from one geographical area to another within Gaza Strip, where farmers in southern governorates suffer from higher temperatures and drought more than central and southern governorates, while the impact of rain changes in northern governorates is more than the other governorates. The following table shows the concepts of climate changes and its dimensions for vegetable farmers in the governorates of Gaza Strip.

Table (1) Awareness of the concept of climate changes for vegetable farmers in Gaza Strip

Answer	Number		%	
Did you hear about the climate changes before?				
Yes	84		80.80%	
No	11		10.60%	
Not Sure	9		8.70%	
What is the concept of climate change?	Yes		No	
	Number	%	Number	%
Change in temperature	19	18.30%	85	81.70%
Change in water level	7	6.70%	97	93.30%
Rain seasons change	10	9.60%	94	90.40%
Weather change (drought and storms)	8	7.70%	96	92.30%
All the above	83	79.80%	21	20.20%

Second: the reasons of climate changes and its relation with agricultural practices

In the framework of determining the causes that contribute the impact of climate changes in Gaza Strip, the wrong agricultural practices has the greatest correlation with the impact of these changes on vegetable farmers in Gaza Strip, as 80.8% of them believe that wrong agricultural practices is one of the main reasons for spreading the phenomenon of climate changes, where 46.2% of them believe that the burning of agricultural waste, excessive use of pesticides and chemical fertilizers and excessive use of water, are the most important forms of wrong agricultural practices that contributed in expansion the climate changes. The highest percentage of vegetable farmers considered that the excessive use of water and agricultural waste burning have the highest relative weight in affecting on the volume of climate changes

by 83.7% and 82.7%, respectively, then the excessive use of chemical fertilizers and pesticides by 81.7% and 76.5% respectively. Hence, all these dimensions are considered one of the most important variables related with climate changes in Gaza Strip. The following table illustrates the relationship between the different agricultural practices and the climatic changes in Gaza Strip.

Table (2) the relationship between wrong agricultural practices and climate changes

Answer	Number		%	
Are wrong agricultural practices have an impact on climate changes?				
Yes	84		80.80%	
No	20		19.20%	
If yes, choose the following:	Yes		No	
	Number	%	Number	%
Burn agricultural wastes	18	17.30%	86	82.70%
Excessive use of chemical fertilizers	19	18.30%	85	81.70%
Use agricultural pesticides	24	23.10%	80	76.90%
Overuse of water	17	16.30%	87	83.70%
All of the above	56	53.80%	48	46.20%

Third: The impact of climate changes on vegetable growers in Gaza Strip

The results indicate that the impact of climate changes on vegetable growers in Gaza Strip was significant, with 96.2% of farmers affected by these changes, while 3.8% of them were not affected by these changes. As for the degree of impact of these changes on vegetable growers, 41.3% of them indicated that the impact of these changes was significant, while 49% indicated that the effects was moderate, 5.8% indicated that the effect of these changes was weak, and the lowest percentage 3.8% were not affected by these changes. The following table illustrates the nature and the degree of these effects.

Table (3) The Effect of Climate Changes on Vegetable farmers in Gaza Strip

Answer	Number	%
Did the climate changes effect on your farm this year?		
Yes	100	96.20%
No	4	3.80%
How far is this effect?	Number	%
Significant effect	43	41.30%
Average effect	51	49.00%
Weak effect	6	5.80%
no effect	4	3.80%

It is note that the most affected crops due to climate change, especially in relation with the effect of temperature intensity as one of the most important dimensions of these changes, was potatoes as 77.9% of vegetable farmers see this. Then the eggplant by 69.2% and finally peppers and cabbage with the same ratio 65.4%, the following table shows the effect of these changes on different vegetable crops.

Table (4) the Effect of Climate Changes on Vegetable Crops in Gaza Strip

What kind of vegetable has been affected by the heat in the previous days?	Yes		No	
	Number	%	Number	%
pepper	36	34.60%	68	65.40%
Eggplant	32	30.80%	72	69.20%
Potatoes	23	22.10%	81	77.90%
Flower and cabbage	36	34.60%	68	65.40%

Agricultural seasons are considered the most important indicators of climate changes which associated with rainy seasons. The different agriculture periods have a direct effect on productivity. 95.2% of vegetable farmers believe that the different agriculture periods in the seasons had the highest impact on productivity. 73.1% believe that the degree of this effect was high, while 26.9% believe that the degree of this effect was weak, as shows in figure (2).

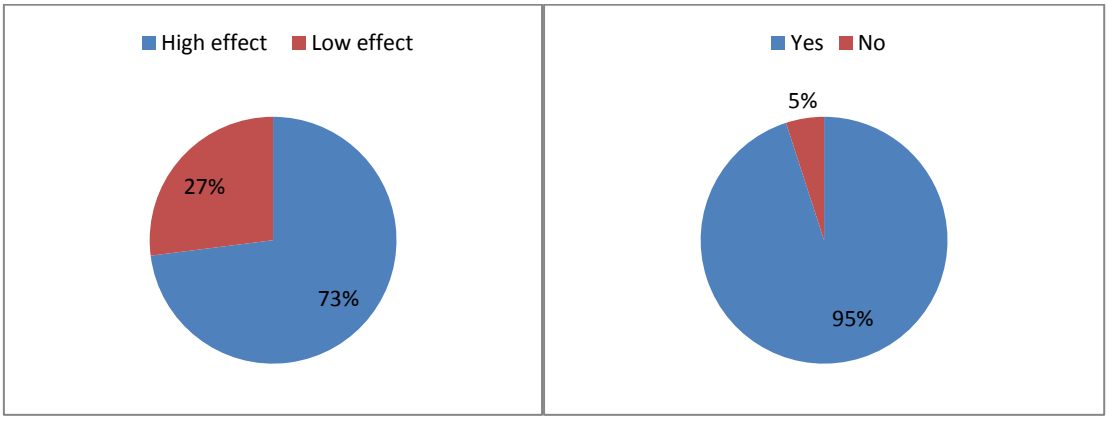

Figure (2): illustrates the belief of the agricultural periods have an impact on agricultural productivity

Fourth: The effect of climate changes on the characteristics of plant

Temperature is one of the most important forms of climate changes affected on the productivity of vegetable crops. The differences in temperature degree has a significant impact on these crops. 84.6% of vegetable growers believe that the differences in temperature degree has the greatest effect on plants in terms of shape. The impact of this differences on color was in the second degree with 83.7%, followed by the effect of temperature differences on plant growth by 66.3%. These changes have an effect on productivity as 59.6% of vegetable farmers seeing this. As for the effect of these changes on total characteristics of plant, 51% of Vegetable growers believe that the difference in temperature degree led to changes in the shape, color, growth rates and productivity of vegetable crops. As shows in Figure (3).

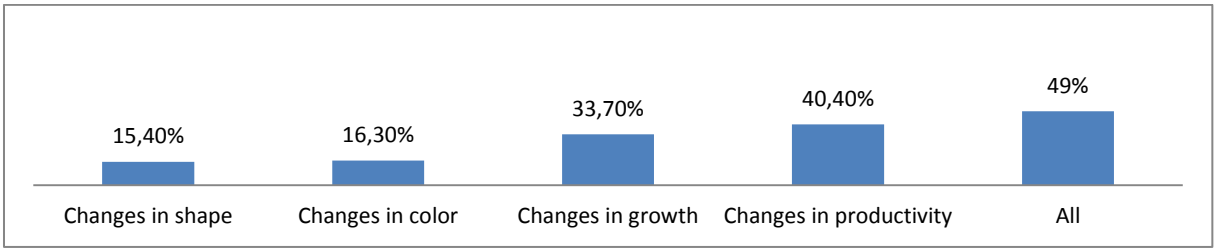

Figure (3) shows the effect of climate changes on plant characteristics

Fifth: The impact of climate changes on the productivity of vegetables

Productivity volume of agricultural crops is the most important factor that governs the economic empowerment of farmers. All measures taken by farmers in terms of technical aspects of plant care, are aimed to maximize the productivity. 65.4% of vegetable farmers believe that climate changes had a significant impact on the volume of vegetables productivity in Gaza Strip, while 27.9% believe that the effect of this changes was medium, 4.8% of vegetable farmers believe that the effects of these changes was weak on the volume Of productivity as shows in figure (4)

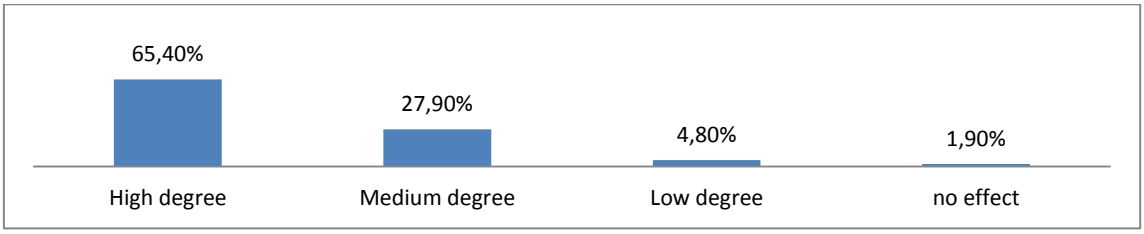

Figure (4) shows the effect of climate changes on the productivity of vegetables

Sixth: The impact of climate changes on water consumption rates

Water issue is one of the most important dilemmas face agricultural sector in Gaza Strip because of water scarcity and high salinity rates. Most reports indicated that water is not suitable for human consumption in Gaza Strip. The impact of climate changes on water consumption volume in the agricultural sector is considered to be one of the most important issues in Gaza Strip, the impact of climate changes on water consumption rate in Gaza Strip was significant. 65.4% of the farmers consider that there is an increases in water consumption for agriculture as a result of these changes, while 27.9% of vegetable growers found that the degree of impact of these changes on water consumption was medium, 4.8% believe that effect of these changes was weak, and finally, 1.9% did not see any effect of these changes on water consumption rates, The following table illustrates this.

Table (5) the Effect of Climate Changes on Water Consumption

Did climate changes effect on water consumption?	Number	%
High degree	68	65.40%
Medium degree	29	27.90%
Low degree	5	4.80%
no effect	2	1.90%

Seventh: The impact of climate changes on fruit tree farmers

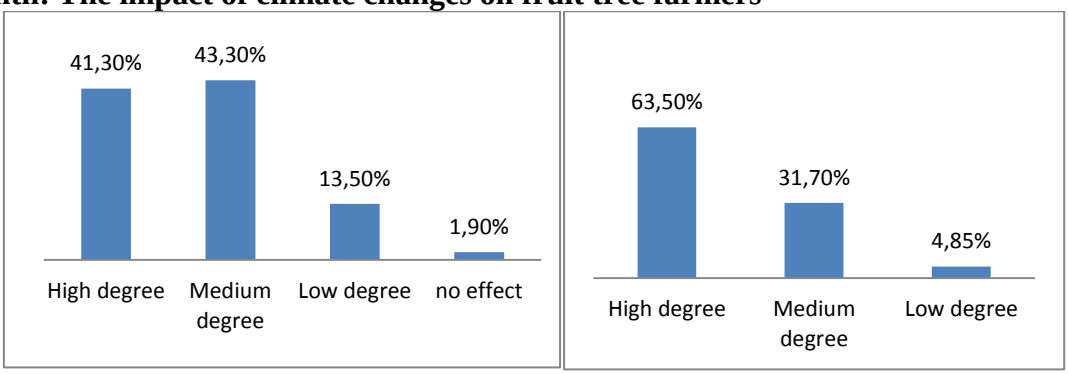

Figure (5) illustrates the impact of climate changes on fruit tree farmers

Climate changes has not only affected on vegetable growers, but has also extended to fruit farmers. The effects of climate changes was the highest on vegetable farmers, while this effect was lower on fruit tree farmers, 43.3% believe that this effect was moderate, 41.3% believe that it was significant, 13.5% believe that it was weak, and 1.9% did not see any effect of climate changes on fruit trees. As shows in Figure (5).

Eighth: The impact of climate changes on animal breeders

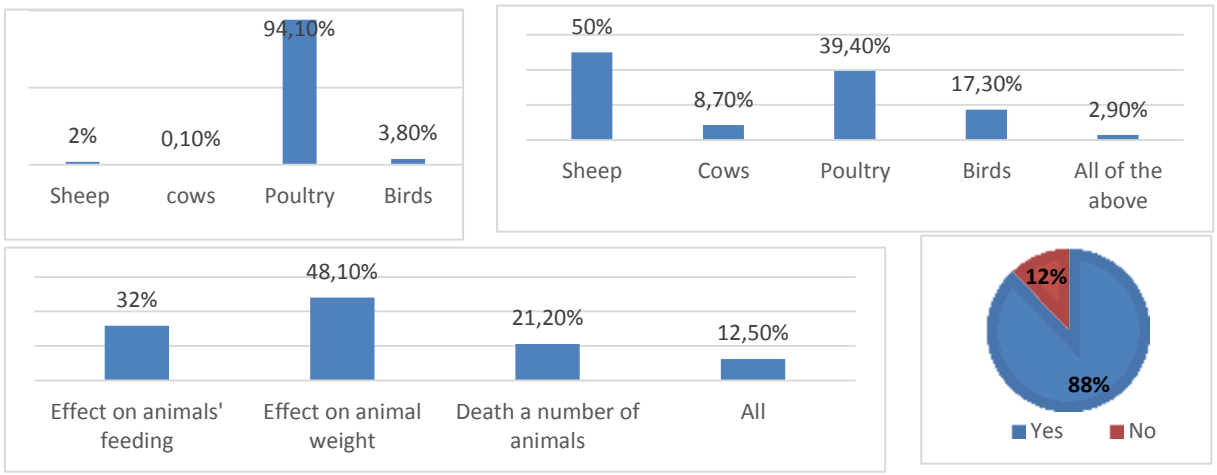

Figure (6) illustrates the impact of climate changes on livestock breeders

88.5% of vegetable farmers considered as livestock breeders, 97.1% of whom are breeders of cows, livestock and birds in various shapes, these farmers believe that the biggest effect of climate changes causing animal and bird aversion, where 78.8% of them see this, most farmers see that the aversion rates of was concentrated in poultry sector with ratio 94.1%, while 68.3% believe that climate changes affected on feeding of animals and birds. 51.9% see that these changes led to a decrease in the weights of these animals, figure (6) shows this.

Ninth: The impact of climate changes on the prices of vegetables in the markets

The effect of climate changes on vegetable and vegetable farmers in terms of productivity and plant characteristics has been reflected in the cost of production and therefore on the prices of vegetables in the markets, where 63.5% of vegetable farmers see that the climate changes led to increase the prices in the market, 31.7% see that the climate changes affected moderately on the prices of vegetables and finally 4.8% see that the reflection of these changes on prices was weak and the following table shows this.

Table 5: table caption

Because of climate changes (high temperatures), Did the prices of vegetables in the market has been affected?	Number	%
High degree	66	63.50%
Medium degree	33	31.70%
Low degree	5	4.85%

Results and discussion

First: Results

1- Most vegetable farmers in Gaza Strip are aware the concepts of climate changes, as 80.8% of them aware these concepts in terms of the different dimensions of it, and the difference is in the extent of their focus on these dimensions according to the different geographic regions within Gaza Strip

2- The highest percentage of vegetables farmers (91.3%) believe that the climatic changes in Gaza Strip are limited in changes in weather in terms of drought, storms and change in rainfall seasons.
3- Most vegetables farmers are linking between the spread of wrong agricultural practices and phenomenon of climate changes, with 80.8% of them see that the spread of wrong agricultural practices like burn agricultural waste and the excessive use of fertilizers and chemical pesticides, are the main cause that contribute the increasing of climate changes in Gaza strip.
4- Most vegetables farmers in Gaza Strip with ratio 96.2%, were affected from various climatic changes, while 49% of them see that the degree of impact of these changes on them was from medium to high degree, while 41.3% of them see that the impact of these changes was very high.
5- Most vegetable crops which affected by climate changes was potatoes. 77.9% of vegetable farmers are seeing this, followed by eggplant (69.2%) and peppers, cabbage (65.4%), all of these crops were adversely affected by these changes.
6- Temperature degree, as one of the elements of climate change, had the highest impact on vegetable growers, as 84.6% of vegetable growers believe that temperature had the highest impact on the plant in terms of shape, color, growth rate and productivity.
7- There is a relationship between the dimensions of the various climatic changes and water consumption rates. Climate changes has a significant impact on water consumption rates in Gaza Strip, with 65.4% of vegetable growers see increase in water consumption for agriculture due to these changes.
8- Increasing of phenomenon of climate changes in Gaza Strip led to a rise in vegetables prices in the markets, as 63.5% of the vegetable farmers believe that these changes led to a significant increase in prices because these changes are relating with the productivity volume and plant characteristics, which reflected on production cost, thus on the input and production prices.
9- Climate changes has been affected on fruit tree farmers and livestock breeders from vegetable farmers, where most fruit tree growers see that the effects of these changes was medium with ratio 43.3%. As for the impact of these changes on livestock breeders, it cause aversion of animals and birds, where 78.8% see this.
Second: Recommendations
1- The competent authorities should endeavor to find ways to support the adaptation of vegetable growers with climate changes and to reduce the impact of these changes on them by introducing new techniques for agricultural work which contribute in reducing the negative impact of changes
2- Introduce the techniques of water harvesting and irrigation techniques by regular pressure as one of the most important methods to combat the scarcity of water which result from low rainfall, increasing heat and drought, as these means will contribute the provision of water sources for agriculture, in addition, it will be reduce the volume of water losses which used in irrigation
3- Intensify awareness campaigns for vegetable growers to face climate changes, especially temperature, rain, wind and humidity, through using irrigation techniques, spraying pesticides, windbreaks and rainwater harvesting pools.
4- Work to educate farmers about the ideal methods of field management to reduce the wrong agricultural practices that contribute widely in spreading the phenomenon of climate changes in Gaza Strip.

Abstract

Increased acidity is very often a limiting factor for decreased soil fertility and unfavorable chemical and physical soil properties. Fly-ash of Kosovo power plants appears as the waste material after burning in the reactors. Material itself causes serious environmental consequences, especially because it is hardly remediated, due to its chemical and physical properties. Since 1963. Kosovo power plants have formed huge fly-ash dumps of very poor remediability, with over than 200.000mt of fly-ash. But, despite of its low remediability, the material has properties to be used in liming of acid soils. The fact that fly-ash of Kosovo powerplants is alkaline, with relatively high content of CaO and $CaCO_3$, recommends it as a material which can be successfully used in melioration of acid soils. In our experiment we have used soil type Distric Cambisol, as a typical acid soil for the region of Kosovo. The results show applied liming material as proper material for use in liming the acid soils. By use the fly-ash for amelioration of acid soil, we have reached significant improvement of pH and other chemical properties, as well as the stability of soil structure.

Key words: *Fly-ash, Kosovo powerplants, liming, acid soils.*

Introduction

Fly-ash occurs as a result of coal combustion in power plants poses a serious environmental problem. On the one hand, the ash landfill is deposited on agricultural land, which excludes them from agricultural production, and on the other hand EF ash is subject to eolation, which affects the quality of the environment kilometers around (Resulović, 1988.). Coal burning in Kosovo's power plants has been carried out since 1963 with the opening of a thermal power plant in Kosovo „A" power 449 MW, which was particularly intensified by the opening of another power plant Kosovo „B" power 580 MW 1980. year. During all the work of Kosovo's thermal power plants, ash dumps have been formed, which involve 2,000 hectares of arable land. Moreover, in EF ashes the dust fraction prevails, which allows its eolation, thus adversely affecting the environment and agricultural crops. According to the reccurability of ash deposits, they are hardly recurable (Cairney, 1987.), and therefore pose an additional problem in the living environment of the area. (Šmit, 1988). The cause of poor recurrence lies also in the chemical properties of EF ash, both in terms of high alkalinity and in terms of cementation of the surface layer of landfills (Đikić et al., 1995.). However, the fact that EF is an alkaline reaction with very high content of CaO recommends the research of its application in alkaline acid calcification. Calculation is a pedomeliorative measure of repair of acidic soils and the materials to which it is made may be different: CaO, CaCO3, dolomit, saturation sludge and others. This study recommends EF ash as a calibration material, given its chemical and physical properties. The available amount of ash is quite sufficient to consider its commercial use in the pessimism.

Materials and Methods

The research used the pedological map of the AP of Kosovo and Metohija (Institut „Jaroslav Černi", 1974.), as well as the soil type Distric cambisol from Klina near Pec. The chemical properties of ash were analyzed by standard methods (Black et al. 1965.). The experient was founded as an indoor one, in experimental pots of volume of 4 dm^3. Soil moisture was mainetned on the level of retentional capacity (33kPa).

The characteristics of the EF ash are presented in the table 2, as well as the properties of the soil used in the experiment (table 1). The use of EF ash was 10 (dosage 1), 30 (dosage 2) and 50 (dosage 3) tha^{-1}, with control without the use of calcification agent. Compost is used as an aditional fertilizer, for the purpose of achieving better solubility of the calcification agent (Banasova, 1989, Flaig, 1981). The culture of cultivation in this regard was barley. Barley was chosen as a typical culture of a given area.

The results were tabulated as well (Table 3). Statistic analyze have been done accordingly, and presented as well.

Results of research and discussion

The soil used in the survey was taken with k.r. Bica, Klina - Pec and by type belongs to distric cambisol. The chemical properties of the soil treated in the sample are shown in the table 1.

Table 1. Chemical properties of soil in the experiment

Depth	pH_{H_2O}	pH_{KCl}	Humus (%)	N (%)	P2O5 (mg/100g)	K2O (mg/100g)	H (meq/100g)	CaCO3
0-12	5,1	4,3	1,2	0,22	7,5	30	22,5	-
13-27	5,0	4,1	0,5	0,14	5,4	25	20,4	-
28-56	5,2	4,2	0	0,10	3,0	20	32,2	-
56-100	5,4	4,4	0	0,10	2,0	25	30,0	-

As seen from the table shown, the soil in the experiment is very acidic with very low humus, with a somewhat higher amount of phosphorus than expected because it was agricultural land as well as with a slightly increased amount of other nutrients for the same reason. Hydrolitic acidity, shows levels of necesarity of liming the soil. The characteristics of EF ash are shown in the table 2.

Table 2. Chemical properties of fly-ash from Kosovo powerplants

Depth	pH_{H2O}	pH_{KCl}	CaO (%)	Na (%)	P2O5 (mg/100g)	K2O (mg/100g)	CaCO3
0-10	10,52	10,0	47,5	1,22	8,5	>40	15,2
11-20	9,11	8,85	41,5	1,14	5,4	>40	18,4
20-30	10,00	9,21	37,2	0,90	3,0	>40	9,2
30-40	9,85	9,45	45,0	1,10	2,0	>40	8,5

The influence of liming material on amelioration of distric cambisol with fly-ash is statisticaly analyzed, and the results have are presented in Table 3.

By unifactorial univariant analysis of variance it was determined existance of statisticaly significant difference at parameters pH_{KCl}, N, K_2O, $CaCO_3$ and H depended on dosage. With the additional *Post-hoc* analyze with using of LSD test, it was determined that mean values of pH_{KCl} are significantly different at dosages 1 and 2, as well at the dosages 2 and 3, while at dosages 1 nad 3 there is no statistically significant difference. Median value of N(%) are significantly statisticaly diferent for dosages 1 and 3 and dosages 2and 3, but there is no statistically signifficant difference at dosages 2 and 1. Analyzing median values of K_2O, it is obvious that statistically signifficant difference exists only between dosages 1 and 3, while

mean values of $CaCO_3$, dosage 1 is significantly different from dosages 2 and 3. Analyzing mean values of hydrolytic acidity, signifficant difference exist at first dosage, compared to second and third.

Table 3. Influence of fly-ash on the soil type distric cambisol in the experiment

Dosage		pH (H2O)	pH (KCl)	Humus (%)	N (%)	P2O5 (mg/100g)	K2O (mg/100g)	CaCO3	H (meq /100g)
1	Mean	6,1000	5,8333	2,7667	,2367	8,4667	35,0000	1,0233	8,8667

	Maximum	6,40	5,40	2,60	,23	8,30	32,00	2,50	7,50
3	Mean	6,5000	5,8667	2,5000	,3033	8,0333	25,0000	1,9333	6,9667
	N	3	3	3	3	3	3	3	3
	Std. Deviation	,26458	,05774	,30000	,03055	,25166	4,35890	,05774	,11547
	Std. Error of Mean	,15275	,03333	,17321	,01764	,14530	2,51661	,03333	,06667
	Minimum	6,20	5,80	2,20	,27	7,80	22,00	1,90	6,90
	Maximum	6,70	5,90	2,80	,33	8,30	30,00	2,00	7,10

As the table clearly shows the melioration of distric cambisol EF ash from Kosovo's thermal power plants, there has been a significant increase in pH. Changing the chemical properties of distric cambisol enabled better nutritional utilization, better cultivation of cultured culture (barley barley), as well as higher yields.

Conclusion

The results of the study of the impact of EF ashes on the repair of distric cambisol indicate that EF ash from the point of view of its chemical properties is a suitable material for the calcification of acidic soils of the distric cambisol type. This is particularly conditioned by the high content of CaO in ash, as well as by absence Na^+ ions.

The performance of the EF ash provided better feedability of the nutrients, which significantly influenced the yield of cultivated culture.

Abstract

Limited fertility of acid soils is caused by a high concentration of H^+ and Al^{3+}ions, presence of some organic acids and heavy metals, but also by a low accessibility of some nutrients (P, Ca, Mg, B, Zn, particularly Mo) and a low microbial activity. This study has been conducted to determine the effects of three levels of liming (partial – 1/3 Y1, half – 1/2 Y1, and complete liming) on the neutralization of the acid reaction, a high content of mobile Al^{3+}, and changes in the concentrations of available forms of Fe, Zn, and Cu in a Dystric Cambisol soil. The complete liming almost completely neutralized the acid reaction, and decreased the level of mobile Al^{3+} below 1.0 mg kg^{-1}. There has been a satisfactory degree of decrease in pH and Al^{3+} in partial (1/3 of Y1) and half (1/2 of Y1) liming. No level of liming had a significant influence on the content of available forms of Fe and Cu, while the content of Zn decreased in accordance to the level of applied lime material and it was the lowest at the maximum doses of CaO applied. The level of changes caused by partial and half-liming has justified these levels of acid repairing, which can be of significant ecological and economic importance.

Keywords: *Dystric Cambisol, liming, aluminum, micro nutrients*

Introduction

There are numerous factors that limit the fertility of acid soils. High concentrations of H and Al ions, some organic acids and heavy metals, as well as low accessibility of nutrients (P, Ca, Mg, B, Zn, particularly Mo) are just some of them. However, Al-toxicity is a major stress factor for plants on soils whose pH ≤ 5.5 (Poschenrieder *et al.*, 2008; Merino-Gergichevich *et al.*, 2010), and in these conditions, the prevailing pressure for the adaptation of cultivated plants is attributed to it (Ryan and Delhaize, 2010). The acidic environment serves to increase the presence of trivalent aluminum cations – Al^{3+} (Lidon and Barreiro, 2002; Kochian *et al.*, 2005), which is the most poisonous of all kinds of Al. More recognizable effects of Al-toxicity have been observed and well-described on the root (Barceló and Poschenrieder 2002; Panda and Matsumoto, 2007). However, damages may be present even on the upper parts of the plants (Merino-Gergichevich *et al.*, 2010), especially on the leaves, about which little is known. Today, there is growing evidence of the negative impact of aluminum on the light absorption, photosynthetic electron transport, gas exchange (Chen *et al.*, 2005a; Chen *et al.*, 2005b; Chen, 2006), photoprotective systems (Chen *et al.*, 2005a; Ali *et al.*, 2008), pigments (Chen *et al.*, 2005a; Mihailovic *et al.*, 2008; Milivojević *et al.*, 2000), as well as on other elements related to the structure or function of the photosynthetic apparatus. In addition to the direct effect, Al also affects plants indirectly, in such a way that aluminum ions, among other things, block the adsorption of phosphorus and potassium, thus disrupting the growth and development of crops (Zheng, 2010). The availability of microelements in different soils, apart from the presence of phosphorus and organic matter, is significantly conditioned by their pH value (Wei *et al.*, 2006; Asadu *et al.*, 2014). Thus, the availability of micronutrients

and toxic ions, as cations (e.g. Al^{3+}, Fe^{3+}, Mn^{2+}), increases with an increase of soil acidity (Porter *et al.*, 2004; Khabaz-Saberi and Rengel, 2010). After Al, an excess of Mn is the greatest factor of limited plant growth on acid soils (Rengel, 2000). Like Al, when manganese reaches the level of toxicity, it also limits the growth and function of plant roots, reduces the absorption of nutrients and water. Liming acid soils is one of the key measures that can preserve or increase their productivity (Mao *et al.*, 2008). That is why this research aimed to, by applying different levels of liming on Dystric Cambisol in the year of application, define their effect on the rate of change of acidity, the content of mobile Al, and some micronutrients (Fe, Zn, Cu) as important factors in fertility.

Material and Methods

The research was conducted in 2010 and 2011 on an experimental field near the town of Leposavic (43^0 16' N; 20^0 36' E), belonging to the southern and central part of the Ibar-Kopaonik region, and located in southwestern Serbia. Leposavic is located at an altitude of 545 m, and is characterized by a temperate continental climate. The soil on which the research was performed belonged to the Dystric Cambisol type. CaO of high degree of fineness was used for liming. In both years, the material was applied in September, more precisely before basic processing, by being properly distributed over the surface and entered into the soil by plowing. The applied rates of CaO were calculated according to the value of Y1 in the soil and the size of the experimental site (50 m^2). Three variants of liming were determined and applied: 1/3 Y1 CaO (V-3), 1/2 Y1 CaO (V-4), and Y1 CaO (V-5); as well as two variants without liming: the version with only the application of NPK (V-2), and the version without liming and fertilizer application – control (V-1). Fertilizers were also applied in the versions where liming was performed. In all cases, the doses of active compounds of nitrogen, phosphorus, and potassium were for N 120 kg ha^{-1}, and for P and K per 90 kg ha^{-1}. Fertilization was performed according to the standard technology for the wheat production. The experiment was set up as a random complete block design (RCBD) in four replications. The size of the base experimental site was 50 m^2, and the crop was wheat, Pobeda cultivar. In both years of research, during the stage of wheat tillering (T), 5 months since the liming and after the harvest (A. H.), 10 months since the liming, the pH was determined on a pH meter with a glass electrode in a 1: 2.5 suspension with water and 1 M KCl. At the same time, the content of exchangeable or mobile Al was determined by using Sokolov's method on a soil extract with 1M KCl by first determining the total substitutional acidity, and then by a deposition of aluminum with NaF and the share of Al^{3+} in the formation of substitutional acidity. Hydrolytic acidity, that is, Y1, was determined only after the harvest and by Kappen's method by treating a soil sample with $(CH_3COO)_2Ca$, and then the neutralization of excess acid was performed with 0.1 M NaOH. The content of available forms of soil microelements (Fe, Cu, and Zn) was determined by atomic absorption spectrophotometry. Germany. The content of available Fe was determined after the extraction into a solution of 1M CH_3COONH_4 (pH 7) in the stage of wheat tillering (T) and after the harvest (A.H.), and for the available Cu and Zn, only after the harvest, upon the extraction (A.H.) in 0.1 M HCl.
Statistical analyses were performed on SPSS software, variant 16. The effects of the treatment on all variants were tested by ANOVA. Statistical differences between the treatments were determined by using the t-test (95 and 99%) by Pearson for Fisher's LSD (SPSS, 2007).

Results and Discussion

The effect of three levels of liming on active, substitutional, and hydrolytic acidity has been in accordance with the applied dose of CaO (Table 1), the highest in the variants with complete liming (V-5), and the lowest in partial liming (V-3). The soil quickly reacted to entered CaO, and changes were obvious and complete already at the first check, 5 months after liming, i.e.

in the stage of wheat tillering. The differences between the treatments where CaO has not been used (V-1 and V-2) and the treatments in which CaO has been used (V-3, V-4, and V-5) are highly significant. The differences between the variants in which liming has been performed can clearly be observed. All the differences are highly significant ($p < 0.01$), except for the changes in active acidity in the tillering stage (T) in 2010, when a difference in the level of statistical significance ($p < 0.05$) has been found between the first (V-3) and the second level (V-4) of partial liming.

The resulting changes, both in active and substitutional acidity, are in favor of the claims of the need for liming acid soils (Busari *et al.,* 2008; Jelić *et al.,* 2011; Mao *et al.,* 2008), in order to perform the neutralization and create favorable conditions for smooth growth and development of plants. It particularly refers to a group of plants that are insufficiently tolerant to soil acidity. The observed changes in pH during one growing season should be emphasized. Namely, in the period between the first (tillering stage) and the second checks (after the harvest), there was a small decline in pH. This trend was expected because numerous processes in the soil, primarily flushing, as well as the adoption of Ca by the plants, led to losses of liming material, which inevitably led to a decrease in pH. For this reason, it is often talked about a time-limited (fixed-term) effect of this measure, which has to be repeated after a while for these reasons. Since the problem with acidity cannot be definitely resolved, a practical approach consisting of a regular application of moderate amounts of lime material, with which soil acidity would be maintained at an acceptable level, is completely acceptable (Garscho and Parker, 2001). The content of mobile Al^{3+}, in both years of research, was strongly changed in all the variants where CaO was applied (Table 2). Thus, trace aluminum content was found in the first measuring, in the stage of wheat tillering, in the complete liming variant. According to the results of other authors, liming had the same effect on other soil types, such as pseudogley (Jelić *et al.,* 2011; Pivić *et al.,* 2011).

Lsd 0,01	0.497	0.398	0.497	0.104

At the same time, also in the variants of partial (V-3) and particularly half-liming, the content of mobile aluminum was reduced to a level at which the risk of its toxic effect on the crops was significantly reduced. In V-3 and V-4 variants, a slight increase in the content of mobile Al was found during the growing season.

Despite an obvious improvement in the reaction of Dystric Cambisol, liming has not had a major effect on the content of available forms of Fe and Cu (Table 3). Namely, the content of Cu per variants, in both years of research, has not indicated any effect of entrained lime material, and the differences between the liming treatment and the control variant are not statistically significant. On the other hand, the content of Fe in the tillering stage, in the part of the experiment when amelioration was performed, did not sufficiently clearly indicate the real impact of lime. In particular, it was because the differences, in the part of the experiment when liming was performed and in the part without liming, almost entirely disappeared when the content of the element was measured after the wheat harvest. The observed difference in available Fe concentration during the growing season was most likely the result of changes in oxidation-reduction conditions, on which numerous processes that transform Fe into available forms and vice versa depend.

Table 3. The changes in the content of available forms of Fe, Zn, and Cu (mg kg^{-1}) after liming

Variants	Fe				Zn		Cu	
	2010		2011		2010	2011	2010	2011
	T	AH	T	AH

V-5	14.50	10.78	30.60	19.55	2.95	2.55	2.55	3.62
Lsd 0.05	3.49	3.89	3.90	1.99	0.39	0.18	0.46	0.13
Lsd 0,01	5.01	5.59	5.61	2.86	0.56	0.26	0.66	0.19

The effect of liming has been observed only on the content of available Zn. Namely, lime material and an increase of pH have caused a decrease in the amount of available forms of this element. The differences of all the variants with liming, in both years of research, have been highly significant ($p < 0.01$) as compared to the control variant. Also, the amount of applied lime material has had an effect on the content of Zn. Thus, the lowest content, in both years, has been found in the variant where complete liming was applied (V-5), and the differences compared to the other two levels of liming (V-3 and V-4) had a statistical significance only in 2011. There is no complete consensus regarding the concentrations of mobile fractions of Zn after liming, so there are opinions that it is being reduced, or that the entered lime does not influence its content (Bošković-Rakočević and Bokan, 2005).

Conclusions

Liming has caused significant changes in Dystric Cambisol, and the changes were rapid and in proportion to the rates of applied CaO. Soon after the introduction, already in the stage of tillering, a decrease in acidity and in the content of mobile aluminum occurred, and of the analyzed microelements, only Zn reacted to entered lime material in such a manner that the content of its available forms was reduced. The degree of achieved changes was adequate to the level of applied liming. Complete liming almost completely neutralized the acid reaction, in traces it brought the content of mobile Al, but it also significantly reduced the availability of Zn, thus jeopardizing the regular supply of plants with this microelement. On the other hand, the level of changes caused by partial (1/3 Y_1) and half-liming (1/2 Y_1) has justified and

promoted these levels of acid soil repairing. The main benefits of lower levels of liming are lower investments in liming material, satisfactory pH neutralization, a reduction in mobile Al below the toxicity level and a lower risk of bringing some microelements to the deficit limits, which is of great ecological and economic importance.

THE CONTENT OF TRACE ELEMENTS IN ALFALFA CULTIVATED ALONG THE HIGHWAY E75 - ROUTE SECTION LOZOVIK-GRDELICA (REPUBLIC OF SERBIA)

Radmila PIVIĆ*, Zoran DINIĆ, Jelena MAKSIMOVIĆ, Milan PEŠIĆ, Sonja TOŠIĆ, Aleksandra STANOJKOVIĆ-SEBIĆ

Abstract

On the section of the highway E75 through Republic of Serbia from Lozovik to Grdelica, the content of trace elements in soils and alfalfa cultivated on Vertisol Eutric cambisol and Fluvisol was studied. The content of Pb, Ni, Cr and Cd were determined in soil and plant material. In all tested soil samples the content of trace elements was below the MPL (maximum permissible levels) values for agricultural soil. The content of analyzed elements in the samples of alfalfa varied depending on the pH value, the content of clay fractions and organic matter in soil on which it was cultivated. The obtained results showed that the values of trace elements in plant species of alfalfa were not above the toxic concentrations values (TC). The content of studied elements in plant material was increased in the soils with lighter texture probably because of the pH value, content of clay fractions and organic matter in soil contributing to their binding, indicating that the soil-plant translocation was affected by the physical and chemical properties of the soil, the location of accumulation as well as the physiology of plant.

Introduction

One of the basic factors of economic growth, certainly, is the developed road infrastructure which implies the existence of high frequency traffic. The E 75 motorway is one of such roads and through the territory of the Republic of Serbia it passes through zones where intensive agricultural production has been developed. It is important to examine the possible impact of the highway on the potential pollution, because of the location on which it is located, both on agricultural land and on cultivated plants along the motorway. The research covered the section of E 75 motorway from Lozovik to Grdelica. During 2010, samples of agricultural land and alfalfa were collected on land such as Eutric cambisol, Fluvisol and Vertisol, on parcels that are 10, 30, 50 and 400 m from the route of the motorway. A large number of authors (Wilson and Pyatt, 2007, Jankievicz and Adamczyk, 2010, Deska et al., 2011) lists data on potential soil contamination by heavy metals, one of the major causes of which is anthropogenic impact, which can be due to emission of exhaust gases, grease, oil and tire residues that are present along the motorway. Environmental risk assessment of soil contamination is particularly important for agricultural areas, due to the fact that heavy metals potentially harmful to human health exist in the soil and can be transferred in significant quantities to the food chain (Szynkowska et al., 2009). High concentrations of trace elements in soil can affect the soil's fertility and may represent an ecological and human health risk if they enter the food chain or leach into receiving waters (Daskalopoulou et al., 2014, Dinić et al., 2018). The mobility of the trace elements and their translocation in the plant are influenced by the content of the clay fraction, organic matter and pH value of soil (Dinić et al., 2018). In a pH range of soil from 5.50 to 8.00 the chromium (Cr) is almost insoluble, while the solubility of cadmium (Cd) decreases with increasing pH values so that at pH>7.50 comes to Cd immobilization (Kabata-Pendias, 2011). In soils with pH (1 M KCl) values from

3.80 to 7.10, Cd is less mobile than Ni (Adriano, 2001). The content of organic matter in the soil does not significantly affect the Cr and Ni mobility, while the mobility of Pb is equally affected by the content of clay and organic matter (The Dutch Environment Ministry, 2009). Assessment of plant bio-concentration factor, Soil-to-Plant bio-concentration factor (Biological Concentration Factor) is one of the ways to evaluate and monitor the translocation of trace elements from soil to plant. With increasing clay content, organic matter and increasing soil pH, BCF for Cd, Cr, Pb and Ni is decreasing. The largest reduction in the coefficient is for Ni (80 times) and at least for Cd (16 times). When assessing pH values for: pH less than 5.5; in the range of 5.5 to 6.5 and greater than 6.5; for the content of the clay fraction: less than 15%; from 15% to 40% and more than 40%; and for organic carbon content (SOC): less than 1%; from 1% to 3% and greater than 3% (Versluijs et al., 1998). Biological Concentration Factor (BCF) values for alfalfa range in a wide range and depend on agro-ecological conditions (McKone and Maddalena, 2007; Al-Rashdia and Sulaimanb, 2013; Solgi et al., 2017).

Material and

Sampling of soil and above-ground part of alfalfa plant material was carried out on the section of E75 from Lozovik to Grdelica during the vegetation period in August and September 2010., based on the coordinates of the sampling site registered with the GPS device, using the data from the pedological map of the Republic of Serbia (Institute of Soil Science, 2013). The locations of the soil type Vertisol, Eutric cambisol and Fluvisol (Škorić et al., 1985, Group of authors 2011, WRB, 2015) were determined, from which a plant species, alfalfa was sampled and studied. Soil and plant sampling spots in the section of the study with corresponding distances and coordinates presented in Table 1.

Eleven soil samples in the disturbed state were sampled to a depth of 30 cm at a different distance from the highway, at 10, 30, 50 and 400 m from the road lanes. The alfalfa plant material, the above-ground part was sampled, with the remark that the year in which it was planted was not recorded. The average sample consisted of 15 to 20 individual samples, whereby the cut was carried out by hand cutting at a height of 3-5 cm of the plant.

In 11 composite soil samples prepared in accordance with SRPS ISO 11464: 2004 - Pretreatment of samples for physical-chemical analyzes, sieved through a sieve of 2 mm in diameter. Soil acidity (pH in H_2O and 1M KCl, v/v - soil:H_2O = 1:5, soil:1M KCl = 1:5) was analyzed potentiometrically, using glass electrode (SRPS ISO 10390, 2007), calcium

carbonate by volumetric method SRPS ISO 10693: 2005-Determination of carbonate content, total contents C was analyzed on elemental CNS analyzer Vario EL III (Nelson et al., 1996). SOM (soil organic matter) was calculated using the formula: SOM content (%) = organic C content (%) x factor 1.724 in carbonless soil samples, ie SOM content (%) = (organic C content (%) - 0.12 x% CaCO3) x factor 1.724 for carbonate soil samples (Džamić et al., 1996). Granulometric composition was analyzed by determination of particle size distribution in mineral soil material, using the standardized method by sieving and sedimentation (ISO 11277: 2009(E), 2009); according to granulometric composition the texture class was determined (ISSS, Baize (1993)).; determination of the total trace elements forms (Cd, Cr, Ni and Pb) was done by inductively coupled plasma-atomic emission spectrometry - THERMO iCAP 6300 Duo (radial/axial view versions) ICP-OES, after the digestion of the samples with aqua regia (ISO 11466:1995, 1995; ISO 22036:2008, 2008). Reference soils NCS ZC 73005, Soil Certificate of Certified Reference Materials approved by China National Analysis Center Beijing China, and reagent blanks were used as the quality assurance and quality control (QA/QC) samples during the analysis. The samples of plant material are air-dried and milled. The sampled plant material were dried at 105^{o}C for a period of 2 hours, using gravimetric method for determination of dry matter contents of plant tissues (Miller, 1998). The analysis of the plant material included the determination of Cd, Cr, Ni and Pb using THERMO iCAP 6300 Duo (radial/axial view versions) ICP-OES after the digestion of the plant samples with concentrated HNO_3 and redox reaction with 30% H_2O_2 for total forms extraction (Soltanpour et al., 1996). The results of the conducted soil analyze represent the arithmetic means of three replicates of each sampling.

Results and discussion

Alfalfa (*Medicago sativa* L.) is a perennial leguminous crop, which is regarded as the leading and most important forage crop for the production of high quality feed, and is used in the fresh state and conserved as well as hay, haylage, silage, meal, pellets and pasta (Vučković, 2004; Jakšić et al., 2013, Pivić et al., 2017). Alfalfa was grown on the following soil types Vertisole, Eutric Cambisole and Fluvisol (WRB, 2015). Some of the properties of these types of land are shown below (Glamočlija et al., 2013).

Vertisols are soils with unfavorable water-air and thermal regime, and some of their properties are the characteristics of hydrogen soils (formed on the substrates containing more than 30% of clay predominantly montmorilonite type). It swells in a wet state, and in dry cracks with the formation of cracks that can reach one meter in depth. The chemical properties of these soils are considerably more favorable. They are characterized by neutral to low alkaline reaction with high adsorption capacity. Base saturation is up to 90%. Humus, total nitrogen is easily accessible. These types of soils in terms of benefits for plant production belongs to the third rating class

Eutric cambisol is formed on different geological substrates. These are mostly medium heavy soils, with clearly expressed texture differentiation within the profile. The humus accumulation horizon is characterized by a very favorable water-air regime, as a result of favorable ratio of large, medium and fine pore. The chemical properties vary depending on the intensity of use, the degree of erosion, the chemical properties of the parent substrate and the degree of development. There are no carbonates and there is low acid reaction. Humus is medium-sized (in the interval from 2 to 5%). It is settled in soils of high ecological and production value. Regarding the benefits and limitations of plant production, Eutric cambisol belongs to second rating class of soils.

Fluvisol-similar soils are formed by transport and deposition of materials in river valleys during floods. The composition and stratification of alluvial varies considerably depending on the water regime of the watercourse, relief, geological substrate and soil. They differ in

mechanical composition, and the differences are accompanied by the mineral composition. These are layered recent river or lake deposits in which the sedimentation process plays a greater role than the genetic development of the soil. These are very fertile soils of a carbonate or neutral reaction. The humus content varies from low to high content. These soils have medium to high content of basic nutrients. They belong to a third rating class that includes soils used for plant production, but with certain limitations. The reaction of the tested soil was from acid to alkaline (pH in 1M KCl 4.90-7.30), according to the carbonate content, no calcareous to medium carbonate (IGDM-7.11), with medium to high organic matter content, SOM (1.65% -6.01%). The physical and chemical properties of the soil samples tested are shown in Table 2.

The interpretation of data on the trace elements content in soil samples was done according to the Rule book of maximum permissible levels (MPL) of dangerous and hazardous materials in soil and water for irrigation and methods for analysis (Official Gazette of Republic of Serbia, 1994), where MPL for Cd is 3 mg kg^{-1}, MAC for Cr is 100 mg kg^{-1}, MAC for Ni is 50 mg kg^{-1} and MPL for Pb is 100 mg kg^{-1}. In the tested soil samples, the trace element content is within the limits of MPL (Table 3).

Table 3. The content trace elements in soil samples

The interpretation of data on the trace elements content in the samples of forage crops was done according to the reference data on toxic concentration (TC), where TC for Cd is 1 mg kg^{-1}, TC for Cr is 5 mg kg^{-1}, TC for Ni is 50 mg kg^{-1} and TC for Pb is 40 mg kg^{-1} (Adams, 1975; Kloke et al., 1984; Kisić, 2012). The results of the conducted plant material analyzes are shown in Table 4.

BLMD - below the limit of the method detection

The content of Cr in plants varies and depends largely on the geological substrate. The source of Cr is also a significant factor that affects the solubility and availability of these elements (Adams, 1975; Kloke et al., 1984; Kastori et al., 1997; NRC, 2005). The content of Cr in the samples tested ranges from 0.64 to 4.89 mg kg^{-1}, which is below the toxic values.

Cd is one of the most toxic and harmful elements that adversely affects soil biological activity, plant metabolism and human and animal health. It is easily absorbed through the root system and accumulated in the aboveground plant parts. The pH of the soil solution is cited as the main factor in the adoption of Cd. The origin of Cd is also an important factor that affects the solubility and availability of this element. The content of Cd in the tested samples of plant material ranges in the range of normal values (up to 1 mg kg^{-1}).

The Ni content in the tested plant parts of alfalfa, also is below toxic levels (50 mg kg^{-1}) in all the analyzed samples, ranging in the range of from 2.15 to 28.92 mg kg^{-1}.

Pb is the least mobile element among the microelements of the soil (Kabata-Pendias, 2011). Pb is poorly adopted and transferred to the above-ground organisms of the plant, except on acidic soils. Plants can accumulate Pb either from the soil or absorbed from the air. Most of the Pb from the soil is not available to plants. Non-oganic Pb forms become accessible to plants only in acidic soils (Wiklander and Vahtras, 1977). Pb originating from the air is the main source of pollution by this element. According to some studies, about 95% of the total amount of lead in the plant can be originated from the air. In all tested samples, the Pb content is below the toxic values (40 mg kg^{-1}) and ranges from 0.11-10.84 mg kg^{-1}.

Conclusion

By analyzing the obtained results of the study of the content of trace elements (Cd, Cr, Ni, Pb) and their concentration in the plant material of the above-ground part of the alfalfa along the E75 from Lozovik to Grdelica, it is determined that content of trace elements are within tolerant values below the toxic for plant material. In the case of the soil sample at location D19 at a distance of 30 m from the traffic lane, compared to other sample tests, the content of

the total forms Cd, Cr, Ni, Pb is the closest to the maximum permissible levels. In the plant sample from this site, there was no increased translocation in the plant material of the examined elements, which is probably due to the neutral reaction (pH in 1M KCl is 6.52). In this sample the content of the clay fraction was determined from 23.6%, which is within the usual range, and the content of SOM is 4.30%, which is below the usual range (according to The Dutch Environment Ministry, 2009).

At the location L39 at a distance of 50 m from the motorway, in the soil zones with the lowest value of the medium reaction (pH in 1M KCl is 4.90), with the content of the clay fraction of 13.4% and the SOM of 2.17%, an increase in the values of Cr, Pb in plant material, but still below the toxic concentration . These results confirm the assumption and point to the conclusion that when interpreting the translocation of elements in traces from the soil to the plant material it is necessary to determine the content of the clay fraction, the content of the organic matter and the reaction of the environment, because only in this way full data can be obtained and the obtained results can be interpreted.

Abstract

Serbia is characterized by a high level of genetic diversity and cultivated plant species which are used as food amount to 4.5% of used biodiversity (193 species). Plant genetic resources (PGR) can be used in breeding programs as a source of specific genes for the development of new varieties, adapted to the new environmental conditions and to expand the genetic base of breeding material, as well as food, in food industry. The paper presents the activities involving the conservation, management and utilization of Plant Genetic Resources for Food and Agriculture (PGRFA), and state of PGR in Serbia. What is the exact number of PGR in Serbia is not known precisely because there is no national inventory of PGR. It is estimated that about 25.000 samples of old landraces and cultivated plants are stored in the form of seeds and about 3.500 samples of fruit and vines are in *ex situ* collections. In Serbia, there are around 20 collections at the National Gene Bank and in institutes. The National Plant Gene Bank have 4.300 samples of 249 plant species: cereals and maize (2.983 sample-7 types), industrial crops (387 samples - 6 types), vegetables (214 samples - 11 types), fodder crops (285 samples - 9 species), medicinal and aromatic plants (389 samples - 216 species). In order to preserve genetic resources it is necessary to plan management activities and efficient and directed usage.

Keywords: *plant genetic resources, conservation, management, Serbia.*

Introduction

Our ancestors collected and started growing certain plants 10.000 years ago, which led to the domestication of almost all agricultural species that are in use today. About 7.000-10.000 different plant species have been cultivated, which accounts 3-4% of plant biodiversity (Hammer, 1995). At the beginning of the 20th century, Russian botanist Vavilov traveled around the world and noticed that the diversity within the agricultural plant species was not evenly distributed. He identified eight centers of diversification of cultivated plant species (Vavilov, 1992). Today, the world's largest plant gene banks are located in those centers of origin. FAO (Food and Agriculture Organization of the United Nations) has collected and kept information on plant expeditions since 1948, has prepared plant catalogs and oversees the collection of plant germplasm around the world. Today there are 1 750 individual genebanks worldwide, that have been established with the goal of collecting and conserving plant genetic resources (FAO, 2010).

Serbia is characterized by a high level of genetic diversity. The Serbia's flora contains about 4.300 species from a total of 11.000 plant species in Europe (Stevanović and Vasić, 1995). Cultivated plant species (193 species) used as food constitute only 4.5% of biodiversity (Prodanović et al., 2015). A significant part of the diversity of the species consists of local populations and old varieties.

According to the European Cooperative Program for Plant Genetic Resources (ECPGR), PGRFA are grouped into eight groups: cereals, fodder crops, vegetables, grain legumes, fruits, alternative plants, industrial plants and potatoes (http://www.ecpgr.cgiar.org). The number of plant genetic resources (PGR) has a tendency of continuous decline, agricultural varieties rich in diversity cease to be cultivated in certain regions, replaced by new uniform varieties and

hybrids that have higher market value and are adapted to modern agricultural practice. In order to preserve genetic resources, it is necessary to manage them in a planned and efficient manner and to be targeted use.
The paper presents an overview of activities that include the preservation, management and utilization of PGRFA, as well as their state in Serbia.

Collecting of plant genetic resources for food and agriculture

The main objective of collecting PGR is to include the maximum amount of genetic variation in the minimum number of samples. Collecting samples is primarily related to scientific expeditions for collecting and sampling, and then keeping them at certain conditions.
During the 20th century, several research missions were conducted around the world. Collecting of plants has a long tradition in Serbia: Josif Pančić has visited Kopaonik 16 times between 1851 and 1886 and has discovered many plant species, the most important being the discovery of spruce *Picea omorika* (Pančić) *Purkyne*.
After the Second World War, especially during the period from the 1960s to the end of the 1980s, numerous expeditions in former Yugoslavia were conducted in order to collect autochthonous genotypes. Collecting missions were organized for maize (Anđelković and Ignjatović Micić, 2012), fodder crops (Tomić et al., 2010), vegetables (Sabadoš et al., 2008), fruits (Keserović et al., 2007). Additional expeditions directed to maize and cereals were carried out in 2006-2010. within the SEEDNet (South Eastern European Development Network on Plant Genetic Resources) program in order to collect autochthonous, local populations and old varieties (Simeonovska et al., 2013).

Conservation of genetic resources

Plant genetic resources are held by conservation *in situ*, *on farm* and *ex situ*.
In situ conservation is applied for the preservation of autochthonous and old types of cultivated plants in their regions of origin or similar areas with favorable agroecological conditions.
By *on farm* conservation is possible to maintain the genetic diversity of locally developed populations in traditional farming systems, usually on farmers' fields.
Ex situ conservation is preservation of biological diversity outside natural habitats, includes botanical gardens, greenhouses and gene banks.
Herbal genetic resources are stored as seeds in gene banks, vegetative material *in vivo* as part of the plant (fruits and vines) or *in vitro* in tissue culture, and DNA material usually at -80°C or in DNA libraries.
Dominant strategy worldwide is *ex situ* conservation, with genetic resources of plants for food and agriculture of about 6 million accessions. Consultative Group on International Agricultural Research (CGIAR) has the largest collection of agricultural plants in the world of about 741.000 samples. About 45% of all accessions in the world's banks are cereals, followed by legumes with about 15%, vegetables with 10%, fodder plants 10%, fruits 6-9%, oils and fibers with 2-3% (FAO, 2010).
The precise number of PGRs in Serbia is not known, but it is estimated that about 25.000 samples of varieties, old and local populations are in the form of seeds. Out of them, the largest part belong to cereals (10.208 accessions, Table 1), then 5806 are maize accessions, 3569 vegetable accessions, 3323 samples of industrial crops, and 2375 samples of fodder crops. Also, about 3.500 fruit and vine samples are in *ex situ* collections (Drinic and Ivanov, 2017). The collections are mainly stored at the institutes and faculties.

Table 1. Number of *ex situ* samples of important crops in world and Serbia

Species	World	Serbia

Sunflower	29 500	696
Sugar beet	24 000	390

In situ preservation mainly refer to the maintenance of wild relatives, since Balkan Peninsula and Serbia could be considered as secondary diversity center for some cereals, vegetables, fodder crops and fruit and vine trees.

On farm (on farmers' fields) in Serbia over 2.000 autochthonous and local populations of plants are grown nowadays. Most of them, predominantly cereals, are evaluated and characterized, and stored in seed bank. The number of fodder crops, medical plants and wild relatives are difficult to estimate, since they could be found both, in *in situ* and *on farm* conditions. Production of old varieties is not economical for farmers without significant financial support from the state. Exceptions are fruit and vine trees that are kept mainly with low maintenance costs, and local populations with specific properties, or for organic production, interesting for the market (Prodanović et al., 2015).

Management and utilization of plant genetic resources

Gene banks play an important role in the long-term preservation of PGRFA. However, in addition to conservation, they collect information about the material they store, which allows users to choose the most suitable genotypes for research.

Types of collections in gene banks are:

1. **Basic collection -** collection of samples and vegetative parts that are stored at -20°C, which ensures long-term sustainability of the material (more than 50 years)
2. **Active collection -** parts of the basic collections (also called working collection), regularly regenerated in the field, and which are immediately available for distribution, usage, multiplication, exchange and evaluation. They are stored at 4°C and 20-30% of relative air humidity, under conditions that ensure that the sample's viability remains above 65% for medium-term sustainability (10-20 years).
3. **Core collection -** contains representative samples, or subgroups that make about 10% of the entire collection but preserve its diversity.
4. **Duplicate collections -** are created when one institution sends samples from its collection to be stored in another institute, so the same samples are held in two places.
5. **Gen collections -** contain genotypes with specific traits of interest for research and development.

Local populations, genetically heterogeneous and adapted to specific local conditions, are a valuable source of gene for drought tolerance, salinity, high temperature, disease resistance or improved grain quality (Drinic et al., 2012). But breeding based on genetic resources is long-term, and opposit to the market demands for development of high yieldig commercial varietes for a short time. Today, genetic resources are valuable for genetic and biotechnological research, e.g. molecular characterization of autochthonous varieties and wild relatives and the

application of genomics can identify a number of genes and specific DNA sequences for desired properties that can be transferred to modern varieties by molecular breeding or genetic engineering.

Therewith PGRFA are increasingly important globally due to the crucial role in the context of climate change, human population increase, and secure food production. In the Svalbard archipelago between Norway and the North Pole, Svalbard Global Seed Vault was set up. It is an object built by the Norwegian Government designed to withstand every test, natural accidents and disasters caused by humans. About 4.5 million seed samples could be stored in it, and so far there are about 780.000 samples of 840 species. The purpose is to preserve seeds and vegetative parts of plants for future mankind's needs, as sources of genes and food (www.croptrust.org).

Plant Genetic Resources for Food and Agriculture in Serbia

Serbia is one of the most important areas of biodiversity in Europe. Wild relatives of cultivated plants, about 1.000 species in Serbia, are found in nature, and a smaller number is stored in germplasm collections. In Serbia, 193 types of plants are used for food and commercial agricultural production, divided into the following groups: cereals (12 species), industrial plants (19 species), fodder plants (43 species), vegetables (71 species), fruit and vines (48 species). Besides, more than 400 types of medicinal plants are officially registered (Ivanov et al., 2012).

The samples of the National Collection of Plant Genetic Resources were officially transferred to the cold rooms of Plant Gene Bank (PGB) on March 31. 2015, where all technical conditions for medium-term storage at + 4°C and long-term storage at -20°C were obtained. In this way, PGB of Serbia was activated, after more than 20 years since the facilities for the needs of the former Yugoslavia PGB were built.

There are 4.300 samples of 249 plant species in the PGB: cereals and maize (2.983 samples - 7 species), industrial plants (387 samples - 6 species), vegetables (214 samples - 11 species), fodder crops (285 samples – 9 species), medicinal and aromatic plants (389 samples - 216 species). Most of the accessions are characterized according to IPGRI/ECPGR descriptors for particular crop.

Draft of National Program for the Preservation and Sustainable Use of BGRHP in Serbia was prepared by the Special Working Group, according to the decision of the Ministry of Agriculture, and with the help of the FAO technical support project. The National Program for the Conservation and Sustainable Use of Plant Genetic Resources has been written in accordance with the stated programs and strategies, as well as with the Constitution of the Republic of Serbia. This is a strategy document describing the current state, outlining goals and proposing measures related to the conservation, use and development of plant genetic resources for food and agriculture. It is intended for numerous users: breeders, agricultural producers, researchers, gene bank, institutes and faculties, governmental and non-governmental organizations, various organizations and individuals, as well as farmers who conserve and use plant genetic resources, which require a stable and predictable policy in this area. It is written in accordance with international conventions, first of all with the Convention on Biological Diversity, the International Convention on Plant Genetic Resources for Food and Agriculture and the Global Action Plan for the Conservation and Sustainable Use of PGRFA (Drinic and Ivanov, 2017).

Conclusions

The issue of preservation of plant genetic resources is of particular importance due to the global climate change, the emergence of new diseases and pests, secure food production and the conservation of biodiversity. Local populations, old varieties and wild relatives represent

an necessary resource for securing progress in plant breeding and sustainable global food production of good quality and in sufficient quantities for today's and future human needs. Serbia is rich in biodiversity, and has about 25.000 accessions in *ex situ* collections in genebanks, mostly in research institutes. *In situ* and *on farm* conservation is applied mainly on fodder crops and medical plants and on some varieties that are interesting for the market nowadays (e.g. growing demand for organic production). Our state's representatives are involved in all international institutions responsible for the preservation, management and utilization of plant genetic resources, and all obligations in terms of biodiversity conservation are implemented through activities in institutions dealing with genetic resources.

Abstract

Large quantities of food waste (FW) are emerging as a result of the increased production in the food industry, which often processes agricultural products. Reduction and utilization of FW is important not only for food security but also for the sustainable use of resources. The slow progress of reducing FW and developing effective waste management strategies can be a problem for almost every country. FW contains complex carbohydrates, proteins, lipids and nutraceuticals, and can be a source of raw materials for commercially important metabolites. The wastes generated during the food supply chain can be used to produce nanoparticles between biofuels, enzymes, bioactive compounds, biodegradable plastics and many other molecules. The utilization of FW for agricultural applications such as animal feed and fertilizer is a common waste management practice. These two waste management practices focus on the reuse and recovery of valuable components in the FW. However, the FWs obtained from different sources involve rich nutrients is accompanied by the risk of unbalanced nutrient composition and the risk of toxic substance presence as well. Topics are up-to-date in Turkey as well as on a global scale. Alternative utilization methods can bring risks as well as opportunities. Many countries are prohibiting or limiting, in particular, some animal feed production, by their legislations on the reduction of FWs. Increasing opportunities for fertilizer production continue with value-added practices. In this study the current situation in Turkey regarding the use of FW as animal feed and fertilizer has been examined. Moreover, the needs and challenges were evaluated by considering the practice in other countries.

Keywords: *Food waste, feed, fertilizer, Turkey*

Introduction

Along with the increase in the production of agricultural and food products, food losses (FL) and waste also reach large quantities. Definitions of FL and FW are not universally agreed upon, which makes studying FW difficult. Multiple terms have been used interchangeably, such as FL, FW, bio-waste, and kitchen waste. Also, often the same terms are used, but with different meanings (Thyberg and Tonjes, 2016). The Food and Agriculture Organization of the United Nations (FAO) defined FW as food appropriate for human consumption that is discarded (generally at retail and consumption stages) (FAO, 2013). FL and FW are often used in scientific literature to identify materials intended for human consumption that are subsequently discharged, lost, degraded or contaminated. Discharge of food material occurs along the entire Food Supply Chain (FSC) (Girotto et al.,2015). FW can also be defined as the outlets of the food industry, which are not currently used for defined end-products, not recycled or used in an alternative manner (Du, et al., 2018).

According to the FAO report "Global Food Losses and Food Waste", 95 percent of FL in developing countries occur "unintentionally" in the early stages of the supply chain (FAO, 2011). These losses refer to financial, administrative and technical limitations in harvesting techniques, transportation, storage and cooling, public infrastructure, means of transport, packaging and distribution systems. In developed countries, FW can be observed mostly at

retail and consumption stages. In these countries, roughly one-third of purchased food is wasted as household waste (Gustavsson et al., 2011; Premanandh, 2011; Prusky, 2011; Dorward, 2012; Wang, 2013). According to this approach, the difference between FL and FW is related to the phase in which the food supply chain has emerged. FL takes places at production, postharvest, processing and distribution stages of food supply chain, FW happens at retail and consumption (FAO, 2014). In this study, each stage of the food supply chain is considered together for wastage used in fertilizer and animal feed production.

Reducing FL and FW is considered to be one of the most promising measures to improve food security in the coming decades (Kummu et al., 2012; Demirbaş et al., 2017) and many international and nongovernmental organizations see reducing FL and waste as a priority for reducing global hunger and resource waste (Koester, 2014). At the same time, FW has been caused serious environmental issues, such as generating greenhouse gases and occupying land resources. With the increasing awareness of the problems associated with FW, different the FW management strategies have been improved (Du, et al., 2018). Some of these FW management alternatives are waste prevention, landfilling and incineration. In this study, animal feed and fertilizer production, which include FW management alternatives are evaluated for Turkey.

Generation stages of food waste

Discharge of food material occurs through the entire Food Supply Chain (FSC) and it involves all sectors of waste management from collection to disposal. A FSC initiates with the production of food from the agricultural sector where both farming and husbandry produce waste or by products that may be either organic waste, FW or FL (i.e. low quality fruits, damaged productions left in the field, good products or by-products with inferior commercial value). The food processing and manufacturing industry produces FL and FW throughout the entire production stage due to the following reasons: damage during transport or inappropriate transport systems, problems during storage, losses during processing or contamination, inappropriate packaging. The retail system and markets also generate FL and FW, largely due to problems in conservation or handling, and lack of cooling/ cold storage (Parfitt et al., 2010). The generation of FW by the end consumer is caused by over- or inappropriate purchasing, bad storage conditions, over-preparation, portioning and cooking as well as confusion between the terms ''best before'' or ''use by'' dates (Papargyropoulou et al., 2014). The main causes of FL and waste in low-income countries appear to be linked to financial, managerial and technical limitations in harvesting techniques, storage and cooling facilities in harsh climatic conditions, infrastructure, packaging and marketing systems. On the other hand the source of FL and waste in medium/high-income countries is due to consumer behavior as well as to a lack of coordination between the process stages in the supply chain.

The retail system may lead to the generation of FW throughout various process stages of food distribution and purchase i.e. damage during transport or non-appropriate transport systems, problems during storage, losses during processing or contamination, inappropriate packaging, problems in conservation or handling, lack of cooling/cold storage. The food supply chain is also affected by loss of products reaching their expiry date (Aiello et al., 2014).

The strategies applied in food waste management

The main action to be taken in FW management strategy is prevention of generation. It can be achieved either attempting to reduce losses and also decreasing the demand for food production, or diverting FL, exceeds, and still safe and edible FW to other end-consumers.

Gustavsson et al. (2011) stated that in developed countries, FW prevention has to focus on the consumer's behaviors at household level, on the other hand in developing countries it must focus on the retail and distribution system.

Several studies proposed that convenience in sorting, storage space at home, availability of sorting facilities, access to a curbside collection system and distance to collection points are determinant factors that can increase the recycling rate (Ando and Gosselin, 2005; Barr and Gilg, 2005; Rousta et al., 2015).

Kibler et al. (2018) classified the main FW management strategies as waste prevention, composting, anaerobic digestion, incineration, thermal conversion, land filling, drying for animal feed utilization, bio-valorization etc. and defined many detailed practices for these methods.

Additionally, agro-industrial residues and household FW no longer suitable for human consumption can be used as feedstocks for the production of bio-plastics and bio-fuels together with the extraction of high-value components. A considerable debate still continues on the manufacture of bioplastics from natural materials, raising the question as to whether they produce a negative impact on human food supply. From this perspective, the utilization of FW as a feedstock in the production of bio-fuels and bio-plastics seems a feasible option.

The utilization of food waste in feed and fertilizer production in Turkey

Regulations on the usage waste materials as animal feed and fertilizer

They mainly refer to rules on the regulations that can be related to FW generation and management in Turkey is shown below (OJ, 2005, OJ, 2011, OJ, 2015a, OJ, 2015b). All regulations are prepared in harmony with the EU.

Regulation on the control of waste vegetable oils (No: 25791, Date: 2005): To define the conditions for collection, transport, recycling/recovery, export, import, and disposal of waste vegetable oils.

Regulation of animal side products not used for human consumption (No:28152, Date: 2011): To specify the procedures and principles of animal by-products and their derivatives not offered to human consumption in order to prevent or minimize risks to public and animal health, food and feed safety.

Waste Management Regulation (No.29314, Date: 2015): To regulate the waste minimization, recycling, recovery, and decrease the usage of natural resources, and to provide waste management.

Compost Notification (No. 29286, Date: 2015): To decrease the biodegradable waste amount landfilled and identify technical criteria for compost plants and quality criteria for the compost products.

Needs and Challenges in the utilization of food waste as feed

FW can be used as animal feed directly or after a pretreatment step, such as dehydration, silage, liquid feeding, etc. In Turkey, although FW is used as animal feed no reliable data about the actual quantities. 85% of the animal feed in Turkey is produced by 162 enterprises registered to the Turkish Feed Manufacturers Association. 9.15 million tons of animal feed was imported in 2016 in Turkey and the imported feed rate increased between 2000 and 2016. Importing 31% of the consumption feed shows that the use of FW in feed production is limited in Turkey (Salihoğlu, et al., 2018). However, there is also a growing interest in organic feed milling. It is clear that these developments will affect the feed import positively.

When international developments are examined in this respect, it is seen that in many countries FWs are subjected to some restrictions and regulations in the production of feed due to the risk of toxic substances. For example, because household FW is vulnerable to contamination by foreign objects, it is not currently recycled in Japan. Again, the EU has the most stringent regulations governing the use of waste as animal feed. For instance, to prevent the spread of prion diseases, the use of processed animal protein, also known as meat and

bone meal, as animal feed has been banned in the EU (Mo et al., 2018). Turkey also continues to be a coordinated process of harmonization with the EU legislation.

Needs and challenges in the utilization of food waste as fertilizer

The main organic fertilizers that can be used instead of chemical fertilizers; compost, green manure, barn stover, chicken stew, horse stew, sheep and goat stew.

Composting involves the aerobic degradation of organic wastes. Under aerobic conditions, organic materials are converted to carbon dioxide, ammonia-nitrogen, or complex recalcitrant materials often referred to as humic substances (Saer et al., 2013; Kibler et al., 2018).

The number of existing active compost plants in Turkey is seven, and their total capacities are less than 200 000 tons/years. Since there is a target in the Turkish legislation for the reduction in the FW should be composted, anaerobically digested or incinerated instead of landfilled. Legislation defining compost criteria was issued in 2015 (OJ, 2015b).Although composting has been accepted as one of the main alternative treatment technologies for FW in turkey, the number of compost plant is still at a minimum. The main reason behind the closure of compost plants in Turkey is their economical unsustainability. The benefit-cost ratio of facilities in Turkey is generally low, and there is not a real compost market. However, there may be potential for compost products to be used in land remediation and restoration schemes (Salihoğlu, et al., 2018).

Conclusion

FW is a complex, interdisciplinary and international issue which has profound effects for global sustainability. Large quantities of food is currently wasted, and FW disposal has been increasing with time. The development of sustainable solutions for FW management represents one of the main challenges for society. A large variety of waste materials could be utilized by the husbandry industry to reduce the amount of conventional protein sources. There is an urgent need for research to fill the knowledge gaps on the usage and processing methods of FW.

Renewing standards and regulations in a timely manner would also help the industry to move towards the use of waste materials as animal feed and fertilizer. Being a major agricultural country and has a thriving food industry, the subject of alternative food waste management systems is becoming increasingly important in Turkey. The research on the subject continues to maintain its actuality for Turkey as well.

Abstract

This study was carried out in order to determine adaptation and some quality traits of some cool season turf grass cultivars at randomized plot design with 4 replicates in Ondokuz Mayis University Experimental Area during 2010-2012. Plot size was 2 m² (1×2 m). In the research 5 cultivars of *Festuca arundinaceae* (Fa), 6 cultivars of *Lolium perenne* (Lp), 5 cultivars of *Festuca rubra commutate* (Frc), 6 cultivars of *Festuca rubra rubra* (Frr), 5 cultivars of *Festuca ovina* (Fo), 7 cultivars of *Poa pratensis* (Pp), 2 cultivars of *Poa trivalis* (Pt), 1 cultivar of *Agrostis stolonifera* (As), 2 cultivars of *Agrostis capillaris* (Ac), 1 cultivar of *Agrostis tenuis* (At) and 1 cultivar of *Festuca rubra trichophylla* were used. Leaf form (1-9), leaf colour and ranging of leaf colour depending on the seasons (1-9), regeneration power (1-5), fresh and dry biomass yields (g m^{-2}) were investigated. Cultivars of *Festuca arundinacea* were different from the others as coarse form (3.3). Two cultivars of *Agrostis stolonifera* were also the same coarse form group. There were pronounced colour change of the whole cultivars depends on the seasons. Compare to the others, colour change of *Festuca rubra* and *Festuca ovina* cultivars were limited. While the highest regeneration power was *Festuca rubra trichophylla*, the lowest was determined for *Poa trivialis*. Four cuttings were made in the second year. The highest biomass yield was obtained from the first cutting and it decreased by advancing cuttings. The lowest fresh biomass yields were obtained from *Poa pratensis* and *P. trivialis* cultivars (62,69 and 97,77 g m^{-2} respectively). *Festuca arundinacea* cultivars produced low and similar biomass yield for each cutting.

Keywords: *Turf grass, Seasonal change, Colour, Biomass yield, Quality.*

Introduction

In the contrary of urbanization and industrialization, recreation area is decreasing day by day. In order to supply human shelter requirement concrete apartment buildings are increased, view of the cities changed and consequence of those issues life quality decreased while stress of humanity is rising. Human is trying to live in congested areas, started to create small green areas inside the cities. After those researches on grass species that can be used in green areas increased (Avcioglu, 2014). The most important part of outdoor recreation areas is turf grass. These areas are used commonly for improve architectural, scenery and aesthetic quality. Heat and drought are the most important factors that restrict the growing of grasses during summer period (Jiang and Huang, 2001). Before choose the grasses, we have to know their usage aim, ecological conditions, sustainability and appearance of them (Harivandi *et al*., 1984). Turf grass has important functions on sports areas, in addition to around the houses. Turf grass species and cultivars selected for sports areas should be resist to pressing on. This trait is crucial for a turf grass, if it is used in sport areas (Yazgan *et al*.,1992). Before establish a sport or recreation area, turf grass cultivars should be suitable to climatic conditions of the region. To know the adapted cultivars in the region is definitely necessary. Cool season grass are suitable to North, East and Central part of Turkey, however warm season grass are more common in South and South-West regions. Province of Samsun is take place in Black Sea

region of Turkey. The area is very suitable for cool season grass due to its cool and rainy winter, mild and humid summer climatic conditions. Previous studies showed that turf grass cultivars belongs to *Lolium perenne L.*, *Poa pratensis L.*, *Festuca sp.*, *Agrostis sp.* are quite suitable to this region (Avcioglu, 2014). In the scope of this study, leaf form, biomass yield, regeneration power and variation of leaf colour according to the seasons of the cultivars that were improved different ecological conditions were determined.

Material and Methods

In this study 40 cool season grass cultivars in 8 species and 4 genus (Lolium, Festuca, Poa, Agrostis) were used. The experiment was established according to randomized plot design with four replicates in Samsun Conditions at November, 2010.

Plot sizes were 2x1=2 m^2, plot number were 40x4=80 and total experiment area was 40x2x4=320 m^2. Seeding rate was altered 25-90 g m^{-2} according to 1000-seed weight and plant characteristics. The seeds scattered with hand on plots and compressed. Leaf form (1-9), leaf colour and ranging of leaf colour depending on the seasons (1-9), regeneration power (1-5), fresh and dry biomass yields (g m^{-2}) were investigated.

Result and Discussion

Leaf form (1-9)

Leaf width of turfgrass plants is formed with the interactions of genetic and environmental conditions. For this reason, the highest and lowest leaf width of turfgrass plants should be determined and it should consider for selection process (Avcioglu, 2014). In terms of leaf form there were significant differences amongst the species. According to the result, coarse leaves were observed in *Festuca arundinacea* (3.3) and it is differentiated from the others (Table 1). The cultivars belong to *Festuca sp.* and *Poa trivialis* had thinner leaf form (Table 1 and Figure 1). These results are compatible to some previous findings, such as; leaf blades of *Festuca* plants twist on, thus their appearance is thin (Hubbard, 1992 and Beard, 1973); *Festuca arundinaceae* has the most coarse leaf form (Acikgoz and Basbug, 1993; Varoglu, 2000; Oztarhan, 2010).

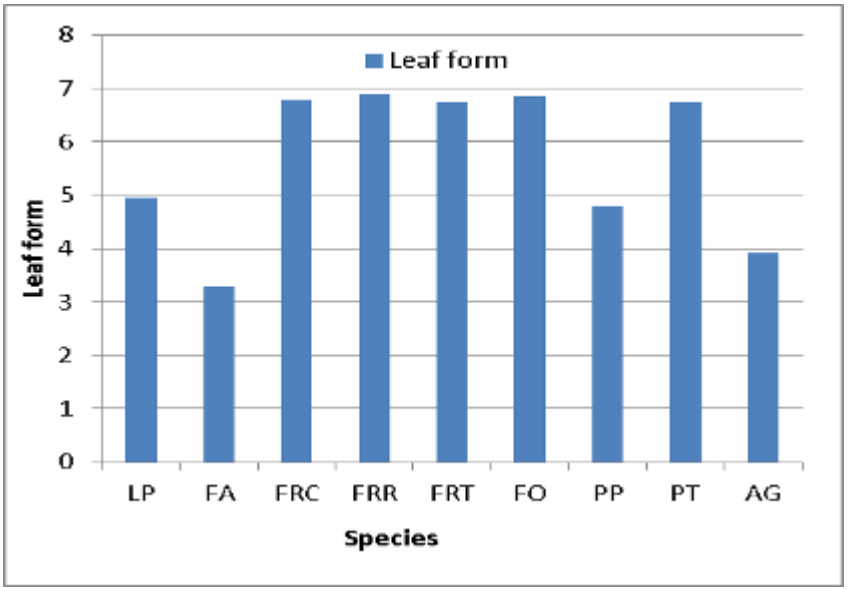

Figure 1. Leaf form of the species

Leaf colour and ranging of leaf colour depending on the seasons (1-9)

The colours of the species and colour variation depending on the seasons are given in Table 1 and Figure 2. The colour was changed significantly from season to season in all species. Colour change was limited in *Festuca rubra* and *Festuca ovina*, compare to the other species. All of the species were generally good appearance and their colour was dark green in spring. Responses of *Festuca arundinacea* and *Lolium perenne* to seasonal changing were similar. Only *Poa pratensis* has the darkest leaf colour in winter. The darkest leaf colour was determined in summer for *Agrostis sp*. cultivars. Though dark green leaf colour was lighten in summer for the whole plants, but the most effected from high temperature ones were cultivars of *Poa pratensis*. Leaf colour of the species was getting recovery in autumn, except for *Poa trivialis*. Yellowish green leaf colour of *Poa pratensis* turned to dark green in winter. Leaf colour of *Festuca ovina* cultivars was stabile throughout the year, except for summer. *Festuca rubra trichophylla* kept green leaf colour over the seasons. The results were compatible with previous findings (Varoglu, 2010; Oztarhan, 2010).

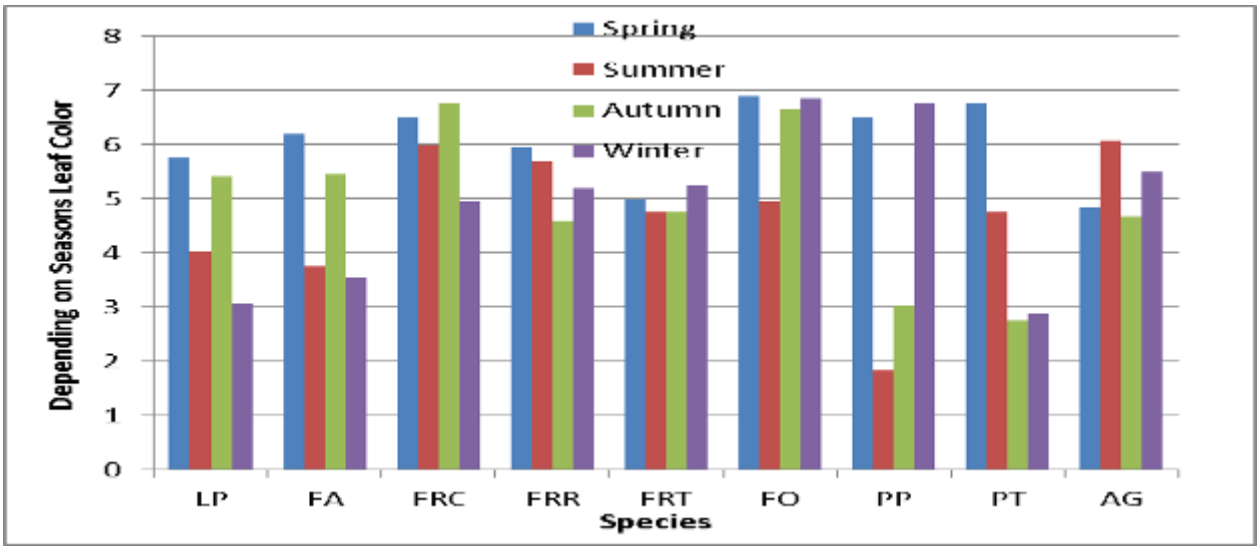

Figure 2. Leaf colour of the species depending on the seasons

Regeneration power (1-5)

Regeneration power data obtained from the cultivars as evaluating according to 1-5 scale (1= very fast growing, 3= medium growing, 5= very slow growing) in spring can be seen on Table 1 and Figure 3. Regard the regeneration power, statistically significant differences were identified amongst the cultivars. The highest regeneration power was in *Festuca rubra trichophylla*, while the lowest was in *Poa trivialis* and *Poa pratensis*. Similar results were obtained by Varoglu (2010).

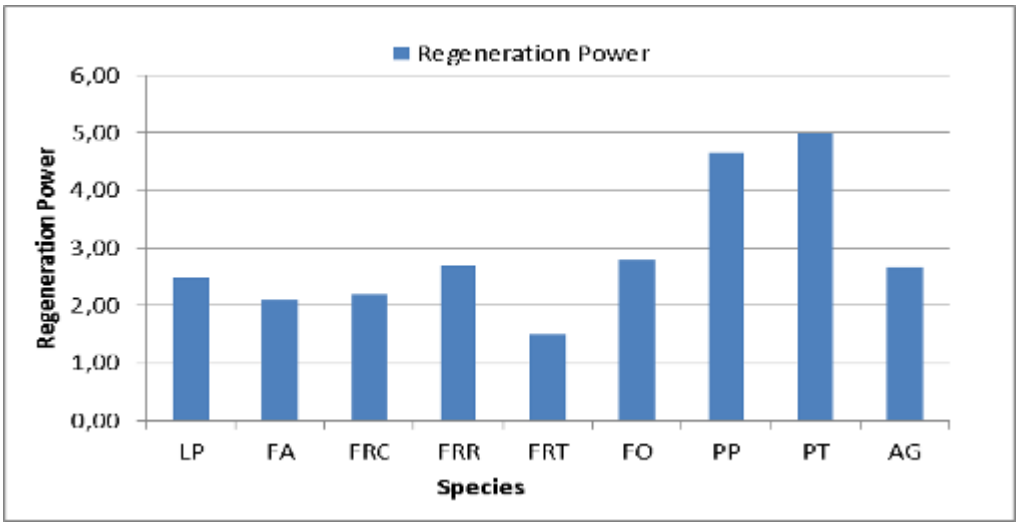

Figure 3. Regeneration power of the species

Fresh and dry biomass yields

Eventhough faster germination and emergence desire after sowing for turfgrass, in full covered turfgrass areas the slowest plant growing was demanded. After cutting faster covered but less biomass produce cultivars were prefered (Avcioglu, 2014). Four cuttings were made in the second year of the study and fresh and dry biomass yields were given in Table 2. There were significant differences among the species for all cuttings, in the point of fresh biomass yield. The highest fresh biomass yields per square meter were 1263.90 g from *Festuca rubra trichophylla*, 469.27 g from *Festuca ovina*, 323.87 g from *Lolium perenne* and 375.40 g, for 1., 2., 3. and 4. cuttings, respectively. On the other hand, the lowest fresh biomass yields were 237.80 g from *Poa trivialis*, 62.69 g from *Poa pratensis*, 97.77 g from *Poa trivialis* and 161.00 g from *Poa trivialis*, in order to consequtive cuttings. The lowest average fresh biomass yields were obtained from *Poa pratensis* and *Poa trivialis* in each one of the four cuttings. *Festuca arundinacea* gave similar and lower fresh biomass yields in the whole cuttings. Though the results have similarities with some previous findings, differentiated from some others. Hosaflioglu (2009) reported that in general the highest and lowest fresh biomass yields obtained from *Poa pratensis* and *Festuca rubra trichophylla* cultivars, respectively. Higher fresh biomass yields were obtained from the cultivars that have coarse tissue and wider leaf blade and it can be varied according to different environmental conditions (Zorer Celebi, 2009).

It is found that considering the dry biomass yield there were significant differences amongst the species in all cuttings. While the highest dry biomass yields for per square meter were obtained from *Festuca rubra tricophyla* with 320.13 g, from *Festuca ovina* with 110.67 g, from *Lolium perenne* with 68.16 g and from *Agrostis sp*. with 74.80 g, the lowest ones were determined for *Poa trivialis* with 50.01 g, for *Poa pratensis* with 12.22 g, for *Poa trivialis* with 18.58 g and for *Poa pratensis* with 32.98 g, respectively in successive cuttings.

***There is no significant differences (p≤0.01) amongst the figures indicated in the same letter within the same column**

Conclusion

Species/cultivars have some superiority to each other because of their different morphological and physiological characteristics. When we consider weed competition, *Lolium perenne* and *Festuca arundinaceae* have to be added to the mixture in order to decrease weed competition because of their faster germination and higher regeneration power in Black Sea Region. There was colour variation distinctively depending on the seasons for all the species. But, compare to the others, cultivars of *Agrostis sp.* and *Poa pratensis* have the potential to keep leaf colour against to changing seasons. Leaf form and appearance of *Festuca rubra*, *Poa trivialis* and *Festuca ovina* are better than the others. In order to keep good conditions of turfgrass areas, especially after cutting in summer period, *Poa pratensis* and *Poa trivialis* should added in mixtures to get benefit their higher regenerating power.

Abstract

Irrigation is needed when rainfall is inadequate to meet plant water needs to increase efficiency in agricultural production. However, the water to be used in irrigation should be given to the root of the plant at the right time and in the right amount. For this purpose, various irrigation methods and systems have been developed. One of the systems that enables to save irrigation water within the developed irrigation systems and helps water directly reach the root zone is the subsurface drip irrigation (SDI) system. On the other hand, SDI systems, besides their many advantages, cannot provide expected benefits especially due to malpractices in operation, maintenance and installation of the system. Due to the simple faults and carelessness in the installation and operation of SDI systems generally installed with high costs and high expectations, SDI systems can sometimes become unusable. Designing a successful SDI system facilitates management and maintenance. It is not enough to design SDI systems properly. Besides the correct installation of the system, high efficiency can be obtained from the products grown under correct maintenance and operation conditions. In addition, it is possible to save irrigation water used in production. For this reason, the issues that need to be considered in the design and operation of subsurface drip irrigation systems (SDI), which have been widely used in irrigation in recent years, are discussed in this study.

Keywords: *Agricultural production, Irrigation method, Plant root zone*.

Introduction

In many parts of the world, global warming and the consequent irregularities that global warming caused in the precipitation regimes threaten the potential of available water resources. Irrigated agriculture is of vital importance in terms of meeting the needs of the rapidly rising human population. However, lands lose their qualities to be used for agricultural purposes due to the rapid industrialization and the effects of urbanization together with the inappropriate agricultural practices. In addition, increased freshwater demand from cities and industrial plants are putting more pressure on reducing the amount of water used in agriculture. Due to the limited water resources and increased water needs of non-agricultural sectors, it is necessary to develop new agricultural irrigation methods and systems so that they can use the available water in a conservative way. The need for this is increasing day by day. From this point of view, it is worth noting that subsurface drip irrigation (SDI) systems, which can save the amount of irrigation water compared to the other irrigation systems. However, the design, installation and management of SDI systems require relevant knowledge and experience. Errors in the installation and management stages cause the expected benefits of the SDI systems established with high costs and anticipations to fail. Today, the use of SDI systems is increasing. However, the system design, installation and operation must be done correctly. In studies earlier, subsurface drip irrigation systems were discussed (Howell at all., 1980; Bucks et all., 1982; Bucks and Davis, 1986). In some studies, the theory and different applications of the SDI were also discussed (Jorgenson and Norum, 1992; Ayars et al., 1999).
In this study, it is aimed to examine the recent developments in subsurface drip irrigation (SDI) systems. In addition, the issues that need to be taken into account in the establishment

and management of the system have been tried to be explained as much as possible. The system components and the issues to be considered in the system design stage are discussed.

Subsurface Drip Irrigation (SDI)

Subsurface drip irrigation systems have been part of irrigated agriculture in the United States for nearly forty years. However, the interest in this system has been increasing in the last 20 years. It is seen that the early drippers and pipes used in the SDI were quite simple and problematic compared to the drippers and pipes produced with the use of modern materials. In the early years, especially the clogging of the drippers and the inability to distribute the water in the desired amount caused some major problems. SDI has been becoming more popular thanks to the introduction of the plastic materials into the production systems and the developments in the dropper designs. However, the plant roots entering into the dripper and plugging the drippers are a problem that continued until recent years. SDI was the preferred system for growing high-value crops (such as fruits, vegetables, peanuts and sugarcane) in the beginning. As the system's stability and lifetime improved, the system started to be used more commonly for the plants with lower economic value. The fact that the system is for a multi-year purpose has come to the point to compensate for the high first installation costs. Over time, the SDI design criteria and equipment used in the installation (such as evacuation line, air vents) have developed. With the development of the special design criteria and usage equipment for different conditions (climate, plant, water quality, soil characteristics), the usage areas, system performance and system resistance of the SDI are also increasing accordingly.

Plant yield in the SDI applications is either the same or more when compared to the other irrigation methods. The use of water and fertilizers is the same or lower in some cases when compared to the surface drip irrigation and other irrigation methods. In the use of wastewater, the preference of SDI applications has increased in recent years. SDI can be a promising method especially in the areas where water quality is low and water saving is important for the future. SDI is an irrigation method (Camp, 2000) that provides a very precise and controlled application for the distribution of water and nutrients to the desired site at the desired time and frequency for optimal plant growth (Camp, 2000).

SDI System Components

Elements of the SDI systems are pump unit, check valve preventing water backpressure, flowmeter or water meter, fertilizer injection system, filter system, main pipeline, manifold pipeline, air suction cups, valves, pressure gauges, laterals, discharge valves. In Figure 1, the layout of the SDI system components is schematically shown.

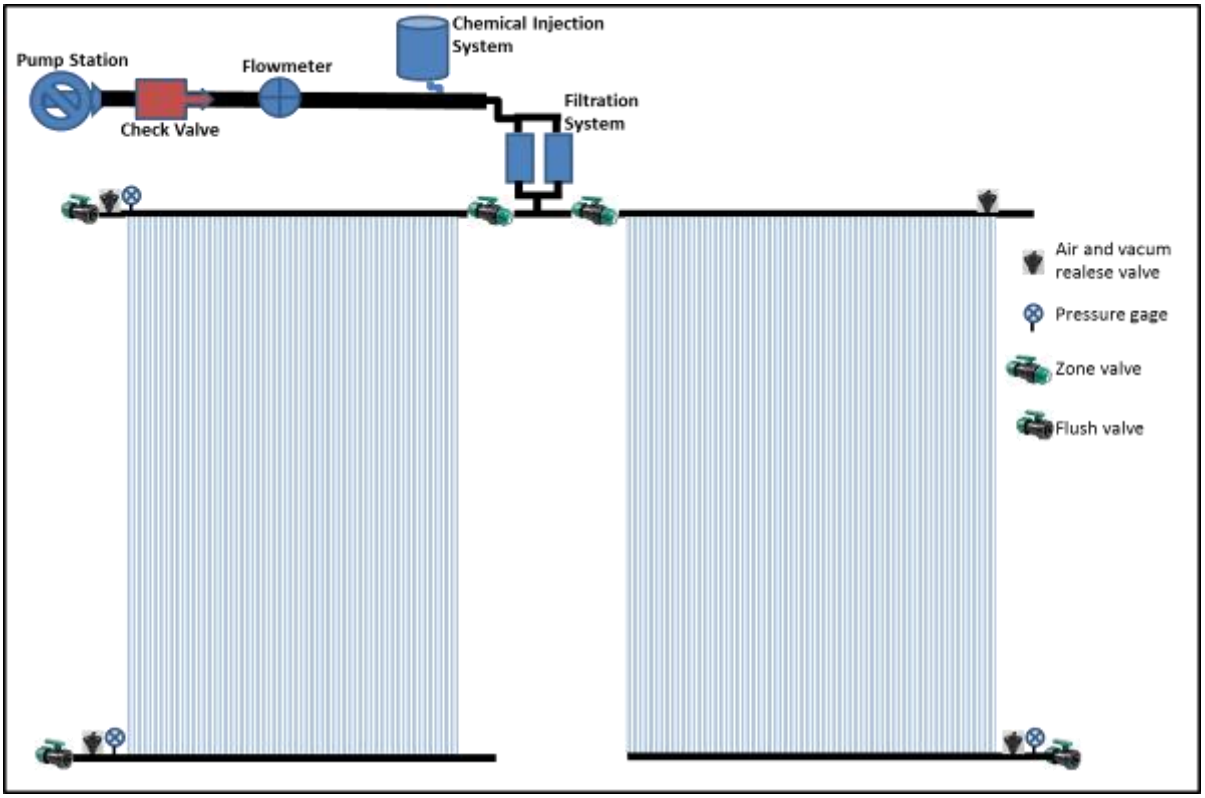

Figure 1. Subsurface drip irrigation system elements (adapted from Lamm et al., 2014)

Each of the system elements described in Figure 1 is handled separately, and each of them is seen to have a vital aspect in terms of management of the system. In the SDI system, the misuse of even one of these elements or ignoring any of them in the design stage can cause some serious problems.

SDI Design Features

In a successful SDI system, design, installation, management and maintenance are closely related to one another. Proper design of the SDI systems is not sufficient to have high yield and the system needs to be installed correctly, as well as the correct maintenance and operation of the system to save the amount of water used in the agricultural production. Prior to the design of the SDI systems, the characteristics of the water source should be assessed and analysis of the irrigation water quality should be made. The maximum and minimum amount of water flow that can be obtained from the water source should be calculated. The type of water source (deep well, irrigation canal, river, lake etc.) is very important. Some physical and chemical properties of the irrigation water should be determined.

At the start of the design process, two basic SDI design features need to be identified:

1) Selection of drip line (lateral diameter) and dripper
2) The shape of the drip line installation (depth to be placed in the lateral line)

The lateral pipe diameter affects the determination of the possible design patterns in the depth design process in which the interaction between the dripping element and the subsequent durability will be carried out. In other words, the choice of these criteria results in the design of the system.

Issues to be Considered in the Management of the SDI Systems

Since the lateral lines are buried under the ground in SDI systems, the risk of clogging is higher than that of the supersonic drip irrigation systems if relevant precautions are not taken. It is necessary to wash the laterals at regular intervals so that the various sized materials do

not accumulate in the drippers over time and cause clogging in the system. The frequency of the washing depends on the wash rate, irrigation water quality characteristics and filtration level of the filtration system. The minimum wash rate for micro irrigation systems is recommended to be as 0.3 m/s (ASEA, 2008). However, the recommended SDI systems are 0.3-0.6 m/s.

Both washing speed or washing line hydraulic properties affect the SDI system design. The high wash rate requires a large amount of water supply. The extension of the wash cycle contributes to an increase in the washing efficiency and a more economical process without requiring a greater wash rate. However, the velocity of the washing water should not be below 3 m/s (Lamm et al., 2014).

In SDI systems, the applied irrigation water is all buried underground. In properly installed and operating systems, wetting of the soil surface is rarely seen. For this reason, the flow meter and pressure indicators must be used to provide clues for feedback during the system start-up.

Some Examples of the Studies Examining the SDI Systems

Phena et al. (1987) reported that the SDI system provides advantages in five different ways when compared to ground surface drip irrigation on irrigated tomato plant: (1) The SDI system requires less labour use compared to the installation of ground surface drip irrigation due to its longer durability. (2) A decrease in soil-borne diseases and weed development due to the dryness of the soil surface has been observed. (3) It was found that the ability to move on the soil increased and the soil compaction rate decreased. (4) It was found that water and plant nutrients were used more effectively. (5) Improvement in the yield and fruit quality characteristics were found out.

Hanson et al. (1997) examined the effects of cablegation irrigation, surface drip irrigation and SDI applications on the lettuce plant. A slight decrease in the yield was found in the surface drop irrigation whereas similar results were obtained in the cablegation and SDI applications. SDI laterals were placed 15.2 cm deep from the soil surface. In both drip irrigation systems, the distance between the laterals was 101 cm. However, in the surface and subsurface drip irrigation areas, 43% and 74% of the water used in the mixed water irrigation was used.

In general, the increase in the plant yield and quality was observed with SDI application. For example, improved yields in cotton plant cultivation were reported under the SDI applications (Smith et al., 1991; Ayars et al., 1998).

Ayers et al. (1999) stated that some plants (generally small-seeded plants) may not be suitable for SDI irrigation during the germination period. However, it was reported that in the areas where the groundwater was near the surface and the groundwater level was high, efficiency and water use efficiency could be increased in the tomato, melon, maize plants by frequent and controlled SDI system irrigation.

Kassab (2005) tested sesame plants under different levels of irrigation using the surface drip irrigation, subsurface drip irrigation and surface irrigation methods. Irrigation was done 4 times in the surface irrigation method and 15 times in the ground surface irrigation methods. Seasonal amounts of irrigation water applied to the treatments; 437 m^3/da in the ground surface irrigation method and 237 m^3/da in surface irrigation methods. The highest yield values obtained according to the irrigation methods were 234 kg/da for the surface irrigation method, 224 kg/da for the subsurface irrigation method and 205 kg/da for the ground surface irrigation method. In the subsurface drip irrigation method, yield decreased by 4.3% compared to the surface irrigation method and 46% savings from the irrigation water.

Douh et al. (2013) conducted a study in Tunisia and examined the placement of SDI laterals in three different soil depths and their effects on the yields of the corn plant and soil moisture. It was stated that the yield of soil moisture and corn plants was higher in the case where the

soil was buried at a depth of 35 cm compared to the cases where laterals were buried at the depths of 5 and 20 cm from the soil surface.

Lamm et al. (2015) made a comparison of centre pivot (CP) and subsurface drip irrigation (SDI) systems with regards to their economic benefits. CP was found to be a more economical irrigation system in the corn cultivation when the cost of installation and service life were considered. However, it was reported that irrigation water used in SDI applications was saved by 25% compared to the CP applications.

Ayers et al. (2015) reported that the use of SDI in walnuts, almonds and tomatoes, which are commonly grown in California region in the United States, increased the yield and quality of the fruit. In addition, it was stated that the amount of water used under the SDI was reduced.

Robles et al. (2016) compared SDI and ground surface drip irrigation systems in terms of water use efficiency and efficiency at a 19-year-old lemon yard in a survey conducted in Spain. It was reported that the SDI system saved 19% of the amount of irrigation water without loss of productivity.

Conclusions

The studies conducted on SDI began to be studied intensively in the mid-80s and early 90s. These studies reveal that SDI applications provide some advantages in the use of fertilizer and water management compared to the other irrigation methods. As the increase in the plant yield and quality was observed, it was found that the amount of plant nutrient leaking into the deeper soil was decreased by the washing. The amount of irrigation water used was also reduced.

Compared to the other irrigation methods, SDI reveals good results in terms of crop efficiency and efficiency in water use. SDI is an irrigation system with a capacity that can enable fertilizer and water management to be carried out at the desired level, especially in the areas where water resources are limited or areas where the groundwater level is high. However, for the system design and installation should get help from a competent person. Adequate information on the use of the system should be provided.

Abstract

As in many cultivated plants, the irrigation of the melon plant when the water needs cannot be met in natural ways causes significant increases in crop yield. However, when the water resources are limited or the irrigation costs are high and when the amount of irrigation water used is reduced, the water requirement of the plant is incomplete. In such cases, there is a need to develop practices that can save irrigation water without causing a significant decrease in the yield and the yield quality. One of the practices that can save irrigation water is irrigation schemes. Particular irrigation schemes can be applied during the whole developmental period of the plant and at certain stages of the developmental period. There are many pieces of researches conducted on melon cultivation under deficit irrigation practices. The aim of this study is to determine the periods during which the plant is most sensitive to the water shortage. Thus, irrigation schedules that will save the most irrigation water used, with the least possible loss in yield and yield quality are determined. In addition, possible responses of the melon plant such as water consumption under furrow and drip irrigation methods have been investigated. Thus, it is aimed to determine the best irrigation method in melon cultivation. In this article, some researches on melon cultivation under different irrigation methods and different irrigation treatments have been evaluated.

Keywords: *Crop yield, Water resource, Deficit irrigation*.

Introduction

Turkey is the second country after China making the most of the melon production in the world. According to the data of 2016, 1.8 million tons of the total annual melon production of approximately 31 million tons in the world is produced in Turkey (Anonymous, 2018).

There are different opinions about the homeland of melon. Pitrat et al. (1999) claim that the types of wild plants which are considered to be Cucumis type are commonly seen in Africa, that the origins of melon come from Africa and the lands in Asia between Turkey and Japan are considered to be the secondary gene centre of melon plant. Günay (1993) recorded Anatolia, Iran, Afghanistan, Central Asia and Southwest Asia as origins of melon plant.

There are many types of melons that can be taken as wild and cultured and exhibit different morphological characteristics spreading over a very wide geographical area. This is exemplified by "Galia" cultivated in Israel and "House" melon cultivated in Japan (Pitrat et al., 2000). Melon species and varieties have significant morphological differences in terms of leaf and fruit characteristics in plants (Şensoy et al., 2007a).

A large portion of the melon produced in Turkey (85%) inodorous (Kırkağaç, Hasanbey, Slots and Winter Yellow) other parts (15%) is counted in the cantalupensis and reticulatus group (Baktemur, 2010). Melon cultivation in Turkey widely made under outdoor production conditions in the Mediterranean region and also can be produced in low tunnels and greenhouse conditions.

As in many plants, the irrigation of plant results in significant increases in yield when the water needs of plants cannot be met with the rainfall. However, irrigation of plants is neglected when there is not enough irrigation water and when water resources are limited or

irrigation costs are high. There are a number of studies aimed at finding out the amount of deficit that can be applied to irrigation water without causing significant decline in the yield and quality in such situations. In this study, some of the research on deficit irrigation in the melon carried out in the world and Turkey were discussed.

Literature Review

Deficit irrigation applications can be made during the whole developmental period of the plant in a single developmental stage. The aim of the study is to determine the stage or stages in which the melon is most sensitive to the water shortage. In this study, it is aimed to find out the irrigation programs that will save the most irrigation water with the least loss in the yield and quality after determining the periods when the melon is most sensitive to water shortage.

Yildirim et al. (2009) investigated the effect of full or partial irrigation applied on the yield and quality of melon in different periods of development (beginning of flowering, beginning of flowering, ripening and harvesting) using a Kırkağaç melon species (Cucumis melo L. To the water deficit treatments to which 50% and 75% of the water applied to the control group was applied. According to the results of the research, continuing the irrigation in maturation period in the treatments other than the control treatments increased vegetative growth and did not significantly affect the yield and dry material. However, when the irrigation level is taken into consideration, a higher water-soluble dry matter content and tastes were obtained in the case of 25% reduction in the irrigation water amount, compared to the 50% water restriction applied without water restriction. As a result of the research, it was suggested that irrigation should be maintained until the beginning of maturation, and irrigation in the ripening period should not be made to have higher yield and quality. As a result of the research, it has been suggested that 25% water reduction can be applied until the maturation period and the irrigation should be cut during the maturation period.

Li et al. (2012) conducted a study under greenhouse conditions, and the soil water content was brought back to the level of field capacity by irrigation when it fell to different levels (45%, 55%, 65% and 75%) of water content in field capacity. The amount of irrigation water applied in the study was found to have a significant effect on fruit thickness, water-soluble dry matter content, soluble sugar content, soluble protein content, vitamin C content and free amino acid content values. In the study, it was found that irrigation should be done at a rate that does not exceed the field capacity when the soil moisture content reaches 25% of the melon content in melon cultivation.

Wang et al. (2017) conducted another study on melon plant and found out that irrigations were planned to be carried out at different plant growth periods, at different levels of soil water content (soil moisture content fell to 45% and 55% and 65%, respectively) and brought to the field capacity by watering. According to the results obtained, it was reported that the effect of low soil water content conditions (when the irrigation water drops to 55% of the field capacity of the irrigation water) during the period from the flowering period to the fruit growth period had a negative effect on the yield.

Alizadeh et al. (1999) conducted a research, and it was found that irrigation of melon plant made with drip and cablegation irrigation methods led to the highest yield from full irrigation and drip irrigation system when the full, 25% deficit and 50% deficient conditions of the plant were considered. It was reported that the treatment irrigated with drip irrigation and 25% irrigation water deficit was applied did not cause any loss in the yield and the irrigation water consumption in cablegation method was three times higher compared to the value regarding the plant water consumption in drip irrigation system.

Kirnak et al. (2005) carried out a research in the province of Şanlıurfa using the Polidor hybrid melon species. In the study, irrigation treatments were arranged according to the evaporation values coming from the Class-A evaporation pan. Irrigation, nitrogen yield and

quality effects of melon plant were investigated together. In the study, it was found out that as the water content increased, fruit weight and size decreased while the amount of water-soluble dry matter increased. It is stated that as the water content increased, the value of leaf-proportional water content decreased, the amount of applied irrigation water and the amount of nitrogen increased, and the plant leaf area increased. In the study, it reported that while the pan coefficient was 0.75, it was found a loss of 14-17% in the yield of moderate water stress, in severe water stress it was observed 55% to 59% yield loss.

Sensoy et al. (2007b) used a Bonanza F1 melon variety as an experimental material in a study conducted in Van province. The effects of irrigation programs on different Class-A evaporation pan and irrigation intervals according to different irrigation intervals were investigated in irrigation methods. It was reported that the highest yields were obtained with a 6-day interval and using the evaporation coefficient of 0.9. The average fruit weight, fruit diameter, fruit length, water-soluble dry matter content and fruit juice pH were measured in the study. It was stated that the amount of irrigation water applied in the study affected the fruit diameter, fruit size, water-soluble dry matter content and fruit juice pH, and irrigation frequency had an effect on average fruit weight.

Dogan et al. (2008) conducted a two-year study in Şanlıurfa province, and different irrigation levels were investigated on the surface of the irrigated water using surface and superficial drip irrigation systems. Irrigation treatments were arranged to give 0, 25, 50, 75%, 100% and 125% irrigation water of the amount of evaporation coming from the Class-A evaporation pan. Pineapple F1 was used as plant material. There was no significant difference in the efficiency between the two irrigation systems used. However, in the calculation of the ideal irrigation water to be applied, it was proposed to use 83% of the evaporation from the Class-A evaporation pan in the under-surface drip irrigation system and 92% in the superficial drip irrigation system.

Wells and Nugent (1980) reported that the high soil water content during the ripening of the melon fruit reduced the amount of water-soluble dry matter in the fruit.

Leskovar et al. (2001) conducted a study in the US Southern Texas, Caravella melon was used as plant material in the Cantalop group. In this study, it was stated that the highest fruit yield and quality were obtained with irrigation systems and surface irrigation systems when compared to cablegation irrigation method, surface irrigation method and superficial irrigation method. In the same study, 53% less irrigation water was used in the drip irrigation method compared to the cablegation irrigation method.

In a study conducted in Spain, it was stated that the lack of moisture in the soil is sensitive to the lack of moisture in the early stages of fruit formation during the plant development. In addition, it was found out that the deficit irrigation condition applied during fruit ripening period increased the content of fruit sugar (Fabeiro et al., 2002).

Sharma et al. (2014) found out that the changes in the fruit yields were affected when the irrigations were applied to different melon species. During two breeding seasons in Texas, three types of foliage [Mission (muskmelon, reticulatus), Da Vinci (tuscan; reticulatus), Super Nectar (honeydew; inodorus)] were used in the conditions in which 100% and 50% of the irrigation water needs were met. In the study, the response to water shortage of varieties was different. In the study, it was stated that the water shortage saved between 37% and 45% in irrigation water in Mission and Da Vinci species, resulting in a moderate decrease in the economic efficiency. It was reported that 50% reduction of plant water consumption value in the Super Nectar variety was not suitable for the Super Nectar variety (Sharma et al., 2014), because 50% reduction of the plant water consumption caused a significant amount of productivity loss. Therefore, the 50% deficit in the water consumption value in the Super Nectar species was not found to be appropriate (Sharma et al., 2014).

Results and discussion

The response to water shortage and quality of melon species can vary considerably (Sharma et al., 2014). However, it is still possible to achieve some general conclusions based on the information summarized in the previous section, without completely ignoring the fact mentioned above. It can be suggested that the period in which the melon is most sensitive to water shortage is the development period from the beginning of flowering to the beginning of the fruit formation period (Fabeiro et al., 2002; Wang et al., 2017). However, it was found out that the deficit irrigation applied during the fruit ripening period increased the content of fruit sugar, and that the level of high soil water content decreased the fruit sugar content in this period (Wells and Nugent., 1980; Fabeiro et al., 2002). It can be suggested that the plant growth period in which water shortage causes the least loss in yield is fruit ripening period (Yıldırım et al., 2009). It is not recommended to reduce the amount of irrigation water to be applied by 25% (Alizadeh et al., 1999) and to apply the irrigation water at a rate of 50% or higher within the water deficit levels investigated (Kırnak et al. 2005). Similarly, irrigation should be done when less than 50% of the available water is consumed in melon cultivation (Wang et al., 2017). However, it can be suggested that irrigation is more appropriate when 25% of the available water is consumed (Li et al., 2012). It was found out that the drip irrigation method could save 53% of irrigation water compared to the cablegation irrigation method (Alizadeh et al., 1999) and it was found out that water consumption increased three times compared to drip irrigation method (Leskovar et al., 2001). In the studies conducted on melon plant; it was found out that the amount of irrigation water applied can change depending on the locality, climate where the fruit is cultivated, melon variety, the irrigation method used and the amount of irrigation water (Table 1). The amount of irrigation water given in Table 1 is the amount of irrigation water applied in conditions without any water deficit.

Conclusions

Less water is used in surface and sub-surface drip irrigation methods than in cablegation irrigation method in melon cultivation. Generally, there is no significant difference between yield and surface irrigation methods. The use of mulch can be effective in reducing water evaporation in melon cultivation because it reduces the amount of evaporation from the soil surface.

When irrigation planning is carried out, it is appropriate to apply water deficit at the rate of 25% or less of the amount of irrigation water under normal conditions if water deficit needs to be applied. In this case, water saving can be achieved without causing a significant decrease in the yield and fruit quality. If the water deficit is applied in any part of the plant development period, it should not be ignored that the melon is sensitive to water shortage during the period from the flowering to the beginning of the fruit ripening period. The lack of irrigation in the period from the start of the maturation period to the harvest may lead to a significant increase in the sugar content in the fruit.

Abstract

Turkey is one of the major centers of diversity in *Colchicum* species from Colchicaceae family. The genus *Colchicum* L. is represented by 47 species, of which, 35 are endemic to Turkey and some are under threat. Turkey has 3 *Colchicum* species in different categories of IUCN Red List. *Colchicum balanse* and *Colchicum troodi* are in Least Concern, *Colchicum leptanthum* is in Critically Endangered of IUCN Red List categories. Major threats of *Colchicum leptanthum* are dam and road construction. The threats to *Colchicum balanse* and *Colchicum troodi* are unknown according to IUCN Red List.

Collection of the all *Colchicum* species is prohibited in the wild at national level by regulation in Turkey. Some morphological and anatomical studies, description of new species, in-vitro propagation and karyotype studies on *Colchicum* were carried out in Turkey. *Colchicum* species have been used as a medicinal plant for more than 3000 years. *Colchicum* species have valuable alkaloids especially colchicine used in medicine. *Colchicum* species have also potential as ornamental plants. Their pharmacological usage and potential as ornamental plants increase their importance. Therefore, it is very important to protect genetic resources of these species. Some of these species are endemic. Lost of these endemic species in the Turkey flora, means their lost from the world. In this review, conservation actions and some information about the endangered *Colchicum* species in the flora of Turkey that are IUCN Red List categories were given and discussed.

Key words: *Endangered Colchicum spp, IUCN Red List, Endemic, Threats, Conservation*

Introduction

Colchicum is a perennial geophyte and belongs to Colchicaceae family. Because of the high frequencies of species and endemics, Turkey and the Balkans are the major centers of diversity and speciation (Persson, 1993; Karakaş Metin et al., 2014). There are 100 *Colchicum* species on the earth (Persson et al., 2011). Turkey has 47 *Colchicum* species and 35 of them are endemic and they are not spread to other countries (Persson, 2007; Kaya et al., 2013)

Colchicum species are very important because of being used for ornamental (landscaping, flowerbeds and rock gardens) and medicinal purposes (Karakaş Metin et al., 2014). However, many plants genetic resources, including *Colchicum* are under genetic erosion because of the environmental and other problems and therefore face with the danger of extinction. *Colchicum* species are one of the most important and endangered species of wild collected bulbs in flora of Turkey.

Turkey has 3 *Colchicum* species in different categories of IUCN Red List. *Colchicum balanse* and *Colchicum troodi* are in Least Concern, *Colchicum leptanthum* is in Critically Endangered of IUCN Red List categories. *Colchicum leptanthum* is endemic to Northeast Anatolia of Turkey (Ekim et al., 2014). There are also some other *Colchicum* species that are reported to be endangered (Tehditaltındakibitkiler, 2018).

International Union for Conservation of Nature and Natural Resources, IUCN

The IUCN Red List Categories and Criteria, is designed as an easily understood system for classifying species at high risk of global extinction (Allen et al., 2014). The IUCN Red List provides taxonomic, distribution, ecological, threat and conservation status information on

taxa that have been evaluated using the *IUCN Red List Categories and Criteria* (IUCN, 2012; Allen et al., 2014). These categories are; Extinct (EX), Extinct in the Wild (EW), Regionally Extinct (RE), Critically Endangered (CR), Endangered (EN), Vulnerable (VU), Near Threatened (NT), Least Concern (LC), Data Deficient (DD), Not Applicable (NA) and Not Evaluated (NE) (IUCN, 2012; Allen et al., 2014).

Colchicum Species of Turkey in IUCN Red List Categories

Turkey has three *Colchicum* species in various categories of IUCN Red List (Table 1).

Table 1. *Colchicum* species of Turkey in IUCN Red List Categories

Colchicum Species	Red List Category	Red List Criteria	Endemism
Colchicum balansae	LC	-	-
Colchicum leptanthum	CR	B2ab(iii,v)	Northeast Anatolia
Colchicum troodi	LC		-

Colchicum balansae

Red list category: Threat category is Least Concern (LC) for *Colchicum balansae.*
Endemism: It is not endemic (Düşen and Sümbül, 2007; Thacker, 2014).
Major threats: The threats to this species are unknown (Thacker, 2014).

Colchicum leptanthum

Red list category: Threat category is Critically Endangered (CR) (Eminağaoğlu et al., 2010).
Red list Criteria: B2ab(iii,v) (Ekim et al., 2014).
Endemism: Northeast Anatolia (Turkey) (Persson, 2001; Eminağaoğlu et al., 2010; Ekim et al., 2014).
Major threats: The species habitat is threatened by dam and road construction (Ekim et al., 2014), grazing (Eminağaoğlu et al., 2010).

Colchicum troodi

Red list category Threat category is Least Concern (LC) (Fragman-Sapir et al., 2017).
Endemism: It is not endemic (Fragman-Sapir et al., 2017).
Major threats: There are no known significant past, ongoing or future threats to this species (Fragman-Sapir et al., 2017).

Other *Colchicum* species that are under threat in Turkey

The other *colchicum* species that are reported to be under threat in Nezahat Gökyiğit Botanical garden are *C. baytopiorum, C. bornmuelleri, C. burttii, C. micranthum, C. micranthum*. These species are endemic to Turkey (Tehditaltındakibitkiler, 2018).

Discussion and Suggestions against Threats

Geophytes are the most preferred group among the ornamental plants due to their aesthetic features, suitability to be cut flowers and their fragrance. They have economic value due to their attractive flowers and usage in the drug industry (Karakaş Metin et al., 2014; Çığ and Başdoğan, 2015; Çakır, 2017). Turkey has rich genetic resources of geophyte including *Colchicum* species. However some of them are under threat. The important endangered *Colchicum* species are growing in different part of Turkey (Fragman-Sapir et al., 2017; Ekim, 2014; Thacker, 2014).

Colchicum species are very important due to their potential usage as ornamental plants and their pharmacological usage. It was reported that *Colchicum* species bloom in different times and can be used in landscape field (Kaya et al., 2013). The major alkaloid of *Colchicum* is

colchicine (Simanek et al., 1990; Düşen and Sümbül, 2007). Colchicine is an agent with antitumor properties used in chemotherapy (Fell and Ramsden, 1967; Düşen and Sümbül, 2007; Pırıldar et al., 2010, Sevim et al., 2010). Therefore, it is very important to protect these genetic resources of *Colchicum* due to their potential usage as ornamental plants and their pharmacological usage. In addition some of these species are endemic to Turkey. Lost of these endemic species in the flora of Turkey, means their lost from the world.

Grazing, dam and road construction are among the main threats for *Colchicum* species in our country, while the other threats to *Colchicum* species are unknown. These threats should be taken under control to protect the areas where *Colchicum* species naturally grown. In protecting the fauna and flora, restoring ecological balance, preserving and protecting rare and threatened plant species all over the world, several arrangements are being implemented (Akçakaya et al., 2000, Ibadullayeva et al., 2011). In order to save the flora Turkey, some measures should be taken. Prohibit or control the collection of all native plants without a special permit is of important. Collection of the all *Colchicum* species is prohibited in the wild at national level by regulations concerning bulbous plants. Nevertheless the government must increase the legislative measures.

Educating the local people about the importance of the native plants under threat is also important to increase the realization and care to flora (Çelikel, 2014). It was also reported that it is important increase awareness of local residents and visitors to reduce human impact (Manvelidze et al., 2009). The endemic and endangered species must be conserved.

Cultivation and propagation studies on these species should be encouraged and increased. In the frame of TUBİTAK project 47 *Colchicum* species (36 of which are endemic) were taken under conservation in Turkey (Kaya et al., 2009). Ellington et al. (1997) reported that corm of *C. autumnale* treated with paclobutrazol showed some basal protuberances. Corms of *C. luteum* were treated in vitro with soluble chitosan added to the MS tissue culture medium and chitosan increased the germination percentage (Wagh et al., 2015). In addition there are some studies about seed germination of *Colchicum* (Antonidaki-Giatromanolaki et al., 2008; Fukai et al., 2013). Studied on *Colchicum* species are mostly about their alkaloid content, especially colchicine activity on some diseases. It is clearly understood that vegetative and generative propagation methods of *Colchicum* species should be increased and improve to their sustainability and restore to the nature. Tissue culture techniques also are important for both propagation and in vitro conservation.

Conclusions

As a conclusion, *Colchicum* species have been of great economic importance from past to present due to their properties in medicine. It is also valuable for biodiversity and due to potential usage of ornamental plants. More research studies on biology, ecology, propagation methods and cultivating techniques of *Colchicum* species are among the main conservation measures for habitat and population of *Colchicum* species. In addition, management of grazing, cultivation in botanical gardens or maintenance in seed banks, reintroduction or reinforcement of populations are important to save endangered *Colchicum* species and other native plants of Turkey.

Abstract

Irrigation is one of the indispensable yield-increasing elements in agriculture especially in arid and semi-arid regions like Turkey. To obtain the benefit expected from irrigation, water use parameters, system designing-projecting criteria and system performances should be determined both at irrigation schemes and – on the parcel scale – in individual irrigation systems. For this purpose, this study was carried out to evaluate some performance indicators of sprinkler irrigation systems on the Sandıklı Plain in Afyonkarahisar, Turkey; to determine the performance of those systems; and to find out what precaution should be taken to increase the efficiency of the systems. The fieldwork of the study was performed on the field including the Koçhisar, Ülfeciler, Örenkaya, Kusura, and Ballık Villages of Sandıklı in 2012. For this purpose, 15 sprinkler irrigation systems were selected in regions where potato cultivation was intense, representing the Sandıklı Plain. Christiansen uniformity coefficient (CU), distribution uniformity (DU), sprinkler pressure as well as sprinkler head displacement and change were evaluated for each system. The water distribution uniformity was determined by doing single lateral line water distribution tests. Average sprinkler flow rates and soil infiltration rates were found between 6.84 and 37.46 mm/h and between 8 and 23 mm/h, respectively. Christiansen uniformity coefficient (CU) ranged from 44 to 86% and distribution uniformity from 25 to 84%. Furthermore, it was determined that the pipe diameters in 4 systems were poor and 11 operators were found within the acceptable level. Considering these obtained results, there may be increases in Christiansen uniformity coefficient and distribution uniformity values in the event that producers make improvements in their irrigation systems. These improvements in the performance indicators will enhance the efficiency in water use.

Keywords: *Sprinkler irrigation system, Christiansen uniformity coefficient, Distribution uniformity, Potato.*

Introduction

One of the most important inputs for the enhancement and sustainability of agricultural production particularly in arid and semi-arid regions is water. Achieving a water-based increase in yield depends on the providing of a plant with water at the time and amount the plant desires. The greatest problem of agriculture in Turkey, as in all arid and semi-arid regions, is the deficient irrigation water. Therefore, it is a must to make best use of the available irrigation water. Obtaining the benefit expected from the lands opened for irrigation depends on the planning, projecting, and operating of irrigation systems in agreement with soil, crop, and topographical conditions. Thus, the possible projecting and operating errors of the systems set up should be determined and, if available, these errors should be corrected. Of 112 billion m³ of annual average total available water in Turkey, 44 billion m³ are used in agriculture and industry and as drinking water. About 73% of this water is used in agricultural irrigation (Gökalp and Çakmak, 2016). The efficient use of water has gained importance as the demand for water is increasing. However, excessive water is still being wasted in agricultural irrigation (Akkuzu et al., 2011). Such cases as aridity, climate change, water

shortage, and technological developments in the recent years have made it inevitable to make a transition to pressurized irrigation methods instead of surface irrigation methods. The most common pressurized irrigation method is the sprinkler irrigation method (Kırnak et al., 2013). Negative cases occur in the sustainability of investments due to the use of materials with various properties in the irrigation area, different water distribution patterns, and low system performances. It is essential to reveal the reasons for this situation in systems with low efficiency and to take the necessary measures to this end (Dinç and Bahçeci, 2006).

Although sprinkler irrigation systems are used to irrigate different crops on the Sandıklı Plain in Afyonkarahisar, which is the study area, they are predominantly used to irrigate potato and sugar beet. This research was carried out to evaluate the performances of the sprinkler irrigation systems used in the potato growing areas out of the crops for which sprinkler irrigation was intensively used; to reveal how efficiently these systems worked; and to determine what kind of precautions should be taken to improve the system performances.

Material and Methods

The Sandıklı Plain, where the research was carried out, is at the geographical location between 29°50'-30°30' eastern meridians and 38°15'-38°45' northern parallels. The lowest mean temperature is 0.9 ^{o}C in January, whereas the highest mean temperature is 23.8 ^{o}C in August. The annual average relative humidity in the region is 61.9%. The annual average total precipitation is 445.2 mm (Anonymous, 2013). The irrigable area on the Sandıklı Plain is 49,372.9 hectares, of these 26,588 hectares (53.85%) were opened for irrigation. Sprinkler and drip irrigation methods are commonly used in Sandıklı plain. The field including the Koçhisar, Ülfeciler, Örenkaya, Kusura, and Ballık Villages, where potato growing was common and the sprinkler irrigation method was employed in irrigation, was determined as a pilot region and 15 sprinkler systems were randomly selected in this field.

The types of sprinkler systems, the number of laterals on the main pipeline, sprinkler spacing, the irrigation water source, the pumping unit, diameters of the main pipe and the lateral pipe and the types and nozzle diameters were determined in the research. Infiltration tests were done in all parcels that have sprinkler irrigation systems according to the Güngör and Yıldırım (1989). The lateral discharges were measured by the help of a water meter in the system. The average sprinkler discharge rate was found by volumetrically measuring the end sprinkler discharges on the laterals. The sprinkler pressures were determined by means of a pitot tube manometer (Figure 1).

Figure 1. Measuring sprinkler pressure and catch can

Christiansen's method was utilized to make a hydraulic evaluation of the lateral pipe diameters (Korukçu and Yıldırım, 1981). The singular lateral method was employed to obtain the water distribution patterns. After obtaining the water distribution patterns as a result of the experiments, Equation 1 was used to find Christiansen uniformity coefficients (Cu) based on

the catch volumes (or depth) but Equation 2 to calculate distribution uniformity (Du) (Christiansen, 1942; Korukçu and Yıldırım, 1981):

$$C_u = \left(1 - \frac{\sum_{i=1}^{n} |h_m - h_i|}{n \times h_m}\right) \times 100 \quad (1)$$

where h_m - the average water depth collected in all catch cans (mm),
h_i - the water depth collected in catch can (mm),
n - the number of observations in the uniformity test.

$$Du = 100 \frac{\overline{X}_{lq}}{X} \quad (2)$$

where X -the average volume of water received on the test area (mm),
$\overline{X}_{lq}$ -the average low-quarter volume of water received (mm)

The average sprinkler rate was calculated:

$$h_m = \frac{q \times 1000}{L_1 \times L_2} \quad (3)$$

where h_m - the average sprinkler flow rate (mm/h)
q - sprinkler discharge (m^3/h)
L_1- sprinkler spacing on the lateral (m)
L_2- lateral spacing (m)

Results and Discussion

Properties of the pumps and pipelines

Electric pumps were used in the parcels with an electric network but pumps with diesel fuel in the parcels with no electric network out of the selected parcels. The power of the pumps in the study area ranged from 27.5 to 85 HP. A 27.5 HP pump, a 30 HP pump, a 32 HP pump and an 80 HP pump were available. Of the rest, 3 were 35 HP pumps, 3 were 40 HP pumps, and 5 were 50 HP pumps.

The main pipelines varied between 45 and 1,000 m in length. All lateral pipelines were arranged as portable in the research area. It was seen that some of the main pipeline was buried in soil in sprinkler irrigation systems No. 12, 14, and 15. Pipes with diameter of 90 mm were used as the main pipeline in 13.4% of the systems, while pipes with diameter of 110 mm were used in 26.6% of them, pipes with diameters of both 90 mm and 110 mm in 46.6% of them, and pipes with diameters of both 110 mm and 125 mm in 13.4% of them. Although it is undesired to use pipes with two different diameters without any lateral separation on the main pipeline since it will cause different pressures, friction loss, and water speed in the system, two different pipe diameters were discovered to have been used in 9 of 15 sprinkler irrigation systems under examination (Table 1).

Table 1. Properties of the pipes used on the main pipelines in the sprinkler systems

Sprinkler System No.	Main Pipe					
	Type	Length	Diameter, mm			
	Plastic	5 (m)	90	110	90-110	110-125
Number	15	2	2	4	7	2
Rate (%)	100	13.4	13.4	26.6	46.6	13.4

Pipes made of two different materials were found to have been used on the lateral pipelines. Pipes manufactured from an aluminum material were used as lateral pipes in 8 sprinkler irrigation systems (53.4%), whereas pipes made of a polyethylene material were used in 7 of them (46.6%). All lateral pipe diameters were 75 mm in the sprinkler irrigation systems (Table 2).

Table 2. Properties of the pipes used on the lateral pipelines in the sprinkler systems

Sprinkler System No.	Lateral Pipe				
	Type		Length		Diameter, mm
	Plastic	Aluminum	5 (m)	6 (m)	75
Number	7	8	7	8	15
Rate (%)	46.6	53.4	46.6	53.4	100

Sprinklers

All sprinklers in the study area were double nozzle. As it will be seen in Table 3, the nozzle diameters of the sprinklers differ from each other. Sprinklers with nozzle diameters of 4.2-5 mm were used in 5 of the 15 irrigation systems, sprinklers with nozzle diameters of 5.5-4 mm in 3 of them, and sprinklers with nozzle diameters of 2-4 mm, 2.5-3.5 mm, 3.5-4.5 mm, 4.15-3.2 mm, 4-6 mm, 4.3-4.8 mm, and 4.5-5 mm in the other sprinkler irrigation systems (Table 3).

Table 3. Properties of the sprinklers used in the study areas

Type	Nozzle Diameter	Number	Rate	a	Discharge
Double Nozzle	(mm)	Piece	(%)	(m)	(m^3/h)
15	2 - 4	1	6.67	18	1.19
	2.5 - 3.5	1	6.67	20	1.12
	3.5 - 4.5	1	6.67	12	1.70
	4.15 -3.2	1	6.67	17.20	1.68
	4 - 6	1	6.67	10.80	2.93
	4.2 - 5	5	33.31	14	2.14
	4.3 - 4.8	1	6.67	13	1.96
	4.5 - 5	1	6.67	14	1.94
	5.5 - 4	3	20.00	12.50	1.90

Sprinkler flow rates

While the sprinkler flow rates ranged from 6.84 to 37.46 mm/h, their infiltration rates varied between 8 and 23 mm/h. The sprinkler spacing on the irrigation systems was designed as 6 m on 10 sprinkler systems, 10 m on 3 sprinkler systems, and 5 m on 2 sprinkler system. The lateral spacing was designed as 15 m on 7 sprinkler systems, 10 m on 6 sprinkler systems, and 12 m on 2 sprinkler systems. The sprinkler flow rate was higher than the soil infiltration rate at 12 sprinkler facilities (77.33%) (Table 4). These values indicate that the soil infiltration rate, one of the most important parameters of the project, was not considered when projecting the parcel-based sprinkler systems.

Table 4. Soil infiltration rates and sprinkler flow rates

Sprinkler System No.	L_1 (m)	L_2 (m)	hm_1 (1st sprinkler)	hm_2 (2nd sprinkler)	Average (mm/h)	Soil infiltration rate (mm/h)
1	10	15	8.19	8.58	8.39	9

15	10	10	9.21	8.97	9.09	23

*L_1: Sprinkler spacing on the lateral, L_2: Lateral spacing, hm: Sprinkler flow rates

Lateral designing

The lengths of the laterals in the sprinkler irrigation systems ranged from 50 to 200 m. Of the irrigation systems, 6.6% used laterals with lengths of 0–50 m, 40% used laterals with lengths of 50–100 m, 26.7% used laterals with lengths of 100–150 m, and 26.7% used laterals with lengths of 150–200 m. As known, it is not recommended that the lengths of lateral lines be greater than 250 m (Güngör and Yıldırım, 1989). No lateral lines longer than 200 m were encountered in the examination carried out in the study area. 40% of the lateral connection shapes were L-shaped, but 60% of them were T-shaped. Of the lateral pipe spaces, 40% were 10 m, 13.3% were 12 m, and 46.7% were 15 m (Table 5).

Table 5. The properties of the lateral pipelines in the study areas

Sprinkler System	Lateral Pipe										
	Number of Lines		Connection Shape		Length (m)				Arrangement spacing (m)		
	1	2	L	T	0-50	50-100	100-150	150-200	10	12	15
Number	12	3	6	9	1	6	4	4	6	2	7
Rate (%)	80	20	40	60	6.6	40	26.7	26.7	40	13.3	46.7

An evaluation of the lateral pipe diameters

The lateral inlet pressure ranged from 1.8 to 3.8 atm, whereas the lateral outlet pressure varied between 1.6 and 3.6 atm. The sprinkler pressures ranged from 1.4 to 3.8 atm. In addition, the pressure remained below 2 atm on Sprinkler Irrigation Systems No. 2, 3, 4, 12, and 13 (Table 6). In order for a lateral pipe diameter to be convenient, the sprinkler pressure losses to take place between the end sprinklers should not exceed 20% of the average operating pressure. Accordingly, the pressure difference turned out above 20% in Irrigation Systems No. 6, 8, 9, and 11 in the study areas. These results are an indication of the inadequacy of these systems in terms of pipe diameters. Nevertheless, the pressure difference was below 20% in the remaining 11 irrigation systems; hence, these irrigation systems were adequate in terms of pipe diameters.

Table 6. The pressure values of the lateral pipes and the sprinklers

Christiansen Uniformity Coefficient (CU) and Distribution Uniformity (DU)

The CU values ranged from 44% to 86% in the study area. The average CU was 63.33% in the evaluated irrigation systems (Table 7). Merriam and Keller, (1978) and Keller and Bliesner, (1990) reported that CU should be greater than 84% for in order irrigation to be regarded as uniform. According to these results, almost all Sprinkler Irrigation Systems has not been realized uniform water distribution. The CU found out higher than 84% only in Irrigation System No. 2. Furthermore, there were differences among the irrigation systems in the same village as well. It might be stated that the different wind speeds measured during irrigation, the different operating pressures and the positions of the sprinklers are the reasons why the CU so different. Another criterion used to evaluate in the sprinklers is the distribution uniformity. The DU values determined considering the water distributions between the laterals were in a quite wide range of 25%-84%. The average DU was calculated as 44.33%. Keller and Bliesner (1990) stated that DU should be greater than 75% for uniform irrigation. The average DU in the study area was approximately 30% lower than this value. When the irrigation systems are examined on an individual basis, it might be stated that an allowable level of uniform irrigation was performed only in System No. 2. The reasons why the distribution uniformity values differed among the irrigation systems are the same as the factors which affected the Christiansen uniformity coefficient. Such factors as the wind speed and direction during irrigation, the operating pressure and change, the distances between the sprinklers and the laterals, the different sprinkler nozzle diameters, their wear or their destruction by the farmers gave rise to the low DU coefficient values. Apart from them, Tarı and Yazar (2010) stated that such factors as not keeping sprinklers in an upright position, their clogging up or their turning would also negatively affect the distribution uniformity value.

Conclusion

Many of the Irrigation Systems in the study area were discovered to have used only one lateral line when performing sprinkler irrigation. The power of the pumps varied between 27.5 and 85 HP, with 50 HP being generally used. Sprinklers with different nozzle diameters and properties were observed on the laterals. Some 11 irrigation systems were found convenient in terms of pipe diameters, whereas inconvenient pipe diameters were used in 4 of them. Moreover, the higher average sprinkler flow rate than the soil infiltration rate in 12 of 15 irrigation systems shows that the infiltration rate was not taken into consideration during designing. Additionally, the sprinklers were observed to have worn over time depending on the frequent use of the system and the exogenous factors. It was seen that sprinklers with different properties were used instead of the broken and deformed sprinklers and that nozzles with different diameters were used instead of the broken nozzles. For all these reasons, the Christiansen uniformity coefficient (CU) and distribution uniformity (DU) values remained below the limit values in almost all irrigation systems. The desired performance values can be obtained in the irrigation systems used at the locality in the event that the project and operating errors determined in this study are eliminated.

Abstract

The worldwide trend of declining biological diversity of plant resources exacerbates the problem of food security. Therefore, the study of the state of honey plants, which allows determining the full range of their species diversity, is relevant. Our studies of honey plants on the territory of the state of Mississippi, USA, found more than 180 species of 99 genera from 41 families, the most numerous of which are *Asteraceae* – more than 39 species (21%), *Fabaceae* – more than 20 species (11%), *Rosaceae* – 18 species (10%). The majority of honey plants studied – 123 species (near 68%) are native species, 53 (29%) – introduced, and 6 (3%) species widely distributed throughout the world. The most of the species are native forest plants, characterized by high level of endemism for the North American region. The bulk – 103 species of all registered (55%) – are evenly distributed throughout the territory of the state of Mississippi. By the place of growth, the registered honey plants are divided into: forestry ones – 79 species (37%), forest belts and ornamental plantations plants – 54 species (24%), field and fodder plants – 20 species (9%), plants of meadows, pastures and wetlands – 53 species (24%), garden and berry plantations plants – 9 species (4%), and plants of vegetable and melons fields – 4 species (2%). Totally, more than 87 species of honey plants from 57 genera of 35 families are cultivated. But the majority of species (more than 60%) are represented only in the wild state, mainly on forest lands.

Keywords: *Biological diversity, State of Mississippi, Honey plant.*

Introduction

Rational use and reproduction of natural resources is of great importance in addressing the problem of food security and sustainable development of agricultural production. These resources include honey plants, which are the food base of honey bees and other pollinators, as well as a source of production of beekeeping products that are important for human nutrition (Kostyleva and Zhitin, 2011). There is a growing recognition that the biodiversity of honey plants is a global asset of current and future generations (Wilson, 1992). At the same time, economic development of territories leads to a decrease in the species diversity of honey plants and scarcity of the honey resources (Naumkin, 2010). It is projected that almost two thirds of the world's plant species are threatened with extinction during the 21st century (Blackmore et al., 2000). It is known that the composition and productivity of honey plant resources depend on geographic conditions (Avetisyan, 1963). The richest in this respect are the humid subtropical regions (Ayers and Harman, 1994). Therefore, the study of the condition of honey plants in one of the representative regions of humid subtropics, which allows determining the full range of their species diversity, is relevant.

Materials and methods

The objects of the research were honey and pollen plants. The studies were carried out on the territory of the state of Mississippi, USA.

The body of honey plants was studied by a botanical survey of the region. All encountered species of honey plants were taken into account with the collection of herbarium material, if it

was necessary to clarify their exact affiliation. Beforehand, the location of counts was randomly determined on the map of the region, covering its northern, southern, eastern, western and central parts. The body of honey plants was studied by a botanical survey of the region. All encountered species of honey plants were taken into account with the collection of herbarium material, if it was necessary to clarify their exact affiliation. Beforehand, the location of counts was randomly determined on the map of the region, covering its northern, southern, eastern, western and central parts. The counts of honey plants were carried out by the route (linear transects) method (Krivtsov et al., 1999) comprising all typical plant associations on each of the dominant melliferous lands, where at least two or three routes were laid.

To determine the quantitative participation of the honey plants the trial plots (10-20) were laid on the routes, every 50-60 steps. Trial plots for wood and shrub plants were 25-100 m^2 (5x5 or 10x10 м) by the projection of crowns, for herbaceous ones - 0.25-1.00 m^2.

The species of honey plants were determined by Gleason and Cronquist (1991) and PLANTS Interactive ID Keys. The accuracy of the determination was checked by the samples of the herbarium of the Mississippi Museum of Natural Sciences. The taxonomy of species was indicated according to GRIN Database.

Results and discussion

In total, over 180 species of honey and pollen plants from 99 genera of 41 families have been registered in the region under study. Including families: *Asteraceae* Dumort. – more than 39 species (21% of the total number of species); *Fabaceae* Lindl. - more than 20 species (11%), *Rosaceae* Adans. - 18 species (10%), *Lamiaceae* Lindl. - 9 species (5%), (*Aquifoliaceae* Lindl.) - 6 species (3,3%); *Polygonaceae* Juss.), *Cornaceae* Dumort., *Magnoliaceae* Juss., *Scrophulariaceae* Juss., *Anacardiaceae* Lindl. - 5 species (2,7%) in each; *Bignoniaceae* Juss., *Ulmaceae* Mirb., *Lythraceae* St.-Hil., *Salicaceae* Mirb., *Cucurbitaceae* Juss. - 4 species (2,0 %) in each; *Verbanacea* St.Hil., *Ericaceae* Juss., *Asclepiadaceae* R.Br, *Oleaceae* Hoffmgg., *Violaceae* Batsch, *Theaceae* Mirb. ex Ker Gawl. – 3 species (1,5%) in each. The remaining families are represented by 1-2 species (1%). The classification of honey plant families by species composition is presented graphically in Figure 1.

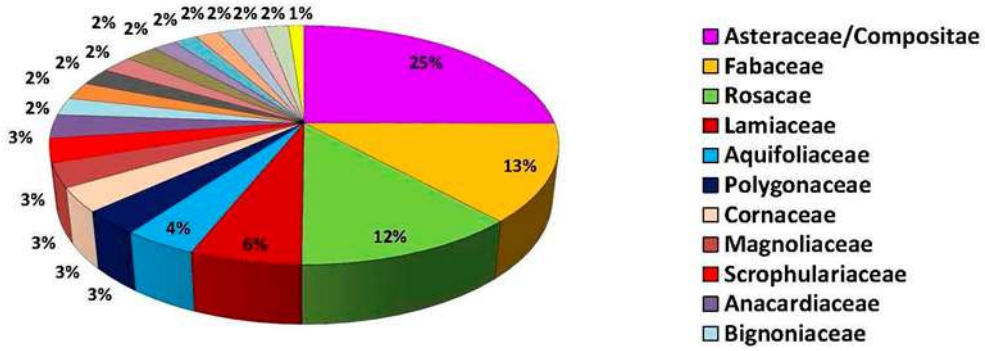

Fig. 1 Classification of honey plant families by species composition

Comparison of our data with other studies (Fulton, http: //www.entomology.msstate ...), conducted earlier in the same region, shows that the species composition of honey plants is more than 3.7 times broader than that given in the list of the indicated author, since our studies were performed more thoroughly, covering more biotopes and plant associations.

The majority of honey plants studied – 123 species (near 68%) are native species, 53 (29%) – introduced, and 6 (3%) species widely distributed throughout the world.
The largest proportion of native species is found in the families: *Bignoniaceae, Verbanaceae, Ericaceae, Ulmaceae, Salicaceae, Cornaceae, Asclepiadaceae, Magnoliaceae, Aquifoliaceae, Anacardiaceae* – 100% in each family; *Asteraceae* – 77%, *Lamiaceae* – almost 67%.
The largest proportion of species introduced from different parts of the world is found in the families: *Oleaceae, Cucurbitaceae, Theaceae* - 100% in each family, *Polygonaceae* - 80%, *Fabaceae* - 72%.
Both the general composition of the melliferous vegetation in a given locality and the entire complex of external meteorological and atmospheric influences, which affect the nectar production of plants, are largely determined by the geographical conditions of growth.
The honey plants in the study region are distributed unevenly (Fig. 2). The bulk - 103 species (55% of all the registered honey plants) are distributed throughout all the territory of the state of Mississippi. Of these, 6 species (more than 3%) were rare, 51 species (28%) were spread sporadically, the remaining 46 species (25%) were found almost everywhere on the territory under the study, i.e., were the most common species.

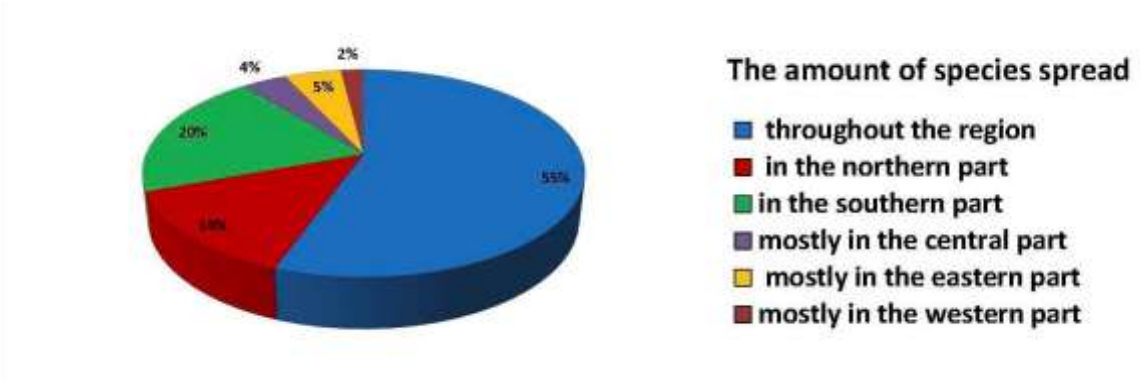

Fig. 2 Geographical distribution of honey plant species in the region

Twenty five species - (almost 14% of all the registered honey plants) are distributed only in the northern part of the region. Of these, 16 species (almost 9%) are rare: *Vernonia fasciculata* Michx., *Helianthus annuus* L., *Eupatorium purpureum* L., *Gaylussacia baccata* (Wangenh.) K. Koch, *Polygonum persicaria* L., *P. cuspidatum* Sieb., *Lythrum salicaria* L., *Decodon verticillatus* (L.), *Salix caroliniana* M., *Aesculus flava* Aiton, *Claytonia linearis* (Douglas), *Prunus avium* L., *Leonurus cardiaca* L., *Pycnanthemum verticillatum* (Michx.) Pers., *P. virginianum* (L.) T. Dur. & B.D. Jacks. ex B.L. Rob. & Fernald, *Nepeta cataria* L.; 5 species (almost 3%) are distributed sporadically: *Cichorium intybus* L., *Symphoricarpos orbiculatus* Moench, *Asclepias syriaca* L., *Scrophularia marilandica* L., *Verbascum blattaria* L. and 4 species (2%) are distributed throughout the north of the territory: *Glycine max* L ., *Ulmus crassifolia* Nutt., *Apocynum cannabinum* L., *Allium cepa* L.
Thirty six (almost 20%) of the species recorded are common in the southern part of the study region, including 13 species (7%) which are rare: *Acacia farnesiana* (L.), *Trifolium hybridum* L., *Vaccinium corymbosum* L., *Sinapis alba* L., *Scrophularia marilandica* L., *Crataegus spp*., *Cucurbita pepo* L., *Citrullus lanatus* (Thu.), *Cucumis melo* L., *Cucumis sativus* L.; 9 species (5%) are distributed sporadically: *Liatris spicata* (L.) Willd., *Parkinsonia aculeata* L., *Trifolium vesiculosum* Savi, *Cornus alternifolia* L., *Ligustrum japonicum* Thunb. *L. lucidum* Aiton, *Triadica sebifera* (L.), *Monarda punctata* L. and 14 species (almost 8%) are distributed throughout the south of the territory: *Baccharis angustifolia* Michx., *B. glomeruliflora* Per., *Gaillardia pulchella* Foug., *Trifolium nigrescens* Viv., *Verbena hastata* L., *Nyssa biflora* Walt., *Clethra alnifolia* L., *Magnolia grandiflora* L., *M. macrophylla* L., *Ilex glabra* L., *I.*

vomitoria Aiton, *I. coriacea* (Pursh), *Serenoa repens* Small, *Cliftonia monophylla* (Lam.) Britton, *Cyrilla racemiflora* L.

In the central part of the region, only 7 species (4%) were distributed, including 2 (1%) rare species: *Verbesina alternifolia* (L.), *Lifrum salicaria* L.; 3 species (2%) are distributed sporadically: *Coreopsis lanceolata* L., *Ilex verticillata* (L.), *Prunus persica* (L.) and 2 species (1%) are distributed throughout the center of the territory: *Helenium autumnale* L., *Monarda citriodora* Cerv. Some species are contemporaneously distributed in two parts of the investigated region: *Lythrum salicaria* L. - in the north and in the center, *Scrophularia marilandica* L. - in the north and south, though rarely found in the latter.

In the eastern part of the study region, we recorded 10 species (5%). Of these, 3 species (2%): *Eupatorium pilosum* Walter, *Aesculus glabra* Willld., *Fragaria* × *ananassa* are rare; 3 species (2%): *Salix interior* R., *Ptelea trifoliata* L., *Rhus / Toxicodendron vernix* (L.) - are distributed sporadically and 4 (2%): *Xanthium strumarium* L., *Alnus serrulata* (Aiton) Willd., *Asclepias verticillata* L. and Magnolia virginiana L. - are distributed throughout the eastern part of the territory.In the western part of the study region, we recorded 3 species (2%). Of these, 2 species (1%): *Sonchus arvensis* L. and *Catalpa speciosa* (Warder) - are rare and 1 (1%): *Taraxacum officinale* Wigg. – is distributed throughout the western part of the territory.

The occurrence of a relatively small number of honey plant species in the eastern, western and central parts of the area under study is evidently due to the fact that the territory of the region is strongly extended from north to south (the region is almost twice as long than it is wide).

We also found many species of honey plants, endemic to North American Atlantic Region (NAAR), which are preserved in the area to a large extent due to the pollination activity of the honey bee. Many of these endemics are threatened or endangered species.

For the Appalachian Province of NAAR (northern part of the state) endemic species include *Magnolia acuminate* (L.) L., *M. macrophylla* L., *Claytonia virginica* L., *Polygonum spp., Viola spp., Salix spp., Clethra spp., Rubus spp., Prunus spp., Crataegus spp., Tilia americana* L., *Gleditsia triacanthos* L., *Robinia pseudacacia* L., *Acer saccharum* L., *Aesculus glabra* Willd., *Catalpa speciosa* (Warder), species of *Penstemon, Solidago, Aster*, and *Eupatorium*.

For the Atlantic and Gulf Coastal Plain Province (southern part of the state) endemics are *Magnolia grandljlora L., M. virginiana* L., *Nyssa biflora* Walter, and species of *Asclepias.*

By the place of growth, the registered honey plants are divided into: forestry ones – 79 species (37%), forest belts and ornamental plantations plants – 54 species (24%), field and fodder plants – 20 species (9%), plants of meadows, pastures and wetlands – 53 species (24%), garden and berry plants – 9 species (4%), and plants of vegetable and melons plots – 4 species (2%).It should be noted that many forest honey plants (more than 33 species, i.e. about 40% of all forest species) are used in green construction and as ornamental plants: *Liquidambar styraciflua* L., *Symphyotrichum spp.*, *Baccharis glomeruliflora* Per. and *B. halimifolia* L., *Eupatorium purpureum* L. and *E. perfoliatum* L., *Catalpa bignonioides* Walter and *C. speciosa* (Warder), *Campsis radicans* (L), *Cercis canadensis* L., *Robinia pseudoacacia* L., *Gleditsia triacanthos* L., *Symphoricarpos orbiculatus* Moench, *Salix nigra* Marsh, *Cornus florida* L.. and *C. alternifolia* L., *Acer saccharinum* L. and *A. rubrum* L., *Aesculus glabra* Willd. and *A. flava* Aiton, *Tilia americana* L. *var. heterophylla* and *T. americana* L. *var. caroliniana, Liriodendron tulipifera* L., *Magnolia virginiana* L., *M. grandiflora* L., *M. acuminata* (L.), *Ilex opaca* A., *I. glabra* L., I. *vomitoria* Aiton and *I. coriacea* (Pursh), *Sabal minor* (Jacq.), *Crataegus spp, Viola sororia* Willd, *Callicarpa americana* L. Some forest species - *Gaylussacia baccata* (Wangenh), *Vaccinium corymbosum* L.) are used as a cultivated plant in the berry patches.

Many wild honey plants (more than 17 species, or about 8%) growing in the open spaces (meadows and pastures, clearing banks of rivers and streams, roadsides, and vacant lots, etc.) are also used as ornamental plants: some species of aster - *Symphyotrichum novae-angliae*

(L.) and others, *Gaillardia pulchella* Foug, *Helenium autumnale* L., *Coreopsis lanceolata* L., *Liatris spicata* (L.) Willd., *Parkinsonia aculeata* L., *Phyla nodiflora* (L.), *Asclepias syriaca* L.and *A. tuberosa* L., *Triadica sebifera* (L.), *Penstemon laevigatus* Aint, *Viola tricolor* L., *Monarda punctata* L. and *M. citriodora* Cerv. or as agricultural crops: *Helianthus annuus* L., *H. tuberosus* L., *Cichorium intybus* L. and the above 2 mint species cultivated as spices.
In the studied region, more than 87 species from 57 genera of 35 families of the honey plants registered by us are cultivated to a greater or lesser extent. The largest number of species of cultural honey plants belongs to the following families: *Fabaceae* - 16 species, *Asteraceae* - 12 species, *Rosaceae* - 6 species, *Aquifoliaceae*, *Cucurbitaceae*, *Magnoliaceae* - 4 species in each family, *Oleaceae*, *Theaceae*, *Lamiaceae* - 3 species in each family. In the remaining families, there are only 1-2 species of cultivated honey plants (Fig. 3).

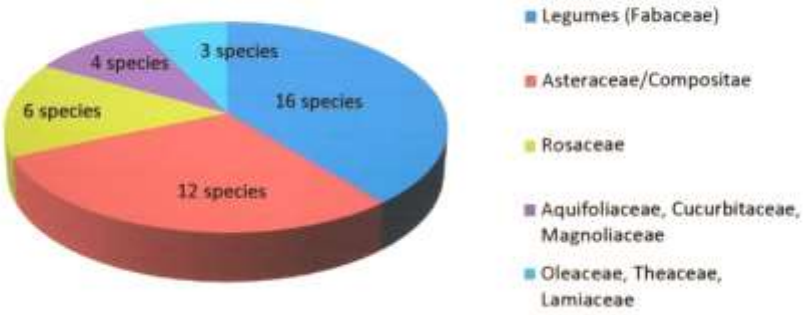

Fig. 3 Classification of the families of cultivated honey plants

In agriculture 33 species of honey plants belonging to 12 families are used: Fam. *Asteraceae* Dumort. - *Helianthus annuus* L., *Helianthus tuberosus* L., *Cichorium intybus* L.; Fam. *Fabaceae* Lindl. - *Vicia villosa* Roth, *V. sativa* L., *Melilotus officinalis* (L.) Lam., *Melilotus albus* (L.) Medik., *Trifolium repens* L., *Trifolium nigrescens* Viv., *Trifolium vesiculosum* Savi; *Trifolium incarnatum* L., *Trifolium pratense* L., *Trifolium resupinatum* L., *Trifolium hybridum* L., *Glycine max* (L.) Merr.; Fam. *Ericaceae* Juss. - *Gaylussacia baccata* (Wangenh.), *Vaccinium corymbosum* L.; Fam. *Vitaceae* Juss. - *Vitis rotundifolia* Michx.; Fam. *Brassicaceae* Burnett - *Sinapis alba* L.; Fam. *Liliaceae* Juss. - *Allium cepa* L.; Fam. *Malvaceae* Juss.: *Gossipium hirsutum* L.; Fam. *Rosaceae* Adans.: *Rubus aboriginum* Rb., *Malus domestica/pumila* Bork., *Pyrus communis* L., *Prunus persica* (L.), *Fragaria x ananassa;* Fam. *Cucurbitaceae* Juss.: *Cucurbita pepo* L., *Citrullus lanatus* (Thunb.), *Cucumis melo* L., *Cucumis sativus* L.; Fam. *Ebenaceae* Gurke: *Diospyros virginiana* L.; Fam. *Lamiaceae* Lindl.: *Monarda punctata* L. and *M. citriodora* Cerv.
55 species of honey plants from 23 families are used in landscaping and decoration: Fam. *Altingiaceae* Lindl. - *Liquidambar styraciflua* L.; Fam. *Asteraceae* Dumort. - *Symphyotrichum novae-angliae* (L.); *Baccharis glomeruliflora* Per., *B. halimifolia* L., *Gaillardia pulchella* Foug., *Helenium autumnale* L., *Coreopsis lanceolata* L., *Liatris spicata* (L.) Willd., *Eupatorium perfoliatum* L., *E. purpureum* L.; Fam. *Bignoniaceae* Juss. - *Campsis radicans* (L.), *Catalpa bignonioides* Walter., *C. speciosa* (Warder); Fam. *Fabaceae* Lindl. - *Cercis canadensis* L., *Gleditsia triacanthos* L., *Parkinsonia aculeata* L., *Robinia pseudoacacia* L.; Fam. *Verbanaceae* St.-Hil. - *Phyla nodiflora* (L.) Greene.; Fam. *Lythraceae* St.-H - *Lagerstroemia indica* L.; Fam. *Caprifoliaceae* Jus.- *Symphoricarpos orbiculatus* Moench; Fam. *Salicaceae* Mirb. - *Salix nigra* Marsh.; Fam. *Cornaceae* Dumort. – *Cornus florida* L., *C. alternifolia* L.f.; Fam. *Aceraceae* Juss.- *Acer rubrum L., A. saccharinum* L.*;* Fam. *Clethraceae* Klotzsc.- *Clethra alnifolia* L.; Fam. *Hippocastanaceae* DC. - *Aesculus glabra* Willd., *A. flava* Aiton; Fam. *Asclepiadaceae* R. Br. - *Asclepias syriaca* L., *A. tuberosa*

L.; Fam. *Tiliaceae* Juss. - *Tilia americana* L., *T. americana* L. var. *caroliniana*; Fam. *Magnoliaceae* Juss. - *Magnolia virginiana* L., *M. grandiflora* L., *M. acuminata* (L.), *Liriodendron tulipifera* L.; Fam. *Oleaceae* Hoffmgg. - *Ligustrum japonicum* Thunb., *L. lucidum* W.T. Aiton, *L. sinense* Lour.; Fam. *Euphoriaceae* Juss. - *Triadica sebifera* (L.); Fam. *Scrophulariaceae* - *Penstemon laevigatus* Aiton; Fam. *Aquifoliaceae* Lindl., *Ilex opaca* Aiton., *I. glabra* (L.) A., *I. vomitoria* Aiton, *I. coriacea*(Pursh); Fam. *Arecaceae* Schultz - *Sabal minor* (Jacq.); Fam. Rosaceae Adans. - *Crataegus spp.*, Fam. *Anacardiaceae* Lin. - *Rhus typhina* L.; Fam. *Violaceae* Batsch - *Viola sororia* W., *Viola tricolor* L.; Fam. *Theaceae* Mirb. ex Ker - *Camellia sinensis* L., *C. japonica* L., *C. sasanqua* Thunb.; Fam. *Lamiaceae* Lindl. - *Callicarpa americana* L., *Monarda punctata* L., *M. citriodora* Cerv.

But the majority of honey plant species (more than 60%) are registered by us only in the wild. Basically, they are represented by forest species, obviously due to the fact that most of the study area is covered with forests.

Conclusion

Honey plants registered by us compose a vital part of biological diversity of the state of Mississippi. The most of species are native forest plants, characterized by high level of endemism. Though numerous honey plants in the region are cultivated, the majority of species is represented only in the wild. Conservation and increase of honey plants resources can be achieved by protecting rare and endangered species of wild honey plants (Kostyleva, 2013), planting selected melliferous species around apiaries, along roadsides, railway tracks and power lines, on empty lands, and lands not having great agricultural value (Ayers et al., 1987).

CONTENT OF NATURALLY OCCURING AND ARTIFICIAL RADIONUCLIDES IN CULTIVATED SOIL IN BELGRADE (SERBIA)

Nataša B. SARAP*, Jelena D. KRNETA NIKOLIĆ, Milica M. RAJAČIĆ, Marija M. JANKOVIĆ, Dragana J. TODOROVIĆ, Gordana K. PANTELIĆ, Ivana S. VUKANAC

Abstract

Radioactivity of soil is one of the main source of human exposure and an important subject of environmental monitoring. The present study was conducted in order to determine the content of naturally occurring radionuclides (U and Th series and ^{40}K) and artificial radionuclides (^{137}Cs and ^{90}Sr) in the surface layer of cultivated soil. The soil was sampled twice a year, in the spring and autumn season of 2017 on 5 locations in Belgrade (Serbia). The concentrations of naturally occurring radionuclides, as well as the artificial radionuclide of ^{137}Cs were measured using HPGe gamma detectors, while the concentration of artificial radionuclide ^{90}Sr was conducted by low level gas proportional counter. The average values of naturally occurring radionuclides were: 43.3 Bq kg^{-1} for ^{226}Ra, 45 Bq kg^{-1} for ^{232}Th, 552 Bq kg^{-1} for ^{40}K, 42.1 Bq kg^{-1} for ^{238}U and 2.1 Bq kg^{-1} for ^{235}U, while the average values of artificial radionuclides were 15.7 Bq kg^{-1} for ^{137}Cs and 0.74 Bq kg^{-1} for ^{90}Sr. The obtained concentrations of investigated radionuclides were in the range of the concentrations reported in the literature for the cultivated soil. No significant variation was noticed between concentrations of naturally occurring radionuclides with respect to the sampling period, while for ^{137}Cs, slight variations were noticed with respect to the location and season. Based on the average values of the activity concentration of gamma emitters in investigated soil samples, the health hazard indices were estimated. The values obtained are comparable with the corresponding world permissible values.

Introduction

Radioactivity arising from natural sources is the main contribution to the annual dose received by the population, exposure resulting from radionuclides inherent in the earth's crust and from cosmic rays. The main sources of external γ-radiation are the radionuclides of the ^{238}U and ^{232}Th series, along with their progeny and ^{40}K (Mohery *et al*., 2014). Gamma radiation emitted from such naturally occurring radionuclides present in all soils represents the main external exposure to human body. With regard to terrestrial gamma radiation, the specific radiation levels are related to the content in the radionuclides of the soils, which in turn depends on the nature of the parent rock. The content of ^{238}U and ^{232}Th is large in the magmatic rocks as granite and basalt, but also from the sedimentary rocks as phosphate rock (Pehlivanovic *et al.*, 2017). The use of fertilizers in farming may result in enhanced levels of natural radioactivity in some particular areas. Studies of soil radioactivity can provide reference data in observing possible future anthropomorphic impact and associated radiological risk to human health (Santawamaitre *et al*., 2011).

Many radionuclides of artificial origin have been released to the environment by different processes. The radioisotopes of caesium and strontium are the most important ones that may be deposited by fallout over soil and plants as they are produced anthropogenically by several types of nuclear activities including past testing of nuclear weapons and nuclear accidents, with one of the largest was Chernobyl at 1986 (Prăvălie, 2014). The main mechanism of

deposition of artificial radionuclides is wet deposition (fallout), as well as dry deposition also (Krstić *et al.,* 2004). The fission products, ^{137}Cs and ^{90}Sr are biologically important, because of their behavior are similar to potassium and calcium, respectively. These radionuclides are deposited in biological systems, especially in sensitive tissues, followed the metabolic path of the mentioned ions. Measurement of natural and artificial radioactivity content in soil is very important to set a baseline level and then plot the trend with time as result of any radioactive release for environmental and public protection purposes (El Samad *et al*., 2013). Therefore, the main objective of this study is to analyze the distribution of naturally occurring radionuclides, as well as the artificial radionuclides in cultivated soil at the teritorry of Belgrade city (Serbia). This study will contribute to the better understanding of radionuclides behavior in the agricultural managed systems. Beside mentioned reasons, the knowledge of radioactivity present in soil enables one to asses any possible radiological hazard to mankind. Hence, based on the average values of the activity concentration for each sites, to estimate the health hazard indices by evaluate the gamma dose rate, the annual effective dose equivalent (outdoor), the external hazard index, the radium equivalent activity and the excess lifetime cancer risk.

Material and Method

In order to measure the content of the natural and artificial radionuclides, the cultivated soil samples were collected on 5 locations at the area of Belgrade city: Zeleno Brdo, Jabučki Rit, Dunavac, Obrenovac and Lazarevac. The soil sampling was conducted in the spring and autumn season of 2017 year. The coordinates of sampling sites and intervals of ambient dose rates are given in *Table 1*. The measurement of the ambient dose rate at sampling locations was performed using a scintillation probe (Model 6150 AD-b produced by Automess, Germany) 1 m above the ground.

Table 1. The GPS coordinates of sampling locations and the corresponding ambient dose rates

Location	**GPS coordinates**		**Ambient dose rate (nSv h^{-1})**
Zeleno Brdo	N: 44° 47'	E: 20° 31'	130 - 190
Jabučki Rit	N: 44° 55'	E: 20° 33'	120 - 130
Dunavac	N: 45° 03'	E: 20° 22'	120 - 130
Obrenovac	N: 44° 39'	E: 20° 12'	87 - 105
Lazarevac	N: 44° 23'	E: 20° 16'	115 - 130

About 2 kg of soil sample was taken from upper layer of 0-20 cm at each sampling site. The preparation of soil samples involved the following: removing plant residues from the basic soil mass, samples drying at 105 °C, grinding and sieving. About 600 g of prepared soil samples were placed in Marinelli beaker of 500 mL, sealed with beeswax and left to reach secular equilibrium for four weeks, before gamma spectrometric measurements. Also, 300 g of prepared soil samples were mineralized at 500 °C by the method of dry burning for radiochemical determination of ^{90}Sr.

The soil were analyzed for ^{226}Ra, ^{232}Th, ^{40}K, ^{238}U, ^{235}U and ^{137}Cs by direct gamma assay, using HPGe gamma detectors with a relative efficiency of 20 % and a resolution of 1.8 keV at 1.332 MeV (with associated electronics provided by Canberra Industries, Meriden, Connecticut, USA). The counting time was 17 h, because of this time providing a precision of

better than ±10 % and a 95 % level of confidence. The spectrum was analyzed using a GENIE 2000 Canberra software.

The geometric efficiency for soil matrices in the Marinelli beaker of 500 mL in volume was determined using standard reference material product a silicone resin matrix 9031-OL-208/08, type ERX, issued by Czech Metrological Institute (Prague, Czech Republic), spiked with a certified series of radionuclides (^{241}Am, ^{109}Cd, ^{139}Ce, ^{57}Co, ^{60}Co, ^{203}Hg, ^{88}Y, ^{113}Sn, ^{85}Sr, ^{137}Cs) with the energies that span from 59 to 1898 keV. The gamma spectrometers were energy-calibrated using the following standard point source gamma emitters to cover a wide range of photopeaks: ^{60}Co and ^{133}Ba (Czech Metrological Institute, Prague), which have traceable to BIPM-*Bureau International des Poids et Measures*.

The soil were analyzed for ^{90}Sr by validated radiochemical analytical method (Sarap *et al.*, 2014). This method is based on the radiochemical separation of ^{90}Y from the sample and consists of oxalate departing calcium from strontium, firing till oxide, and usage of aluminium as collector for ^{90}Y. The samples were stored for 18 days to reach the radioactive equilibrium between ^{90}Sr and its radioactive daughter radionuclide of ^{90}Y. After 18 days, the radioactive equilibrium is disturbed, ^{90}Y departs on collector $Al(OH)_3$, which is then firing till oxide and on that way, ^{90}Sr is determined via ^{90}Y. The measurements were performed in planchet of 59 mm diameter, using α/β low-level gas proportional counter Thermo Eberline FHT 770 T (ESM Eberline Instruments GmbH, Erlangen, Germany). The counting time was 1 h. The low-level gas proportional counter was efficiency-calibrated using standard point source of ^{90}Sr (Czech Metrological Institute, Prague), which has traceable to BIPM.

To assess the radiation hazards associated with the study soil samples, the following indices have been defined (Beretka and Mathew, 1985; Diab *et al*., 2008; UNSCEAR, 2010; Avwiri *et al*., 2012): The gamma dose rate in nGy h^{-1}, the external hazard index and the radium equivalent activity in Bq kg^{-1}, which were calculated based on the activity concentrations of ^{226}Ra, ^{232}Th and ^{40}K; The outdoor annual effective dose equivalent in mSv, which was calculated based on the absorbed gamma dose rate, the conversion factor (0.7 Sv Gy^{-1}) and the outdoor annual exposure time (1752 h); The excess lifetime cancer risk, which was calculated based on annual effective dose equivalent, average duration of life (estimated to be 70 years) and the risk factor (Sv^{-1}), i.e. fatal cancer risk per Sievert, that amounts 0.05 Sv^{-1} for the public and stochastic effects (Taskin *et al*., 2009).

Results and Discussion

The results of measurements of gamma emitters and radiostrontium in soil samples collected at different sites at the area of Belgrade city are presented in *Table 2*. The activity concentrations of natural radionuclides in Bq kg^{-1} ranged from 25 to 71 for ^{226}Ra, 30-70 for ^{232}Th, 500-610 for ^{40}K, 25-81 for ^{238}U and from 1.4 to 3.7 for ^{235}U, while the activity concentrations of the artificial radionuclides were: between 3.1 and 40 Bq kg^{-1} for ^{137}Cs, and for ^{90}Sr the values ranged below of minimal detectable concentration to 1.04 Bq kg^{-1}. The obtained values in this study are typical for soil samples at area of the Republic of Serbia and can be comparable with world average values (UNSCEAR, 2010; Avwiri *et al*., 2012; El Samad *et al*., 2013; Milenkovic *et al*., 2015; Sarap *et al*., 2016). Having in mind the measurement uncertainties given in *Table 2*, seasonal variations of the radionuclides activity was not significant in the examined cultivated soil, except for the content of ^{137}Cs at Zeleno Brdo. There is exist possibility of re-location of sampling site. However, the differences in activity concentrations of some naturally occuring radionuclides, as well as the artificial radionuclide of ^{137}Cs by the locations are evident. Unlike ^{137}Cs, artificial radionuclide of ^{90}Sr did not showed a significant difference in activity concentration in relation to the sampling site.

Table 2. The activity concentration of investigated radionuclides (Bq kg^{-1}) in cultivated soil of Belgrade for spring (I) and autumn (II) of 2017 year

Location / Season		^{226}Ra	^{232}Th	^{40}K	^{238}U	^{235}U	^{137}Cs	^{90}Sr
Zeleno Brdo	I	45 ± 3	50 ± 4	590 ± 40	40 ± 5	2.4 ± 0.2	3.1 ± 0.4	< 0.51
	II	54 ± 3	52 ± 4	570 ± 40	42 ± 6	1.9 ± 0.2	21 ± 1	0.59 ± 0.16
Jabučki Rit	I	36 ± 2	35 ± 3	520 ± 30	34 ± 10	1.5 ± 0.1	6.4 ± 0.5	< 0,81
	II	25 ± 2	30 ± 2	510 ± 30	31 ± 4	1.7 ± 0.2	4.0 ± 0.5	1.04 ± 0.19
Dunavac	I	29 ± 2	35 ± 3	580 ± 40	38 ± 5	1.8 ± 0.2	6.7 ± 0.4	< 0.53
	II	37 ± 3	34 ± 3	560 ± 40	34 ± 7	1.5 ± 0.2	6.8 ± 0.7	0.64 ± 0.22
Obrenovac	I	35 ± 2	40 ± 3	610 ± 40	25 ± 8	1.5 ± 0.1	40 ± 3	0.75 ± 0.14
	II	36 ± 2	36 ± 3	570 ± 40	31 ± 4	1.4 ± 0.1	19 ± 1	0.64 ± 0.16
Lazarevac	I	71 ± 4	70 ± 4	510 ± 30	81 ± 6	3.7 ± 0.3	25 ± 2	< 0.99
	II	65 ± 4	68 ± 5	500 ± 30	65 ± 7	3.5 ± 0.3	25 ± 2	< 0.94

Based on the obtained activity concentrations of ^{226}Ra, ^{232}Th and ^{40}K, the following health hazard indices were calculated: the gamma dose rate (*D*), the outdoor annual effective dose equivalent (D_E), the external hazard index (H_{ex}), the radium equivalent activity (Ra_{eq}) and the excess lifetime cancer risk (*ELCR*). The estimated values of these indices are showed in *Table 3*. All values obtained for radium equivalent activity are below than recommended value of 370 Bq kg^{-1} (UNSCEAR, 2010). The mean gamma dose rate in air (70.4 nGy h^{-1}) and outdoor annual effective dose (0.087 mSv) are insignificantly higher than the world average of 57 nGy h^{-1} and 0.07 mSv, respectively (UNSCEAR, 2010). The calculated values of external hazard index are lower than world permissible unity, which means that the radiation hazard is low and indicates that will not lead to respiratory diseases and skin. Average excess lifetime cancer risk is close to the average world value of 0.29×10^{-3} (Taskin *et al*., 2009). This implies that the radioactivity of these areas no health hazard effect on the populace, and therefore the chances of occurrence of cancer are insignificant in general.

Table 3. The assessed health hazard indices associated with the studied soil samples

Location	D (nGy h^{-1})	D_E (mSv)	H_{ex}	Ra_{eq} (Bq kg^{-1})	ELCR (10^{-3})
Zeleno Brdo	78.0	0.096	0.45	167.1	0.33
Jabučki Rit	55.4	0.068	0.32	116.6	0.24
Dunavac	60.0	0.074	0.34	126.2	0.26
Obrenovac	64.1	0.079	0.36	135.3	0.27
Lazarevac	94.3	0.116	0.56	205.6	0.40
Average	**70.4**	**0.087**	**0.41**	**150.2**	**0.3**

Conclusion

In this study, the distribution of natural and artificial radionuclides in cultivated soil was analyzed. The obtained results are confirmed the literature data that the most of investigated radionuclides are retain in the arable horizon of agricultural soil. Health hazard indices analysis is used in studies about radiation to arrive at a better and safer conclusion on the health status of a population and environment. The values of estimated health hazard indices were below or insignificant higher than the standard limits for such environment. Hence, to radiation exposure in investigated areas will pose no significant the health risk to population and to environment.

Abstract

This study examines the effect of different rates of 2,4-D and Paraquat herbicides under *in vitro* conditions on the cellulolytic activity of 20 strains of cellulolytic fungi isolated from the chernozem soil taken from Mount Fruška Gora. Results showed that high rates of 2,4-D (60, 120 and 240 μg/ml) inhibited the cellulolytic activity of *Fusarium aquaeductum* var. *dimerum, Fusarium solani var. argillaceum, Aspergillus candidus, Aspergillus ustus* and *Fusarium* sp. (L-7). Lower rates of 2,4-D (30 and 60 μg/ml) stimulated the cellulolytic activity of most *Penicillium* species. Paraquat exhibited higher toxicity to cellulolytic micromycetes and their cellulose degradation ability. Its inhibitory effect was observed at rates as low as those above 3μg/mL. Inhibition increased with increasing rates of the herbicide, with only eight fungi retaining at least some degree of cellulose degradation ability at 24 μg/mL Paraquat. Most species of the genera *Aspergillus* and *Penicillium* showed high sensitivity to Paraquat at rates as low as 6 μg/mL. At 24 μg/mL, none of them had the ability to degrade cellulose. A considerable degree of resistance to Paraquat was exhibited by *Fusarium* spp. (*Fusarium nivale* and *Fusarium solni var. argillaceum)* and *Hormodendrum sp.* (L-11), which retained their cellulolytic activity even at Paraquat rates of 6 μg/mL, whereas *Hormodendrum sp.* (L-10) retained its cellulolytic activity even at twofold higher rates of Paraquat (12 μg/mL).

Keywords: *cellulolytic fungi, 2,4-D, Paraquat*.

Introduction

The last six decades have been characterized by an abrupt expansion in the use of agrochemicals in crop production, with plant protection agents playing an important role in the process (Liu *et al*., 2002). Their absence has led to a decline in crop yield by 32-78% (Cai, 2008). However, in addition to their main role, once they enter the soil, pesticides may also have side-effects on the soil biological component and, indirectly, on the cycling of elements, as well as a range of other adverse health impacts (Djukic *et al*., 2007; Kalia and Gosal, 2011). These effects primarily refer to changes in the community composition, numbers and enzymatic activities of beneficial soil microorganisms, and alterations in the dynamics and direction of soil biological processes. Based on these considerations, herbicides can be classified into agrochemicals which have extremely variable impacts (Mandić *et al*., 2005; Riah, *et al*., 2014). Overall, low (recommended) rates of herbicides do not generally cause adverse effects on soil microorganisms. Initial depression is followed by the recovery of the microbial status of the soil. Microorganisms use herbicides as their source of energy, phosphorus, carbon and nitrogen, which often increases their biomass (Araujo *et al*., 2003; Zabaloy *et al*., 2008). However, most results show that herbicides have an adverse effect on soil microorganisms by reducing their numbers and enzymatic activities; therefore, these parameters are often used as bioindicators of the soil ecological status (Killham, 2002; Das

and Varma, 2011). The reduction in the numbers and activities of microorganisms is induced by changes in their biosynthetic mechanisms and cell membrane permeability, and disturbances in their enzymatic activities (Sannino and Gianfreda, 2001; Hussain *et al*., 2009). The degree of this impact is dependent on herbicide type, rate and application timing, duration of exposure, solubility, soil pH, soil organic content and cumulative co-metabolic effects (Zain *et al*., 2013; Mohiuddin and Khan, 2013). Herbicides have different effects on different types of microorganisms. The most common parameters of their active effect on the soil microbial status are the numbers and enzymatic activity of fungi (Zain *et al*., 2013), and their ability to degrade cellulose and other polymeric compounds in the soil (Lynd *et al*., 2002), even herbicides themselves (Zahid *et al*., 2016). Soil fungi are important cellulase producing microorganisms. However, their activity is heavily disturbed through direct or indirect exposure to herbicides (Smith and Mayfield, 1977).

The objective of this study was to examine the effect of 2,4-D and Paraquat herbicides under *in vitro* conditions on cellulose degradation by different species of micromycetes isolated from the chernozem soil taken from Mount Fruška Gora.

Material and methods

Under laboratory conditions (*in vitro*), different rates of 2,4 D (2,4-dichlorophenoxyacetic acid) and Gramoxone (Paraquat) (dichloro-1,1-dimethyl-4,4-bipyridine) were used to evaluate their effect on the cellulose degradation ability of 20 strains of cellulolytic fungi isolated from the chernozem soil sampled from Mount Fruška Gora (19°48'58" E and 45°09'25", altitude 507 m): *Aspergillus candidus, Aspergillus ustus, Penicillium sp. funiculosum, Penicillium nalgiovensis, Penicillium sp. purpurogenum, Penicillium piscarium, Penicillium* sp. (L-8), *Fusarium* sp. (L-7), *Fusarium* (tn-11), *Trichoderma* sp. (111), *Fusarium avenaceum* var. *herbarum, Fusarium solani var. argillaceum*, *Fusarium nivale*, *Hormodendrum* sp. (L-10), *Hormodendrum* sp. (L-11), *Nigrospora* sp., *Stachybotrys atra, Verticillium candelabrum, Mycelia sterilia* and *Fusarium aquaeductum* var. *dimerum*. The nutrient solution (3g $NaNO_3$, 1g K_2HPO_4, 0.5g $MgSO_4 \cdot 7H_2O$, 0.5g KCl, 0.03g rose bengal, 30μg streptomycin/1mL nutrient medium, 1L distilled water) was supplemented with 2% powdered cellulose (pure cellulose) and a single herbicide. The herbicide 2,4-D was used at 30, 60, 120 and 240 μg/mL, and Gramoxone (Paraquat) at 3, 6, 12 and 24 μg/mL, in three replications. The resulting solutions were inoculated with the spore suspensions of the tested micromycetes and incubated in a thermostat for 12 weeks at 28°C. Thereafter, the amount of cellulose (%) remaining in the nutrient solution was determined by potassium dichromate oxidation (Petkov, Markova, 1969). Cellulose residues were the result of difference in carbon content between cellulose-containing soil samples and soil samples without cellulose (control). The importance of differences in the level of cellulose degradation (%) for each individual fungus, as dependent on the herbicide application rate, was assessed by LSD test (Statistica SPSS 5).

Results and discussion

The results obtained in control treatments showed high variations in cellulolytic activity i.e. cellulose degradation ability across the micromycetes tested (Tab. 1, 2). The highest cellulolytic activity was exhibited by *Hormodendrum* sp. (L-11), *Fusarium aquaeductum* var. *dimerum, Mycelia sterilia* and *Fusarium* sp. (L-7). This result is in agreement with the findings of Tomas *et al*. (2011) reporting that *Hormodendrum* fungi had pronounced cellulolytic activity under optimal culture conditions. Similar data were observed for some species of *Fusarium* (Panagiotou *et al*., 2003) and *Mycelia sterilia* (Sunitha *et al*., 2013). The cellulolytic activity of some micromycetes was inhibited by the herbicide 2,4-D (Tab. 1), particularly when applied at high rates (60, 120 and 240 μg/mL) in *Fusarium aquaeductum* var. *dimerum, Fusarium solani var. argillaceum, Aspergillus candidus, Aspergillus ustus* and

Fusarium sp. (L-7). This result complies with the report of Joshi and Gupta (2008) on the significant inhibitory effect of 2,4-D on the growth and, hence, enzymatic activities of some *Fusarium* species and *Aspergillus ustus*. The low ability of these fungi to degrade this herbicide is another reason for its toxic effect (Vroumsia *et al*., 2005). In contrast, at almost all rates, this herbicide had no significant effect on the cellulolytic activity of *Fusarium avenaceum* var. *herbarum*. Low rates of 2,4-D (30 and 60 μg/mL) enhanced the cellulolytic activity of most *Penicillium* species examined. This may be associated with the marked ability of these micromycetes to rapidly mineralize 2,4-D and use it in their own metabolism (Vroumsia *et al*., 2005; Joshi and Gupta, 2008).

Table 1. Mean values of percent cellulose degradation by cellulolytic fungi (%) as dependent on 2,4-D rate (30, 60, 120, 240 μg /mL)

Strains of fungi	2,4-D, μg /mL

Means followed by the same lowercase letters in rows are not significantly different ($p > 0.01$) according to LSD test

As opposed to 2,4 D, Paraquat exhibited higher toxicity to the cellulolytic micromycetes and their cellulose degradation ability (Tab. 2). Its inhibitory effect was observed at rates as low as those above 3μg/mL. The degree of inhibition increases with increasing rates of Paraquat. At the highest rate (24 μg/mL), only eight fungi retained some degree of cellulose degradation ability. Most species of *Aspergillus* and *Penicillium* were highly sensitive to Paraquat at a rate as low as 6 μg/mL. At 24 μg/mL, none of them showed the ability to degrade cellulose. This result is consistent with Smith and Lyon (1976) who observed a linear decline in the growth and germination of *Aspergillus* and even some *Penicilluim* species as the Paraquat application rate was increased from 500 to 2000 mg/L, which consequently affected their enzymatic activity. The inhibitory effect of Paraquat on fungal growth and cellulose degradation was also reported elsewhere (Smith and Mayfield, 1977). As found by the authors, the application

of Paraquat above its recommended label rate reduced cellulose degradation and soil respiration by 39-58%. The degree of inhibition decreases with increasing content of organic matter in the soil i.e. its increasing sorption (Bromilov, 2003). In this regard, many authors have observed that the inhibitory effect of Paraquat on cellulolytic fungi is more pronounced under *in vitro* conditions than under natural soil conditions, even at rates twice lower than the recommended label rate (Zain *et al*., 2013).

Table 2. Mean values of percent cellulose degradation by cellulolytic fungi as dependent on Paraquat rate (3, 6, 12, 24 µg /mL)

Strains of fungi	Paraquat µg /ml				
	0	3	6	12	24
	Cellulose degradation, %

This research (Tab. 2) showed that the cellulolytic activity of some species of *Fusarium* (*Fusarium nivale* and *Fusarium solni var. argillaceum)* and *Hormodendrum sp.* (L-11) was retained even at a Paraquat rate of 6 µg/mL, and that of *Hormodendrum sp.* (L-10) even at a rate twice as high (12 µg/mL). These results are supported by the findings of other authors who reported a decrease in the cellulolytic activity of some micromycetes in the soil only after the Paraquat application rate reached 500-1000 mg kg^{-1} soil i.e. above 12.5 mg l^{-1} under *in vitro* conditions (Bozarth *et al*., 1965; Wilkinson and Lucas, 1969).

The fact is that the cellulolytic activity of the micromycetes belonging to *Fusarium* and *Horodendrum* as important plant pathogens is resistant to Paraquat. This suggests that, under particular conditions, the use of this herbicide can exert a negative selection pressure on soil microorganisms for the dominance of the types of fungi which cause serious crop diseases.

Conclusion

The tested micromycetes exhibited various degrees of cellulolytic activity i.e. cellulose degradation ability. The highest cellulolytic activity was found in *Hormodendrum* sp. (L-11), *Fusarium aquaeductum* var. *dimerum, Mycelia sterilia* and *Fusarium* sp. (L-7). High rates of 2,4-D (60, 120 and 240 μg/ml) inhibited the cellulolytic activity of *Fusarium aquaeductum* var. *dimerum, Fusarium solani var. argillaceum, Aspergillus candidus, Aspergillus ustus* and *Fusarium* sp. (L-7). This herbicide had no significant effect on the cellulolytic activity of *Fusarium avenaceum* var. *herbarum*. Lower rates of 2,4-D (30 and 60 μg/ml) stimulated the cellulose degradation ability of most *Penicillium* species tested.

Paraquat showed higher toxicity to cellulolytic micromycetes and their cellulose degradation ability. Its inhibitory effect was observed at rates as low as those above 3μg/mL. Inhibition increased with increasing rates of the herbicide, with only eight fungi retaining at least some degree of cellulose degradation ability at 24 μg/mL Paraquat. Most species of the genera *Aspergillus* and *Penicillium* were highly sensitive to Paraquat at rates as low as 6 μg/mL. At 24 μg/mL, none of them had the ability to degrade cellulose

A considerable degree of resistance to Paraquat was observed in *Fusarium* spp. (*Fusarium nivale* and *Fusarium solni var. argillaceum)* and *Hormodendrum sp.* (L-11), which retained their cellulolytic activity even at Paraquat rates of 6 μg/mL, whereas *Hormodendrum sp.* (L-10) retained its cellulolytic activity even at twofold higher rates (12 μg/mL).

UNAUTHORIZED (ILLEGAL) GOLD MINING IN RIAU PROVINCE, INDONESIA

Sri Wahyuni BINTI KADIR

Universitas Islam Riau (Islamic University of Riau), Indonesia
Corresponding author: sri_wahyuni6969@ymail.com

Abstract

Mineral resources as natural resources will contribute to the economic development of the country in accordance with the mandate of the 1945 Constitution. Governments as resource authorities must regulate their use to prevent wastage and optimize revenues from resource exploitation to gain the greatest benefit for the welfare of the people. The regulation on mining is referred to in Article 33 paragraph (3) of the 1945 Constitution and Law No. 4 of 2009 on Mineral and Coal Mining. In this case illegal mining in Riau based on 2014 were 12 cases, 2015 were 15 cases and 2016 were 16 cases.The main problem in this research is how to solve from the side of law and from the government side.There are many news about illegal gold mining in various places in Indonesia and especially Riau. Riau region has the potential of natural resources in the form of gold is large enough with good quality. This makes local entrepreneurs and communities start doing gold mining and most of them are illegal. These mining activities causes conflicts between communities in the areas near the mine with gold mining actors who did not care about the aspects of environmental sustainability and carried out without permission. The perpetrators of gold mining without permission is not only from the Riau region but begin to develop from outside the Riau region as well. Although efforts to control and prosecute perpetrators have been carried out, they do not have any significant effect on these illegal mining activities. Unauthorized mining business activities shall be subject to criminal sanction as set forth in the criminal provisions of Article 158 of Law No. 4 of 2009 concerning the mining of Minerals and Coal, states that: Every person who engages in mining business without Mining Business license, Mining Permit, Special Mining Business License as referred to in Article 37, Article 40 paragraph (3), Article 48, Article 67 paragraph (1), Article 74 paragraph (1) shall be imprisoned for a maximum of 10 (ten) years and a maximum fine of Rp. 10,000,000,000 (ten billion rupiahs).

Keywords: *Legal Mining, Gold Mining, Illegal Mining, Mining Law.*

Introduction

The Law of the Republic of Indonesia Number 4 of 2009 concerning Mineral and Coal Mining regulates the relationship between the state and a person or legal entity in the utilization of excavated materials and provides a prohibition as well as a sanction of imprisonment and a fine to a person or legal entity that violates it. In mining, the government provides opportunities for Indonesian legal entities, cooperatives and individuals and local communities to carry out mineral and coal exploitation based on permits, which are in line with regional autonomy, given by the government and / or regional government in accordance with their authority. each in accordance with the provisions of the legislation. Mining business must provide maximum economic and social benefits for the welfare of the people (Departemen Pertambangan, Indonesian Mining Department). If mining business activities are carried out without a permit, it can be subject to criminal law as stated in the criminal provisions of article 158 of Law Number 4 of 2009 concerning Mineral and Coal Mining. Every person who conducts a mining business without a Mining Business License as referred to in article 37, article 40 paragraph 3, article 48, article 67 paragraph 1, article 74 paragraph 1 and paragraph 5, shall be sentenced to a maximum of ten years in prison and a maximum fine of ten billion rupiah (UU 4/2009, Indonesian Mining Law Number 4 year 2009).

Material and Methods

Mining activity activities in Indonesia are now being questioned by various circles, including the Kuantan Singingi Regency which has the potential of natural resources in the form of large enough gold metal minerals with good quality, and its presence is almost spread throughout the districts namely Kuantan Tengah, Benai, Singingi, Singingi Hilir, Kuantan Mudik, Gunung Toar, Hulu Kuantan and Cerenti. This has made local entrepreneurs and communities begin mining in a crowd. The mining activity caused conflict between communities in the area around the mine and gold mining actors who were not concerned with environmental sustainability and carried out without permission (Salim HS, Mining Law in Indonesia, 2005). The perpetrators of gold mining without permission are not only residents who come from the area of Kuantan Singingi Regency but are starting to develop from outside the district area with large capital. Although the effort to control and prosecute the mining actors has been carried out, the effort does not have a significant effect on the illegal mining activities.

Results and Discussion

Basically the mining business has a positive impact on national development, namely increasing the country's foreign exchange, increasing local revenue, accommodating workers and improving the socio-economic, health and cultural conditions of the people who live in the vicinity of the mine. In addition mining activities are carried out in areas on land using heavy equipment in the form of excavators to explore minerals and sand that contain gold metal in the soil and enter into cavort boxes to filter gold metal mineral granules from sand and stone then using mercury to separate gold metal mineral grains from sand which resulted in ex-mining land becoming dead and damage to the forest in the area around the mine and many gaping holes in the ex-excavation and when it rained the hole was filled by rainwater which is very vulnerable to natural hazards such as floods and landslides. The perpetrators of gold mining without permission are not only residents who come from the area of Kuantan Singingi Regency but are starting to develop from outside the district area with large capital. Although the effort to control and prosecute the mining actors has been carried out, the effort does not have a significant effect on the illegal mining activities. Based on the findings in Kuantan Singingi Police during 2009, there were 4 criminal case files of gold mining without a permit which was carried out by the investigation process and was declared complete by the Public Prosecutor and the suspect was sent along with evidence to the Taluk Kuantan District Procuratorate to be prosecuted in court and The Rengat District Court which convened in Taluk Kuantan examined and tried criminal cases with a regular hearing at the first level court, stating that the defendant had been proven legally and convincingly guilty of committing a gold mining crime without a permit and imprisoned and fined the defendant in accordance with the article 158 of Act Number 4 of 2009 concerning Junto Mineral and Coal Mining Article 55 paragraph 1 to 1 of the Criminal Code in Law Number 8 of 1981. In 2010, there were 17 unlicensed mining case files that were investigated by the Kuantan Singingi Resort Police Investigator. Of the 17 prkara files, 2 case files about alleged criminal acts of manganese exploration mining were allegedly carried out without permission in the area of the manganese exploration exploration mining permit, which is currently in the process of being investigated to complete the Prosecutor's instructions. While 15 more cases about illegal gold mining practices committed by the perpetrators of mining in the Kuantan river and in the hilly / land area in the area of Kuantan Singingi Regency by sucking / digging the minerals of sand and stone containing gold metal in the Kuantan river in in the soil and put the excavated material into a slude box or box cavort then use mercury to separate gold metal grains from sand and water. Of the 15 case files, 13 case files have been declared complete by the Public Prosecutor then the investigator sends the suspect and evidence to the Taluk

Kuantan District Attorney to be prosecuted in court while 2 more cases are still under investigation to complete the prosecutor's instructions in order improvement of the investigation of the case file. Of the 13 cases, 7 case files were submitted by the Investigator to the Taluk Kuantan District Attorney to be prosecuted in a court hearing and the Rengat District Court convening in Taluk Kuantan examined and tried and claimed the defendant had been proven legally and convincingly guilty of gold mining without permission and impose imprisonment and fines on the defendant in accordance with Article 158 of Law Number 4 of 2009 concerning junto Mineral and Coal Mining Article 55 paragraph 1 of the Criminal Code, while 6 case files are still under prosecution of the public prosecutor (Department of Mining).
In 2010 almost all court decisions of perpetrators of gold mining without permission were sentenced to 1 year and 8 months as well as criminal penalties for each defendant of ten million rupiah.
In order to support sustainable national development, the objectives of managing minerals and coal include:

a. Ensuring the effectiveness of the implementation and control of mining business activities in an efficient, effective and competitive manner.
b. Ensuring the benefits of mineral and coal mining in a sustainable and environmentally sound manner
c. Ensure the availability of minerals and coal as raw materials and / or as energy sources for domestic needs
d. Support and develop national capacity to be more able to compete at the national, regional and international levels
e. Increase the income of local, regional and state communities and create jobs for thegreatest possible welfare of the people.
f. Ensuring legal certainty in the operation of mineral and coal mining business activities.

Law Number 4 of 2009 concerning Mineral and Coal Mining confirms that Mineral Mining is mineral mining in the form of ore or rock, outside the earth market, oil and gas and ground water, and mining is a mining business activity to produce associated minerals and minerals.
In Law Number 4 of 2009 concerning Mineral and Coal Mining provides provisions / rules that regulate the relationship between the state and a person or legal entity in the utilization of minerals, as follows:
1. In Article 36 of Law number 4 of 2009 states: business license
Mining consists of two stages:

a. Exploration mining business licenses include general investigation activities, exploration and feasibility study.
b. Production operation permits include construction, mining, processing and purification and transportation and sales.

2. In Article 40 paragraph 3 of Law Number 4 of 2009 states: Holder mining business license that intends to cultivate other minerals in its mining business license area, must submit a new mining business permit to the Minister, Governor and Regent / Mayor in accordance with its authority.
3. In Article 48 of Law Number 4 of 2009: Mining business license Production Operations are given by the Regent / Mayor, Governor and Minister.
4. In Article 67 paragraph 1 of Law Number 4 of 2009 states Regents / Mayors provide People's Mining Permits especially to local residents, both individuals and community groups and / or cooperatives.
6. In Article 74 paragraph 1 paragraph 5 of Law No. 4 of 2009 states Permit

Special Mining Businesses are given by the Minister with due regard to regional interests. Special Mining Business Permit holders are given 1 type of metal mineral or coal in 1 special mining business license area.

Based on data obtained from the Mining and Mineral Resources Office of Kuantan Singingi Regency, Owners and Companies that have mining business licenses within the Kuantan Singingi Regency are listed as follows:

1. Gold Mining Production Operations as many as 4 owners / companies.
2. Solid Bitumen Mining Exploration of 2 Company owners
3. Production operations Manganese mining as many as 5 company owners
4. Existing coal mining as many as 9 company owners
5. Group C materials (sand and stone) as many as 12 company owners.

Kuantan Singingi Regency holds maximum untapped wealth, namely gold content. From the data of the potential gold content that was recorded by the Mining Service of Kuantan Singingi district, the potential for gold content is estimated at around 64.2 tons with details of the location as follows: Logas Village, Singingi District, 2.4 tons, Sentajo Village 2.8 tons Kuantan District Tengah, Bawang River is 12 tons in Singingi sub-district, Sungai Jake in Kuantan Tengah District is 18 tons, Sungai Bulus is 13 tons, Bukit batabuh in Kuantan Mudik District is 10 tons. Ironically, although the potential of gold mining in this area is very large, until now this potential has not been managed properly. This potential then motivates the community to carry out gold mining activities without permission, as a result of which has a negative impact on the local environment. Although efforts have been made to approach and control the Kuantan Singingi district government and resort police, the activities of gold mining without the permit continue. Based on the findings, unlicensed gold mining in the area of Kuantan Singingi Regency is not only a mining business activity, some residents traditionally use hoes and crowbars to dig holes and then lift them with baskets and then separate gold metal mineral ores with a miner or by using just a panning tool in taking sand in the river then panning / separating gold metal mineral ore from sand, but the gold mining business without permission is done mechanically by using rafts and machines to suck the minerals of sand and stone containing the existing gold metal in the river, then put the mineral material into a slude box to filter gold metal mineral granules from sand and stone and then use mercury to separate gold grains from sand and water, which causes the river water to become cloudy and polluted disease outbreaks for people in the mine area.

In addition, mechanical mining efforts are also carried out on rock / hills in the mainland of Kuantan Singingi Regency by using heavy equipment in the form of excavators to explore the minerals of sand and stones containing gold metal in the ground and then put the excavation into the cavort box to filter gold metal mineral grains from sand and stone and then use mercury to separate gold grains from sand and water which resulted in ex-mining land becoming dead and damage to the forest in the area around the mine and many gaping holes were found very large in the former quarry and when it rains, the hole is filled with rainwater which is very vulnerable to natural hazards and floods and landslides.

Gold mining without the permit does not take into account environmental sustainability and prioritizes personal or group interests and does not have a mining business license from the Kuantan Singingi Regent. Mining activities without permits have a negative impact which results in the destruction of forests that are in the area of the mine, river contamination, disease contractions for people living in the area around the mine and conflict between communities around the mine and loss of state income or local revenue.

According to Kusnadi, the perpetrator of gold mining without permission, that gold mining activities carried out in the river without permission, use rafts and machines to suck up sand and use mercury to separate gold seeds from sand and water. On average one day can produce at least 1 ounce of gold and can reach 3 kilograms per month (Informan).

The same thing was also conveyed by Wahyudi, the gold mining agent without permission, that the gold mining activities he did in Petapahan without permission from the authorized official. Cases of gold mining without permits handled / processed by police in the form of (Information from Mining Department):

1. Mining carried out without a mining business permit document from the government in accordance with the provisions of the legislation
2. Mining outside the concession / area of the mining business license
3. Mining other minerals outside the mining business permit granted for one type of mineral.
4. Not yet have the completeness of the permit but has already carried out mining activities.
5. Mining carried out in prohibited places (Informan):

a. By using excavator heavy equipment which resulted in ex-mining land becoming dead and damaged forests and many gaping holes were found which were very susceptible to natural disasters such as floods and landslides.
b. By using rafts and machines to suck sand from the river which results in turbid and polluted river water as well as contracting diseases for the people in the mine's circumference
c. Use mercury to separate gold metal seeds / minerals from sand and water.

In its development, gold mining without permission always follows the times. This can be seen from the form of illegal mining of gold metal minerals which have the characteristics grouped as follows (Information from Police):

1. Viewed from business actors, consisting of:
a. Local people are people around the mining location who are working in the mining sector
b. Newcomers are outsiders from the mining location who try to make a living through mining
c. Local entrepreneurs are entrepreneurs who have capital that live around the location of the miners.
d. Newcomers are outside entrepreneurs from the mining area who come deliberately to mine.
e. Investors are capital owners who are working in the mining sector.
f. Person of the Apparatus, namely a person or person from the apparatus and the government who illegally supports the practice of mining without permission.
2. Judging from the status of its business activities carried out on:
a. Own land
b. State-owned land such as protected forests, nature reserves and others
c. Riverside
3. Judging from the commodity / quarrying material, consisting of Gold (Group A).

As for the factors that cause illegal mining are:

1. Law: Public ignorance of the laws and regulations that apply in the mining sector.
2. Economy
a. Limited employment opportunities and business opportunities in accordance with the level of expertise / skills of the community below
b. Poverty in various ways, economically poor, knowledge and skills.

Factors affecting illegal mining are:

1. Main factors:
a. The miners do not care about licensing regulations / provisions
b. Gold metal mineral deposits found on community land and in rivers can be found easily
c. Attractive gold metal prices and easy marketing
d. The economy of the community around the mine site is generally poor.
2. Supporting Factors:
a. There is support from strong investors.
b. Anticipatory policies from the government have not been effective
3. Driving factor:

a. The fee sharing system is very profitable
b. Misuse of permits granted for 1 type of mineral is used to cultivate other minerals
c. The economic crisis caused limited employment
d. Mining equipment is widely available and inexpensive at rentals such as excavators as well as mining equipment in rivers such as machines, rafts, slide boxes and cavort boxes are easily made.
e. There is a perception that illegal mining activities are very helpful in alleviating poverty.

The perpetrators of gold mining without most permits are not required to be maximized with the following considerations:

a. Most of these perpetrators were told to do or participate in the crime of gold mining without permission.
b. The perpetrators of gold mining without permission do not know the laws and regulations that apply in the mining sector
c. The defendant admitted frankly his actions
d. The defendant was polite during the course of the trial
e. The defendant admitted guilt, regret and promised not to repeat his actions later on.

Judges' consideration of imposing a criminal sentence on the perpetrators of gold mining without permission, among others:

a. Most of these perpetrators are told to do or participate in the crime of gold mining without permission and do not know the laws and regulations that apply in the mining sector.
b. Judging from the status and education of the convict.

Conclusion

Unlicensed gold mining activities in the area of Kuantan Singingi Regency are not only some residents traditionally separating gold metal mineral grains contained in the river but this activity is carried out mechanically by using rafts and other mining machinery and equipment to suck sand minerals and stones that contain gold metal and put mining material into the slude box to filter further using mercury to separate gold metal grains from sand and water which results in turbid and polluted river water. In addition, the activities of unlicensed gold mining are carried out on land mechanically by using heavy equipment in the form of excavators to dig and insert mining material into the cavort box to filter further using mercury to separate gold metal grains which result in damage to the forest and the large number of holes very vulnerable to the dangers of floods and landslides.

ANIMAL HUSBANDRY

STATE OF PLAY AND RECOMMENDATIONS CONCERNING THE SANITARY QUALITY OF DRINKING WATER FOR SHEEP AND GOAT FARMS IN THE COMMUNE OF AIN ZAATOUT

Hassina Hafida BOUKHALFA*, Sara BENOUAKHIR

DEDSPAZA Laboratory, Agronomical Sciences Department, Mohamed khider University Biskra, Algeria
*Corresponding author: hassinaboukhalfa@gmail.com

Abstract

The scientific and technical study on the sanitary quality of drinking water for farm animals is intended to assess the level of risk (identification of biological, chemical and physical hazards). In order to show the inventory of livestock (sheep and goats) of the municipality of Ain Zaatout, a field survey was carried out on a set of farms in terms of water and water installation (watering). We were interested in the origin of the drinking water, the number and the hygiene of the drinkers as well as their load. The evaluation of the sanitary quality of the water in the farms requires the carrying out of bacteriological and physicochemical analyzes at the level of the boreholes, the sources of water and the drinkers on these exploitations in order to detect the levels of contamination of the farms drinking water and degree of drinkability. The work carried out has allowed us to classify drinking water in this town as water of good bacteriological quality and of average physico-chemical quality which therefore requires giving recommendations and suggestions to ensure a good behavior of the farms through the improvement of the sanitary quality of water (nutrition) which protects animal health and animal production (sheep and goats) therefore.

Keywords: *drinking water, bacteriological quality, physicochemical quality, sheep, goats.*

Introduction

Livestock depend on a constant and regular supply of water; animal organisms are composed of 65 to 80% of water. That makes it a determining factor in the course of digestion and metabolism of food; it ensures the transport of nutrients in the body and it allows the excretion of metabolic end products (urine, feces, sweat) and the secretion of milk (dairy animals). In addition, water is a key element in regulating body temperature (breathing, sweating) and osmolarity (Jean-Blain, 2002).

A water deficit in animals leads first to a reduction in food intake and then leads to a decline in performance, increased susceptibility to disease and increased aggression of animals around water points (Jean-Blain, 2002; Steiger Burgos et al., 2001). Inadequate fluid intake can also lead to dehydration, heart rate and respiratory acceleration. These symptoms can lead to death of the animals in case of prolonged lack, especially in young and small subjects. In fact, they have very few body water reserves, which make them particularly vulnerable when the water supply is insufficient for their needs (Basselin, et al., 1999).

The relative importance of the different sources of water supplied to animals is poorly known, regardless of the type of farming (above ground or outdoors). Drinking water can come mainly from the public drinking water distribution network, from private wells that are subject to disinfection treatment or natural resources (Pierroux, 2008; Simonet, 2001; UPA-Estrie, 2002).

The regulations on drinking water are few and the inventory that follows cannot claim to be exhaustive. These regulations have two explicit objectives, the protection of human and animal health and that of animal welfare. They are most often general, limiting themselves to specifying that the water must be of "adequate", "appropriate", etc. quality. These formulations are often similar, whatever the objective (Dermaux, 1999; Medd and Brgm,

2004). The decrees relating to the controlled labels of origin do not set, in general, requirements on the quality of the water to be used throughout the chain, in particular for the watering of the animals (Medd and Brgm, 2004). The management of regulated products (ex Plant and Environment Directorate) of National Agency for Food Safety Environment and Labor, in charge of the evaluation of phytopharmaceutical products, evaluates their ecotoxicity, in particular their effects on birds and mammals via their presence in drinking water in accordance with the guide Consumer Health and Protection 4145/2000.

Some biological hazards can persist for weeks to months in water depending on temperature, exposure to sunlight, and competition with other aquatic microorganisms (Medd and Brgm, 2004). The degree of contamination of drinking water by micro-organisms varies greatly depending on the origin of the water. For example, surface water, streams, ponds, other natural water points, and sometimes very shallow wells (depth <1 m), can be highly contaminated due to runoff. Infiltration results in a large number of bacteria, viruses or parasites (Exova, 2009). The use of a water reservoir and direct watering in ponds or water holes particularly expose animals to microbiological pollution. In addition, flocks can be the cause of contamination of surface water or poorly protected catchment. For example, a cow can release 10 million Salmonella per gram of droppings, while the generally accepted oral infective dose for a domestic animal is at least one million bacteria (Dubreuil and Sauvageau, 1993; Medd and Brgm, 2004). Minerals such as arsenic, calcium, magnesium, selenium, chlorides, fluorides and sulphates can be naturally present in the water resources, and their concentrations vary due in particular to the geological nature of the lands crossed. These water resources are also subject to diffuse pollution by various chemical substances (nitrates, pesticides, etc.) related to human activities. Water used for livestock watering can be contaminated by these chemicals, leaching polluted soils for surface water, or by infiltrating pollutants deep into the groundwater after heavy rainfall (Métivet, 1996; Beilage, 2002).

Contagious diseases caused by pathogenic bacteria, viruses and parasites are very often linked to the consumption of water that does not meet minimum criteria of potability. They constitute for health the most common and widespread risk. It is therefore important to establish norms and indicators of potability and quality and especially to verify that they are respected, especially on points of access to water and if necessary to adapt them according to the zones and local peculiarities.

The aim of this paper is to study the sanitary quality of drinking water for livestock and to purpose assessing of the risk level for animal health, and for human health via the consumption of products derived from animals. The objective of the bacteriological analysis of water is not to make an inventory of all the species present, but to look for either those that are likely to be pathogenic, or those that are indicative of faecal contamination.

Material and Methods

In order to show the inventory of the farms of the commune of "Ain Zaatout" a field survey was conducted on all farms asking on water and watering facilities, we were interested in the origin of the drinking water, the number and the quality of the drinkers as well as their load.

We realized our practical study on the state of the breeding places and the recommendations relating to the sanitary quality of the water in the commune of "Ain Zaàtout", region of "El'outaya", city of Biskra, Algeria. It is within the Aurès known by the name of "Beni Ferah". To evaluate the sanitary, bacteriological and physicochemical quality of livestock watering, we have sampled water from boreholes, water sources and drinking troughs. Bacteriological and physicochemical analyzes were conducted to detect contamination levels and to determine the degree of drinkability of the drinking water at the farms of Ain Zatout commune.

The study area is divided into two regions because it contains two water wells. The first borehole in the first region is called "Ah M'nie" precisely to "yekhf n'souf" irrigates this first region and the region of "Afra" from which five samples were taken. Three water samples from "Ah M'nie" and two water samples from "Afra", from five internal waterers on specific and different farms. In this region there are many external watering places (springs of open water) from which we took two water samples, one to "Ah M'nie" and the other to "Afra" where sheep and goats water before and after their pastures. Only one water sample was taken from this first borehole. The second borehole located in the second area is called "Dachra" precisely behind the town hall, irrigates this entire second region from which we took five samples of water from five internal waterers on specific and different farms. In this area also are external drinking troughs from which we took a single sample from a single external water source where sheep and goats congregate before and after their pastures. Only one sample of water to be analyzed was also taken from the second borehole.

The bacteriological analysis of water was conducted to identify the rate of contamination by bacteria and make it unfit for consumption. The identification of faecal coliforms, enterococci, Heterotrophic Aerobic and Facultative Anaerobic Bacteria, and atypical colonies follows a scientific method for bacteriological examination of water samples, used in the laboratory recognized by the Ministry of the Environment (Laboratory Accreditation Program). The carefully completed analysis request form must always accompany the samples. The temperature plays a very important role in the solubility of the salts, and consequently the conductivity and the pH; it also has an influence on the biological activity of certain microorganisms in the water. The temperature has been measured in situ. Conductivity or pH meters usually have a built-in thermometer.

The pH (Hydrogen potential) measures the concentration of H + ions in the water; this is a characteristic that reflects both the acidity and the basicity of the water. It influences the form and availability of nutrients in the abatement water and should be between 6.5 and 8.4. At these values the solubility of most micro-elements is optimal. It has been measured in the field using a pH meter. Electrical conductivity (EC), expressed in dS/m measured at 20°C, is one of the most commonly measured parameters. Particularly in arid and semi-arid regions to estimate the total value of soluble salts in water.

Chemical analyses also have been performed according to National Agency for Food Safety, Environment and Labor standards. We dosed Ca^{++}, Mg^{++}, Na^{+}, K^{+}, Cl^{-}, So_4^{-}, Hco_3^{-}, Nh_4^{+}, No_3^{-}, Fe and Mn.

Results and Discussion

The results of the analyzes show a total germ concentration varying between a maximum of 30 on farms and a minimum of 0 to 7 in boreholes and water sources. The measured values of the total germs make it possible to classify drinking water in the study area as water of good bacteriological quality according to the norms of National Agency for Food Safety, Environment and Labor (Anses, 2010).

Trials show a complete absence of fecal germs, fecal streptococci or Enterococci and Staphylococci in the waters of the two boreholes and the three water sources and in the watering places of the ten farms. The samples were free of bacterial spores of the sulphitoréductive anaerobes and clostridium sulphito-reducing agents in the two boreholes and the three water sources and the ten farms according to the standards (Anses, 2010). There was no Salmonella sp. also in these samples, according to the same standards. The abatement water of sheep and goats in the study area had a satisfactory bacteriological quality, according to the standards (Anses, 2010).

Microbiological analyzes are based on the search for bacteria considered as indicators of faecal contamination: these bacteria have been chosen because they are present in large numbers in the stool of warm-blooded animals, which are frequent sources of fairly serious

contamination, they are easily detectable, and they do not grow in pure source. The indicator of choice is the search for Escherichia coli, or that of thermotolerant coliforms (bacteria of the same genus as E. coli) and is still widely used. Drinking water must not contain it. It is a good indicator of potability. Other indicators are added, such as the search for enterococci, and the spores of Clostridium perfringens. Livestock watering water analyzed in the commune of Ain Zaatout shows acceptable bacteriological quality, so we can say that there is good potability in terms of boreholes and water sources. On the other hand, this potability is average at the level of the drinking troughs on the farms. This deterioration in the quality of drinking water at farm level can be caused by the lack of hygiene that is not correctly practiced by about 50% of farmers, according to the results of the survey.

Knowledge of the temperature of the drinking water is important because it plays a role in the solubility of the salts, in the dissociation of the dissolved salts and thus on the electrical conductivity and on the determination of the pH. The temperature of the water taken from the sources and the boreholes was between 5°C and 8°C, and those of drinking water between 15°C and 26°C, which classified these waters as good for consumption.

The pH values of drinking water (boreholes, water sources, waterers) are relatively neutral to slightly alkaline; the averages are between 6.6 and 8.3. According to the drinking water quality grid, the analyzed waters intended for watering animals are of good quality.

The CE values of the water are between 2040 µm/cm and 1056 µm/cm; this is related to the presence of the ions, so it is the mineralization which depends on the temperature of the waters and the crossed lands.

	Exploitation10	81	67	133	10	303	312	155	0	7	0,3	7 ,0

A list should be drawn up listing the various physical and chemical parameters to be controlled and which define the potability of a water and the values limit not to exceed. From a chemical and physical point of view these different parameters make it possible to determine if a water is drinkable.

In addition to the usual parameters, certain specific parameters must be analyzed according to the region and the problems encountered. One distinguishes for the establishment of the chemical potability of a water:

- Undesirable substances: their presence is however tolerated as long as it remains below a certain threshold (fluorine F- and nitrates for example).
- Substances with toxic effects as lead (Pb), chromium (Cr), arsenic (Ar), cadmium (Cd) are part of it. The tolerated levels are extremely low, sometimes of the order of one millionth of a gram per liter.

Livestock drinking water subject of analysis in the commune of Ain Zaatout shows an acceptable physicochemical quality, so we can say that there is a good physico-chemical drinkability at the level of boreholes and water sources and average drinkability at the level of watering facilities.

Conclusions

Watering with contaminated water can lead to various organic disorders in the animal (possibly to the point of death) or loss of production or reproduction performance. That is why it is important to define what should be water of "adequate quality", as it is mentioned in the regulation. The bacteriological analyzes carried out on samples from different water points in our study show the total absence of total and faecal coliforms, coagulase-positive staphylococci, faecal streptococci or enterococci, spores of the sulphitoréductive anaerobes and clostridium sulphitrate reducers, and salmonellae, but also the presence of susceptible microorganisms (the total germs) at very low rates, not exceeding the limits. These results allow us to say that there is a bacteriological potability of drinking water in the municipality examined. The physico-chemical analyzes carried out showed normal levels of physical parameters and chemical substances at the level of boreholes and water sources, while in drinking troughs, the existence of minerals such as chlorides (Cl-), sulphates (So4-),

ammonium (Nh4 +), nitrates (No3-) was noted, with rates that exceed limits set by international legislation and standards. These results allow us to say that there is some physico-chemical drinkability of drinking water in the municipality. The results recorded allow us to classify drinking water in the commune of "Ain Zaatout" as a water of good bacteriological quality and of average physico-chemical quality. However, in these farms, the maintenance of the facilities of drinking troughs is recommended in order to guarantee the hygiene of materials in direct contact with drinking water. An annual analysis for the control of water quality is mandatory to meet good farming practices.

The survey carried out and informations got from the farms allows us to link this situation to several causes, like the absence of hygiene practices, the breeding methods, the number and the load of cattle, the systems of traditional installation of drinking troughs, the installation system of pipelines without maintenance, the lack of labor, the excessive use of pesticides in growing areas, the presence of these elements in organic matter of animal origin;, the development of farms, excessive fertilization of agricultural areas by fertilizers, droppings and various manure.

Abstract

Poultry is a valuable and economical source of animal protein, particularly for developing countries, which has justified its very rapid development worldwide over the last fifty years. This evolution was the result of the industrialization of production thanks to the contributions of the various research carried out in the fields of selection, feeding, habitat, prophylaxis and end product technology. Our work was carried out at the level of Zâb-chergui in the city of Biskra (Algeria) and focuses on the diagnosis of buildings and equipments of poultry breeding in this region. Through a field survey, we aim to identify broiler breeders in this region and do either a quantitative and qualitative analysis of their activities. Our results reveal an inadequate situation of the majority of the farms visited in building quality and equipment. This situation has led to mortality rates above the acceptable limit for this type of farming. We propose recommendations for improving broiler farming to have better production under better conditions in this region. A good building should be equipped with dynamic ventilation, fluorescent tubes, air heaters, flushes and the presence of a sanitary lock.

Keywords: *equipment, broiler, building, production, Zâb-chergui.*

Introduction

In Algeria, the poultry sector is largely dominated by intensive modern poultry farming. The introduction of the intensive poultry model from 1975 onwards through the import of high-tech industrial poultry complexes has limited the development of traditional poultry farming, particularly the exploitation of local breeds. The annual national production of the poultry sector is considerable; it is estimated at more than 253 000 tonnes of white meat and almost 4.5 billion of eggs for consumption, thus ensuring more than 50% of the feed intake of animal products in 2011 (Ministry of Agriculture and Rural Development, 2012).

The poultry farms require from the farmer, a strict observation of the optimal ambient conditions (temperature, humidity, lighting, renewal of air), and otherwise serious troubles, both in terms of performance and on the sanitary level, do not delay in arriving. Lastly, rational management of poultry premises requires very precise indications regarding interior equipment. (Technical Institute of Poultry, 2001)

The choice of the location of the building is crucial because it defines the internal environment of the latter. During implementation in a valley, it is found a lack of wind, a lack of air renewal in static ventilation especially in hot weather, moisture and ammonia, resulting in health problems and a fall average daily weight gain (ADG) at the end of rearing (Boulakroune and Taleb, 2015; Djermouni and Fas, 2016). However, during implementation on a hill, there is an excess of air intake on the prevailing wind side, harmful especially during start-up (lack of heat regulation of chicks), insufficient ambient temperature and transverse air sweep resulting in diarrhea and dirty litter from the first day (Rosset, 1988; Djermouni and Fas, 2016).

The surface area of the buildings depends on the length and the period of rearing of the poultry and the type of production: For the chickens, one can retain as standard of density, 20 chicks / m² of building. This standard can be adapted according to the age at which the poultry is transferred to a farmhouse: the earlier the transition, the higher the density can be. So in practice, for a band of 200 chicks, it is necessary to have a 10 m² chick.

For breeding huts for broilers: it is advisable not to exceed the standard density of 8 chickens / m² (Fernard, 1992).
Static or Natural Ventilation is the simplest system; ventilation is provided by natural movements of the air inside the henhouse. Vertical ventilation is achieved by windows and horizontal ventilation is achieved by means of hatches placed on the façades (Bellaoui, 1990, Laraba and Lezzar, 2016).
Dynamic ventilation is much more efficient than natural and more recommendable for cold climates (Fernandez and Ruiz-Matas, 2003, Laraba and Lezzar, 2016). This ventilation requires the use of humidifier fans generating more expenses but effective in all seasons (Bellaoui, 1990, Laraba and Lezzar, 2016). The renewal of the air can be perfectly controlled by regulating the flow of the pressure and the speed of the air. This air is also extracted or pulsed by known theoretical flow rate (Djerrou 2006, Laraba and Lezzar 2016, Cherouana 2016). Fluorescent tubes (neons) perform better than incandescent lamps. The norm specifies 5 watts / m2 to be able to ensure 30 to 40 lux, the strongest intensity during the first days of the start, so as to allow the chicks to occupy well and use their living space (Castello, 1990; Bentchikou and Bachtarzi, 2015).
For heating two options are most often used: air heaters (heat guns) or radiant heaters. Unit heaters require precise adjustment for a room temperature. Heating power: 100 to 150 watts / m2 and capacity of the fans: from 2,000 to 5,000 m3 / hour. Radiants are much more common (and recommended) in the production of quality-differentiated chickens. Standard: 1 radiant of 1,400 kcal for 650 chicks or 1 radiant of 3,000 kcal for 800 chicks (Castello, 1990; Laouni and Dakhia, 2016). There are different models of drinking troughs, circular drinking trough still called "plasson", cup or mini drink, 1 per 100 animals, and nipple or "nippel" with or without salvage cup. The pacifier model is the most commonly used. In this case, there is 1 pacifier for 13 animals. The diet is almost always automated. There is then a plate for 70 animals (When feeding is manual, the standard is a hopper (20 kg) for 60 animals) (Bentchikou and Bachtarzi, 2015; Laouni and Dakhia, 2016).
Currently the intensive breeding of broilers in the city of Biskra becomes important, following the rise of private investments oriented towards the sector. For this, we propose the study of the equipment of poultry breeding in this region. The present paper is dedicated to the study of poultry farming equipment.

Material and Methods

Through a field survey, we aim to identify broiler breeders in the region of Zâb-chergui of Biskra (Sidi Okba, Loutaya, Djemourah, El Kantra, Biskra and Zribet el ouad), quantitative and qualitative analysis of their activities and the state of their livestock building (year of construction, orientation, density , etc.). In addition, to explore the equipment of the livestock building (water troughs, feeders, etc.), and also the mortality rate recorded by farmers in this region. The results of the survey are statistically processed by SPSS software.
According to statistics obtained from the Directorate of Agricultural Services of the city of Biskra (2018), the broiler buildings are scattered as shown in the following table.

Table 1. Distribution of broiler buildings in the city of Biskra

Areas		Number of buildings

The survey was conducted on a study area as most of the respondents were in the Zab-chergui region. Figure 1 shows the distribution of farmers in this area.

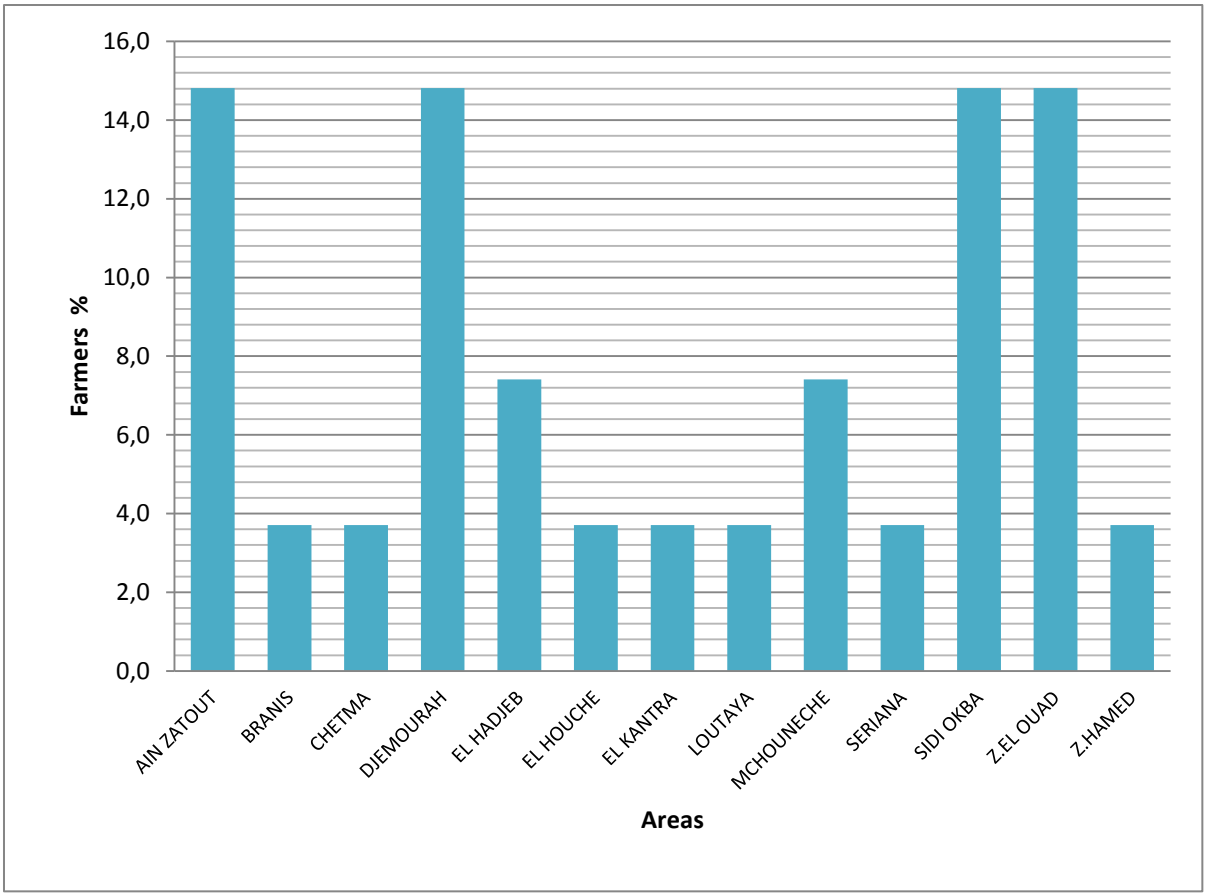

Figure 1. Distribution of farmers in area

Results and Discussion

According to the results recorded, the age of the breeders (27 breeders) is on average 43.88 ± 8.335. The most common age is 40 years old and ranges from 28 to 60 years old. 50% of breeders are under 45 years old.

The way in which buildings are asserted by the breeders is the majority owner (87.5%), the remaining breeders are tenants (12.5%). The majority of the buildings visited were permanently shut down (45%), 33% in production and the rest (22%) in crawl space.

During the survey, the majority of breeders (78%) were fattening, while the others (22%) were in the start-up phase. Most of the buildings visited (43.8%) were built between the years [2003-2010], compared to 31.3% between the years [2011-2016] and the rest of the buildings between the years [1984-2002].

Half (50%) of the buildings visited are badly oriented (towards the East /West) and the others (50%) are in a good orientation in North/South. Proper orientation of the building avoids exposure to prevailing winds, cold winter in the north and summer heat in the south.

We found that more than half of the buildings visited (56.3%) meet the standards of density of poultry breeding against other buildings have different and substandard densities. According to the results of the survey, the majority of the farmers considered (68.8%) have only one building, whereas the other breeders have more than 2 buildings which are in parallel. The majority of the hulls (88%) used belong to two types; traditional (hard) and light tunnel against the rest of these buildings (12%) is in the form of the rigid tunnel.

All of the poultry farm buildings in the Zab-chergui region are semi-dark, do not have chickens and have a dynamic ventilation system. It has been noticed that the majority of the livestock buildings visited (75%) do not have a sanitary lock at the entrance and that 25% of the buildings have a sanitary lock and that respect the sanitary standards. The majority of the

farmers leave their buildings in crawl spaces between 15 to 20 days with relative percentages of 25% and 43.8%.

The majority of the livestock buildings (69%) are equipped with incandescent lamps, 12% of buildings have low-consumption lamps and the rest of these buildings (19%) meet poultry farming standards and use fluorescent tubes (neon lights) as the best type of lighting.

It was found that all the farmers surveyed complied with the standards of poultry breeding in terms of heating. The majority of breeders (93.8%) use radiants in their buildings as a heating source but the other breeders (6.3%) use a type based on fan heaters.

We observed that 63% of the breeders use circular waterers (Plasson) in their livestock buildings, 31% of breeders use linear waterers, but only 6% of these farmers use teats (pipettes). Although the latter system is most commonly used in poultry farming standards. Half of the farmers (50%) have a private water network, but the others have based on public networks which are considered as their only source of drinking water used in their poultry farming. We found that more than 68% of the breeders use hoppers in their livestock buildings as a type of feeder, but only 31% of farmers use the plates.

During the visit of the livestock buildings, it was found that 56.3% of the breeders use wood chips as litter, 25% of the breeders use the ground straw and 12.5% of the breeders use the mixed litter (between wood chips, wood and chopped straw). On the other hand 6.3% of breeders do not use litter in their buildings since they are equipped with farm batteries.

According to the results of the survey on expensive chicken farming, the average mortality rate was found to be 5.52 ± 4.11 and with an interval of [1%, 15%]. More than half of the farmers (56%) have practices that do not respect poultry farming standards (they have a mortality rate of $\geq 3\%$), while 44% of the farmers have adequate practices (they have a mortality rate $\leq 3\%$).

The majority of the breeders with a mortality rate $\geq 3\%$ have light (greenhouses), semi-dark buildings with a dynamic ventilation system and poorly oriented (TSE / WEST) which causes an increase in the area of exposure to the prevailing winds, which is harmful especially during the start-up period (lack of thermoregulation of chicks, diarrhea and soiled litter from the first day). These breeders do not control the ambient conditions (ambient temperature, ventilation, hygrometry, litter quality, light):

- Improper light installation (do not respect the luminous intensity standards).
- Do not regulate the flow of pressure and air velocity.
- Use poor litter quality.
- Poor distribution of watering equipment and feeds on the building surface.

They do not respect the sanitary standards (lack of sanitary locks in their livestock buildings) and the density which influences the quality of the litter, which causes a decrease of the homogeneity then a reduction of growth. These parameters are all factors that apprehend the bioclimatic environment of birds and if they are not properly controlled and managed rationally, they cause an increase in the mortality rate.

To have a good building, well equipped and well prepared and for the success of poultry farming, it is necessary that the poultry farmer masters several components relating to hygiene, breeding standards, environmental conditions. Accounting and management elements , etc. For this purpose we propose the following recommendations:

1. Choose a good layout of the building (avoid obstacles and sites too exposed and too cashed to proscribe).
2. Ensure better insulation of the building to make the indoor climate conditions as independent as possible from external climatic conditions.
3. Building in good orientation (North/South) to avoid exposure to prevailing winds.
4. In poultry farming, the practice of the single band (only one age and one strain per farm) so as to respect the golden rule of "all-in-all-empty" farming.

5. Health protection requires the establishment of sanitary barriers and the practice of crawlspace since the quality of the latter must be related not to its duration, but to the effectiveness of disinfection.
6. The proper use of poultry equipment requires the application of certain accompanying measures, namely:

- Drinking and feeding equipment should be evenly distributed over the entire surface of the building.
- The change of the starting material by that of growth will have to be done gradually.
- Be sure to clean the waterers at least once a day at startup and twice a week thereafter.
- It is advisable to use only the fresh food and to distribute only small quantities in order to avoid the accumulation of the litter and droppings in the feeders and to add the food there as often as necessary.

7. The poultry farmer must master the ambient conditions (ambient temperature, ventilation, hygrometry, bedding quality, light) to achieve a better level of physiological comfort of the birds.

Conclusions

To obtain the best performance of broilers namely: a low mortality rate, a better weight growth and an improved consumption index, the efforts must be concentrated on: the design of the buildings, the rules of hygiene and the necessary equipment to create a suitable atmosphere inside the building.
The diagnosis of poultry farming equipment in the region of Zâb-chergui in Biskra wilaya reveals that most farmers in this region have badly-shaped buildings of hard or soft shell. The latter do not have sanitary gates and are equipped with incandescent lamps, a radiant-based heating system, circular waterers and feed hoppers. The majority of these breeders use litter made of wood chips. These farming conditions have resulted in mortality rates that exceed the standards recognized by the majority of broiler breeders in the region. Inside the building, the breeding standards must be required.
To succeed in raising broilers, it is necessary to have a building:

- Well oriented towards North/South (to avoid the prevailing winds).
- Rigid shell type.
- With a type of fluorescent tubes (neons) because they are more efficient than incandescent lamps.
- Based on unit heaters (heat guns) as a type of heating since they have the advantage of being compact and low maintenance.
- Equipped with nipples or "nippel" with or without recovery cups and hoppers. Because they are the most commonly used.
- Equipped with flax shives since they constitute an excellent litter as long as their price is reasonable. Straw (with reduced absorbency), sawdust (too dusty) and softwood or treated wood chips should be avoided.
- Has sanitary barriers (sanitary lock).

CHARACTERIZATION OF CAMEL BREEDING IN SOUTHEASTERN ALGERIA

Kahramen DEGHNOUCHE[1]*, Lahcen DEGHICHE[1], Nassima DIAB[2]

[1]Laboratory DEDSPAZA. Mohamed Khider University Biskra, Algeria
[2]Technical Institute for the Development of Saharan Agriculture, Algeria
*Corresponding author: dkahramen@yahoo.com.ph

Abstract

The study of camel breeding in southeastern Algeria during 2017 and from 30 breeders surveyed, showed that it was practiced in the majority of cases by small breeders whose herds did not exceed 25 heads (46.67%), sedentary (66.68%), age between 40 and 60 (75%), with a primary education level (37%) and 80% of whom practiced it for reasons of multiplication of the species between them. Reproduction was natural, the period of struggle was from November to April. The age of the breeding of the females was 4 years, of the males more than 5 years. We noticed predominance of reproductive females (66.90%) of the El Hamra breed (85%), raised especially for dress sought to manufacture the most famous Algerian Bernous and Kachabia. The production of milk and camel meat was low in the economy of the region and it was practiced only for self-consumption because of the free conduct of herds and the lack of routes in plant production and sources of water and the stringent climatic conditions of the current year.

Key words: *farm management, camel, herder, flock, range, arid zone.*

Introduction

The breeding system is an old activity that is part of a current economic context, it has a social and economic function by maintaining an activity, jobs and income in difficult regions and contributing to quality productions (meat, wool, skins ..) (Bencherif, 2011). About 200 million pastoral households raise almost 1 billion heads of camels, cattle and small ruminants in countries with large pastoral areas. Extensive pastoral production takes place on 25% of the world's land and provides 10% of the world meat production (FAO, 2001).

In Algeria, pastoralism is characterized by a great diversity of herds (sheep, cattle, goats and camels), huge rangelands stretching over 30 million hectares (land routes, Saharan, steppe, forest) and a large diversity of pastures (Bencherif, 2011).

The Algerian Saharan space is dominated by arid and semi-arid areas of more than 80%, through which animals are raised. Among these animals, the dromedary which had the power to take advantage of the essential food in this area. The environment with scarce resources and opportunities for agricultural development is limited (Adamou, 2008).

In recent years, there has been a fragility of rangelands in the Saharan environment (degradation of vegetation cover) due to the combination of several natural factors such as climate change (high temperature, scarcity of rainfall) (Aidoud, 1989) and anthropogenic notably anarchic and irrational grazing, which has led to a decline in camel breeding (Senoussi, 2011). Research on camel rearing systems and the management of this farming in the arid Algerian region are especially relevant to the Sud-Ouest regions (Ouargla, Ghardaia, Béchar) and aim at the knowledge of their diversity, the place of camel breeding and its role within the production units. On the other hand, dromedary has received little attention in the south-east region despite its specificities and abilities. We can make the current observation that this is a marginalized breeding, most of the time absent from development actions, despite the fact that it is the first victim of the degradation of pastures and which has a productive potential, still unknown.

In order to promote this animal of economic importance, this study aims to identify and to know the different camel farming systems existing in the south-eastern region of Biskra and to diagnose its different compartments.

Materials and Methods

From the 44 existing breeders in the wilaya (DSA, 2016), 30 were surveyed from January to April 2017. Regardless of the mode of rearing practiced, the majority of the breeders surveyed were chosen on the basis of their availability and cooperation, as well as the importance of livestock and herds in each location. The 30 selected breeders are distributed through the study region as follows; Besbess (22.23%), Doucen (19.94%), El Hadjeb (12.36%), Alhouche (13.65%), which represent the highest concentration followed by Ras El Miaad (4.63%), Ouled Djelal (7.43%), Chaiba (4.27) and Sidi Okba (5%). The low concentration is found in El Outaya (2.32%) and Zribet El Oued (1.61%) (Figure 1).

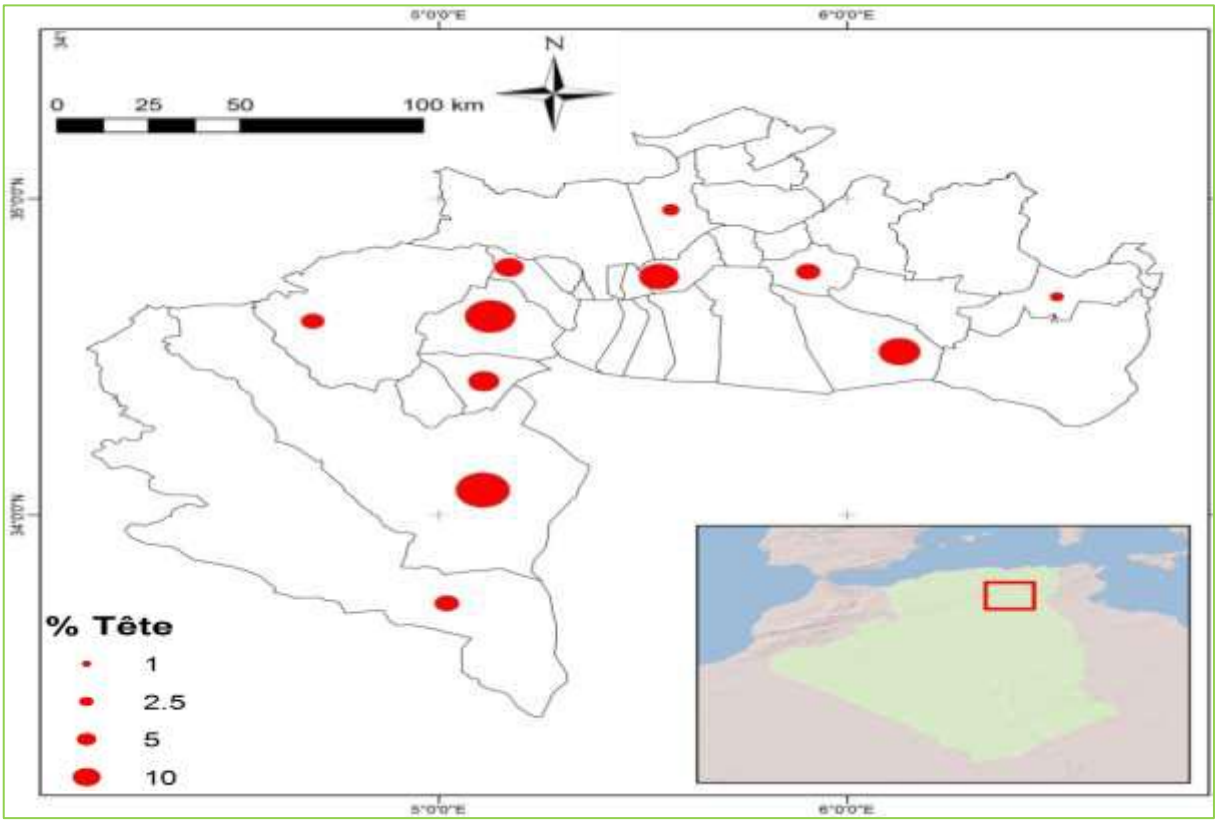

Figure 1: Importance of camel breeding in the region of Biskra

Conduct of the investigation

Our study is based on surveys conducted with herders, the herd is the main unit of investigation, supplemented by direct field observations and informations collected from different sources (breeders, veterinarians and livestock technicians).

Our survey was developed to highlight:

- the socio-economic status of pastoralists (age, sex, educational level, sources of income and way of life),
- the herd structure (size and reproduction),
- the rearing method (livestock management),
- the feeding system,
- livestock productivity.

Statistical analysis

Data processing was facilitated by the use of SPSS and Excel software. The descriptive statistical analysis of the data made it possible to produce synthetic results, to characterize and highlight the main indicators (socio-economic, production, reproduction, etc.) structured by theme already established.

Results and Discussion

To diagnose camel breeding in the South East region of Algeria, it is important to go through the identification of breeders, their typologies as well as the situation of herds and pastures through a survey.

Breeder

This part concerns the specificity of camel breeders, which is the central object of the production system, both as a decision-maker of the motivation of its breeding and as the main actor of this activity.

Habitats and lifestyles

Survey results showed that 66.68% of breeders are sedentary, while 26.66% are semi-nomadic and 6.66% are nomads (Figure 2). Three different types of housing have been identified among camel breeders. region of Biskra: the tent the house in hard and mixed housing tent and house hard.

Figure 2. Identification of livestock systems in the study area

Sedentary breeders predominate, because of the difficulty of moving their herds north in the spring (Achaba), the unavailability of the shepherd who moves with the herds and the high cost of transport. While nomads are represented by a low rate because they own a limited number of head (less than 10 head) able to transport them using their own vehicles.

Sex, age and level of education

Survey analysis showed that 100% of the surveyed breeders are male, indicating that camel breeding in the study area is a strictly male activity. Although women have dromedaries (inheritance), they entrust them to trustworthy men because of the difficulty of its breeding. 96.66% of these breeders are married, and 3.34% single. Married couples with children, on average 5 children for all the interviewed breeders.

Generally the age of breeders is for 75% between 40 and 60 years old. This age corresponds to the active period of an individual's life. Despite the small percentage (25%) of breeders over the age of 60, mainly nomads, they still remain a source of knowledge and know-how for young breeders. The transmission of the craft to children is a practice followed by all breeders, it remains a profession that is learned in family, passed from one generation to another, from father to son.

The level of education of the interviewed breeders is 16% of illiterates, 25% have not exceeded the average level and 37% have a primary level. The rest of the breeders, 22%, were deprived of any schooling except the Koranic school. This low rate of unschooled farmers (16%) represents the elderly and nomadic pastoralists whose permanent displacement does not allow them to follow schooling. As a result of the sedentarisation of pastoralists, young breeders are attracted more and more by the pursuit of the school curriculum, which explains the high rate of schooling 37% and 25%.

Sources of income

For the majority of breeders, camel breeding is considered as a means of saving and valorization in the region, for this reason that breeders practice different categories of profession. The results of our survey revealed a high rate (65%) of breeders with a liberal professional activity. They are either traders, merchants, transporters, or service providers (masons, mechanics, carpenters ...).

The rest of the breeders in our survey are either only camel drivers (7%) who live solely on the incomes of their breeding or practice a production system based essentially on the breeding-farming association (28%).

Herd

Guarding

Note that the camel breeding in the study area is characterized by a herd kept totally or partially. Depending on the composition and size of the flock and its destination, guarding (Figure 3) is done by the breeder and his children or by the shepherd, in other cases by both at the same time. 65% of the breeders surveyed are shepherds associated with the owner of herds who only help them during the breeding season and at the time of the watering. 35% of the breeders surveyed are owners of their herds.

Figure 3: Guarding the flock (Chaiba)

Size of herds

The treatment of survey results revealed 3 distributed classes as follows:

1st Class: groups small herds with a number of up to 25 heads. This class is met with 14 breeders, a rate of 46.67% of the total number of breeders.

2nd class: it groups herds from 25 to 49 heads. It is represented only by 5 breeders, ie a rate of 16.67% of the breeders surveyed.

3rd Class: groups herds of more than 50 heads, at 11 breeders, a rate of 36.67% of the breeders surveyed.

Structure of herds

In general, the composition of the camel herd varies according to a variety of factors, the most important of which is the vocation of breeding for either meat production or milk production. According to the survey, the total number of camels of the breeders surveyed (30 breeders) is of the order of 4,103 heads divided into 22.50% males with 66.90% breeding camels and 10.60% chameleons . The predominance of productive camels is due to the prohibition of female slaughter unless they are unproductive or reformed.

Reproduction

The majority of breeders surveyed (80%) take into account only the selection of males (fertility, height, disease resistance and tolerance to drought). Few selection (20%) is based on females (size of the udders, duration of lactation). All females are considered breeding stock for the maintenance and growth of the flock, but attention is always concentrated on males. According to the survey, all the breeders surveyed (100%) indicate that a single breeding male can ensure the fertility of 50 to 80 camels, in accordance with the results reported by Oueld Laid (2008), who reported that only one male can breed 80 females per season. This is why these breeders often keep one or two other males in their herds to use them when needed, according to Ben Issa (1989), these males who do not have to fight with the stallion, head of the herd.

The camel herd of the region of Biskra composed essentially by the El-Hamra (85%), Soufia (12%) and Targuia (3%) breeds, the latter being characterized by the scarcity of hairs, while the El -Hamra most wanted because of the color of her dress and the hairs are very appreciated and much requested by nomadic families for the making of khaïma, bernous and kachabia.

Livestock products.

Meat production

According to the results of our investigation, the sale of dromedaries is much more the males during the spring, the female is sold only if she is sick or old. The participation of camel meat in the economy of the region is low compared to that of sheep, beef and goat meat. This is explained by the fact that this breeding is practiced in the majority of cases (80%) for reasons of multiplication of the species between breeders.

Conclusion

Camel breeding in Algeria is obviously experiencing a revival of interest. However, this renewal must be maintained by a significant increase in the number of camel heads, but also by the increase in production (especially meat and more recently milk), by greater integration into the official and parallel trading systems, and by a certain intensification productions under the impulse development policies that are often voluntarist and without doubt, thanks to a better taking into account of this breeding by political authorities.

FACTORS CONDITIONING GROWTH IN SHEEP IN SEMI-ARID REGION OF ALGERIA

Kahramen DEGHNOUCHE*, Bessama NACER CHERIF, Hafida Hassina BOUKHALFA

Laboratory DEDSPAZA, Mohamed Khider University Biskra, Algeria
*Corresponding author: dkahramen@yahoo.com.ph

Abstract

Ruminant livestock is one of the key sectors of Algerian agriculture in which the component (small ruminant) predominates. This study was carried out in a semi-arid region of Algeria with a population of 200 lambs Ouled Djellal, with the aim of analyzing growth performance and specifying factors influencing this performance. The analysis of the least squared variance was carried out and the main factors tested were the parity, the size of the litter and the sex of the lamb. The results showed that the lamb weighed 4.19 kg at birth, 6.04 after10 days, 7.29 kg after 20 days, 8.44 kg after 30 days and 18.30 kg after 90 days. The mean growth rate was 179.55 g/d between birth and 10 days, 120 g/d between 10 and 20 days, 107.41 g/d between 20 and 30 days and 149.26 g/d between 30 and 90 days. Birth weight was very strongly related to weights at typical ages (10, 20, 30 and 90 days). Also, the average daily gains were highly correlated with each other. The litter size had significant influence on birth weight at 10 days, 20 days, 30 days, 90 days, and all daily average gains ($P < 0.05$). On the other hand, the sex and parity did not have significant influence on live weight at different ages or on the average daily gain from birth to weaning ($P > 0.05$).

Key words: *Ouled-Djellal lambs, growth performance, birth weight, ADG, sex, parity, and litter size.*

Introduction

The main problem of the sheep sector in Algeria is the low productivity ofthe flocks. The growth and viability of lambs, considered among the main components of sheep weight productivity, must be improved by selection. However, effective selection must be based on the genetic evaluation of animals. This, to be precise, requires knowledge of the factors of variation due to the environment and genetic and phenotypic parameters of the economically important characters.

Despite the exceptional growth of this sector, sheep meat remains inaccessible for a large part of Algerian households with medium and low incomes.

The low productivity of domestic herds is attributed according to Bencherif (2011) to a misbehavior of breeding and feeding of herds which is often of extensive type. The objective of this work is to study and analyze the impact sex of the lamb, and the size of the litter on measurable criteria (birth weight, weight at typical ages, average daily gains at ages types) in the Ouled Djellal lambs from birth to weaning in order to provide the breeder with assistance in managing the herd on the basis of reproduction and growth criteria on the one hand and to allow genetic evaluation ewes based on prolificacy and dairy value.

Materials and Methods

Animals

The study concerned a number of 200 lambs (male and female) of Ouled Djellal breed from multiparous and primiparous ewes that did not undergo heat synchronization. They were born between October 10th and December 9th, 2016. They were raised in semi-intensive, in addition to breast milk, they had barley hay at their disposal and they were previously identified with numbered earrings, they were housed in sheepfold with natural light.

Weighing the lambs was done using a scale with a maximum capacity of 50 ± 0.1 kg, and all information from birth to weaning is recorded on individual growth records for each lamb.

Checks carried out

Lambs are identified and weighed at birth. Then, they are weighed at the age of 10 days, 20 days, 30 days and weaning at 90 days. The average daily gain (ADG) between d0-d10; d10-d20; d20-J30 and d30-d90 were calculated from weights at the corresponding age-types.

The factors of variation considered:

- The sex of the product (male, female)
- The size of the litter (single, double)

Statistical analysis:

Descriptive statistics and one-way analysis of variance (ANOVA) were performed with the SPSS software (2013 version 20) for live weight and average daily gain analysis. The correlation results were calculated by the Pearson test for the evaluation of the relationship between live weight at different growth phases of lambs. All the averages of the results were calculated with their mean standard errors (mean ± S.E.M.). The statistical difference was reported at ($P<0.05$). - The generalized linear model (GLM) was used to test the effects of the factors on the variables, by the application of the T test for independent samples to estimate the meaning or the homogeneity between the different sets of data (comparison test between the averages). - The frequencies of each quantitative variable were graphically represented using Excel (2007).

Results and Discussion

Growth performance from birth to weaning

Depending on the size of the litter:

Weight at birth

The mean live weight of the lambs at birth is 4.19 ± 0.94 kg. Single lambs tend to have higher birth weights compared to doubles (4.70 ± 0.54 kg vs. 3.88 ± 0.30 kg) respectively (Figure 1).

Weight at typical ages (10, 20, 30 and 90)

Single lambs tend to have greater weights than twins throughout the experiment (Figure 2)
Mean weights observed at 10, 20, 30 and 90d correlate very significantly with birth weight ($r = 0.56$ $P = 0.009$; $r = 0.57$ $P = 0.008$; $r = 0.54$ $P = 0.013$ and $r = 0.63$ $P = 0.003$ respectively).
Birth weight and mean weights at 4 typical ages differ significantly with litter size ($P < 0.05$)

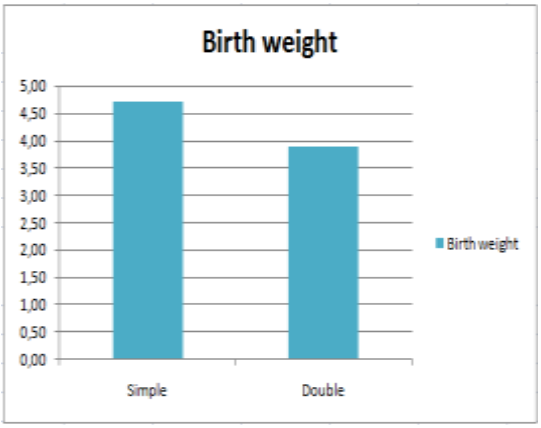

Figure 1: Difference in birth weight between single and double lambs

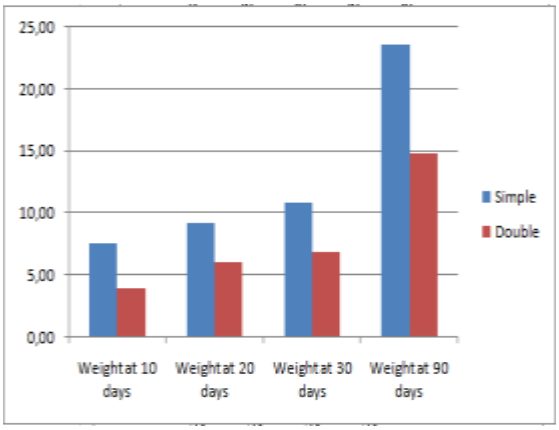

Figure 2: Variations in weights at different typical ages (kg) by litter size in Ouled Djellal lambs.

Average Daily Gain

It appears that singles tend to have higher ADGs compared to doubles (Figure 3). The correlations are significant between the average daily gains at the different typical ages, (the 30 day ADG is correlated with the 20-day ADG with a correlation coefficient r = 0.68 and P = 0.001, it is also correlated with the ADG at 90 days with a correlation coefficient r = 0.64 and P = 0.002, also the 90 day ADG is correlated with the 20 day ADG with a correlation coefficient r = 0.57 and P = 0.008). There is no significant correlation between birth weight and average daily gain at 30 days after birth (P> 0.05 / P = 0.30), whereas it is a milk production index.

Evolution of the weight:"Growth curve"

The live weight in single and double lambs evolves according to a first order polynomial regression curve, the equations are respectively y = 4.108x -1.163 and y = 2.478x - 0.362 of which (x is the time and y is the weight). Single birth lambs always grow larger than doubles. They tend to have higher live weights than doubles from birth to weaning.

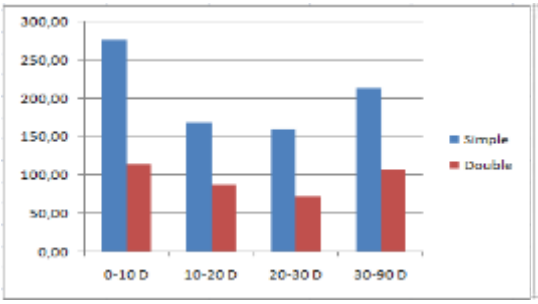

Figure 3: Variations in average daily gains (g) by litter size in Ouled Djellal lambs.

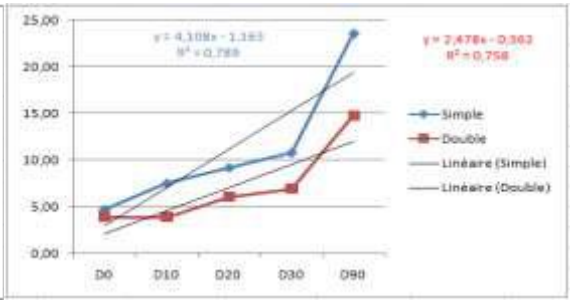

Figure 4: Evolution of weight relative to litter size in Ouled Djellal lambs

According to sex:

Birth weight:

The average live weight of lambs at birth is 4.19 ± 0.94 kg. Male lambs showed a slight difference in birth weight compared to lambs (4.37 ± 0.5 vs 4 ± 0.42 kg respectively) Birth weight did not differ significantly with lamb sex (p> 0.05)

Weight at typical ages (10, 20, 30 and 90days)
Male lambs tend to have higher weights than ewe lambs for the duration of the experiment (Figure 5). The weights at the different typical ages do not differ significantly with the sex of the lamb (P> 0.05 / P = 0.23, P = 0.16, P = 0.29, P = 0.86 respectively at the typical ages 10, 20, 30 and 90 days).

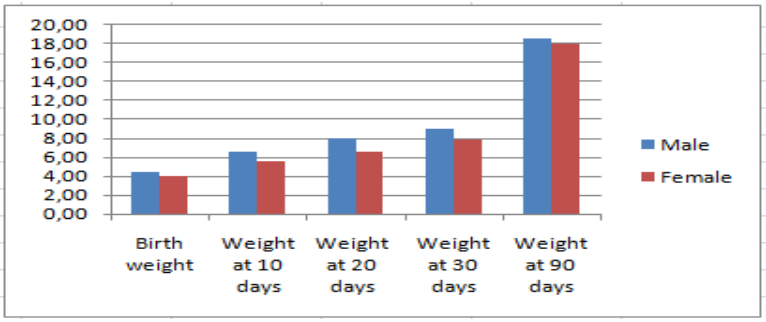

Figure 5: Variations in weight (kg) by sex in Ouled Djellal lambs

The average daily gains:
It appears that males have higher ADGs than ewes from birth up to 20 days, and then the opposite (Figure 6). Also at the typical ages, ADGs do not differ significantly with the lamb sex (p> 0.05 / P = 0.40, P = 0.34, P = 0.62 and P = 0.59 respectively at the ADGs at 10, 20, 30 and 90 days) (Figure 6)

Evolution of the weight «Growth curve»
Live weight in male and female lambs evolves according to a first order polynomial regression curve, the equations are respectively y = 3.092x + 0.027 and y = 3.031x - 0.699 of which (x is the time and y is the weight). Male lambs are still growing
faster than ewe lambs (Figure 7). They tend to have higher live weights than females from birth to weaning. (Figure 7)

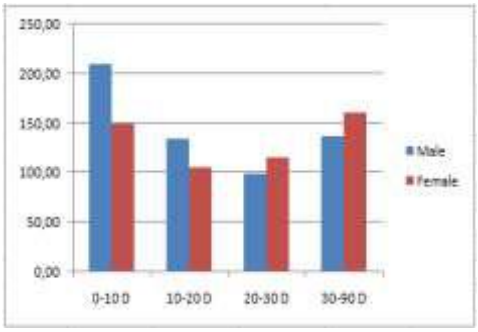

Figure 6: Variations in average daily gains (g) by sex for Ouled Djellal lambs.

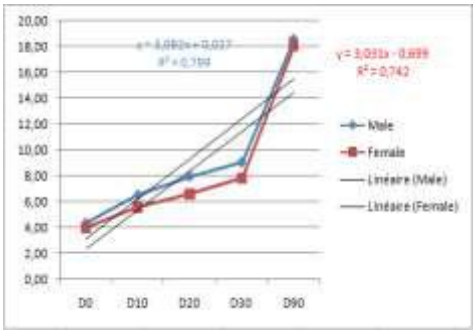

Figure 7: Evolution of weight by sex in lambs Ouled Djellal.

The mean live weight of lambs at birth (4.19 kg) is similar to the mean birth weight reported in lambs born from crosses between Ouled Djellal females and D'men males (3.99 kg) (Lebied et al. 2015) The weight results for the different typical ages found in this study are very similar to those reported by Bendiab and Dekhili (2012) for lambs of the same breed. The superiority in weight gain in favor of simple birth type has also been reported by Kerfal et al, (2005).

Conclusion

The results obtained at the end of this study allowed us to show that:

- Live weight and average daily gains of Ouled Djellal lambs from birth to weaning are closely related to litter size.
- Similarly, a very significant correlation was observed between mean weights at typical ages and birth weight.
- The growth performance of pre-weaned Ouled Djellal lambs is not related to the sex of the lamb.
- These weight and growth performances testify to the satisfactory growth potential of lambs of the Ouled Djellal breed.

At the end of these results, it appears that the "size of litter" factor has a significant influence on growth performance, which must be taken into account

Finally, this work should be supplemented by the identification and study of the effects of other factors which can induce the growth of lambs, future breeders, in other words the future of the Ouled Djellal breed.

PERFORMANCE CHARACTERISTICS AND THE EFFECT OF TWO-WAY SELECTION OF THE BARBARY PARTRIDGE (*ALECTORIS BARBARA*) IN CAPTIVITY

Farid MEZERDI*, Kamilia FARHI, Mohamed BELHAMRA

Agriculture Sciences department, Mohamed Khider University, Biskra, Algeria
*Corresponding author: mezerdif@yahoo.fr

Abstract

Since 2000, an effort has been made to obtain a Barbary partridge population for restocking. We collected data on the characteristics of the performances of our captive population during three years of experimentation (2012, 2013 and 2014) from the program initiated for the Algiers region. In addition, we conducted a detailed study on the two-way selection, based on the expression of the slow feathering allele (KK) and the fast one (kk). Our results for the performance traits showed that during the year, the average number of egg / female in 2013 (17.46) was higher than the year 2012 and 2014, because of the disturbances recorded during these years, and the fertility of eggs during the three years of our experiment with an average rate of 82.27%. The effect of bidirectional selection based on the expression of the slow feather allele (KK) and fast allele (kk) was marked by the appearance of the fast feathering genotype determined by the recessive allele (k).The results obtained from three (3) generations F12-13-14 showed that 80% of chicks belong the fast line and 20% belong the slow line.

Keywords: *Barbary partridge, line, population, allele, generation.*

Introduction

The Barbary partridge is smaller than the other genera of *Alectoris* the difference between it and the Red-legged partridge is its red brown collar spotted in white bordering its bluish gray bib (Thonon et *al.*, 1977; Svensson et *al*. 2014). Also, it is more redhead than all *Alectoris* (Couzens, 2006). The total length of our bird is between 32 and 34 cm and its wingspan is from 46 to 53 cm (Geroudet, 1978; Heinzel et *al.,* 1995) and from 46 to 49 cm depending on the male weight compared to the female weight (Cramp and Simmons, 1980). species morphology Transformation is a fundamental part of evolution, for which the physical parameters as hatching are important in egg health and influencing the growth of nestlings until fledging (Benharzallah et *al.* 2015, Mezerdi et *al*. 2015 and Mezerdi et *al*. 2017).Our research consist to continue the selection of Barbary partridge restocking line F11 to F14 in the objective of obtaining samples with important genetic and sanitary quality, of both lines (fast and slow), raised and controlled at the hunting center of Zeralda.

Material and method

Our biological material, native of Beni-Slimane in the province of Medea (36 14'03.38LN ET 319426.20LE), was brought in the year 2000, at the hunting center of Zeralda. During three years of survey, the concerned breeders of our research (N=180 couples/year), represent the generations: F11-F12-F13. The main object purpose of a genetic amelioration program is to classify a restocking line (Boukrabouza et *al.*, 2003 and Belhamra, 2005). The breeders' preservation protocol in winter consists of avoiding the visual contact between males and females; they are separated in homo-sexed groups in parquets (GavardGongallud, 2000). The distance between these parquets is almost 100m. Earlier in the reproduction season, males start to sing and yell as signs to their females to start their coupling. During 91 days, we have collected the eggs, every Wednesday of the week. We measured many zootechnical

parameters such us: the number of the collected eggs, the rate of laying eggs the number of incubated eggs ; the unfertilized eggs ; the rate of the embryonic mortality; the production of chicks and the rate of egg hatching, to identify the quality of the eggs and the reproduction success. Also, we conducted a chicks selection by feathers, because the partridge chicks of the first day of the fast line present a developed and longer wing cover feathers than those of the slow line. (Fig.1).

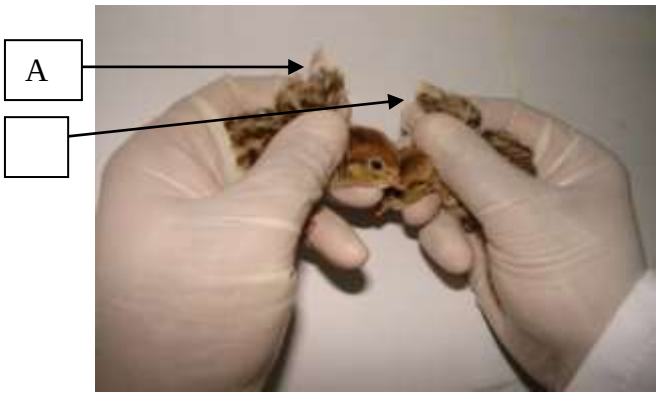

Figure 1: The feather form of the fast line (A) and the slow line (B).

Results and discussion

The characters of the performances of our Barbary partridge population

After three years of work successively 2012; 2013 and 2014, we have gathered some data concerning the performances characters of our population in captivity.

The zootechnical characters in 2012

The breeders of the year 2012, matches the generation F11 of our population. This year's birds are disturbed, because we have moved them into a smaller and a less enlightened place to develop the laying parquets, and we only had the chance to gather six series. Forthe first series of 19.04.2012. we have collected only 154 eggs. So, in six weeks we have incubated 980 eggs (Table1), whose size oscillates between a minimum of 0.38 and a maximum of 1.28 egg/week (Fig.2) We notice that there are two periods of laying averagefrom the first series to the third with a peak of 1.38 than a second one with a decrees of the laying, until the last series which corresponds to the sixth one with 0.38 egg/week.

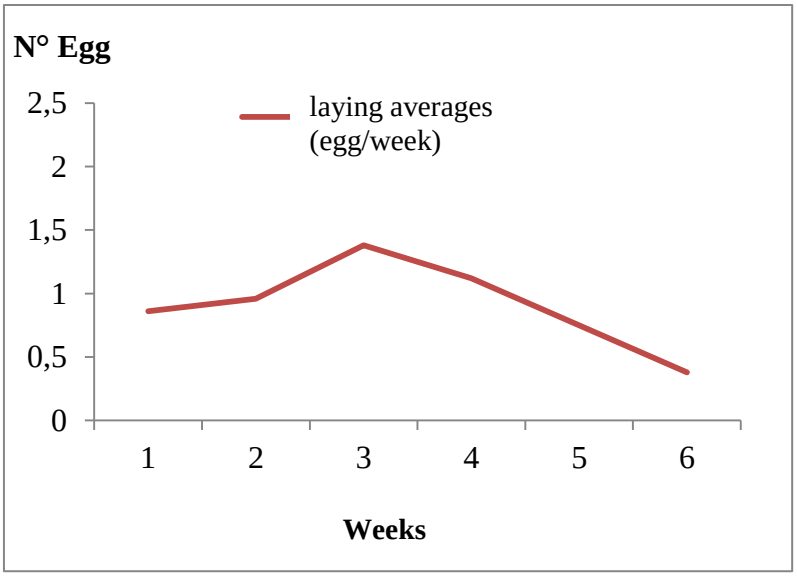

Figure 2: The variability of laying averages of the Barbary partridge during 2012.

During our experimentation in 2012, we noticed that the fertility rate and the egg hatchability rate starting from the 4th week reached a maximum value of 91.58% and 95.05%, and the minimum value in the last series with 26.47% and 36.76% successively. The same series of maximum values, we also registered a maximum rate of egg-hatching of 96.35%, but we registered the minimum value during the first series with 57.01%. We also notice that the rate of embryonic mortality is more important during the first week of laying eggs with a medium rate during 6 weeks of 15%.

For the phenotypic characteristics, we noted that the distribution of the phenotypic frequencies in 6 weeks (Fig3) shows that most of our population birds are at 80% of active phenotype. We have noted that during the first week, the frequency of both lines fast and slow express in the same way. But starting from the second week the phenotypic frequency of the fast line is more important until the last week with a rate of 93.75% and 6.25%for the slow line because this line's chicks couldn't resist in the last series.

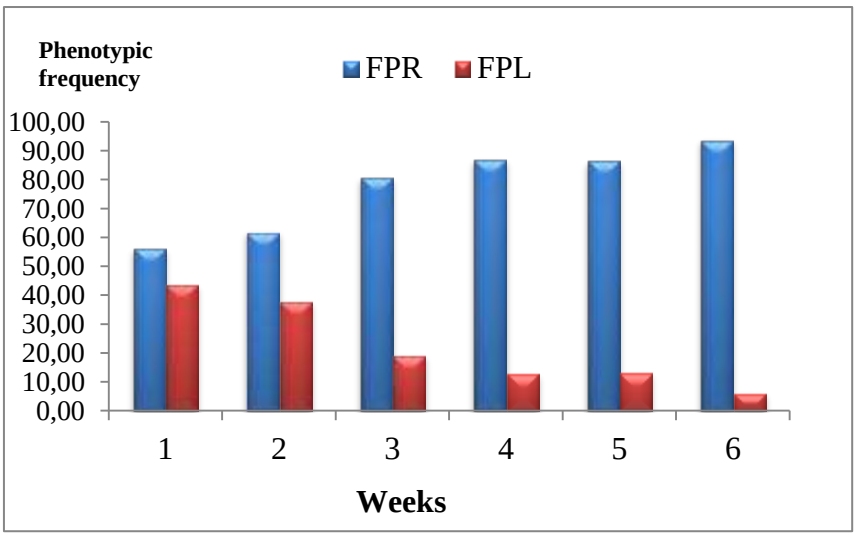

Figure 3: The variation of both lines' rates (slow and fast) in 2012.

Zootechnical characteristics in 2013

2013's breeders correspond to the F12 generation of our population. Our population is characterized by avariability in the laying size between a minimum of 0.33 and a maximum of 2.19 egg/week. During 12 weeks of follow-up , we have collected 3142 eggs (Table 1). In the middle of laying weeks which correspond to the 4th and the 8th week, we have registered a certain stability of laying average (>2 egg/week). This period synchronizes to the participation of all population females in the egg laying (Fig4). This explains that our population is well adapted to the captivity conditions. However, last year we have noticed a maximum of laying (>1.38 eggs/week). After the 8th week, a decrease of laying which reached 0.33 egg/week had been registered in the 12th week.

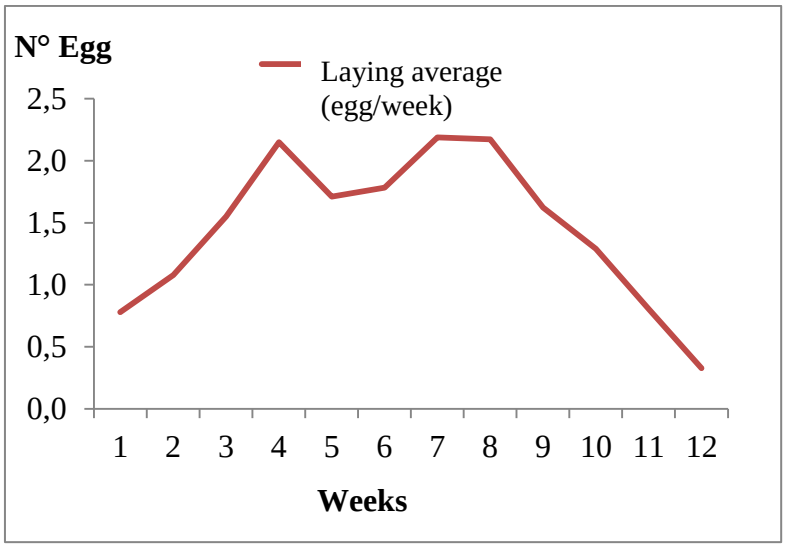

Figure 4: The average variability of laying of the Barbary partridge in 2013.

During 2013, we noted that the eggs' fertility rate is of 95.02%, in the 6th week, and a minimum value during the 12th week with 83.05%. Furthermore, the hatchability rate and the egg-hatching rate reached their maximum values during the 8th week with 86.96% and 95.51% and minimum values during the 12th week with 66.1% and 79.59% successively. The average embryonic mortality rate is 9.61%.

In 2013, the distribution of phenotypic frequencies over the 12 weeks (Fig5) shows that most of our population birds at 80% of active phenotypes. We notice that during the 1st week, the frequency of both lines fast and slow is expressed in a similar way with an advantage of the slow line. Starting from the 2nd week, the phenotypic frequencies of both lines is separated until the last week with a rate of 93.75% for the fast line and 6.25% for the slow one, in parallel with the year of 2012.

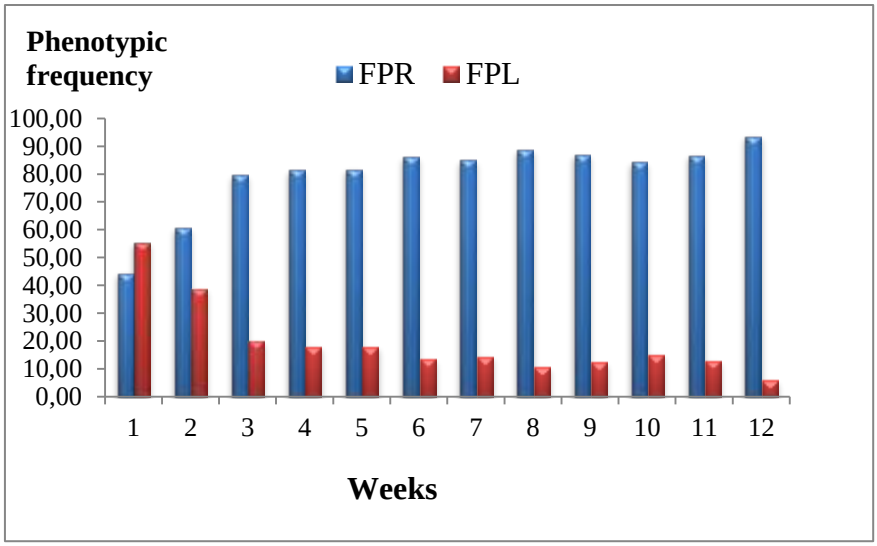

Figure 5: Variation of both lines'rates in 2013.

Zootechnical characteristics in 2014

The 2014 breeders correspond to the F13 generation of our population.

The laying size variability between a minimum of 0.21 and a maximum of 2.46 eggs/week. A planning during the reproduction period, affects the egg production, in the first weeks which is less than 0.35 egg/week. During 9 weeks of follow-up, we have collected 1936 eggs (Table1). Since the 3rd week, our population's females start to enter in the laying phase reaching in the 6th week 2.46 egg/week (Fig.6). In the last three weeks, we have noted a brutal decrease of egg laying reaching only 0.21 egg/week.

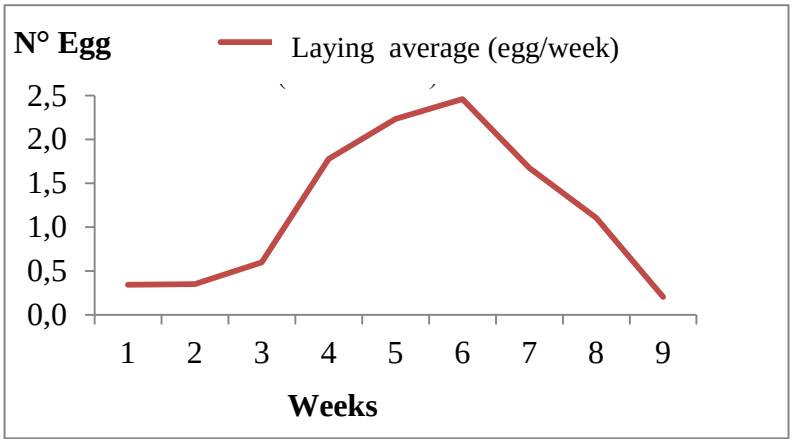

Figure 6: Variability of laying averages egg the Barbary partridge in 2014.

In 2014, we have registered that the fertility rate is about 92.46% during the 8thweek, and a minimum value during the 2nd week of 68.25%. Over the 1st week, the hatchability rate is too low with 45.16%, and then it starts to increase to reach a maximum value of 87.75% in the 7th week. Furthermore, the hatching rate in the 1st week is too low with 65.12% and it reaches a maximum value in the 6th week with 97.46%. the average rate of embryonic mortality 5.11%.

The distribution of phenotypic frequency in 2014, over 9 weeks (Fig.7), also shows that most of our population birds at 80% of active phenotypes. We note that during the three first weeks, there was a decrease in the slow line until the 3rd week and carry out 34.13%. Then, stability on both phenotypic frequencies.

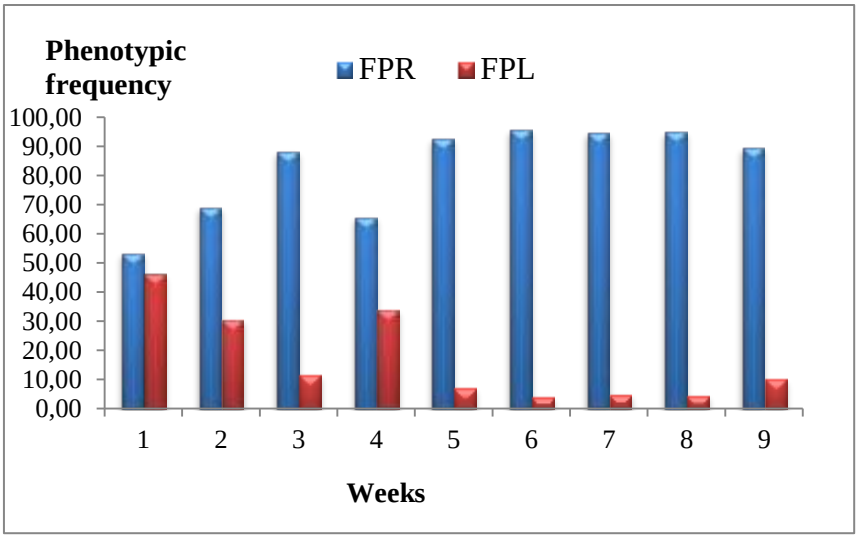

Figure 7: Variation of both lines' rates (fast and slow) in 2014.

Phenotypic effects on the frequency evolution of the allele k over three years of experimentation

The production of chicks in 2012 corresponds to the F12 generation of our population, which contains 617 birds, whose 77.72% of individuals of the fast line phenotype and 22.28% of the slow line, with an average of 6 weeks of laying. The production of chicks in 2013, corresponds to the F13 generation of our population, which contains 2332 birds, whose 80.16% of individuals of the fast line and 19.84 % of the slow line, on an average of 12 laying weeks. The chicks' production in 2014 correspond to the F14 of our population which contains 1397 birds, whose 82.82% of individuals are of the fast line phenotype and 17.18% of individuals are of the slow line phenotype, on an average of 6 laying weeks.

We propose a hypothesisthat if the males are homozygous (kk) and the females (k-) the descendants are at 100% fast phenotypes, and if the males are homozygous (KK) and the females are (K-) or (k-) the descendants are at 100% slow phenotype. But the case of our population and during three years of follow-up, the descendants F12-13-14 are at 80% individuals of the fast phenotype and 20% of the slow phenotype, so the parents are for heterozygous male sex (Kk) and female sex (k-).

The biological indicators and the performances' characteristics of the reproductive population of the generations F12-13-14

During3 years, we sampled 180 couples as a reproductive population. The conservation method of breeders in winter time, by the separation of males from females, has a positive effect on the egg fertility, over the three years of experimentation, with an average rate of 82.27%. The rate of fertility in 2011 was 89.09% (Mezerdi, 2011). This fertility rate is almost similar to the average fertility rate of 8 years for the Red-legged partridge with 84.1%, but more important than that of the gray partridge with 74.8% (Bay1975). The fertility rate is affected by the environment conditions and management, which is confirmed by Mourao et *al*. (2010).

In 2012, the F11generation; our population laid only 980 eggs in 6 weeks interval only. This laying fluctuation is caused by the disturbance during the reproduction period. The number of eggs per hen during the three years of our partridge remained inferior to that of their neighbours in the red-legged partridge, in 2012 (5.44 egg/hen/year), in 2013 (17.46 egg/hen/year) and in 2014 (10.76 egg/hen/year). But according to Cosse and *al.*, 2002, the red-legged partridge (49 eggs/hen/year) and achieved (53 eggs/hen/year) with females of 2

years old (Mourao et *al.,* 2010). These results exceed 2000 data (Khataoui and Oulmane, 2002). Over the period 2004 to 2010, Boukrabouza (2011) noted a strong laying fluctuation of 1400 to 3700 eggs. These fluctuations are caused by the breeding conditions and to the emergence of disease-related problems (Alitaleb and Bousaid, 2011).

The performances' results of our population of the Barbary partridge, over these three years from 2012 to 2014 are inferior to the one of Mezerdi (2011). According to these results, it presents to us the necessity to develop and ameliorate the adaptation techniques and to select a line of acclimatization on the basis of an encouraging character for the durability and the stability of the social links. This line presents a social motivation with the breeding conditions in groups (Belhamraet*al.*, 2007, Schweitzer, 2009 and Mezerdi, 2011), and a strong sensitivity to selection from one generation to another on the common pheasant (Boukhamza, 2007,BelhouaneandAbbou, 2010,Farhi,2011 and Larinouna,2011). The selection of the birds' lines allows to search for different characters and the quality of the birds' production in captivity, within different breeding problems. For our population of Barbary partridge F11-12-13, the egg-hatching rates are in the order of (78.87-88.46 and 87.98), respectively during three years of follow-up, we notice that there is an increase compared to 2012 and 2013. On the other hand we notice a decrease of the egg-hatching rate of birds from a year to another (Fasenkoet*al.*, 1992,Eliblet*al.*, 2002, Yilmaz and Tepeli, 2009). Also, the average egg-hatching rate of three year is of 85.1%. It is more important compared to the Red-legged partridge which is of 79.8% (Cosseet*al.*,2002). However, our results concerning the embryonic mortality rates over the 3 years are in the order of (15%-9.61% and 5.11%) respectively with and average of 9.04%. We noticed from these results, that the rate of the embryonic mortality decreases from year to another, in contrary to what had been noted by Yilmaz and Tepeli (2009) in Chukar partridge. Over the three years of follow-up, we have noted that the perturbation which presents during the reproduction period, affects the egg laying date. In addition to that, we have noticed an effect on the performance parameters of our population. Also the study of Gonzalez-Redondo (2006) on the Red-legged partridge, shows that the laying date has an effect on the fertility rate and the egg hatching. Many studies showed that the bad control of the physical parameters, during the phase of conservation and incubation, have a negative effect over the embryonic mortality (Le Bars and Simon (2005) *in* Belhouane and Abbou, 2010). The causes due to these technical factors can achieve an embryonic mortality going up to 16.63% (Mezerdi, 2011).

The selections in the descendants F12-13-14

During three years of follow-up, the majority of the descendants of the phenotypic frequencies of our population are of 80% for the fast line and 20% for the slow line. We propose the assumption that the genotype of the breeders is (k-) for the females and homozygous genotype (kk) majority or heterozygote (Kk) for the fathers. The animals of the active line are characterized by a low reactivity to a new stimulation (Faure, 1975) and are not very emotional and not very aggressive (Faure, 1982). Conclusion

Conclusion

Over the 3 years of this study, we have observed that in the year of 2013, we picked up 17.46 (egg/female). This production is superior to the two other years 2012 and 2014, but is remains far enough of the average of the egg laying acquired in the other species of partridge. We have also showed that the disturbance of adults, during the reproduction period, effects the date of the egg laying, the number of eggs and their fertility. With a regular follow-up of the physical parameters (Tp° and H %) while the phase of incubation, correspond perfectly, to the needs of the metabolism of the embryonic development without stress. These parameters affect negatively the egg hatching rate, which give a bad production of chicks. During 3 years and over 27 weeks of hatching, the average exceeds 80%. The phenotypic variability shows

dominance of the order of 80% of chicks from the generations F12-13-14 carry recessive alleles k- and kk, starting from females with fast feathering k- and recessive homozygote males kk. On the other hand, the slow bird morphology would be the descendants of the fast females' k- and the presumed heterozygote males Kk.

CHARACTERISTICS OF BULLS' ACCOMMODATION FOR THE BOSNIAN-HERZEGOVINIAN BULLFIGHT

Ajla ALIŠAH*, Aida KUSTURA, Almira SOFTIĆ, Salko MURATOVIĆ, Velija KATICA, Abdulah GAGIĆ

Abstract

Contemporary livestock production is conceptually fairly "merciless" towards male animals.They are mainly used for the meat production, breeding or as a working animals. It happens really often that the conditions of their accommodation and exploitation are very difficult. The criteria for male specimens are defined by their production purpose and vary depending on whether they are fattening or reproductive animals. Reproductive males, comparing them with ather males are in the best position regarding living conditions. However, on the territory of Bosnia and Herzegovina there is however one category of animals that, thanks to the tradition over 300 years old, enjoys all the rights and privileges which, unfortunately, almost do not enjoy any other species and categories of animals in the world, except those in the wild. They are fighting bulls, in Bosnia known as „bak", who many either intentionally or out of ignorance, compare with bulls for Spanish Corrida. We must note that, apart from the species and sex of animals, they have nothing in common. The fighting bulls are the category of cattle whose goal is expressing their dominant patterns of behavior, such as mutual fights, which are otherwise happening in a natural environment. To make the fighting bulls a real alpha males, they must have, in addition to genetic and other predispositions, first of all good housing conditions, which is a topic of our work. In order to try to get closer to what conditions they enjoy, we tried to compared them to, according to livestock standards, the best positioned breeding bulls, used in breeding centers, about which almost no literature data exist. For this reason, comparative data are very poor, but from the aspect of the ethology and animal welfare it is very easy to conclude which accommodation parameters are better, because the animal welfare is compared with what it would have in a natural environment, which primarily implies the space they live in.

Keywords:*bull, Bosnia-Herzegovina bullfight, ethology, nutrition, accommodation.*

Introduction

The Bosnian and Herzegovinian bulls,called "fighting bulls" are extremely interesting national sports competitors, in the nation known as „bode" or bulls fight. Quite and totally wrong, these manifestations in the public are called corridas with which, besides the species and sex of the animals involved in them, they have nothing more in common. With the tradition of maintaining over 300 years of age, the Bosnian-Herzegovinian bull's fight is a traditional competition specially raised bulls from which are expected to be male individuals in the full, natural sense of that status.

Male animals in livestock production

Regardless of the characteristics, modern livestock production is conceivably rather "merciless" toward male animals. They are used mainly for the production of meat, for breeding or for working animals, often in extremely difficult conditions of exploitation. The male genotype, in relation to the female sex, determines physiological characteristics such as

rapid growth, realistic higher body weight and better food conversion, which is decisive for the desirability of introducing them to meat production (7; 11; 12; 25). This statement refers to all types of domestic animals, whether intensive or semi-intensive production. Male animals of some species, such as pigs, cattle or small ruminants, are castrated very early in order to further accelerate the growth of body weight and eliminate the undesirable smell of meat that is due to the presence of male sex hormones (7; 16; 18).

Zootechnical conditions for holding male cattle

Cattle (Bovinae) belong to the genus Mammalia, the line of two-aisles (Artiodactila), the subspecies of ruminant (Ruminantia), the family of cavalrymen (Cavicornia) (6; 13; 17; 19; 20). These are animals who are lonely, but they feel better in the group - the herd. Therefore, almost all of the wild cattle live in the herds. Within their own herd, they are rarely fighting each other except for food or water, when they move along a narrow path or when they leave the stable. Until they become accustomed to each other, they exhibit mutual intolerance (14; 15). Although cattle are relatively able to tolerate stable tipe of housing, recent zootechnical stances in exploiting this species of animals advice the principle of returning to the natural way of keeping under the clear sky. According to them (14; 15), the barn should only be "necessary evil" at a time of extremely unfavorable climatic conditions. This is explained by the facts, but also by the assumptions that the stable tipe of housing disturbs certain functions of the organism of animals, and changes the established social relations and established patterns of behavior.

Basic principles of hygiene accommodation of bulls

Bulls can be placed in indoor, classic stables with or without discharge, and in semi-open and open stables with mandatory drains (2; 4; 8; 9; 13; 23). According to the internal arrangement, stables are different, and in what kind of accommodation solutions will be applied, the number of animals and the size of the farm play an important role. Stables usually have a form of rectangles with frontal sides, which in our geographical circumstances are directed towards the south, southeast. The windows are located on the longitudinal sides of the stables, and the light coefficients, in the ratio of the surface of the windows and floors are 1:10 to 1:12 for the younger and 1:15 for older animals. The height of the stables is different. In small stables it is 2.5 m, medium size 2.8-3.2 m, and in large 3.5-4.0 m. Accommodation criteria for male animals are defined by their purpose and vary depending on whether they are fattening or reproductive animals. Male animals are located in closed stables on bearings on the connection or freely in group or individual boxes. Stables can have discharges that are mandatory for breeding animals. Fattening cattle bearing have a length of about 1.70 m and a width of about 1.10 m. The chain system is similar to the cows. The bearing are slammed, and the extermination is done through the extermination channel located behind the legs of the animals. Free hold of male heifer and bulls in fattening is organized in group boxes, and depending on local climatic conditions it is realized in semi-open stables. The floor area under these circumstances depends on the body weight of the individual and ranges from 3.5 to 4.5 m2 per bee (2; 7; 23).

Breeding bulls are usually located in artificial insemination centers. They are kept linked to a chain or more often freely. Linked to a chain means a long bearing and a secured outlet, while free hold is realized in individual boxes that also end up with outflow. When they are on chain, bulls bind around the door with a chain fastened to the front edge of the jasper. If necessary, the chain can be shortened. In this way, they are able to smoothly move back and forth and up and down. Individual boxing is 4.5 to 5.0 m long and 4.0 m wide. It consists of a moving part and a bearing. Regardless of whether it is free hold or bulls on the chain, the bearing is 3.5 m long, 1.5 m wide and lined with straw mats . The discharge dimensions are

usually 5.0 x 4.0 m. The bearings or boxes are separated by a solid fence 1,5 m high. The minimum surface area of the stables with associated infrastructure per adult breeding bull should be 10 m² (2; 23). Under the stables as well as bearing must be dry and clean. Bulls must not be located immediately near the door, nor in the dark parts of the stables from which they do not have a good view of the environment. In such circumstances they can become very irritable and aggressive (3; 4; 5; 13). The concern about the hygiene of the bulls should be guided by people who understand the work and what is very important people who loves this job.

Material and methods of work

Material

In the performance of the experiment, four bulls of different ages and categories were included.

Name: **Svilonja**
Location: Sanica;Unsko-Sanski Kanton
Breed: in the Bushas type
Age: 8 years
Body weight: 670 kg.
Category: medium
Participation in fights: yes
Victories: yes
Reproducibly active: yes
Accommodation: a long bearing on a link in a traditional barn; free grazing on pasture, walking and staying outside the barn whenever climate conditions allow it, including at least 2 days a week in the winter when there is a lot of snow

Ime: **Žujo**
Location:Bijeljina; regija Bijeljina
Breed: in the Bushas type
Age: 5th year
Body weight: 670 kg.
Category: medium
Participation in fights: yes
Victories: yes
Reproducibly active: yes
Accommodation:
- a long bearing on a link in a traditional barn; free grazing on pasture, walking and stays away from the stables throughout the year whenever climate conditions allow

Ime: **Baki**
Location: Kakanj; Ze-Do Kanton
Breed: in the Bushas type
Age: 8 years
Body weight: 800 kg.
Category: heavy

Participation in fights: yes
Victories: yes
Reproducibly active: yes
Accommodation:
- a long bearing on a link in a traditional barn; free grazing on pasture, walking and staying outside the barn whenever climate conditions allow it

Ime: **Čupo**
Location:Preočica-Vitez; Srednja Bosna
Breed: in the Bushas type
Age: 5 years
Body weight: 950 kg.
Category: heavy
Participation in fights: yes
Victories: yes
Reproducibly active: yes
Accommodation:
- a long bearing on a link in a traditional barn; free grazing on pasture, walking and staying outside the barn whenever climate conditions allow it.

Daily activities for all four bulls outside the standstill period:
- main training: walking with wooden load on the shoulders for up to 1 hour, and walking along and down the hill to 2 hours
- fitness training: walking along and down the hill to 2 hours
- Five to seven days before thefight without training
- reproductive engagement: after the season point in the period from November to January

To determine the ambient parameters we used:

a) VOLTCRAFT 4U1 ENVIRONMENTAL METER, technical data:
   - features of luxmeter: 0.01-20.000 lux, resolution:0.1/1 lux
   - features of sound level meter: 35-130 dB, resolution; 0.1dB;
   - features of thermometer: internal -20°C-+750°C
   - features of hygrometer: 25-95% RH
b) IR 800-20D infrared termometer Voltcraft, technical data:
   - response time:150 ms
   - resolution temperature: 0.1°C

Methods of work

Determination of zootechnical aspects:
Calfs after separating from the mothers at the age of about 3 months are held in joint boxes and outdoor. After separation of calves for fattening, future reproductive individuals from selected parents continue to live together in group boxes and on the outflows. During this period, the owners closely follow the behavior of the remaining male calves, that is, the bulls, in particular, the behavior of the dominant individual. After the separation of heifers from the age of 15 to 18 months, the mails under the control of the owner continue to stay together in mixed herds. After three years, one, two or at most three young bulls will be selected for future fighting bull who will be under special treatment. They are housed in individual bearing, ensuring the maximum stay on the open pasture, they start with a special diet

program, they are introduced into the training process and if they continue to show behavior characteristic of the dominant male animals, the owners translate them into the fighting buuls. With this passage, without any coercion in terms of stimulating their masculinity or aggressiveness by the owner, the bulls ensure their privileged position of the future players of the Bosnian and Herzegovinian bull fights. Thanks to this, they will spend a pleasant life with the expectation of the owners to be only what is essentially their natural task - to be the dominant male individuals (1; 21; 22; 24).

Determination of zoo-hygienic indicators:
In addition to the selection method, one of the important criteria for determining the zootechnical status of bulls for a bull fights is to determine the zoohigenic parameters of their accommodation in the stables. These parameters were determined by measuring the value with the help of appropriate measuring instruments. We determined the area and the volume of the accommodation space, the area of the bearing, the values of the most important ambient parameters - temperature, relative humidity and air velocity, noise in objects, light coefficient, and surface temperature of bulls at the level of the head and hull, to determine the degree of benefit in the stables.

Results and discussion

All observed bulls were kept in classical closed stables with secured outflows. The stables as well as their individual parts were built in accordance with the defined zoohigenic norms. The walls are made of solid building material, (to a coefficient of 0.9 to 1.1), the floors and bearings are made of concrete with a concave glaze made of lightweight concrete (the inclination of the floors and deposits to the channel for extermination was between 2% and 3%). The internal design and layout of technological parts and equipment were in accordance with the norms for free hold and holding bulls on the chain. The total useful area of the stables floor ranged from 19.25 to 51.84 m² per bull, and based on the determined ceiling height values, a useful volume of 48.125 to 184.03 m³ per bull was defined (Table 1).

Table 1. - Useful area and volume of stables where the bulls were located

Bull	category	floor area (m²)	volume of stables (m³)	number of bulls	the surface is given per bull (m²)
Svilonja	medium	19,25	48,13	3	6,42
Žujo	medium	51,84	184,03	6	8,64
Baki	heavy	40,50	141,75	1	40,50
Čupo	heavy	27,74	71,58	3	9,25

The surface of individual bearing for the observed bulls ranged from 4.07 to 8.00 m², and the volume of the associated area ranged from 10.17 to 20.00 m³. For stratification, pure straw was used in quantities of 3 to 4 kg (Table 2)

Table 2.- Surface area, volume of belonging area for bulls and daily straw for stratification

Bull	category	area of bearing (m²)	volume of space (m³)	quantity of straw (kg)
Svilonja	medium	4,07	10,17	3,5
Žujo	medium	4,86	17,25	3,0
Baki	heavy	8,00	20,00	4,0
Čupo	heavy	7,52	19,40	3,5

The determined interrelation of the surface of the light openings and the useful floor area, ie the light coefficient in the stables of the observed bulls ranged from 1: 9 to 1: 13.5 (Table 3 ..).

Table 3.- Luminous coefficients in stables for accommodating bulls

Bull	category	floor area (m²)	window surface (m²)	light coefficient
Svilonja	medium	19,25	2,10	1:9,16
Žujo	medium	51,84	5,76	1:9,00
Baki	heavy	40,50	3,00	1:13,5
Čupo	heavy	27,74	2,40	1:11,5

The average measured values of the temperature and relative humidity of the air in the stables, the surface temperature of the skin at the head and hull level, and the noise intensity and airflow velocity are shown in Table 4. The air temperature oscillated between 17.9 ° C (Čupo) and 26.8 ° C Baki) and relative humidity between 40% (Baki) and 73.5% (Chupo). The measured values of the noise level and the velocity of air flow in the stables were very uniform and the surface temperature of the head and hull skin oscillated from 21.9 ° C (Svilonja) to 26.5 ° C (Žujo) and from 28oC (Svilonja and Čupo) to 30 oC (Zujo and Baki).

Table 4.- Values of ambient parameters and surface temperature of the skin of bulls

Bull	air temperature (°C)	relative humidity (%)	noise (dB)	air flow rate (m/s)	surface of the skin of the head (C°)	surface of the hull skin (C°)
Svilonja	19,9	61,95	47,9	<2,3	21,9	28
Žujo	22,1	70,00	47,8	<2,3	26,5	30
Baki	26,8	40,00	47,8	<2,3	25,0	30
Čupo	17,9	73,50	47,8	<2,3	22,3	28

Results and discussion

In our earlier research (10) we concluded that it is primarily because of the human interest, the welfare of commercial animals in relatively acceptable limits, and that they have a higher index of well-being than most animals belonging to the category of pets. The stated position of these categories of animals in fact shows that the people from their holding primarily expects appropriate economic benefits, which is why it also ensures the relatively acceptable quality of the particular accommodation factors. Therefore, it is no surprise that reproductive individuals, and therefore reproductive bulls, enjoy zoo-hygienic and nutritional benefits that are inconceivable or difficult to achieve in commercial individuals. Through the relatively well-defined zootechnical standards of holding breeding bulls (2; 6; 8; 9; 23), we will try to compare the results achieved in our research. Future Bosnia and Herzegovina fighting bulls grow up in mixed herds. They are not forced to show their early sexuality only to brutal fights with same-sex animalsa, as is the case with bulls for Spanish coridas (26). On the contrary, their dominant social position can be fought and expressed in a completely natural way by numerous patterns of behavior, of which aggression and combat actions are only one part. In such circumstances, the behavior and position of the alpha male is clearer that it is a good basis for the owner to recognize the potential alfa mail and to pay special attention to him in the later period of life (1; 21; 22; 24). When it comes to the position of fighter, the bull gets a status that is unfortunately, however much it was unreasonable to compare, there are not many people in the world. Our results imply the conclusion that their good status and

preferences are almost impossible to be objectively compared with breeding bulls from commercial livestock production. In this sense, a slightly easier job is to consider only the hygienic indicators of accommodation. As we have already pointed out, it is not disputable that because of the human interest, reproductive animals in commercial production have a special, preferential status. They provide the best accommodation and ambient conditions, the best nutrition and the like. Zootechnical and zoohigenic standards are mainly referenced according to the position and needs of this category of animals. Through the results of our research, it is clearly visible that all four observed bulls- Svilonja, Žujo, Baki and Čupo are kept in accordance with the highest zoohigenic norms of combined holding in classical closed stables, with secured outdoors for free movement in the outer environment. With a much larger total useful area of barn floors per bull, but also with the total volume of space per bull, the observed bulls have provided much higher accommodation comfort than the norms for breeding bulls in the selection centers. Other micro-ambient parameters such as temperature and relative air humidity, room illumination, noise intensity and air flow velocity also reflect a well-kept hygienic environment that is by no means lagging behind the highest standards of accommodation of highly valuable breeding animals. This statement is most clearly confirmed by the measured values of the temperature of the surface of the skin on the head and the hull of the bulls, which indicate a harmonized thermal processing process as an indicator of the good benefits provided by the accommodation space. However, the data on practically completely free movement of observed bulls outside the stables on surfaces reaching more than one hectare significantly outweigh the recommended outflow area for breeding bulls that move within a few tens of square meters per one bull (2; 23).

Conclusion

Due to the issues of nutrition, reproduction and protection from predators, the larger accommodation space in relation to breeding bulls, guarantees a completely natural way of life in the most optimal conditions of its manifestation. Usually to natural death. And from this aspect, Bosnian and Herzegovinian fighting bulls belong to animals with the most privileged life.

Abstract

The objective of studie was to examine effect of nutrition on hematological parameters of cross-bred lambs fattening. The study was conducted on 20 cross-bred lambs from different pramenka types, divided in two groups. The lambs of one group were fed with mixture of cereals and sunflower meal without mineral-vitamin premix with 12.26% protein, but for the feeding of second group of lambs were used feed mixture for older lambs with 14.69% protein. During the fattening period the lambs from both group were fed hay *ad libitum*. Measurments of hematological parameters were measured on the 21st and 35th day of fattening. The results were statisticly analyzed, statistically significant differences and correlation coeficient were determined. The gain of hematological parameters was determined within the both groups according to age of lambs during fattening. The results indicated that the group lambs fed mixture of cereals and sunflower meal achieved better but not statisticaly significant ($p>0.05$) hematological parameters, comparing to lambs fed with feed mixture.

Key words: *fattening, hematological parameters, lamb, feed*

Introduction

Animal nutrition efficiency has a significant effect on the profitability of production systems and provides the ability to identify and select animals with enhanced conversion ability of food into the animal product (Basarab *et al.,* 2003). The economic importance of sheep farming is based on the biological characteristics of sheep, which enable relatively poor vegetation of pastures to become highly valuable products. A significant place in lamb feeding in the fattening, in addition to adequate energy supply, belongs to meal proteins or sources of protein in the meal. Protein nutrients, besides providing animals high value protein, also have a positive effect on production indicators (Memiši *et al.*, 2002).

In addition to nutrition, hematologic indications play a significant role in assessing the physiological, nutritional and pathological status of the animal, and their determination in the blood of the sheep completes a picture of the matabolic profile (Antunovic *et al.,* 2009b), which is a good indicator of health status and nutritional status. Amakiri *et al.,* (2009) have pointed out that it is very difficult to estimate the current health status of animals without a detailed blood test. Hematological indicators of sheep are affected by the breed, physiological state, season, altitude, breeding systems (Soch *et al.* 2010; Soch *et al.,* 2011). Changes in the hematological profile were established earlier in other species, both at birth and in the suckling period. Bornez *et al.* (2009) found a significantly higher number of erythrocytes, higher hemoglobin and hematocrit content, and a higher number of leukocytes, in the blood of lambs at 70 days old fed with concentrate and wheat straw, comparing to sucking lambs at the age of 30 days. Therefore, anything that affects blood, medicines, pathogenic microorganisms or nutrition will certainly affect the entire body negatively or moderately in terms of health, growth, maintenance and reproduction (Oke *et al.,* 2007). Lack of nutrients can affect blood hematologic parameters as well as evaluate the clinical and nutritional health status of the animals because the intake of nutrient components has measurable effects on blood

composition and can be considered as an appropriate benchmark for long-term nutritional status (Olabanji *et al.,* 2007; Daramola *et al.,* 2005).
The aim of the study was to investigate the effect of different percentage of protein in feed mixture on hematological parameters of crossbreed lambs.

Materials and Methods

The study was conducted on 20 cross-bred lambs from different pramenka types, divided in two groups. Initial body weights of lambs in the group I were 18.90±2.03 kg and in the group II 18.40±1.05 kg. The age of the lambs at the start of experiment was 55 - 60 days, and the fattening lasted for five weeks. The lambs of one group were fed with mixture of cereals and sunflower meal without mineral-vitamin premix with 12.26% protein (group I), but for the feeding of second group of lambs were used feed mixture for older lambs with 14.69% protein (group II). During the fattening period the lambs from both group were fed hay *ad libitum.*
Blood for laboratory analysis was taken after weighing lambs with a puncture of the neck vein (*v.jugularis externa*) in vacutainer tubes with ethylenediamine tetra-acetic acid (*EDTA*). Blood plasma of the examined animals was tested for the following hematological parameters: red blood cell count (RBC), white blood cell count (WBC), white cell differential count (WCDC), hematocrit (PCV), hemoglobin (Hb) and red blood cell indices: MCH (Mean Cellular Hemoglobin), MCHC (Mean Cellular Hemoglobin Concentration) and MCV (Mean Cellular Volume). Measurments of hematological parameters were measured on the 21st and 35th day of fattening. The obtained results were statistically analysed using Microsoft Excel 2010, module Data Analysis. A star system was used to indicate the level of significance and correlation coefficient ($p<0.05$*; $p<0.01$**, $p<0.001$***).
This study was in accordance with the Rules of procedure of Ethical Committee of Veterinary Faculty University of Sarajevo and was approved by the Committee.

Results and Discussion

Blood is a circulating tissue composed of cells suspended in a fluid intercellular substance (plasma), with the main function of homeostasis maintenance and animal growth (Etim *et al.,* 2014a). Nutrition, and the breeding system have an important influence on hematological parameters (NseAbasi *et al.,* 2014); Etim *et al.,* 2014b), as well as on the health status of farm animals (Oyawoya *et al.,* 2004). The results of the research show that the lambs of the group fed by mixture of cereal and sunflower meal without mineral-vitamin premix with 12.26% of protein in the 21-day fattening period, exhibited somewhat higher hematological parameters, but not statistically significantly higher ($p> 0.05$) than lambs that were fed with a complete feed mixture for older lambs with 14.69% protein. During the 35-day fattening period, the first group of lambs also exhibited somewhat higher hematological parameters, with justifiable statistical significance for differences in PCV and MCV at $p <0.05$. Lower values of hematological parameters were determined within both groups with the lambs getting older for fattening period, except the number of erythocytes (Table 1). In lambs, rumen does not function until 7 weeks of age, so lambs in the first weeks of age are labeled as functionally nonruminants (Antunović *et al.,* 2000) and are more sensitive to different stress conditions. By comparing the obtained results with the results of Novoselec *et al.,* (2015) we can conclude that the values of RBC, Hb, and MCHC and MCH are lower, while PCV and MCV values are higher, in both groups and for both fattening periods, where in his experimental design he used feed mixture with 17.73% protein.
Olayemi *at al.* (2000) conducted a study of haematological parameters in Western African dwarf sheep in various breeding systems, and found that animals that were intensively bred showed higher PCV, Hb and MCV values consistent with our results. The increased level of

Hb concentration is attributed to the ability to undergo infection, good nutritional status as well as animal breeding (Anwar *at al.,* 2012). According to Boronez *et al.*, (2009), MCV is affected by stress during blood taking in lambs.

Examining the production-hematological parameters of lambs fed on meals with the addition of pumpkin seed during the 70 days of lambs age, the authors (Novoselac *at al.,* 2017*)* found lower values for MCV, MCH, MCHC compared to ours in the experimental as well as in control group, and higher values of RBC and PCV, while the values of Hb and WBC were similar. Also, the mentioned authors in the 100-day period, which in our case approximate the 35 days of the fattening, found higher values for RBC, Hb, while the values of the other parameters are somewhat less or similar. The authors in this study used 16.13% protein in control and 15.50% in experimental group of lambs (Novoselac *at al.,* 2017).

The higher values of MCHC often occur in analytical errors (Jones and Allison, 2007), and in haemolysis, and are decreased in reticulocytosis or iron deficiency (Polizopoulou, 2010). The values of erythrocyte (RBC) of our study, in both groups and for both fattening periods, with a slight increase at the end of the fattening period, were generally below the reference value of Weiss and Wardrop (2010); https://www.merckvetmanual.com/special-subjects/reference-guides/hematologic-reference- ranges); Iyiola-Tunji e*t al.,* (2015); Antunović et al., (2010), which could be interpreted by the causes of different etiology, the consequence of regeneration, (Kraft 1999a), or in the emergence of anemia Awodi *et al.,* (2005).

Comparing the results with the results of Shek Vugrovečki *et al.,* (2017), erythrocytes values were lower, while the values of erythrocyte indices differed by less than or above the reference values, with the difference that the female lamb of Lika pramenka between two and seven years of age.

Table1. Values of some hematological parameters of lambs

21^{th} day fattening		
Parameters	Group I	Group II
WBC (10^9/L)	10.38	10.31
RBC (10^{12}/L)	4.90	4.89
Hb(g/L)	124.00	122.50
PCV (%)	32.00	32.00
MCV (fl)	67.85	68.16
MCHC (%)	38.04	37.67
MCH (pg)	25.95	25.97
35^{th} day fattening		
Parameters	Group I	Group II
WBC (10^9/L)	8.12	7.47
RBC (10^{12}/L)	5.91	5.93
Hb(g/L)	83.40	78.00
PCV (%)	39.00*	33.00
MCV (fl)	68.46*	57.77
MCHC (%)	21.41	23.54
MCH (pg)	14.61	13.66

*Statistical significance difference ($p<0.05$)

Results of White Cell Differential Count in lambs in two different fattening periods (Table 2) did not deviate from the reference values according to Weiss and Wardrop (2010). Comparing the values of white cell differential count in two periods of fattening, at the end of the fattening period, the parameters were lower except eosinophils, with no significance ($p> 0.05$) but all values were within the reference limits. Eosinophils are considered an important

indicator in response to invasion of parasites and their growth is often associated with the appearance of parasitic resistance (Balic *at al.,* 2000).

Table 2. Values of white cell differential count (WCDC)

21^{th} day fattening		
Parameters	Group I	Group II
Lymphocytes (%)	54.10	54.40
Neutrophils (%)	29.20	31.20
Eosinophils (%)	2.40	7.00
Monocytes (%)	1.90	1.82
35^{th} day fattening		
Parameters	Group I	Group II
Lymphocytes (%)	49.90	48.90
Neutrophils (%)	28.60	29.30
Eosinophils (%)	8.80	8.90
Monocytes (%)	1.40	1.60

The correlation coefficient values showed statistical validity on the level of very high significance of differences ($p < 0.001$) between RBC and PCV, RBC and MCV in both groups of lambs at the 21^{st} day of fattening period, while significant justification of the differences ($p < 0.01$ and $p < 0.05$) was established between RBC and MCH, RBC and MCHC, respectively. At the end of the fattening period, the correlation was very high ($p < 0.001$) for RBC and PCV, RBC and MCH, up to high ($p < 0.01$) for RBC and MCHC, RBC and MCV, and significant differences ($p < 0.05$) between RBC and Hb in the first group of lambs. A total correlation was obtained between RBC and MCH, and RBC and MCV in the second group of lambs (Table 3). According to the available literature (Mhori e*t al.,* 2005; Hrković-Porobija *et al.,* 2013; Nozad *et al.,* (2014); Antunović *et al.,* 2017) justifiably significant correlations have been established. We have to emphasize that above mentioned authors used adult sheep, or other types of animals in different experimental treatments.

Table 3. Correlation factors (r) between some haematological parameters

Ratio	21^{th} day fattening		35^{th} day fattening	
	Correlation with P-value		Correlation with P-value	
	Group I	Group II	Group I	Group II

Conclusion

The results of the research show that the lambs of the group fed by mixture of cereal and sunflower meal without mineral-vitamin premix with 12.26% protein, had achieved higher hematological parameters, but not statistically significantly higher ($p > 0.05$) in relation to the lambs that were fed with a complete feed mixture for older lambs with 14.69% protein, except

for PCV and MCV on the end fattening. Correlative values showed significant justified differences for individual hematological parameters in both groups of lambs in fattening.

Abstract

In practical conditions of hatching eggs production, different types of packaging for collecting, transporting or storing eggs are used. The packaging is made of different materials, mostly cardboard or various plastic materials. Cardboard flats are usually used only once, while plastic packaging materials allow multiple uses. The aim of study was to investigate the hatchability of broiler breeder eggs stored for 5 or 10 days before incubation, in plastic or cardboard flats. Study was conducted under the conditions of the commercial hatchery. A total of 1.200 eggs originated from Cobb 500 parental flock, were divided into four equal groups of 300 eggs depending on the length (5 or 10 days) and type of packaging (cardboard or plastic flats). Following parameters were analyzed: egg weight loss during storage and incubation, hatchability of all and fertilized eggs, as well as early, middle, late and total embryonic mortality. The variance analysis was used for statistical processing of egg loss, and a chi-squared test for other incubation indicators. The storage length and types of packaging has affected only egg weight loss during storage, but not during incubation ($p<0.01$). Hatchability indicators, as well as embryonic mortality had similar values among all groups ($p>0.05$). According to the data obtained from the research, it can be concluded that both types of packaging are suitable for storage of hatching eggs.

Keywords: *Hatching egg, Storage length, Storage material, Flats, Incubation.*

Introduction

Boiler meat production is associated with the production of day-old chickens, sector that includes broiler breeder farms responsible for production of hatching egg, as well as hatcheries responsible for incubation and delivery of day-old chicks to market. Fertility and egg traits, especially egg weight, shell quality, shape index and internal quality, are indicators monitored throughout entire period of exploitation of broiler breeders, due significant influence on hatchability and day-old chick quality (King'ori, 2011). Eggs are daily collected several times, mechanically or manually, and stored in flats of different materials, mostly plastic or cardboard. Advantages of plastic flats in regard to cardboard are numerous in practical production, e.g. eggs are more quickly cooled to adequate temperatures (13-19°C) after collecting due better air circulation, or sanitization and mechanical cleaning are possible contrary to cardboard flats which are not suitable for such purposes (Bell and Weaver, 2002). Egg storage in different flats on breeder farm or hatchery can vary from a few days to several weeks, which depends on organizational plan of day-old chick production. Hatchability and day-old chick quality usually are unaffected by storage in appropriate conditions up to 7 days, but further prolonging has a direct negative effect on these parameters (Fasenko, 2007).
The aim of this study was to compare egg weight loss and hatchability of eggs stored for five and ten days in plastic and cardboard flats.

Material and Methods

In this study was used a total of 1.200 hatching eggs from one 32 weeks old Cobb 500 flock grown at commercial farm in the northern part of Republic of Srpska. All eggs were laid and collected on the same day, and after transport to commercial hatchery were individually marked and divided, depending on flat type - cardboard or plastic, and storage length - five or ten days, in four equal groups with 300 eggs. Storage and incubation conditions were identical for all groups. Egg weight was individually determined using a technical scale before and after storage, and at transferring eggs in hatcher (day 18^{th} of incubation). Egg weight loss during storage and incubation was determined according to formulas given by Egbeyale *et al*. (2013). At hatching day, the number of hatched chicks was determined; all unhatched eggs were broken in order to determine embryonic mortality, while the eggs without signs of early death were categorized as unfertilized eggs. Dead embryos, depending on time of death, were assigned to one of three categories: early (1-7), intermediate (8-14) and late mortality (15-21 days of incubation). Fertility, hatchability of set and fertilized eggs, as well as early, medium, late and total embryonic mortality were calculated according to formulas given by Alasahan and Copur (2016). Data on egg weight loss during storage and incubation were subjected to two-way analysis of variance with *post hoc* Tukey test ($p<0.01$), while hatchability and mortality parameters were analyzed using a chi-square test.

Results and Discussion

Weight loss of eggs during storage and incubation are presented in table 1.

Table 1. Fresh egg weight (mean ± SD) and weight loss (mean ± SD) during storage and incubation of eggs stored in cardboard (C group) and plastic flats (P group)

Flat	Storage, days	Fresh egg weight, g	Egg weight loss during storage, %	Egg weight loss during incubation, %
C	5	60.07 ± 2.63	0.34 ± 0.07^{c}	10.48 ± 2.05
	10	60.12 ± 2.37	0.69 ± 0.15^{a}	10.31 ± 1.80
P	5	59.78 ± 2.72	0.40 ± 0.07^{b}	10.65 ± 1.52
	10	59.99 ± 2.62	0.71 ± 0.10^{a}	10.34 ± 1.30

^{abc} – values with different letter in the same column are statistically different ($p<0.01$)

Flat type and storage length were significant factors for egg weight loss during storage ($p <0.01$). Higher percentage of weight loss had eggs stored for ten days in plastic (0.71%) and cardboard flats (0.69%) compared to eggs stored for five days in cardboard and plastic flats, which was also significantly different (0.34 vs. 0.40%). Egg weight loss during incubation ranged from 10.31 (eggs stored for ten days in cardboard flats) to 10.65% (eggs stored for five days in plastic flats). This parameter was not affected by flat type and storage length ($p>0.05$) although it was relatively lower in eggs stored for ten days in both types of flats. A relatively higher egg weight loss during storage reported Khan *et al*. (2014) after five and nine days long storage of Rhode Island Red eggs (1.35 and 2.52%, respectively), Senbeta (2016) after five and ten days long storage of Leghorn eggs (1.63 and 3.27%, respectively) or Egbeyale *et al*. (2013) when stored commercial pullet egg in periods of six and nine days (0.87 and 1.95%, respectively). Reduction in egg weight during storage is related with water loss which occurs through shell pores depending on air temperature and humidity and storage length (Bell and Weaver, 2002). Relatively comparable values obtained Reijrink *et al*. (2009) during egg storage of same commercial hybrid as in this study (0.15, 0.43, 0.64 and 1.21% for 3, 5, 8 and 12 day long storage). Moreover, storage length did not affect egg weight loss during

incubation (10.45, 9.64, 9.47 and 9.84, respectively), which is also in agreement with results obtained in this research. Similarly, Goliomytis *et al*. (2015) did not confirm any effect of storage length (4, 12 and 16 days) on weight loss during incubation of commercial broiler strain (9.04, 9.01 and 8.83%, respectively). On the other hand, flock genotype and age, as well as storage length significantly affected weight loss during incubation according to Alsobayel *et al*. (2013). Weight loss during incubation of Japanese quail eggs is related to weight loss during storage, as reported Romao *et al*. (2008), since long stored eggs had a lower weigh loss during incubation compared to fresh incubated eggs or eggs stored a few days. Lacin *et al*. (2008) compared weight loss during incubation of Japanese quail eggs stored in perlite, hay or without storage material during three storage periods (1-3, 6-8 or 12-14 days). The average weight loss was higher in the environment in which no storage material was used (1.99%), compared to perlite (1.58%) and hay (1.67%). Weight loss of boiler hatching eggs during incubation in standard commercial practices varies in range 10.30-11.40%, with the best hatchability performances achieved when this parameter varies from 10.90 to 11.10% (Tona *et al*., 2001). Hatchability and embryonic mortality of eggs stored for five and ten days in cardboard and plastic flats are presented in table 2.

Table 2. Hatchability and embryonic mortality (%) of eggs stored in cardboard (C group) and plastic flats (P group)

Flat	Storage, days	EF, %	HSE, %	HFE, %	TEM, %	EEM, %	IEM, %	LEM, %
C	5	97.0	90.0	92.8	7.2	4.5	0.3	2.4
	10	97.7	88.7	90.8	9.2	6.1	1.7	1.4
P	5	96.7	89.3	92.4	7.6	5.9	0.3	1.4
	10	96.7	85.7	88.6	11.4	6.9	1.7	2.8

F – Egg fertility; HSE - Hatchability of set eggs; HFE - Hatchability of fertilized eggs; TEM - Total embryonic mortality; EEM - Early embryonic mortality; IEM - intermediate embryonic mortality; LEM - Late embryonic mortality

^{abc} – values with different letter in the same column are statistically different ($p<0.05$)

Egg fertility among groups had relatively uniform values and ranged from 97.0 (five days of storage in cardboard flats) to 97.7% (ten days of storage in cardboard flats). Hatchability of set eggs varied from 85.7 (ten days of storage in plastic flats) to 90.0% (five days in cardboard flats), whereas hatchability of fertilized eggs ranged from 88.6 (ten days in plastic flats) to 92.8% (five days of storage in cardboard flats). Egg fertility and hatchability were not affected by flat type and storage length ($p>0.05$). Total embryonic mortality had the lowest value in group of eggs stored for five days in cardboard flats (7.2%), while the highest value had group of eggs stored for ten days in plastic flats (11.4%). All embryonic mortality parameters were not affected by flat type or storage length ($p>0.05$). Reijrink *et al*. (2009) reported that hatchability of set and fertilized eggs stored for 5, 8 and 12 days was 62.7 and 86.3, 59.6 and 82.9, and 59.3 and 80.1%, respectively, with comparable hatchability of eggs stored for 5 and 8 days. In accordance with mentioned, Goliomytis *et al*. (2015) in incubation of eggs stored for 4, 12 and 15 days also obtain non-significant differences in hatchability of set (87.5, 87.5 and 80.0%, respectively) or fertilized eggs (89.7, 91.3 and 84.2%, respectively), as well as total embryonic mortality (10.3, 8.7 and 15.8%, respectively). Also, Egbeyale *et al*. (2013) have determined comparable hatchability of eggs stored for six (83.81%) and nine days (69.79%). Significant decrease in hatchability of set and fertilized

eggs stored for five days (58.78 and 74.90%) compared to storage of nine days (5.65 and 7.35%) reported Khan *et at*. (2014) or Senbeta (2016) after egg storage of five and ten days (68.23 vs. 54.69%). Duress *et al*. (2015) compared five different materials, available in conditions of traditional poultry production in rural area, as egg storage container (plastic egg trays - control group, bamboo baskets, cartons, clay pots, polythene bugs, and teff grains) for 4, 8, 12, 16 and 20 days long storage. Hatchability among the groups of eggs stored for four days showed comparable values, while after eight days it was still generally comparable. Longer storage periods resulted in significantly lower hatchability especially of eggs stored in clay pots. Higher hatchability (53.90%) of Japanese quail eggs stored in perlite compared to eggs stored in hay (46.20%) or without storage material (42.20%) reported Lacin *et al*. (2008), whereas embryonic mortality was unaffected by storage material. Long-term storage of hatching egg is associated with deterioration of internal egg quality, as well as reduction of vital cells in embryo which can affect development and metabolism (Fasenko, 2007). The absence of significant differences in hatchability of long stored eggs, according to Yassin *et al*. (2008), can be associated with flock age, since eggs of older flocks are more susceptible to negative effects of prolonged storage.

Conclusions

The storage of broiler hatching eggs in cardboard and plastic flats during five or ten days showed that egg weight loss during storage is significantly affected by flat type and storage length, while this effect was not determined for egg weight loss during incubation. Hatchability and mortality parameters showed comparable values irrespective of flat type or storage length.

Abstract

The aim of the study was to analyze selected external and internal quality traits of table eggs of weight class large (L), originating from five different producers, present on Banja Luka (Entity of Republic of Srpska, Bosnia and Herzegovina) market. Three packs with 10 eggs, as repetition, for each egg producer were purchased, which encompass a total of 150 table eggs used in this analysis. All the eggs were produced in cage system and were seven days old on the day of analysis, which included determination of the following traits: egg weight, weight and proportion of main egg components (shell, albumen and yolk), egg shape index, unit surface shell weight, egg shell thickness, albumen height, Haugh units, yolk index, yolk color, and yolk albumen ratio. Data were analyzed using descriptive statistics and one-way analysis of variance (ANOVA). According to the obtained results, significant differences among the egg producers were found for egg weight, yolk weight, albumen weight, egg shape index, albumen height, yolk index, Haugh units and yolk color ($p<0.05$). However, shell weight, shell weight per unit surface, shell thickness, proportion of main egg components, and yolk albumen ratio had similar values among different producers ($p>0.05$). The samples of the eggs purchased on Banja Luka market generally showed satisfactory values regarding the external and internal quality parameters.

Introduction

Eggs are characterized by high nutritional value, competitive price and availability on the market, as well as ease of preparation for consumption. They are a source of easy-digestible proteins of high biological value, polyunsaturated essential fatty acids, liposoluble vitamins, minerals and various antioxidants, ingredients that have a positive impact on human health; but also contain high level of cholesterol, which is why egg consumption has been reduced or limited in the past, due to the risk of cardiovascular disease (Zaheer, 2015). The quality of table eggs, as well as the conditions for packaging, labeling and storage of the eggs on the market of Bosnia and Herzegovina is regulated by the Regulation on standards for the placing of eggs on the market (Official Gazette B & H, 25/2010). Eggs are classified into A-class or fresh eggs and B-class, with A-class eggs divided in four weight categories: small (<53 g, S), medium (53-63 g, M), large (63 -73 g, L), extra-large (> 73 g, XL). Also, the Regulation defines the conditions for A-class eggs in terms of the quality of shell, albumen and yolk. Zelić *et al*. (2015), based on the example of Tuzla city, reported that consumers in Bosnia and Herzegovina eat eggs every day (57.53% of respondents), mostly bought in stores (32.19%) or super-markets (26.03%). Also, consumers prefer to buy eggs of domestic origin (97.95% of subjects) in the weight class L (50.00%) or M (35.62%). They consider ease of preparation and nutritional value as main benefits of eggs, and cholesterol levels, short shelf life and susceptibility to damage during transportation as their main disadvantages. Tolimir *et al*. (2017) also found the importance of egg quality parameters for consumers (73.28% of respondents) in Belgrade city, who mainly buy larger eggs in super- and hypermarkets. The quality of table eggs can be estimated by determining the indicators of internal and external

quality. Indicators of external quality refer to egg weight, index of shape and properties of the shell (weight, cleanness, color, strength and thickness), and internal quality to the properties of the albumen (e.g., weight, proportion, height, Haugh unites) and yolk (color, index). The initial quality of the eggs, determined by the above mentioned indicators, is influenced by a large number of factors, such as genotype, age, health status, nutrition and welfare of the layers, and production system (Roberts, 2004; Ledvinka *et al*., 2012). Egg quality analysis during three production cycles of one hybrid in five producers, according to Škrbić *et al*. (2006), showed differences in egg weight, height of the albumen, Haugh unit, yolk color and shell thickness among cycles, which can be attributed to differences in the parental flock and quality of feed. However, the quality of table eggs in the markets may vary a lot, depending on the factors that come to light during egg manipulation after delivery from the farm. Tolimir *et al*. (2017) found differences in the quality of eggs among super- and hypermarkets in the city of Belgrade, as well as differences on the level of market, regardless of producer. Abo Omar and Aref (2000) found that certain quality indicators vary depending on the place of purchase (super-markets, public markets or broiler selling shops). Similarly, Moula *et al*. (2013) found that the best quality of eggs in supermarkets, compared to public markets or shops. Storage length and conditions, in particular temperature, are a key factor in preventing deterioration and preserving the quality or freshness of table eggs in sales (Roberts, 2004). The quality of eggs in a market of four producers of similar production technology, reported by Youssef *et al*. (2014), differs in more than one indicator (shell weight per unit of surface area, albumen and yolk percentage, Haugh units, yolk index and color). Kralik *et al*. (2012) found that eggs originated from three different producers in the Osijek area (Croatia) do not differ in egg weight, albumen weight and height and Haugh units, but there is a difference in yolk weight, weight of the shell, shape index, shell thickness and yolk color. Recent study, conducted in the same city, also showed the influence of producers on certain egg quality indicators (Kralik *et al*., 2017). The aim of study was to analyze selected external and internal quality traits of table eggs of weight class large (L), originated from five randomly selected producers, present on Banja Luka (Entity of Republic of Srpska, Bosnia and Herzegovina) market.

Material and Methods

Three packages of 10 eggs of weight class L per manufacturer were sampled, so a total of 150 eggs were analyzed in April 2018. During the purchase of eggs, the eggs of the same age were chosen (determined on the basis of the data on the packaging). All eggs were packed in the same packaging - cardboard box and storage conditions were identical - refrigerated showcases. Quality analysis included the individual determination of selected indices of external and internal quality traits of each egg (Englmaierová *et al*., 2014; Youssef *et al*., 2014.) The egg weight (EW) was determined using a technical scale. The width and length of eggs was determined using a micrometer, in order to calculate the shape index (SI) according to the formula SI = (egg width / egg length) x 100. The analysis was continued after breaking eggs on a flat surface, so albumen (AH) and yolk height (YH) were measured using a tripod micrometer, and also a yolk diameter, using a micrometer. The yolk index (YI) was calculated as YI = (width of the yolk / height of the yolk) x 100. The shell weight (SW), as well as the yolk mass (YW), has been determined using a technical scale. The albumen weight (AW) was defined as AW = EW - (YW + SW). The proportions of shell (SP), albumen (AP) and yolk (YP) were calculated according to the following formulas: SP = (SW / EW) x 100; AP = (AW / EW) x 100; YP = (YW / EW) x 100. The yolk color is determined by the DSM yolk color fan (1-15 points). The weight ratio of egg yolk and albumen (YAR) was calculated as YAR = YW / AW. Haugh units (HU) were calculated as HU = 100 log x (AH + 7.57 - 1.7 x $EW^{0.37}$). The shell thickness (ST) was determined by a micrometer, on the equatorial area of the shell

with membranes at three different points. The shell weight per unit area (SWUSA) was determined as SWUSA = SW / SSA, and the shell surface area (SSA) was calculated as SSA = 3.9782 x $EW^{0.7056}$. The data were subjected to descriptive analysis and one way analysis of variance with *post hoc* Tukey test ($p<0.05$).

Results and Discussion

Values of external egg quality traits are presented in Table 1.

Table 1. External egg quality traits (mean ± stand. error)

Quality traits	Producers				
	A (n=30)	B (n=30)	C (n=30)	D (n=30)	E (n=30)
EW (g)	66.85^{b}±0.69	64.18^{d}±0.43	70.04^{a}±0.17	65.05^{cd}±0.41	66.13^{cb}±0.34
SI (%)	76.35^{b}±0.49	76.98^{b}±0.71	76.02^{b}±0.51	75.90^{b}±0.36	80.85^{a}±0.71
SW (g)	6.61^{a}±0.10	6.50^{a}±0.10	6.70^{a}±0.13	6.46^{a}±0.09	6.56^{a}±0.11
SP (%)	9.93^{a}±0.19	10.14^{a}±0.16	9.56^{a}±0.17	9.94^{a}±0.14	9.91^{a}±0.15
ST (mm)	0.41^{a}±0.00	0.40^{a}±0.01	0.39^{a}±0.00	0.39^{a}±0.00	0.40^{a}±0.01
SWUSA (mg/cm^2)	85.87^{a}±1.49	86.73^{a}±1.35	83.97^{a}±1.52	85.37^{a}±1.18	85.60^{a}±1.30

EW - Egg weight (g); SI - Egg shape index (%); SW - Shell weight (g); SP - Shell proportion (%); ST - Shell thickness (mm); SWUSA - Shell weight per unit of surface area (mg/cm^2)
^{abc} – values in same row with different letters are statistically significantly different ($p<0.05$)

The obtained results indicate there are significant differences for the egg weight and egg shape index ($p<0.05$) between the eggs of different producers. The eggs in the weight class L, according to the Regulation, must have a weight from 63 to 73 g (Official Gazette B & H, 25/2010). The egg weight is determined by genotype, weight and age of layers, intensity of laying, nutrition and ambient conditions (Ledvinka *et al*., 2012). The average egg weight varied from 64.18 (producer B) to 70.04 g (producer C). The obtained values of shape index indicates that analyzed eggs generally had a round shape, because their range is from 75.90 (producer D) to 80.85% (producer E), which is more than 74% in eggs of a normal or optimal shape (Kralik *et al*., 2012). The shape index varies between genotypes, but also varies during the laying cycle. As an example, eggs in the initial stage of laying often have an untypical shape (Ledvinka *et al*., 2012). The proportion of shell in analyzed eggs ranged from 9.56 (producer C) to 10.14% (producer B). The Obtained values of shell thickness, ranged from 0.39 (producers C and D) to 0.41 mm (producer A), indicates satisfactory shell quality, as well as values of shell weight per unit area (83.97-86.73 mg/cm^2 in producers C and B, respectively). These three shell characteristics are at the same time indicators for assessing the strength of the shell, very important egg quality trait, which influences percent of eggs broke during collection, transport or storage. Kralik *et al*. (2012) reported that the L-class eggs of three different manufacturers had a shape index of 80.70, 74.37 and 77.56%, as well as shell thickness of 0.43, 0.39 and 0.41 mm, and according to a recent study of same authors, analysed M-class eggs of two manufacturers, showed shape index of 76.67 and 79.04% and shell thickness of 0.362 and 0.380 mm (Kralik *et al*., 2017). The average shell thickness, according to Abo Omar and Aref (2000) varies from 0.372 to 0.395 mm, and Moula *et al*. (2013) reported values of 0.352-0.397 mm. Youssef *et al*. (2014) in their study found values of egg shape index of 74.7-75.7%, shell thickness of 0.358-0.393 mm, and values of shell weight per unit of surface area of 78.79-87.54 mg/cm^2. Casiraghi *et al*. (2005) in their egg quality survey of all weight classes in stores in northern Italy obtained values of 75.7-77.4%

for egg shape index and from 0.40 to 0.42 mm for shell thickness. Perić *et al*. (2016) found the shape index of 75.83%, and shell thickness 0.382 mm for the eggs from conventional production on the market in Novi Sad (Serbia). The quality of eggshells, as reviewed by Roberts (2004), varies depending on genotype and age of layers, nutrition, ambient conditions, especially temperature, and health and wellfare status. Ledvinka *et al*. (2012) points out that modern layer hybrids differ in weight and strength of the shell, while the shell weight ratio and its thickness are not closely related to the particular hybrid.
Values of internal egg quality traits are presented in Table 2.

Table 2. Internal egg quality traits (mean ± stand. error)

Quality traits	Producers				
	A (n=30)	B (n=30)	C (n=30)	D (n=30)	E (n=30)
AW (g)	43.85^{ab}±0.71	41.43^{d}±0.41	45.53^{a}±0.37	42.02^{cd}±0.38	43.55^{cb}±0.31
AP (%)	65.86^{a}±0.52	64.57^{a}±0.34	65.17^{a}±0.50	64.73^{a}±0.40	65.76^{a}±0.29
AH (mm)	7.29^{a}±0.23	7.38^{a}±0.25	5.54^{b}±0.16	7.45^{a}±0.20	7.90^{a}±0.17
HU	82.85^{a}±1.54	84.04^{a}±1.62	68.90^{b}±1.37	84.55^{a}±1.22	87.08^{a}±0.97
YW (g)	15.98^{b}±0.31	16.25^{b}±0.24	17.61^{a}±0.32	16.41^{b}±0.28	16.11^{b}±0.19
YP (%)	24.05^{a}±0.44	25.34^{a}±0.35	25.22^{a}±0.47	25.28^{a}±0.40	24.32^{a}±0.25
YAR	0.37^{a}±0.01	0.39^{a}±0.01	0.39^{a}±0.01	0.39^{a}±0.01	0.37^{a}±0.01
YI (%)	48.57^{a}±0.72	46.75^{ab}±0.65	44.47^{b}±1.60	47.43^{ab}±0.60	47.75^{ab}±0.43
YC	14.03^{a}±0.12	13.45^{ab}±0.21	13.73^{ab}±0.18	13.03^{b}±0.21	13.28^{ab}±0.21

AW - Albumen weight (g); AP - Albumen proportion (%); AH - Albumen height (mm); HU - Haugh units; YW - Yolk weight (g); YP - Yolk proportion (%); YAR - Yolk/albumen ratio; YI - Yolk index (%); YC - Yolk color

^{abc} – values in same row with different letters are statistically significantly different ($p<0.05$)

Significant differences in the albumen weight, Haugh units, as well as yolk weight, index, and color among samples from different producers have been identified ($p<0.05$). The weight and proportion of the albumen varied from 41.43 (producer B) to 45.53 g (producer C), and from 64.57 (producer B) to 65.86% (producer A), respectively. Yolk weight and share values were in the range from 15.98 to 17.61 g (producers A and C), and 24.05 - 25.34% (producers A and B), respectively. There is a positive correlation between egg weight and the weights of its parts, especially yolk and albumen, although their share in eggs of different weight can still be different (Ledvinka *et al*., 2012). The yolk/albumen ratio (YAR) varied from 0.37 (producers A and E) to 0.39 (producers B, C and D). This relationship is influenced by genetics, hen age and egg size. Suk and Park (2001) reported that YAR varied from 0.38 to 0.40 during the laying cycle, and also a negative correlation between YAR and egg weight. The higher values of YAR were found by Moula *et al*. (2013) (47.98%) and Youssef *et al*. (2014) (43.74-48.48%). The quality of the albumen is usually determined by measuring of its height. On the basis of albumen height and egg weight, Haugh units are calculated, as generally accepted indicator of egg quality and freshness (USDA, 2000). The higher the value of Haugh units, the better the quality of the albumen. The albumen height in this study varied from 5.54 (producer C) to 7.90 mm (producer E), while Haugh units ranged from 68.90 (producer C) to 87.08 (producer E). The average value for fresh eggs, according to Englmaierová *et al*. (2014), is 88.5 Haugh units. Firm albumen has 72.0 or more Haugh units, i.e. such eggs are in AA category, while eggs with 60.0-71.9 are in category A (USDA, 2000). Kralik *et al*. (2012) analyzed three egg producers, and found albumen height of 6.36, 6.17 and 6.17mm,

respectively, while Haugh units were 77.31, 75.31 and 75.43, respectively, while their recent study (Kralik *et al*., 2017) showed lower albumen quality (albumen height 5.03 and 5.27 mm, Haugh units 70.36 and 71.33). Abo Omar and Aref (2000) report that eggs on the market have average values of 77.8-85.9 Haugh unit, which is comparable to 79.92, found by Moula *et al*. (2013). Tolimir *et al*. (2017) surveyed egg quality in the super- and hypermarkets in the city of Belgrade and found albumen height values of 6.4-7.2 mm, or 78.3-84.3 Haugh units in eggs stored up to ten days. The lower quality of the albumen (albumen height ranged from 3.282 to 5.074 mm and Haugh units ranged from 50.23 to 68.2) was found by Youssef *et al*. (2014). The differences in the albumen height and Haugh units value, according to Roberts (2004), can be attributed to the storage conditions, in particular the length and temperature of storage, but also with genotype and age of hens, and the production technology (production system, nutrition, health). Jones *et al*. (2010), in their study of egg quality in the markets, did not establish clear relation between the albumen height and the Haugh units values from one, and the age of eggs on the other side. The yolk index in our study varied from 44.47 (producer C) to 48.57% (producer A). The yolk index in fresh eggs usually fluctuates around 45.0% (Englmaierová *et al*., 2014), with tendency to decrease during the storage period due to the weakening of the yolk membrane (Roberts, 2004). One of the most important quality traits, besides the egg weight and shell strength, is yolk color. This visual property is equally important to consumers and the food industry, and the intensity of the yolk color depends on the type and quantity of pigments in food (Beardsworth and Hernandes, 2004). In our study, yolk color values ranged from 13.03 (producer D) to 14.03 (producer A). Consumers prefer eggs with a yolk in a darker yellow shade, closer to orange, which corresponds to value of 14 according to DSM yolk fan (Beardsworth and Hernandes, 2004). The lighter shades of yellow (6.24-7.11) in domestic conditions of egg production were found by Pandurević *et al*. (2015), while on egg market in neighboring countries higher values of yolk color were found, such as 12.66-13.90 (Kralik *et al*., 2012), 13.16 (Perić *et al*., 2016) or 10.9-13.2 (Tolimir *et al*., 2017).

Conclusions

Based on the results of our study, it can be concluded that the values of the quality indicators vary depending on the producer. The obtained values of the egg quality indicators meet the standard criteria, except for one sample characterized by the relatively lower internal quality when compared to samples of other producers. Analysed eggs generally have a round shape and a shell of satisfying thickness. In terms of internal quality, Haugh units indicate high quality albumens, while the yolks are characterized by darker shades of yellow. Eggs included in our study originated from intensive production, which assumes that adequate accommodation, nutrition and health care of hens are provided, which are preconditions for good laying capacity and quality of eggs. Also, keeping of eggs for a long time under adequate conditions can significantly slow down the process of deterioration of egg quality. In order to better understand the quality of table eggs on the market from the city of Banja Luka, further research, with a longer period of monitoring and sampling from more producers, should be conducted.

Abstract

The Neretva rudd (*Scardinius plotizza*) is an endemic species, which lives in the watercourses of the Neretva river basin in Bosnia and Herzegovina and Croatia. Population structure was studied on 55 individuals caught by gill nets at Deransko Lake. The aim was to determine the population structure according to length and mass, and relationship between the length of gut and total body length. The results are presented in the form of frequency histograms, linear and mass structure, and the regression relation between total body length and length of gut. Individuals with total body length of 22-24 cm were dominant, with maximum total length of 40.4 cm. The maximum recorded weight was 1127.7 g. The frequency histogram of body mass showed that weight class 100-200 g dominated, too. Positive allometric growth with high b-value of 3.25 was determined. Coefficient of correlation (r=0.99**) shows full relation connectivity between total body length and length of gut. This research provided new results on structure of population of the endemic Neretva rudd.

Keywords: *Neretva rudd, population, length, body, Deran Lake.*

Introduction

The freshwater ihtiofauna of Adriatic basin is characterized by a large number of endemic species, which are distributed on a restricted area (Mrakovčić *at al*., 1995, 2006). For these species, there is a small number of published scientific papers, referring to their systematic position, distribution, problem of endangerment and biological-ecological character (Crivelli and Maitland, 1995a, b; Kottelat and Freyhof, 2007). The Neretva rudd (*Scardinius plotizza*) is also one of these interesting species (Heckel and Kner, 1858). It is an endemic species distributed on a very restricted area. The Neretva rudd inhabits lower watercourses of the Neretva river basin in Bosnia and Herzegovina and Croatia (Vuković, 1977; Mrakovčić *at al*., 2006; Kottelat and Freyhof, 2007). In Bosnia and Herzegovina, it was recorded in the Neretva River basin till the locality Čapljina and in the swamps of Hutovo Blato (Vuković, 1977; Mrakovčić *at al*., 2006; Kottelat and Freyhof, 2007). Neretva rudd is mainly feeding with water plants, detritus and invertebrates (Vuković, 1977; Kosorić, 1978; Mrakovčić *at al*., 2006). In the Croatian red list of freshwater fish species, and according to IUCN status (Mrakovčić *at al*., 2006), the data for *S. plotizza* is deficient (DD). Genius *Scardinius* (Bonaparte, 1873) is widespread in the whole Europe. According to Kottelat (1997) this genus covers five, and according to Kottelat and Freyhof (2007) ten species with restricted area of distribution. *S. hesperdicus* (Bonaparte, 1845) and *S. scardafa* (Bonaparte, 1837) are distributed in the area of Italy; in the area of Greec are endemic species *S. acarnanicus* (Economidis, 1991) and *S. graecus* (Stephanidis, 1937); *S. knezevici* (Bianco and Kottelat, 2005) inhibits the waters of Albania, Montenegro and Macedonia; in Turkey is *S. elmaliensis* (Bogutskaya, 1997); *S. racovitzai* (Müller, 1958) is in Romania and *S. dergle* (Heckeland Kner, 1958) and *S. plotizza* (Heckle and Kner, 1858) are distributed in the waters of Bosnia and Herzegovina and Croatia. The Neretva rudd is a species that is retained in flocks, and inhabits clean, shallow, peaceful river flow and lakes of lower Neretva basin with plenty underwater vegetation. The publications about Neretva rudd biology and ecology are rare and outdated, and they are mostly about the general biology issues (Vuković and Ivanišević, 1962;

Vuković and Ivanović, 1971; Vuković, 1977) and distribution (Kosorić, 1978; Kosorić *at al*., 1983). More recent data of Neretva rudd are related to length-weight ratio (Dulčić *at al*., 2009), morphometric and meristic characteristics (Prusina *at al*., 2009) and growth (Ivanković *at al*., 2017).

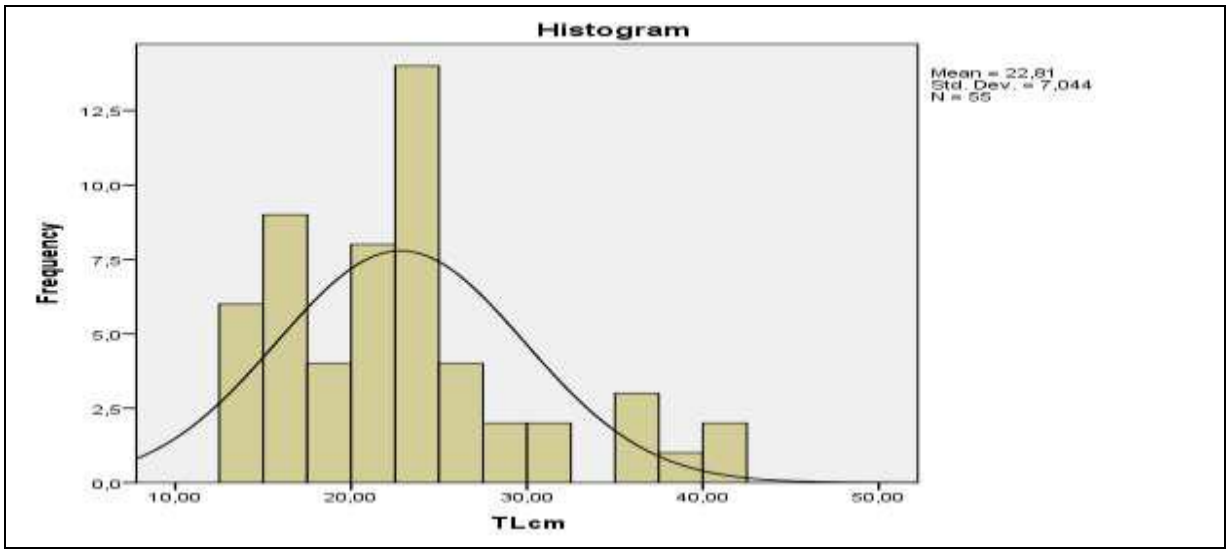
The aim of the present work was to provide data about length and mass structure of the Neretva rudd population, and relation between length of gut and total body length. The results are presented in the form of frequency histograms, linear and mass structure, and the regression relation between total body length and length of gut.

Material and Methods

The sampling was done in the area of Deransko Lake that is a part of the Hutovo Blato swamps in Bosnia and Herzegovina. Fishes were caught by anchored gill nets, mesh diameter 28-72 mm and 30 meters long, while net height varied from 1 to 3 meters. Nets were set up at night and checked the next morning. Fish population that has been processed was total 55 specimens of Neretva rudd and they weren't analysed for sex determination. Determination of species was done by system key for determination of fish species presented by Vuković (1977) and Freyhof and Kottelat (2007). Collected specimens were processed by standard ichthyologic methods where total body length (TL; cm) was measured by ihtiometar and the body mass (TW; g) were analysed by analytical scale. Digestive tract was extracted from the analysed fishes, after cutting out the oesophagus and anus. Thereafter, length of the digestive tract was measured (DP; cm).

Results and Discussion

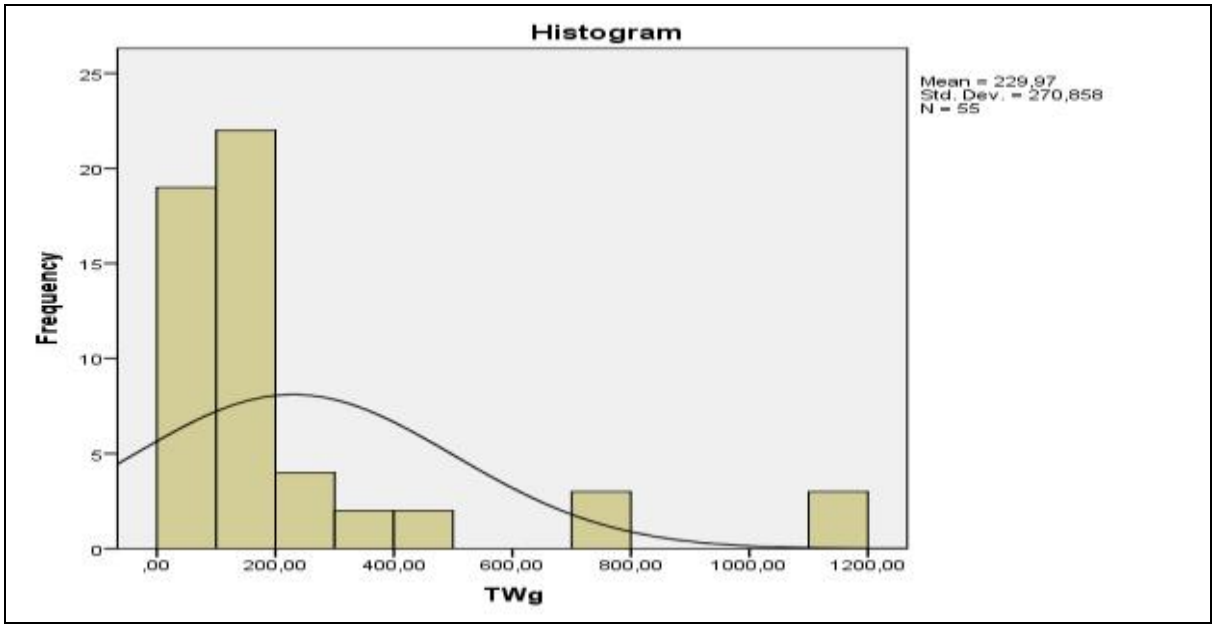
The maximum registered total body length of Neretva rudd was 40.4 cm and the minimum 14.2 cm. In the histogram: frequency of total body length Neretva rudd (picture 1), it's noticeable that the majority of specimens were in the fifth class with total body length between 22 and 24 cm. Truman *at all.* (2012) came to similar results, according to them; prevailing specimens of Neretva rud in the Hutovo blato are in the classes with total body lengths from 19 to 21 cm. The tenth size class with total body lengths from 38 to 40 cm was the least represented.



Picture 1. Frequency of Neretva rudd total body lenght

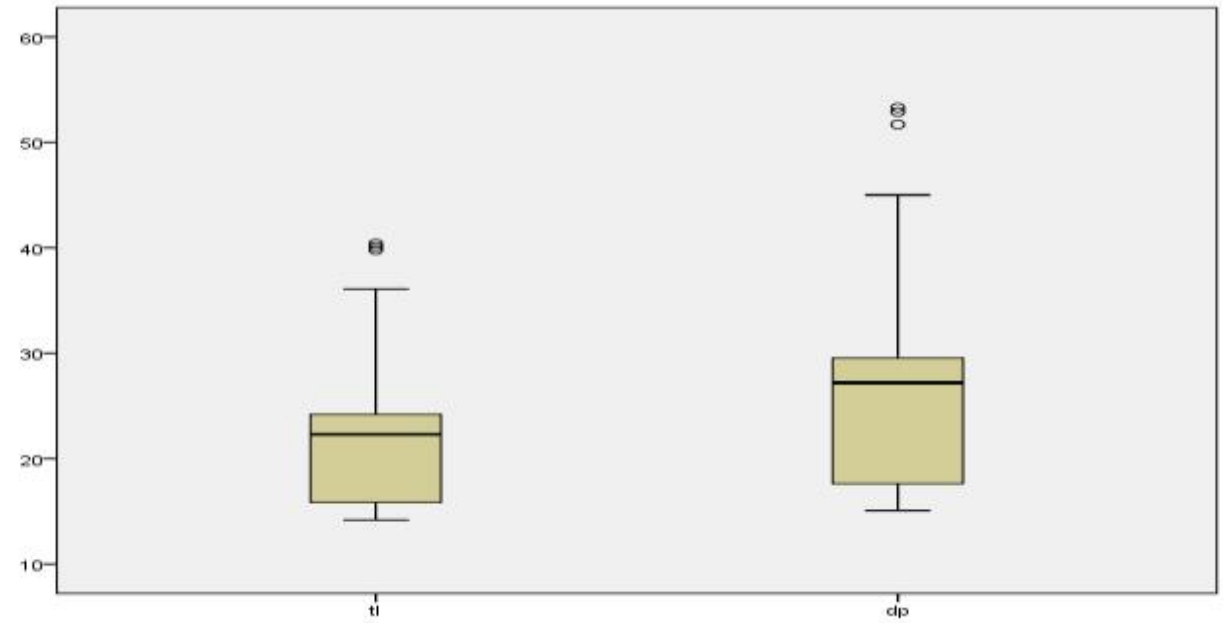
The maximum measured body weight of Neretva rudd was 1127.7 g., while the minimum was 36.9 g. The average body mass of 55 measured specimens was 229.97 g. The frequency histogram of Neretva rudd body mass showed that it is classified in seven classes according to

body mass, where the second class with a body mass of 100 to 200 grams dominated, while fourth and fifth mass classes, with body mass of 300 to 500 g had a minimum value (picture 2).



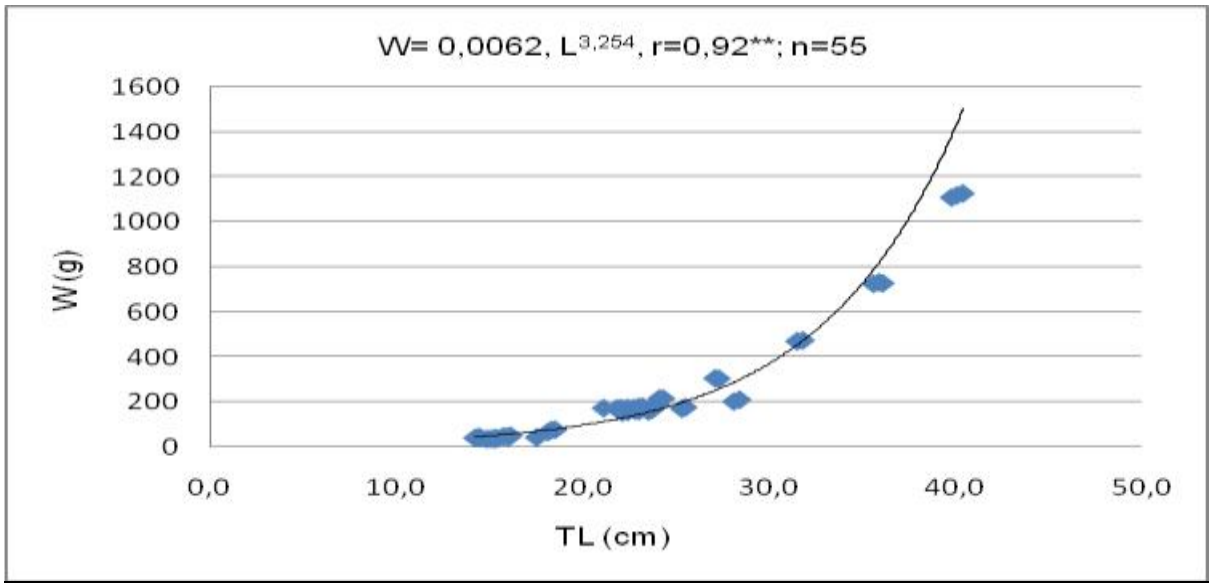
Picture 2. Frequency of Neretva rudd body mass

The gut length, of the Neretva rudd, ranged from a minimum of 15.1 cm to a maximum of 53.3 cm with the average value of 27.37 cm (picture 3).



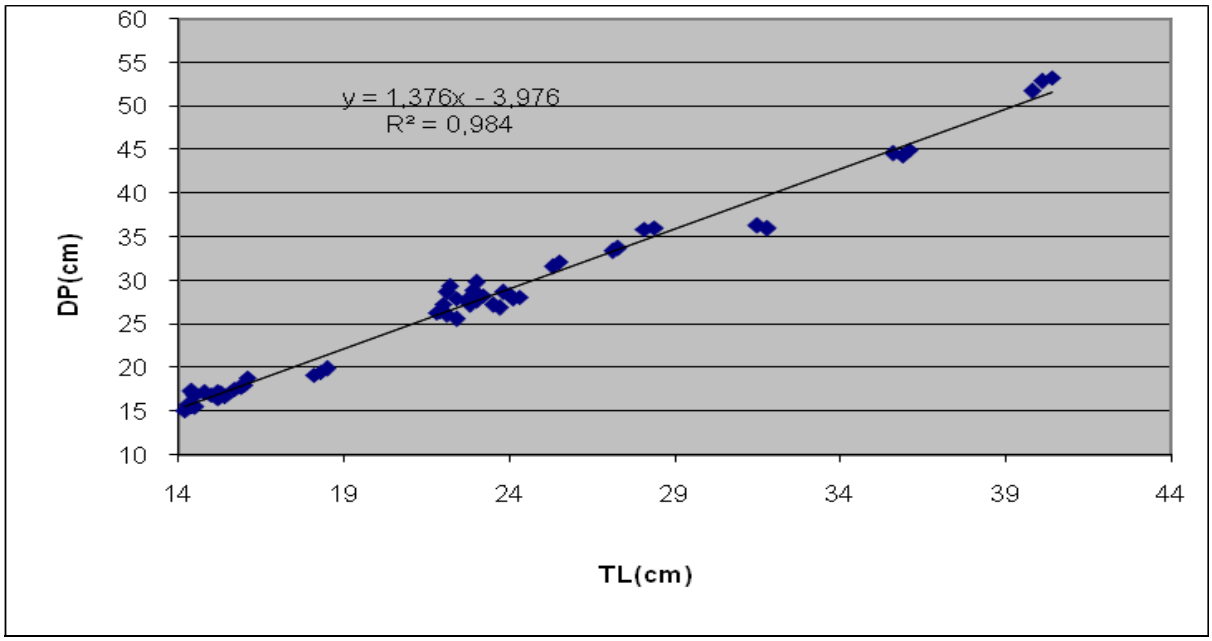
Picture 3. Minimum, maximum and average value ($\bar{x}$) of overall gut length (DP) and total body length of Neretva rudd

The function that best describes length-weight relationship specimens of Neretva rudd is: W = 0.0062 $L^{3.25}$ with the determination coefficient R^2 = 0.85. According to the obtained b-constant value of 3.25, demonstrated positive allometric growth for whole sample of Neretva rudd specimens (picture 4).



Picture 4. The length-mass relation between total length (cm) and body mass (g) of Neretva rudd from the Deran Lake

Correlation coefficient (r = 0.99**) shows full relation connectivity between total body length (TL) and length of gut (DP) (picture 5). With increasing of total body length for 1cm the length of gut will increase by 1.37 cm.



Picture 5. Regression relation between total body length (TL, cm) and length of gut (DP, cm) of Neretva rudd

In this research, the body length of the largest caught specimen was 40.4 cm, which is in accordance with the maximum length of 51 cm reported in Coast Pink (2016). Local fishermen's claims that this species can grow up to 3 kg body mass (Bistrobih.ba, 2016). Since the Neretva rud is relative with the rudd (*S. erythrophthalamus*) they can be compared, from the same Adriatic area. Rudd is the most numerous species in the Vransko Lake at island of Cres. In this lake, the largest caught specimen had the total body length of 61.7 cm, and

body mass of 3623 g (Šprem *at al*., 2010). Its fast growth has been confirmed by Scheibl (1998). Valić *at al*. (2013) are suggesting, according to the phylogenetic analyses, that in the Vransko Lake dunabe rudd was not introduced, but that it is an endemic species *Scardinius hesperidicus*, whoes morphological characteristics of maximal body length and body mass revealed new data about maximal values. Neretva rudd from the Deransko Lake, after first year reached the length of 12.76 cm (Ivanković *at al.*, 2017), similar to Tutman *at al*. (2012), who have caught one specimen of these species with body length of 12.5 cm, and they also concluded that all specimens, under one year of age, are less than 9 cm long. The rudd from Vransko Lake grows even faster, and reaches a length of 19.03 cm after the first year (Scheibl, 1998). The link between length of the rudd at the age of one year and its width was shown by Tarkan *at al*. (2010). They found generally faster growth at the specimens with lower width, but also the obvious larger variations in the body length at the one-year-old fishes from the southern populations (40-46^{0}N), where is also a habitat of studied Neretva rudd. Many researches who studied fish's diet found a link between the length of the digestive tract and the type of diet. Coefficient of correlation between total body length (TL) and length of gut (DP) shows full relation connectivity for the specified length of Neretva rudd from the Deransko Lake. Vuković (1963) also indicates the existence of a certain link between the length of gut and the standard fish length.

Conclusions

The rivers of Bosnia and Herzegovina are known for the existence of many endemic species and subspecies of fish. In the lower watercourses area of the Neretva river basin, which belongs to Adriatic basin, a certain number of endemic species has been recorded. The data about this species are limited. Only a few papers are covering their ecology, biology, taxonomy and their mutual relationship. One of these species is the Neretva rudd and according to IUCN red list it is registered as worryingly vulnerable species. The maximum registered total body length of Neretva rudd, from Deransko Lake, was 40.4 cm, and the maximum body mass was 1127.70 g. From the shown frequency histogram for the body length, it can be concluded that the majority of specimens were in the classes with total body length between 22 and 24 cm, while in the frequency histogram for the body mass dominated specimens of Neretva rudd between 100 and 200 g. Correlation coefficient (r = 0.99**) between total body length and length of gut shows full relation connectivity between the specified features. Relation between length of gut and total body length indicates omnivorous diet. Positive allometric growth, for the Neretva rudd, with high b-value of 3.25 was determined.

Abstract

With an aim to determine the phenotype correlation between certain incubation characteristics of the line hybrid British United Turkey (BUT) Big 6 eggs, a study was conducted of two groups of eggs laid by turkeys of 34 (TA_{34}) and 45 (TA_{45}) weeks of age. Average egg mass before incubation was 80.37 g (TA_{34}) and 85.71 (TA_{45}), and average mass of newly hatched turkey poults was 52.62 g and 55.80 g. Differences were statistically very significant ($P<0.001$). Absolute and relative egg mass loss until day 25 of incubation was also larger in case of the older turkey flock. Egg mass loss until day 25 was 9.20 g and 11.41% (TA_{34}), and 11.41 g and 12.38% (TA_{45}). Observed differences were statistically significant ($P<0.001$). In contrast to the previous indicators, difference in the relative share of the poult in the egg mass (0.38%) was not significant ($P>0.05$).

Turkey's age significantly affected egg mass and poult mass increase, absolute and relative loss of egg mass from day 25 of incubation, while the poult percentage in the egg mass was similar in both age groups of turkeys. Apart from the turkey's age having impact on the increase of the average egg mass, the egg mass also had significant impact on other observed indicators during the incubation period. These statements are confirmed by the calculations of the phenotype correlation coefficients between the observed indicators as well as most of the results of other authors (researchers) who studied this matter related to turkey and other poultry's eggs.

Key words: *turkey age, eggs, turkey poults, phenotype correlation, British United Turkey hybrid Big 6.*

Introduction

It is an established fact that appropriate rearing technology, nutrition and age of the parent poultry flock significantly affect incubation values of eggs for fertilisation and, consequently, the quality of the newly hatched offspring. Numerous studies were conducted in relation to this issue, with an aim to determine the impact of the age factor of different types of poultry on egg fertilisation, egg mass, offspring mass, egg mass loss during incubation period, and their mutual phenotype correlations. Most of related research refers to hens and quails, followed by turkeys, geese and ducks.

In relation to hen breeds, hybrids and mongrels, notable research was conducted by Abiola *et al.* (2008), Mitrović *et al.* (2010), Egbeyale *et al.* (2011), Yamak *et al.* (2015), Iqbal *et al.* (2016), on quails (Alkan *et al.* 2008), geese (Đermanović *et al.* 2008, Mitrović *et al.* 2018) and ducks (El-Hanoun *et al.* 2012, Đermanović *et al.* 2017). These authors mostly conclude that egg mass and offspring mass of the hens, quails, ducks and even geese, increase with their age. They also report strong, very strong and even total positive phenotype correlation between the egg mass of different types of poultry and the mass of newly hatched offspring.

Regarding turkeys, Rahn *et al.* (1981), Tullett (1981), Christensen and McCorkle (1982), Meir *et al.* (1984), Hristakieva *et al.* (2009), Mróz *et al.* (2010), Amir *et al.* (2015) and Hristakieva

et al. (2017) conducted much more extensive studies. They found similar effects of turkey's age and egg mass on the incubation indicators and their correlation.
Mróz *et al*. (2010) report that the egg mass of the Broadbreasted White Turkey grows linearly with its age from 81.9 g (turkeys 33 weeks old) to 101.4 g (turkeys 57 weeks old).Similarly, Hristakieva *et al.* (2009) report average egg mass of 84.67 g in 32 weeks old Heavy Meat turkey (HM), and 88.97 g at 44 weeks of age. Amir *et al.* (2015) observed two flocks of Converter turkey hybrids reared in the summer season and the winter season. During the production cycle lasting 24 weeks they observed a trend of egg mass increase with some oscillations, so that the average egg mass ranged between 75.98 g and 97.54 g.
Mróz and Orlovska (2009) report an inclination towards egg mass increase in Bronze turkey (81.9 g to 101.4 g) from 33 to 57 weeks of age, and the average mass of newly hatched turkey poults (59.1 g to 72.6 g), while the share of poults in the egg mass ranged between 72.8% and 87.2%. Hristakieva *et al*., (2017) who studied North Caucasus turkey, report average egg mass before incubation to be 82.04 g in turkeys 34 weeks old, and 84.22 g egg mass in turkeys 46 weeks old, while the relative egg mass loss until day 25 of incubation was 9.96% and 12.47% respectively. Average egg mass of one day old poults was 55.93 g and 54.45 g, and the relative share of curic in the egg mass was 68.16% and 64.58% respectively. Nestor *et al*. (1982) investigated incubation values of turkey eggs of different turkey hybrid line types (3 medium heavy hybrids + control and 6 heavy hybrids + control). Depending on turkey's age, average egg mass of medium heavy hybrids was 79.4 g (at the onset of the laying), 83.4 g (in the middle of the laying period) and 83,6 g (at the end), while in heavy hybrid lines average egg mass was 83.0 g (beginning), 90.6 g (middle) and 90.1 g (end).
Meir *et al*. (1984) report egg mass loss of 12% until day 25 of the incubation period. Tullett (1981) reports the same loss percentage of turkey egg mass, Christensen and McCorkle (1982) somewhat lower (11.5%), while Rahn *et al*. (1981) report considerably lower loss percentage (10%). Moran and Reinhart (1979) reached a slightly different conclusion regarding effects of turkey's age on egg mass and poults mass, *i.e*., on the absolute and relative egg mass loss until day 25 of incubation. Hristakieva *et al*. (2017) report positive correlation, $r_p = 0{,}77^{***}$ (young turkeys – 34 weeks old) and $r_p = 0.65^{***}$ (older turkeys – 46 weeks old), between the egg mass of the Nort Caucasus Bronze turkey and the egg mass of the one day oldpoults. The egg mass had significantly smaller effect on the egg mass loss until day 25 of incubation ($r_p = -0.31^{ns}$ and $r_p = 0.01^{ns}$), as well as the share (percentage) of the poult in the egg mass ($r_p = 0.14^{ns}$ and $r_p = -0.04^{ns}$).
The main purpose of this study was to determine the egg mass, egg mass loss during incubation, poults mass and share of the poult in the egg mass, as well as the phenotype correlation between observed indicators in BUT Big 6 turkey hybrids 34 and 45 weeks old.

Materials and methods

With an aim to determine the phenotype correlation between some incubation characteristics of the BUT Big 6 line hybrid eggs, a research was conducted of two groups of eggs laid by turkeys from different age groups. Two hundred (200) eggs coming from two different flocks were obtained from the farm „Bagrdan" in Jagodina, Serbia. The age difference between the flocks was 12 weeks, *i.e.* 3 months (one flock was 34 weeks old and the other was 45 weeks old). One of the flocks was in its maximum laying intensity period (peak), while the other was in the middle of the production cycle which lasted from the week 32 to week 56 of the parent flock's age. Egg incubation was carried out in the experimental laboratory of the Faculty of Agriculture, University of Belgrade.
100 eggs laid by the 34 weeks old turkeys (TA_{34}) and 100 eggs laid by the 45 weeks old turkeys (TA_{45}) was placed into the incubator. All eggs were individually measured, shells were marked with pencil and eggs were disinfected by the formaldehyde vapors before being

laid into the incubator. More specifically, egg mass was individually measured before laying into the incubator and on day 25 of incubation as well as the mass of the poults which dried after hatching. Based on the egg mass on the first and on the 25th day of incubation, absolute and relative egg mass loss was determined for this period and for each egg weight group. When eggs were moved from the laying tray to the hatching tray on the 25th day, they were individually placed into specially constructed partitions to make sure which poult comes from which egg.

At the end of the incubation period egg mass of one day old poults was determined which allowed the calculation of the relative share of the poult in the egg mass, *i.e.* the percentage of the poult (PP) in the egg mass, according to the following formula: PP = [(poult mass/egg mass) x 100]. Special attention was paid to those eggs from which healthy and vital poults were hatched. Basic data analysis was carried out with *Stat.Soft.Inc.* (2003) STATISTICA (data analysis software system), version 6, by implementation of the standard variational-statistics methods (descriptive statistics).

For most of the observed indicators in each of the egg weight groups, arithmetic mean ($\bar{x}$), arithmetic mean error ($s_{\bar{x}}$), standard deviation (S) and variation coefficient (VC) were calculated. Testing of the difference significance between observed incubation characteristics was carried out by implementation of the t-test according to the adequate formula. Furthermore, phenotype correlation coefficients (r_p) between observed characteristics were calculated according to the appropriate formula, primarily between egg mass and other incubational egg values (absolute and relative egg mass loss until day 25 of incubation), *i.e.* one day old poults (poult mass and the relative share of the poult in the egg mass).

$$r_{XY} = \frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2 \sum_{i=1}^{n}(y_i - \bar{y})^2}}$$

Phenotype correlation coefficients strength was discussed on the basis of the Roemer – Orphal classification refered to by Tavčar (1946).

Results and discussion

Average values, absolute and relative variation measures of the basic studied indicators related to egg incubation of the BUT hybrid Big 6 are given in Table 1, and the difference significances of average values in Table 2. It should be noted that the analysis covers hatched eggs. The total number of hatched eggs was 76 (TA_{34}) and 72 (TA_{45}).

Table 1. Average values and variability of egg mass and one day old poults mass in turkeys of different age (TA_{34}) and (TA_{45})

Turkey age	Indicators	$\bar{x}$	$s_{\bar{x}}$	S	C.V.
TA_{34}	Egg mass before	80.37	0.63	5.47	6.81
TA_{45}	incubation (g)	85.71	0.62	5.33	6.22
TA_{34}	Loss of egg mass until	9.20	0.12	1.06	11.52
TA_{45}	day 25 of incub. (g)	10.62	0.14	1.21	11.39
TA_{34}	Loss of egg mass until	11.41	0.08	0.76	6.31
TA_{45}	day 25 of incub. (%)	12.38	0.16	1.34	10.82
TA_{34}	One day old poults	52.62	0.48	4.23	8.04
TA_{45}	mass (g)	55.80	0.47	3.97	7.11
TA_{34}	Relative share of the	65.44	0.15	1.21	1.85
TA_{45}	poult in egg mass (%)	65.06	0.14	1.20	1.84

TA_{34} = turkeys 34 weeks old; TA_{45} = turkeys 45 weeks old.

Table 2. Difference significance of average values of observed indicators during incubation

Indicators	TA_{34}	TA_{45}	Difference	Significance
Egg mass before incubation (g)	80.37	85.71	-5.34	***
Loss of egg mass until day 25 of incubation (g)	9.20	10.62	-1.42	***
Loss of egg mass until day 25 of incub. (%)	11.41	12.38	-0.97	***
One day old poults mass (g)	52.62	55.80	-3.18	***
Relative share of the poult in the egg mass (%)	65.44	65.06	0.38	NS

TA_{34} = turkeys 34 weeks old; TA_{45} = turkeys 45 weeks old.
NS = P>0.05; *** = P<0.001.

Average egg mass in turkeys 34 weeks old was 80.37 g, in turkeys 45 weeks old it was 85.71 g, while the average mass of one day old poults was 52.62 g and 55.80 g respectively. Average egg mass loss until day 25 of incubation was 11.41% (younger turkey flock) and 12.38% (older flock). In the younger flock the poult share in the egg mass was 65.44% and in the older flock it was 65.05% (Table 1).

It is evident from the data in Table 1 that the 34 weeks old turkeys produced eggs 5.34 g lighter than the 45 weeks old turkeys, and this difference was statistically very significant (P<0.001). Likewise, one day old poults of younger turkeys had statistically significant (P<0.001) smaller average mass. Eggs laid by the 34 weeks old turkeys also had smaller absolute (g) and relative (%) egg mass loss until day 25 of the incubation period. Differences were statistically very significant (P<0.001). In contrast to previous indicators, poult share in the egg mass was almost equal and the difference observed (0.38%) was not statistically significant (P>0.05). Based on these facts, it can be concluded that turkey's age made significant impact on the increase of the egg mass, poult mass, absolute and relative egg mass loss until day 25 of incubation, while the percentage of the poult in the egg mass was of similar value in both age groups. Nestor *et al.* (1982), Mróz and Orlovska (2009), Hristakieva *et al.* (2009), Mróz *et al*. (2010), Amir *et al.*(2015), Hristakieva *et al*. (2017) have established that the age of turkeys of different genotypes affects the increase of egg mass and poult mass. Similar conclusion related to other types of poultry (hens, quails, geese and ducks) were made by Abiola *et al.* (2008), Mitrović *et al*. (2010), Egbeyale *et al*. (2011), Yamak *et al* (2015), Iqbal *et al*. (2016), Alkan *et al.* (2008), Đermanović *et al.* (2008), Mitrović *et al*. (2018), as well as El-Hanoun *et al*. (2012) and Đermanović *et al*. (2017).

A slightly different conclusion was reached by Moran and Reinhart (1979) who report that the relative egg mass loss in fertilised eggs until day 25 of incubation did not depend on the age of the layer, being equal in both groups (13.7%). Average mass of one day old male and female poults coming from the older group was equal (54.2 g), while the average mass of female poults laid by the younger turkeys was 53.0 g, and the mass of male poults was 53.3 g (average 53.1 g). Relative poult mass at hatching (in egg mass %) was 62.8% (55th week) and 64.0% (48th week). Research demonstrated a strong correlation between the egg mass and one day old poults mass, as the heaviest poults hatched from the heaviest eggs, and *vice versa*, in both observed groups. Relative poult mass at hatching of the 91.3 g average egg mass was 64.2%, and in 78.2 g eggs it was 62.6%.

Moran and Reinhart (1979) report a significantly larger egg mass loss until day 25 of incubation (13.7%) in comparison to our results (11.41% and 12.38%). Similar egg mass loss until day 25 of incubation (12% - 11.5%) is reported by Meir *et al*. (1984), Tullett (1981), Christensen and McCorkle (1982), and significantly smaller (10%) by Rahn *et al*. (1981). Hristakieva *et al*. (2017) report smaller relative egg mass loss until day 25 of incubation in the younger turkey flock (34 weeks old) in comparison to the older flock (46 weeks old) as well as the larger percentage (share) of the poult in the egg mass, which is to some extent in line with our results.

Phenotype correlation, *i.e.* correlation coefficient matrix between observed indicators and correlation significance is given in Table 3.

Table 3. Correlations between mass and egg parameters

Indicator	***Egg mass (g)***	***Loss until day 25 (g)***	***Loss until day 25 (%)***	***Poult mass (g)***	***Poult% in egg mass***
Egg mass (g):					
Young turkeys (34w)	1.00	0.509^{***}	0.243^{*}	0.777^{***}	0.242^{*}
Old turkeys (45 w)	1.00	0.401^{***}	-0.122^{NS}	0.770^{***}	0.170^{***}
Loss until day 25 (g):					
Young turkeys (34 w)		1.00	0.612^{***}	0.589^{***}	0.217^{NS}
Old turkeys (45 w)		1.00	0.534^{***}	0.405^{***}	0.178^{NS}
Loss until day 25 (%):					
Young turkeys (34 w)			1.00	0.216^{NS}	-0.410^{***}
Old turkeys (45 w)			1.00	-0.121^{NS}	-0.214^{NS}
Poult mass (g):					
Young turkeys (34 w)				1.00	0.691^{***}
Old turkeys (45 w)				1.00	0.466^{***}
Poult % in egg mass:					
Young turkeys (34 w)					1.00
Old turkeys (45 w)					1.00

NS = P>0.05; * = P<0.05; *** = P<0.001.

Positive correlation was determined in both flocks (TA_{34} and TA_{45}) between the average egg mass before incubation and the absolute and relative egg mass loss until day 25 of the incubation period and between newly hatched poults and the relative share of the poult in the egg mass. Correlation between the egg mass and the relative egg mass loss until day 25 of incubation was negative (r_p = - 0.122), but the correlation coefficient was not statistically significant (P>0.05), Table 3. Other correlation coefficients were statistically significant (P<0.05), and very significant (P<0.001). Similar findings were made by Hristakieva *et al.* (2017), however, they report no correlation between the egg mass and poult share in the egg mass. Đermanović *et al.* (2008) report total correlation (r_p = 0.987) between the egg mass before incubation and one day old poults mass, Alkan *et al*. (2008) established strong phenotype correlation (r_p = 0.72) between the Japanese quail eggs and the offspring mass, Yamak *et al*. (2015) determined very strong correlation (r_p = 0.862) between the egg mass and one day old chicken, and Mitrović *et al*. (2018) report total correlation (r_p = 0. 986) between the egg mass and one day old goslings.

Data given in Table 3 demonstrate that strong correlation and medium positive correlation ($r_p = 0.691^{***}$ and $r_p = 0.466^{***}$) was established between the average poult mass and poult share, in both flocks, and the correlation coefficients were statistically confirmed at P<0.001 level. Negative correlation was found between the share of the poult in the egg mass and the relative egg mass loss until day 25 of incubation, in both groups of eggs, *i.e.* in both age groups of turkeys ($r_p = -410^{***}$ i $r_p = -0.214^{NS}$). Similar correlation between these indicators in North Caucasus bronze turkey aged between 34 and 46 weeks was reported by Hristakieva *et al.* (2017).

Conclusion

Based on determined average egg mass and newly hatched poults mass, absolute and relative egg mass loss until day 25 of incubation and the relative poult share in the egg mass, following conclusions can be made:

- Eggs and newly hatched poults originating from the older flock (TA_{45}) had statistically very significantly ($P<0.001$) larger average mass than those coming from the younger turkeys (TA_{34}). Average egg mass before incubation was 80.37 g (TA_{34}) and 85.71 g (TA_{45}), and the average mass of the newly hatched poults was 52.62 g and 55.80 g, respectively.
- Absolute and relative egg mass loss until day 25 of incubation were also bigger in the older flock. Egg mass loss until day 25 was 9.20 g and 11.41% (TA_{34}), and 10.62 g and 12.38% (TA_{45}). Differences were statistically significant ($P<0.001$).
- Contrary to the previous indicators, the difference in the relative share of the poult mass in the egg mass (0.38%) between the flocks was not statistically significant ($P>0.05$).

Calculations of the phenotype correlation coefficients between the indicators during egg incubation originating from two different flocks of turkeys (TA_{34} and TA_{45}), lead to the following conclusions:

- In the TA_{34}group, strong positive correlation ($r_p = 0.509^{***}$) was determined between the egg mass and the absolute egg mass loss until day 25 of incubation, very weak ($r_p = 0.243^{*}$) in case of the relative egg mass loss, very strong in case of the one day old poult mass ($r_p = 0.777^{***}$), and very weak ($r_p = 0.242^{*}$) between the egg mass and the poult share in the egg mass. Similar correlation was found in the TA_{45} group, except between the egg mass and the relative egg mass loss until day 25 of incubation, where the negative phenotype correlation ($r_p = -0.122$) was found, which was not statisticaly significant ($P>0.05$).
- Strong positive correlation was found between the absolute egg mass loss and the relative loss as well as one day old poults, which were statistically significant ($P<0.001$), while very weak correlation was found between the absolute egg mass loss and the poult share in the egg mass and the correlation coefficients in both egg groups ($r_p = 0.217$ and $r_p = 0.178$) were not significant ($P>0.05$).
- Very weak and medium negative correlation was determined between the relative egg mass loss and the poult mass, as well as the poult share in the egg mass in both groups, except between the relative egg mass loss and the poult mass where the positive correlation was found ($r_p = 0.216$) which was not statistically significant ($P>0.05$).
- Strong phenotype correlation (TA_{34}), and medium phenotype correlation (TA_{45}) was found between the average poult mass and the poult share in the egg mass and correlation coefficients were calculated ($r_p = 0.692$ and $r_p = 0.466$) which were statistically significant ($P<0.001$).

Based on this information, we can conclude that turkey's age had significant impact on the increase of egg mass, poult mass, absolute and relative egg mass loss until day 25 of incubation, while the percentage of the poult in the egg mass was of similar value in both age groups of turkeys. Apart from the significant impact of the turkey's age on the increase of average egg mass, egg mass also had a significant impact on the increase of absolute and relative egg mass loss during incubation (until day 25), average one day old poults mass and the poult share in the egg mass, but not on the relative egg mass loss in older turkeys (TA_{45}) where the negative coefficient beween the egg mass and the relative egg mass loss was determined ($r_p = -0.122$), which was not statistically significant. These final conclusions are confirmed by the calculations of the phenotype correlation coefficients between observed indicators, as well as most of the results of other authors (researchers) studying this matter in relation to turkey and other poultry eggs.

Abstract

An experiment was conducted on 20 lambs during 2016 using chamomile dry flower meal (ch). Animals were randomly allocated into 4 groups [CGCH (0% ch), EGCH2 (2% ch, EGCH4 (4% ch) and EGCH6 (6% ch)] by 5 heads. Animal health as well as palatability of rations was visually acceptable. Initial average live body weight (LBW) of all animals was 26 ± 1.5 Kg. Average LBWG/week was significantly (P<0.05) the best in group EGCH2 (3.42±0.48 kg/week/head). FCR was higher at the end of the trial in EGCH2 (6.09±0.40) where animals were fed with 2% chamomile supplemented to daily ration in comparison with all other groups. On the other hand, after cooling L* meat samples of lamb were better in EGCH2 followed by EGCH4, CGCH and EGCH6. Redness of meat from animals slaughtered decreased insignificantly (P > 0.05) 24h after cooling in all groups CGCH (18.99 ± 4.53 to 15.78 ± 2.99), EGCH2 (21.6 ± 7.8 to 15.4 ± 1.14), EGCH4 (17 ± 2.7 to 14.01 ± 1.97), EGCH6 (20.2 ± 4.43 to 18.32 ± 2.16). Yellowness b* decreased after 24 hours of cooling in all groups. At 24 hours' *post-mortem*, pH of fresh meat at slaughter was significantly (P<0.05) more acidic (5.57±0.054) in CGCH and EGCH6 (5.59) than EGCH2 (5.75) and EGCH4 (5.67). After 1 month of freezing CGCH became less acidic (5.79) in comparison with EGCH2, EGCH4 and EGCH6 averaging the level of 5.72, 5.77 and 5.67, respectively (P>0.05). The study of water holding capacity showed that drip loss was minimal in EGCH6 where the loss was (17.86 % ±1.47). Furthermore, tenderness of cooked meat after 24 hours of cooling was higher (P<0.05) in EGCH6 (8.4mm±0.7) followed by EGCH2 (5.64 mm± 2.1) than CGCH (5.5mm ±0.4) and EGCH4 (5.2 mm ±0.9). It is concluded and recommended to use rations containing chamomile meal in the daily feeding of Awassi sheep.

Introduction

A major concern in the farming of small ruminants is loss in production, of which one of the main causes has been identified as food deficiency, mainly caused by high cost. Major challenges in such agricultural businesses are to ensure an enhanced net yield and to minimize high expenditure of concentrate feed. Many recent research data (Busquet *et al*., 2005; Jordan *et al*., 2006; Chaves *et al*., 2008; Benchaar *et al*., 2011; Duval *et al*., 2011; Klevenhusen *et al*., 2011 and many others) has been done regarding this aspect, and various strategies have been studied in introducing feed supplements and feed additives. An additive that has been addressed severe criticism is antibiotics (Anthony *et al*., 2001; Anderson *et al*., 2003; Casewell *et al*., 2003; Collignon, 2003). There are some important reasons behind the restriction of the use of antibiotics, some of which are the drug resistance established in bacteria and the drug residues found in meat (Bager, 2000). Elimination of antibiotics from the diet has resulted in poor performance and in an increase in the susceptibility to diseases. Attempts were made to find other alternatives in order to overcome such challenges. One of

which has shown immense interest in recent years is the utilization of growth promoters of natural origin. Odoemelam *et al*. (2013) observed that there are strong indications that herbs, spices and their products exert antioxidative, antimicrobial and growth promoting effects in livestock. The antioxidative effects of some of the herbs and spices in protecting the quality of feed as well as that of food derived from animals fed these substances cannot be ruled out (Odoemelam *et al.*, 2013). Aromatic plants, have been used since ancient times as folk medicine and as preservatives in foods (Christaki *et al*., 2012). The best known aromatic plants, such as oregano, rosemary, chamomile, sage, anise, basil, etc., originate from the Mediterranean area. Currently, the demand for these plants and their derivatives has increased due to the fact that they are natural, eco-friendly and generally recognized as safe products. Therefore, aromatic plants and their extracts have the potential to become new generation substances for human and animal nutrition and health (Christaki *et al*., 2012). Lee *et al*. (2004ab), Ciftici *et al*. (2005), Erats *et al.* (2005) and Zhang *et al*. (2005) have reported that in the new century the use of antibiotic growth promoters as a feed additive has been banned. Such antibiotics have been added to animal feed rations for improving growth performance, disease prevention and for proliferation of useful microorganisms in the intestinal microflora. After banning the use of most antibiotic growth promoters' scientists looked for alternatives. Therefore, they focused on herbs, spices and plant extracts (essential oils- EO) as possible antibiotic alternatives. Their addition to the feed ration or water improved the feed intake, feed conversion ratio, and carcass yield action (Patel *et al*., 2018). From these aromatic plants we can mention chamomile (*Matricaria chamomilla*). It is important to take into consideration when fed to animals that improved animal health can be translated to improved food safety and quality, which benefits the consumer (Sacchetti *et al*., 2005). For this purpose, this study aims to investigate the impact of supplementing sheep with chamomile dry flower meal, as natural phytogenic compounds at various concentrations in basic rations instead of adding antibiotics and antioxidants. These groups of Awassi male lambs are observed for body performance and meat quality as compared to control antibiotic-free group.

Materials and Method

A total of twenty Awassi Sheep, 3 months old, were purchased from Bekaa valley not far from Beirut/Lebanon. The site was designed to study the impact of feeding male sheep different supplementation levels of chamomile dry flowers meal on body performance and meat quality during the fattening period at an ambient temperature of 25°C, water and feed were offered *ad libitum* for the duration preceding the experimental period. When the experiment initiated, all animals were fed the basal ration (BR) for 5 days and with chamomile after allotting them randomly by 5 heads into 4 groups. Animals of the control group (CGch) were fed free choice antibiotic-free and antioxidant-free basal diet in mashed form based on yellow corn-soybean meal mixture and hay. The remaining 3 groups were fed the following experimental rations: Animals of group (EGch2) were fed BR supplemented with 2% Chamomile dry flowers meal; EGch4 received BR with 4% Chamomile dry flowers meal; EGch6 consumed BR with 6% Chamomile dry flowers meal. All experimental rations fed to animals were *iso-proteinic* and isoenergetic not exceeding 18% of crude protein and 2671.7±40.1 MEkcal/kg of feeds. Daily observations of the lambs showed that no health problems were noted. Live body weight (LBW) was measured individually every week using electronic balance (kg). Initial average live body weight (aLBW) of the sheep was 26±1.5Kg with no significant difference ($P>0.05$) among groups. Live body weight gain (LBWG), feed conversion rate (FCR) and cost-price of 1kg mutton produced was calculated on weekly basis. The meat physical properties were studied *(post mortem)* after 24h of cooling and 1 month of deep freezing, where L*, a*, b* colours and pH level were determined using a chromometer and pH-meter by the method of Offer and Knight (1988). Cooking loss was examined

according to Honikel (1998), the thawing loss was determined and the hardness (tenderness) was estimated using a Penetrometer. One way analysis of variance (ANOVA)) of the results obtained were calculated to evaluate the statistical differences between treatments and replicate means using "Sigmastat software V. 3.5". Mean values ± SD were used. Significant effects were further explored using Tukey's multiple range tests to assert the interaction among treatment means. A significance level of P<0.05 was used. Pearson' correlation of different traits was measured whose results was recorded as p<0.05*, P<0.01** and P<0.001***.

Results and Discussion

The results obtained for feed intake (FI) at the end of the experiment were significantly different (P<0.05) in group CGCH where it attained its maximal level (112.8±12.9kg/head) and its minimal (89.9±9.13kg/head) in EGCH6 whose animals were fed basic ration supplemented with 6% chamomile i.e. Palatability of rations and appetite of animals were positively acceptable in all animal groups where no feed rejection was noticed. This can be explained by the fact that decreased feed consumption has attributed to higher flavouring effects of 4% and 6% chamomile flower meal supplementation to BR decreasing feed intake. These results were in opposite to those findings obtained by Kolacz *et al*. (1997), Kamel (2001), Alçiçek *et al*. (2003) and Panda (2005) who applied essential oils of herbs and spices in animal feeding resulting in increased feed intake in comparison with rations exclusive of any herb supplementations. The average live body weight at the initiation of the trial was calibrated (P>0.05) between 26.4±1.13kg, 26.1±0.67, 25.72±2.1 and 26.2±2.2kg in CGCH, EGCH2, EGCH4 and EGCH6, respectively. The highest LBW was recorded in group EGCH2 (42.5±0.89kg) after 8 weeks of feeding BR supplemented with 2% chamomile followed by CGCH (41.2±1.62kg), EGCH6 (40.2±2.43Kg) and EGCH4 (39.42±2.99kg). This was explained by the positive correlation (r=0.928***) of LBW with the FI since animals of CGCH and EGCH2 consumed more and hence there LBW was higher. This reading matches with the results obtained by AL-Kassie *et al*. (2010) and Kolacz *et al*. (1997), that showed a significant improvement of LBW due to the main constituents of the herbs; the supplementation of 2% chamomile dry flowers meals played a role to enhance the activity of thyroxin hormone that accelerates the nutrients metabolites and biochemical reaction in the animal body (Mahmmod, 2013).

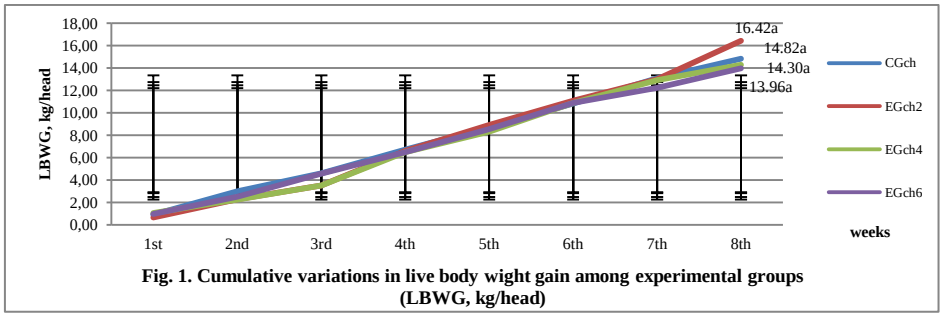

Fig. 1. Cumulative variations in live body wight gain among experimental groups (LBWG, kg/head)

Mean values with letter" a" are insignificantly different (P>0.05)

The recorded results (Fig. 1) of LBWG agree with the data presented by Spernakova *et al*. (2007), who had demonstrated that the addition of Chamomile to BR developed higher body weight gain compared to control group whose animals were fed basic rations with no herb addition due to the active health stimulating elements found in the herbs that show their positive effect on performance. Feed conversion (Fig. 2) was improved significantly (P<0.05) with the addition of chamomile dry flower meal to the basic ration where the most efficient FCR was obtained in EGCH2 (6.09±0.40) vs. CGCH (7.69±1.11). Even though, insignificant data (P>0.05) was obtained between EGCH4 (6.50±0.46) and EGCH6 (6.52±0.84) but still

was lower than CGCH. The obtained results are identical with the findings of Santurio *et al*. (2007) who concluded that when chamomile dry flowers meal are added at a level of 1% of the diet, the body weight gain and feed conversion ratio increased due to the positive impact of the biochemical active components of the herb in the form of antimicrobial, antifungal and antioxidant defense property against harmful body microorganisms.

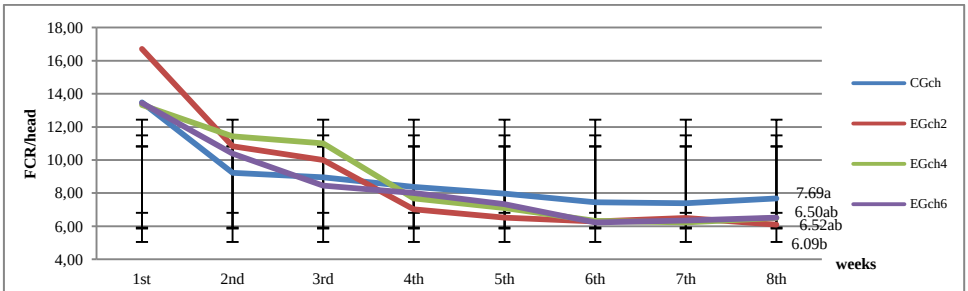

Fig. 2. Cumulative average of weekly variations in Feed conversion ratio among experimental groups (FCR/head)

Mean values with different letters "ab" are significantly different (P<0.05)

The PH have increased in CGCH meat from 5.57 after 24 hours of cooling and then attained the level of 5.79 after 1 month of freezing (P>0.05) in comparison with EGCH2, EGCH4 and EGCH6 averaging the level of 5.72, 5.77 and 5.67, respectively (P>0.05). The slow freezing process leads to development of crystals in muscle tissues. When defrosting, crystals tear the up cells, leading to a greater inter muscular distribution of salinity, thus a decrease in the acidity (P>0.05) was noticed in groups CGCH (5.79±0.045), EGCH4 (5.77±0.08) and EGCH6 (5.67 ± 0.06) and only a slight decrease in salinity in EGCH2 (5.72±0.02). The meat colour was affected by the interaction of myoglobin pigment with the absorbance and reflectance of light (AMSA, 2012). There was a significant difference of luminance L* between the groups, after 24h of cooling where, the highest one was for EGCH2 followed by EGCH4, CGCH and EGCH6. After one month of freezing, L* of mutton increased in CGCH (42.5±1.64 to 49.19±4.9) and EGCH4 (43.2±0.45 to 43.5±3.42), yet in contrast it decreased (P<0.05) in EGCH2 (50.24±3.34 to 39.92±1.07) and EGCH6 (40.118±0.9 to 39.65±1.64) but the higher was for CGCH (49.19 ± 4.9) followed (P<0.05) by EGCH4 (43.5±3.42) and EGCH2 (39.92±1.07). After one month of freezing, redness (a*) continued to decrease in EGCH4 to (13.86) and EGCH6 to (14.95) and increased in CGCH to (17.5) and in EGCH2 to (19.36) while yellowness b* value increased in all groups EGCH4, CGCH, EGCH6 and EGCH2 (13.5, 12.68, 12.3, 10.9, respectively) with a significant difference in EGCH2. The result was logical because of the meat tenderness after 1 month of freezing, where EGCH2 had the more tender meat. The denaturation of myoglobin proteins due to the high temperature effect and the formation of metmyoglobin, was the reason of this drop in redness a* of meat. This obtained result agrees with the study conducted by (Hanczakowska *et al*., 2015) revealing that adding natural antioxidants may improve oxidative stability of the meat, what can be the reason for smaller changes in meat colour. Changes in weight of the meat samples were due to the surface evaporation caused by the differences in temperature and relative humidity between the environment and the meat sample (Cano-Muñoz, 1991). The drip and thawing losses were due to the breakdown of the cell membrane and the diffusion of water outside the cell. After cooling in the refrigerator for 24 hours from slaughter, the mutton loss of their initial weight was significant (P<0.01), where EGCH2 loss was (28.1%±2.79) followed by EGCH4 (27.64%±0.76) and then CGCH (20.23%±2.72). The minimal loss in water appeared in EGCH6 where the loss was (17.86%±1.47). After 1 month of thawing the loss increased in all groups respectively EGCH4 (38.12%), EGCH2 (31.17%) and then CGCH (24.86%) followed by EGCH6 (20.47%), and the difference was highly significant (P<0.01),

especially between EGCH4 and EGCH6. Cooking losses of cooled and frozen samples shows that the cooking loss of frozen samples was higher (P>0.05) than the loss of cooled samples (32.8%>30.8% in EGCH4), (32.2%>23.1% in EGCH2), (31.9%>30.3% in CGCH) and (28.4% 22.4% in EGCH6). Nevertheless, water loss in samples after cooking frozen mutton were significant (P<0.05) between CGCH (higher loss) and EGCH6 (least loss). This decrease in weight or the high cooking loss was very normal due to the decrease in the water holding capacity by the effect of proteins 'denaturation'. Cooking loss and LBWG were found to be negatively correlated (r = - 0.468*). The tenderness of the cooked meat 24 hours after cooling was higher (P<0.05) in EGCH6 (8.4mm±0.7) followed by EGCH2 (5.64mm±2.1), CGCH (5.5mm±0.4) and EGCH4 (5.2mm±0.9). PND (Penetrometer values) of the meat 24 hours after cooling were significantly different between animal groups. Thawing and cooking after one month of freezing, the meat became heavier in all samples with no significant difference (P>0.05), but it was more tender consecutively in groups EGCH2 (5.56mm), EGCH6 (5.43mm), CGCH (5.36mm) and EGCH4 (4.88mm). Tenderness of meat was negatively correlated with the results of the variable L* (r = -0.408*). These results agree with those of Hergenreder (2011) stating that after freezing, cooked meat is tougher than the cooked meat after cooling and in contradiction with the results achieved by Koohmaraie *et al.* (1998) stating that frozen samples cooked after thawing are tenderer than those cooked after cooling.

Conclusion and Recommendations

Scarce results were found regarding local as well as international practical applications in comparing the influence of chamomile additions fed at different percentages: 2, 4 and 6% as a replacement to antibiotic and antioxidant additions. Beneficial effects of chamomile in small percentages mixed with basic rations and fed to Awassi sheep may arise from activation of feed intake and digestive secretions, immune stimulation, anti-bacterial, antiviral or anti-inflammatory activity and antioxidant properties. This situation requires the world to restrict using antibiotic growth promoters in sheep feed and push the Lebanese farmers to follow a new method of feeding their lambs rations supplemented with natural herbs and spices such as chamomile as growth promoters without using synthetic antioxidants.

As a result, this study shows that it is highly recommended to use 2% chamomile flower meals as a supplementation to 100 kg of basal diets in the daily feeds of Awassi sheep during the growth period, as a replacement to antibiotic and antioxidant additives, which has proved to give the meat a better quality mostly similar to that of organic meat which is a major demand of customers nowadays. Lastly, we suggest performing this practice on a commercial level to determine the real economic effect of using natural herbs and spices, such as chamomile, on the body performance and the meat quality. As future work, this study should be conducted on Awassi male sheep fed basic rations with more and less concentrated supplementation (%) revealing the appropriate concentration that leads to higher animal performance.

Abstract

Animals were randomly allocated into four groups [CGth1 (0% th), EGth2 (2% th), EGth4 (4% th) and EGth6 (6% th)] by 5 heads and fed rations containing thyme meal (th). Results showed that initial LBW/head at the beginning of the experiment was insignificantly different averaging to 13.17±1.47 Kg (P>0.05). Average LBWG at the end of 1st week of the trial was insignificantly (P>0.05) lower (0.93±0.25 kg) in CGth1 group in comparison with all other experimental animal groups - EGth2 (1.37±0.29 kg), EGth4 (1.47±0.35 kg) and EGth6 (1.43±0.25 kg) /week/head. This increase became significant (P<0.05) at the end of the trial at 8th week attaining in EGth2 (1.67±0.58kg), EGth4 (2.00±0.00) and EGth6 (2.00±0.00) in comparison with CGth1 (1.00±0.00kg). Note that the highest increase (P<0.05) in weekly LBWG was noted in the 7th week in EGth4 (4.50±0.00 kg). Cumulative LBWG of animals in EGth4 at the end of the trial was significantly (P<0.05) higher (20.33±0.57 kg) than EGth2 (15.67±1.53 kg), EGth6 (15.70±1.15 kg) and CGth1 (14.67±1.16 kg). The most efficient FCR at the end of the experiment was in group EGth4 attaining the level of 2.92±0.16 which was significant to all other groups, CGth1 (3.75±0.52), EGth2 (3.68±0.24) and EGth6 (3.73±0.28). Based on our results, it is expected to have better quality of meat in EGth4 where 4% dry thyme meal was added to the basic ration. It is concluded and recommended to use rations containing thyme meal in the daily feeding of Awassi sheep.

Keywords: *Awassi lambs; Thyme dry meal; Body performance.*

Introduction

One of the main concerns in the farming of small ruminants is the loss in production, and primarily it is caused by the high costs which leaded to food deficiency. Major challenges in such agricultural businesses are to ensure an enhanced net return and to minimize high feed costs. Many recent research data (Busquet *et al*., 2005; Jordan *et al*., 2006; Chaves *et al*., 2008; Benchaar *et al*., 2011; *et al*., 2011; Klevenhusen *et al*., 2011 and many others) has been done regarding this aspect, and various strategies have been studied in introducing feed supplements and feed additives such as antibiotics, an additive that has been severly criticized (Anthony *et al*., 2001; Anderson *et al*., 2003; Casewell *et al*., 2003; Collignon, 2003). There are some important reasons behind the restriction of the use of antibiotics, some of which are the drug resistance established in bacteria and the drug residues found in meat (Bager, 2000). Elimination of antibiotics from the diet has resulted in poor performance and in an increase in the sensitivity to diseases. Attempts were made to find other alternatives in order to overcome such challenges. One of which has shown immense interest in recent years is the utilization of growth promoters of natural origin. Odoemelam *et al*. (2013) observed that there are strong indications that herbs, spices and their products exert antioxidative, antimicrobial and growth promoting effects in livestock. The antioxidative effects of some of the herbs and spices in protecting the quality of feed as well as that of food derived from animals fed these substances cannot be ruled out (Odoemelam *et al.,* 2013). Aromatic plants, have been used

since ancient times as folk medicine and as preservatives in foods (Christaki *et al*., 2012). The best known aromatic plants, such as oregano, rosemary, chamomile, sage, anise, basil, etc., originate from the Mediterranean area. Currently, the demand for these plants and their derivatives has increased due to the fact that they are natural, eco-friendly and generally recognized as safe products. Therefore, aromatic plants and their extracts have the potential to become new generation substances for human and animal nutrition and health (Christaki *et al*., 2012). Lee *et al*. (2004ab), Ciftici *et al*. (2005), Erats *et al*. (2005) and Zhang *et al*. (2005) have reported that in the new century the use of antibiotic growth promoters as a feed additive has been banned. Such antibiotics have been added to animal feed rations for improving growth performance, disease prevention and for proliferation of useful microorganisms in the intestinal microflora. After banning the use of most antibiotic growth promoters' scientists looked for alternatives. Therefore, they focused on herbs, spices and plant extracts (essential oils- EO) as possible antibiotic alternatives. Their addition to the feed ration or water improved the feed intake, feed conversion ratio, and carcass yield action. From these aromatic plans we have chosen the thyme. The Thyme or *Thymus vulgaris* is a medicinal herb in the Lamiaceae family, cultivated worldwide for culinary, cosmetic perennial and medical purposes. The growing interest of consumers in substances of natural origin in addition to the increasing concern surrounding potentially harmful synthetic additives has resulted in the use of aromatic plants, their extracts and essential oils, as functional ingredients in the pharmaceutical, food and feed industries. Plant derived components have considerable potential to fulfil such demands. It is also important to take into consideration that improved animal health can translate to improved food safety and quality, which benefits the consumer (Sacchetti et al., 2005). Therefore, this study aims to investigate the impact of supplementing sheep different aromatic plants such as the thyme, as natural phytogenic compounds at various concentrations in basic rations instead of adding antibiotics and antioxidants. These groups of Awassi male lambs are observed for body performance as compared to control antibiotic group.

Material and Methods

A total of twelve Awassi Sheep, 3 months old, were purchased from Rashaya - Bekaa valley for this experiment. The site was designed to study the impact of feeding male sheep different supplementation levels of thyme meal on body performance and meat quality during the fattening period at an ambient temperature of 25°C, water and feed were offered *ad libitum* for the duration preceding the experimental period. When the experiment initiated, all animals were fed the basal ration (BR) for 5 days and with thyme dry meal supplementation after allotting them randomly by 3 heads into 4 groups. Animals of the control group (CGth1) were fed free choice antibiotic-free and antioxidant-free basal diet in mashed form based on yellow corn-soybean meal mixture and hay. The remaining 3 groups were fed the following experimental rations: Animals of group (EGth2) were fed BR supplemented with 2% thyme dry meal; EGth4 received BR with 4% thyme dry meal; EGth6 consumed BR with 6% thyme dry meal. All experimental rations fed to animals were *iso-proteinic* and isoenergetic not exceeding 18% of crude protein and 2671.7±40.1 MEkcal/kg of feeds. Daily observations of the lambs showed that no health problems were noted, except a slight greenish diarrhea was noticed in CGth1 group. Live body weight (LBW) was measured individually every week using electronic balance (kg). Initial average live body weight (LBW) of the sheep was 13.17±1.08Kg with no significant difference ($P>0.05$) among groups. Live body weight gain (LBWG), feed conversion rate (FCR) and cost-price of 1kg mutton produced was calculated on weekly basis. One-Way analysis of variance (ANOVA)) of the results obtained were calculated to evaluate the statistical differences between treatments and replicate means using "Sigmastat software V. 3.5". Mean values ± SD were used. Significant effects were further

explored using Tukey's multiple range tests to assert the interaction among treatment means. A significance level of P<0.05 was used.

Results and Discussion

The results obtained for feed intake (FI) at the end of the experiment were significantly different (P<0.05) in group EGth4 where it attained its maximal level (59.31±12.9kg/head) and its minimal in CGth1 whose animals were fed basic ration i.e. Palatability of rations and appetite of animals were positively acceptable in all animal groups where no feed rejection was noticed. This can be explained by the fact that decreased feed consumption has attributed to higher flavouring effects of 4% thyme dry meal supplementation to BR decreasing feed intake. These results agree with those findings obtained by Manuel et al. (2009) who applied essential oils of herbs and spices in animal feeding resulting in increased feed intake in comparison with rations exclusive of any herb supplementations. The average live body weight at the initiation of the trial was calibrated (P>0.05) between 13.00±2.00kg, 13.67±0.58, 11.67±1.16, and 14.33±0.58kg in CGth1, EGth2, EGth4 and EGth6, respectively. The highest LBW was recorded in group EGth4 (32±1kg) after 8 weeks of feeding BR supplemented with 4% thyme dry meal and the lowest one in CGth1(27.67±1.155kg). This reading matches with the results obtained by AL-Kassie et al. (2010) and Frankie (2009), and Christaki et al. (2012), that showed a significant improvement of body weight (BW) due to the main constituents of the herbs; the supplementation of 4% thyme dry meal meals play a role to enhance the activity of thyroxin hormone that accelerates the nutrients metabolites and biochemical reaction in the animal body (Mahmmod 2013).

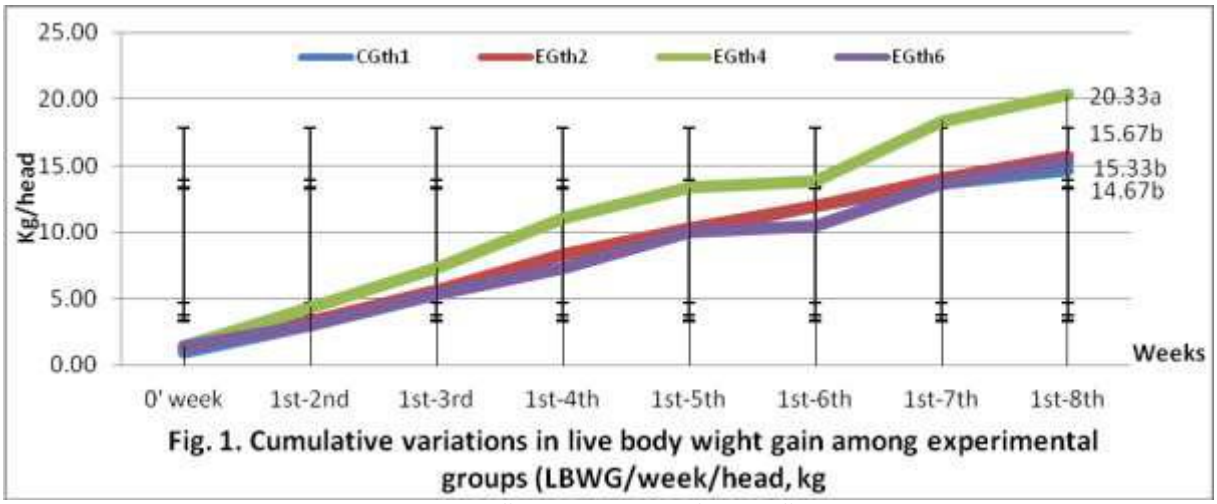

Fig. 1. Cumulative variations in live body wight gain among experimental groups (LBWG/week/head, kg

ab Mean values with different letters are significantly different (P<0.05)

The recorded results (Fig. 1) of LBWG had demonstrated that LBWG changed largely between the four groups during the experimental weeks where it was the highest in EGth4 in many stages of the experiment. Feed conversion (Fig. 2) was improved significantly (P<0.05) with the addition of thyme dry meal to the basic ration where the most efficient FCR was obtained in EGth4 (2.93±0.165ba) vs. CGth1 (3.75±0.524a). Even though, insignificant data (P>0.05) was obtained between EGth2 (3.68±0.24a) and EGth6 (3.83±2.283a) but still was lower than CGth1. The obtained results are identical with the findings of Windisch et al., (2008) who concluded that when thyme flowers are added at a level of 3kg/100kg of the diet, the body weight gain and feed conversion ratio increased due to the positive impact of the biochemical active components of the herb in the form of antimicrobial, antifungal and antioxidant defense property against harmful body microorganisms.

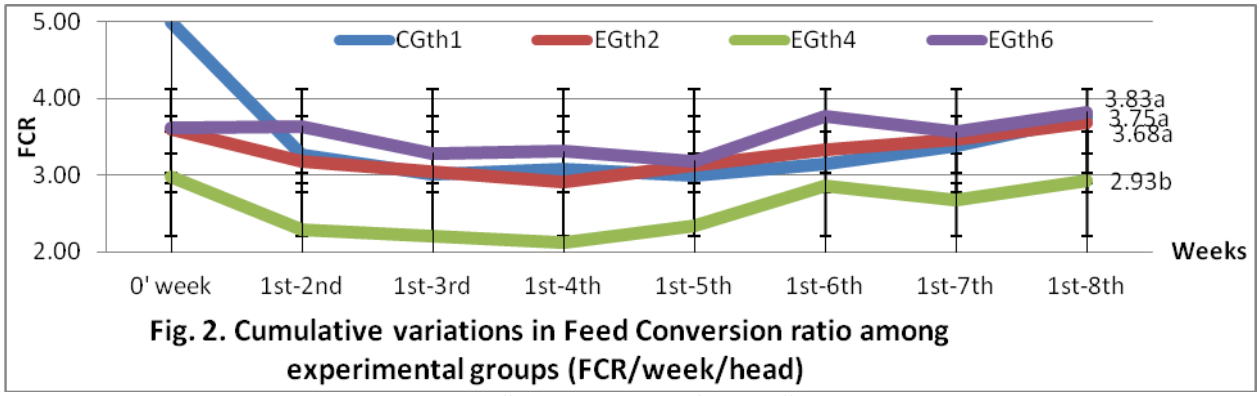

Fig. 2. Cumulative variations in Feed Conversion ratio among experimental groups (FCR/week/head)

ab Mean values with different letters are significantly different (P<0.05)

Conclusion and Recommendations

Scarce results were found regarding local as well as international practical applications in comparing the influence of thyme additions fed at different percentages: 2, 4 and 6% as a replacement to antibiotic and antioxidant additions. Beneficial effects of thyme in small percentages mixed with basic rations and fed to Awassi sheep may arise from activation of feed intake and digestive secretions, immune stimulation, anti-bacterial, antiviral or anti-inflammatory activity and antioxidant properties. This situation requires the world to restrict using antibiotic growth promoters in sheep feed and push the Lebanese farmers to follow a new method of feeding their lambs rations supplemented with natural herbs and spices such as thyme as growth promoters without using synthetic antioxidants.

As a result, this study shows that it is highly recommended to use 4% thyme dry meals as a supplementation to 100 kg of basal diets in the daily feeds of Awassi sheep during the growth period, as a replacement to antibiotic and antioxidant additives, which has proved to give the meat a better quality mostly similar to that of organic meat which is a major demand of customers nowadays. Lastly, we suggest performing this practice on a commercial level to determine the real economic effect of using natural herbs and spices, such as thyme, on the body performance and the meat quality. As future work, this study should be conducted on Awassi male sheep fed basic rations with more and less concentrated supplementation (%) revealing the appropriate concentration that leads to higher animal performance.

COMPARISON OF PHYSICAL-CHEMICAL INDICATORS OF DIFFERENT MUSCLES OF CARCASS OF FATTENED CALVES OF HORNLESS HERFORD, ABERDEEN-ANGUS AND LIMOUSINE BREEDS

Nikolay MARKOV*, Snezhana SLAVKOVA, Tsvetelina DIMITROVA

Research Institute of Mountain Stockbreeding and Agriculture, 5600 Troyan, Bulgaria
*Corresponding author: ncm64@mail.bg

Abstract

A comparative analysis of physical-chemical indicators of different muscles [*m semitendenosus, m. semimembranosus* and *m. longisimus dorsi*] was made from the carcass of fattened calves of Hornless Hereford, Aberdeen-Angus and Limousine in the meat farm of the Experimental Base at the Research Institute of Mountain Stockbreeding and Agriculture in Troyan, Bulgaria located in the mountain region. Breed and sex affected the main indicators characterizing the physicochemical and quality composition of the meat. Based on the water-holding capacity indicator in %, the best results were found in the fattened calves of Aberdeen-Angus in the three studied muscles. They surpassed Hornless Hereford calves, respectively with 4.09%, 7.48% and 2.36%, and Limousine calves with 11.90%, 17.38% and 13.50%. The muscles of calves from Hornless Hereford had the highest significance of tenderness in penetrant units, followed by the calves of Aberdeen-Angus and Limousine ($P<0.001$).

Protein content had higher values in Limousine calf muscles. The superiority of *m. semitendinosus* is 1.85%, with *m. semimembrenosus* by 0.92% and at *m. longisimus dorsi* was 2.21% of Aberdeen Angus breed. Compared to the muscle content of calves of Hornless Hereford, the values were relatively the same for *m. semiteenosenosus*, and the superiority is 0.92% for *m. semimebranosus* and 1.07% for *m. longisismus dorsi* ($P <0.001$). The fat in the carcass muscle of Limousine calf had the highest values 1.61%, 1.71% and 2.49%, followed by the fat in the muscles of calves of Aberdeen Angus and Hornless Hereford ($P<0.001$).

Introduction

The quantity and quality of beef and veal depend on a number of factors: type, sex, age, diet, breeding system, market and marketing interest (Todorov, 1987; Videv, 1994; Kalev, 2012; Polskih, 2015). The type and breed of animals greatly influence the fattening capacity and meat productivity. In the process of ontogenetic and phylogenetic development, the individual productive types and breeds of cattle have formed such a constitutional type that corresponds to their main productivity (Kadiiski et al., 1987; Todorov, 1987; Videv et al., 1987; Kalev, 2004; Kalev and Dimov, 2012). Allen (1990) and Mandell et al. (1997) assume that the significant differences in the growth potential of cattle of the same age depending on the breed are mostly related to the fat deposition phase. The accumulated valuable information from the experiments carried out so far has to be supplemented by new studies of biological and technological character (Videv, 1994; 1996; Chamboza et al., 2003; Mancini et al., 2005; Miroshnikova et al., 2005; al., 2007; Marinova and Popova, 2011; Tanana et al., 2016). Atanasov et al. (2009) compare fish meat (trout and carp) with veal, pork, lamb, turkey and chicken and report higher protein and vitamin A. The fat content of trout and carp ranges in broad limits. Pinkas and Marinova (1984) in a study of *m. longisismus dorsi* on 484 bulls of different breeds prove that pH values (6.19) are significantly higher than normal and the collagen content has average values that vary widely. Xiang Xie et al. (2012) compare the quality of male calf meat to five breeds – three local Chinese and two foreign – Simmental

and Limousine, slaughtered at 18.5 months of age, taking samples of *m. longisismus dorsi* and found that the breed had a relatively weak effect on most meat parameters. In Bulgaria for veal is considered the meat of fattened male and female cattle up to 2 years of age. The physico-chemical composition is not a constant value during the life of any animal. The physical and chemical composition of veal depends on the breed, sex, age, anatomical location and animal fattening ability. Agricultural establishments in the agriculture and food industry in the Republic of Bulgaria are obliged to comply with the basic requirements of Regulations EC 2073/2005 and EC 1441/2007 on microbiological criteria for food products. The regulations are still recommendatory for Bulgaria (Enikova, 2008). The aim of the present study is to compare the physical-chemical composition of muscles of beef of different genotypes of meat cattle raised in the region of the town of Troyan.

Material and Methods

The subject of the study were three groups of beef calves: 5 male calves of Hornless Hereford, 5 male calves of Aberdeen-Angus and 5 males of Limousine breed raised to 15 months of age in the Experimental Base of RIMSA in Troyan, Bulgaria. The animals were being bred and fed at free will following a suitable meat technology. The groups were equally aligned and raised under the same conditions. The control slaughter of calves from each group was performed according to the method of Zahariev and Pinkas (1979). For the purpose of the experiment, a material was taken from 3 muscles according to a fixed scheme from the left carcass half [m. longissimus dorsi (LL)] obtained from the back, from the cranial edge of the ninth thoraic vertebra to the caudal edge of the 10th thoracic vertebra, [m. semimembranosus SM] taken from the lateral part of the leg and [m. Semitendinosus (ST)] prepacked from the caudal part of leg of fattened calves with a live weight of 450 kg of the three breeds. The carcass weight of the calves varies from 270 to 290 kg. It is compact, rounded and well developed. Its hip portion is broad and level. The thighs are well-formed muscles. The back and loin are broad and dense, almost to the withers. The shoulder-blade, sternum, and vertebrae are significantly muscled. Samples of the above-mentioned muscles were taken after slaughter, placed in a refrigerated bag and transported to the meat laboratory of RIMSA-Troyan for analysis. Three samples were taken from each muscle from the same topographic sections. Separate physicochemical parameters were analyzed with "FoodScan-2000" apparatus (USA). Standard methods for water holding ability of meat (WHC) were used, the tenderness was determined by the method of Grau and Hamm (1953), modified by Pinkas and Marinova (1984) and the mineral substances following Poppandopul et al. (1956).
All data were processed statistically by using MS Excel and presented in a table.

Results and discussion

The results of the investigation of physical and chemical composition of different calf muscles are presented in Table 1.

Table 1. Physical-chemical composition of different muscles of carcass of fattened calves.

The polydisperse system is characteristic for veal. Death in the slaughter of cattle leads to the breakdown of the buffer system of their organism. The normal pH of carcasses of calves after slaughter was 7-7.2, gradually decreasing to an acidic reaction. pH affects the meat colour. At pH 5.6 beef had a bright, colourful colour. With an increase in pH above 6.5, the colour usually changes to dark with different variants. pH 24 of the medium showed higher values for all three samples of *m. semltendenosus*, *m. semimbrannosus* and *m. longisimus dorsi* in Aberdeen-Angus breeds, respectively for the first with 0.91, the second muscle with 0.89 and for the longest muscle with 0.92 points in comparison with the breed Hornless Hereford and 0.99 for the first with 0.92 for the second and 1.02 points for the third compared to Limousine, but it was within the permissible (Pinkas and Marinova, 1984).

The dry matter expressed in % was the highest in calf muscle Limousine for *m. semiteenosenosus* by 2.5%, for *m. semimembrenosus* by 2.1% and for *m. longisimus dorsi* with 4.18% compared to the calf of the breed Hornless Hereford and with 2.5% for *m. seitendenosus*, 2.1% for *m. semimranranusus* and with 4.8% for *m. longisimus dorsi* for Aberdeen Angus calves.

The water content was with the highest values in the muscles of the Aberdeen-Angus calves, respectively 78.00%, 77.3% and 78.68%, and with the lowest values in the muscles of Limousine calves, respectively 74.9%, 75.3% and 73.4%.

The ratio of dry matter: water had a direct relation to the juice of meat in the examined muscles. It varied from 0.27: 1 to 0.35: 1 in the tested samples of the three breeds. It was most favourable in the tested muscles of Limousine breed: 1: 0.34, 1: 0.35 and 1: 10.35.

Water holding capacity of water in % was higher for muscles of Aberdeen-Angus calves with 4.09% for *m. semiteenosenosus*, with 7.48% for *m. semimembranusus*, and 2.36% for *m. longissimus dorsi* compared to the muscles of the calf of the breed Hornless Hereford. Higher were the differences in the values between (WHC) in the muscles of calves of Aberdeen-Angus breed compared to those of Limousine breed respectively for *m. semiteenosenosus* 11.9%, *for m. semimranranusus* 17.37% and for *m. longisimus dorsi* 13.5%. Water holding capacity is a factor reflecting the quality of veal. Juiciness, tenderness, taste, as well as some technological properties depend on the amount of bound water (P<0.001).

Meat tenderness was higher in the muscles of calves of Hornless Hereford for *m. semitendenosus* with 20.90 penetrant units and for *m. lomgisimus dorsi* with 13.4 penetrant units. In *m. semimembranusus*, however, had this advantage for Aberdeen-Angus breed with 9.9 penetrant units. There were significant differences in values compared to muscles of Limousine calves, respectively 14.4 penetrant units for *m. semiteenosenosus* (ST), 7.2

penetrant units for *m. semimranranusus* and 31.6 penetrant units per *m. longisimus dorsi* (P<0.001).

Collagen is a connective tissue protein, incomplete protein, insoluble in water, and salt solutions associated with the formation of sarcolemma. It was the most common in the body, up to 1/3 of all available proteins. The muscles of Hornless Hereford showed superiority – at m. semitendinosus (ST) of 0.2%, at m. semimembranosus (SM) with 0.01% and in the longest muscle with 0.79%, compared to the muscles of Aberdeen-Angus calf, the differences being relatively minimal.

Protein content had higher values in Limousine calf muscles. The superiority of *m. semitendinosus* (ST) was 1.85%, for *m. semimembrenosus* was 0.92% and for *m. longisimus dorsi* is 2.21% compared to Aberdeen-Angus breed. Compared to the muscle content of Hornless Hereford's calves, the values were relatively the same for *m. semiteenosenosus*, and the superiority was 0.92% for *m. semimebranosus* and 1.07% for *m. longisismus dorsi* (P<0.001).

The amount of fat is an indicator that is involved in determining the nutritional value of veal. Fat in muscles in Limousine breed surpassed those of the calves of Aberdeen-Angus breed. It was with 0.49% for *m. semitendenosus*, for m. semimembranosus with 0.27% and for *m. longisimus dorsi* with 1.57%, the differences were larger with the examined muscles of Hornless Hereford – 0.61%, 0.51% and 1.03%.

The fat: protein ratio was the highest in muscles of Limousine breed, as it is 0.072: 1 for *m. semiteen,* 0.080: 1 for *m. semimeterranus* and 0.112: 1 for *m. longisimus dorsi*. Aberdeen-Angus breed occupied an intermediate location with the following results for the tested muscles: 0,072: 1 for *m. semiteenosus*, 0,080: 1 for *m. semimebranosus* and 0,112: 1 for *m. longisimus dorsi*. The lowest values of the ratio were observed in the muscles of Hornless Hereford, 0.044: 1 for *m. semiteenosenos*, 0.052: 1 for *m. semimranranusus* and 0.069: 1 per *m. lõngisimus dorsi*.

The Fat: Water Ratio determines the "Maturity" index in the muscles of the three breeds tested. This indicator ranged from 0.012: 1 to 0.377: 1, with a significantly higher value in the muscle samples of Limousine calves – 0.021: 1 0.022: 1 and 0.377: 1.

The investigated mineral substances ranged from 0.92 mg /% to 1.08 mg/% in the muscles of the three breeds and were within normal range. Beef is one of the most important sources of phosphorus in the human body. Its level in the examined muscles ranged from 0.021 mg /% to 0.06 mg/%. Calcium (Ca) was involved in various metabolic processes of the human body. Its level in the examined muscles of the three breeds ranged from 0.40 mg/% to 0.51 mg/%.

The obtained by us data are similar in value and correspond to the results of Xiang Xie et al. (2012), Polskih (2015) and Tanana et al (2016).

Conclusion

Breed, sex and genotype affect on the main indicator characterizing the physical-chemical and qualitative composition of the various muscles of beef calves. The physical-chemical properties of veal determine its importance for human nutrition, diet and culinary use of people.

The water-holding state of water in % is higher for calve muscles in Aberdeen-Angus breed, respectively 4.09% for *m. semitendenosus*, with 7.48%, for *m. semitendenosus,* with 7.48% for *m. semimembranusus*, and 2.36% for *m. longissimus dorsi*, compared to the muscles of calves of Hornless Hereford breed. Higher are the differences in the values between in the muscles of calves of Aberdeen-Angus compared to those of Limousine breed respectively for *m. semitendenosus* 11.9%, for m. semimembranosus 17.37% and for *m. longisimus dorsi* 13.5%. Meat tenderness is higher in the muscles of calves of Hornless Hereford for *m. semitendenosus* with 20.90 penetrant units and for *m. lomgisimus dorsi* with 13.4 penetrant

units. The tenderness in *m. semimembranusus*, has 9.9 penetrants units higher in Aberdeen-Angus breed compared to the other two breeds. Protein content has higher values for Limousine calf muscles. The superiority of m. semitendinosus is with 1.85%, in *m. semimembrenosus* is with 0.92% and for *m. longisimus dorsi* is with 2.21% compared to Aberdeene Angus breed. Muscles in Limousine breed are superior in fat content in comparison to muscles groups of calves of Aberdeen-Angus breed. In *m. semitendenosus* with 0.49%, for m. semimembranosus with 0.27% and for *m. longisimus dorsi* with 1.57%, the differences in the examined muscles of Hornless Hereford are greater – 0.61%, 0.51% and 1.03%.

Abstract

As the world population continues to increase, so does the demand for protein. Researchers predicted that traditional sources of protein for livestock would become increasingly scarce because of the need to feed a progressively larger human population that will compete with an expanding intensive livestock industry that is being forced to exclude animal protein sources in animal feeds. As a result, a considerable effort has been made to explore the use of plant proteins that can be grown in areas where soybeans are not agronomical successful. A trial was conducted in "Al Jarrah animal farm" during May- July of 2016 at Bekaa Valley for 8 weeks to fatten fifteen male Awassi sheep lams after weaning fed concentrate mix containing soybean meal (SBM) and Fava seed meal (FSM) as legume-protein source in different proportions in isocaloric and iosprotienic rations. Five different rations were under investigation were fed to five groups by three lambs each under the same management and environmental conditions: A1 (25% SBM: 75% FBS), A2 (50% SBM: 50% FBS), A3 (25% SBM: 25% FBS), A4 (100% FBS: 0% SBM) and A5 –control (0% FBS: 100% SBM). Best results were obtained in group A2 and A3 with feed conversion ratios (FCR) 4.6 and 4.4, final live body weight gain (LBWG) 10.9 and 10.8 kg and profit of 1.27 $/1 kg of LBWG and 1.19 $/1 kg of LBWG, respectively. No signs of antinutritional or gastro-intestinal disturbances were observed among all experimental groups.

Keywords: *Awassi lambs; Faba beans; Soybean; Body performance.*

Introduction

As the world population continues to increase, so does the demand for protein. Farrell (1997) and Magoda and Gous (2011) predicted that traditional sources of protein for livestock will become increasingly scarce because of the need to feed a progressively larger human population that will compete with an expanding intensive livestock industry that is being forced to exclude animal protein sources in animal feeds. As a result, a considerable effort has been made to explore the use of plant proteins that can be grown in areas where soybeans are not agronomically successful. Evans *et al*. (1972) noted that Vicia faba is an important crop in those areas of the world where cereal monoculture is practiced and soybeans cannot be produced economically as it requires a cool season for best development.

Duc (1997), Haciseferogullari *et al*. (2003) and Hossain and Mortuza (2006) published that the nutritional value of faba bean has always been traditionally attributed to its high protein content, which ranges from 27 to 34% depending on genotypes. Most of these proteins comprise of globulins (79%), albumins (7%) and glutelins (6%). They added that, Legume seeds contain several comparatively minor proteins including trypsin inhibitors, lectins, lipoxygenase and urease, which are relevant to the nutritional quality of the seed.

Many researchers as McDonald *et al*. (1973), Liener (1976), Cerioli *et al*. (1998), Antongiovanni *et al*. (2002), Matthews and Marcellos (2003)), Martinez *et al*. (2005), Morbidini *et al*. (2005), Dvořák *et al*. (2006), Esenwah and Ikenebomeh (2008) who studied

the effect of using FBS as an alternative to SBM found no adverse effect in including it in the daily rations of ruminants.
The objective of the present paper is to evaluate the influence of replacing totally or partially soybean meal with faba beans in rations fed to weaned lambs of local Awassi sheep on cost price of meat and some traits of body performance.

Material and Methods

This trial was conducted in Bekaa Governorate/Lebanon 5 Km of Zahle, 75 km from Beirut during May-June 2015. Relative humidity (RH%) and environmental temperature (ºC) recorded during this period of the year ranged between 50.3 - 76.9 and 16.6 - 24.6, respectively.
Fifteen 100-120 days weaned Awassi male lambs weighing 23.33 ± 0.52 kg/head started a fattening experiment. Animals were dipped and treated for all kinds of helmentic worms and vaccinated against all prevailing diseases in the area. The animals were in good health. Each animal-group was fed free choice forage feeds (about 1 kg/head of wheat straw) and around half kg/head of the experimental mix-rations and free access to fresh water. All rations were isocaloric (2.9 Kcal/kg ME) and adjusted to the same level of crude protein (17%) as recommended by NRC (1989) and based on cotton seed meal (CSM), wheat bran and corn, fed continuously with different ratios of Soybean meal (SBM) : Dry milled Fava bean seeds (FBS) for the whole experimental period as shown in table 1. A5 animal-group was fed basic ration (BR) exclusive of FBS, however A1, A2, A3, A4 received BR containing different ratios of SBM to FBS- 75%SBM: 25% FBS, 50% SBM: 50% FBS, 25% SBM: 75% FBS and 0% SBM: 100% FBS, respectively (table 1).

Table 1. Composition of the experimental rations (% as fed basis) fed to each animal-group with their cost-prices ($/ton)

		A1	A2	A3	A4	A5 (Control)
Cost price of Ingredients ($/ton)	**Ingredients**	**75% SBM+ 25%FBS**	**50% SBM+ 50%FBS**	**25% SBM+ 75%FBS**	**100% FBS**	**100% SBM (Basic ration-BR)**
600	SBM	11.1	7.4	3.7	0.0	14.8
325	CSM	7.4	10.0	13.0	15.8	5.1
350	FBS	3.7	7.4	11.1	14.8	0.0
150	Wheat bran	16.0	15.0	12.7	12.3	14.7
250	corn	61.7	60.1	59.4	57.1	65.4
	Total	100.0	100.0	100.0	100.0	100.0
	CP	16.8	16.8	16.8	16.8	16.8
	ME Mcal/kg	2.9	2.9	2.9	2.9	2.9
	Cost price of rations ($/ton)	282	276	271	264	291

Data obtained was analyzed using the analysis of variance (ANOVA) procedure of Sigmastat v.3.5 (Jandel corp. 2004) with $P<0.05$ statistical significance of treatment effects. Live body weight gain of each animal (LBWG/head), Feed intake of each animal-group (FI/group) and apparent feed intake of each lamb (aFI/head) and food conversion ratio of each group (FCR/group) and aFCR/head, were weighed and calculated weekly. Interaction of treatment means was tested using the All Pairwise Multiple Comparison Procedures (Duncan's Method) at 5% significance level. Mean ± SD (Mean values of the traits ± Standard Deviation) was

used in all obtained statistical studies. Cost-price of LBWG obtained ($/1 kg) was calculated to explore the feasibility of the study.

Results and Discussion

Random distribution of all animals resulted in almost equal average weight among the five animal groups. Difference in the initial Live Body weight (W_o) was statistically insignificant ($P>0.05$) where it averaged between 22.8 ± 0.41 kg in group A4 and 23.7 ± 0.35 kg in group A2.

No health problems were noticed and palatability of feeds (FI) was acceptable as inspected daily where no left behind ration remaining was collected. No signs of indigestion or diarrhea or any blood signs in manure were observed.

The amount of concentrate mix fed to animals did not exceed 49.6 kg/animal group for the whole period of the experiment. In 1st week the apparent daily feed intake (adFI/head) per animal in all groups averaged to 729 g/head whereas, at the end of 8th week this value increased to 1032 g/head. At the beginning of each consecutive week all animals of each group were weighed and fed daily mix concentrates (kg) in calculation to 3% of total live body weight obtained.

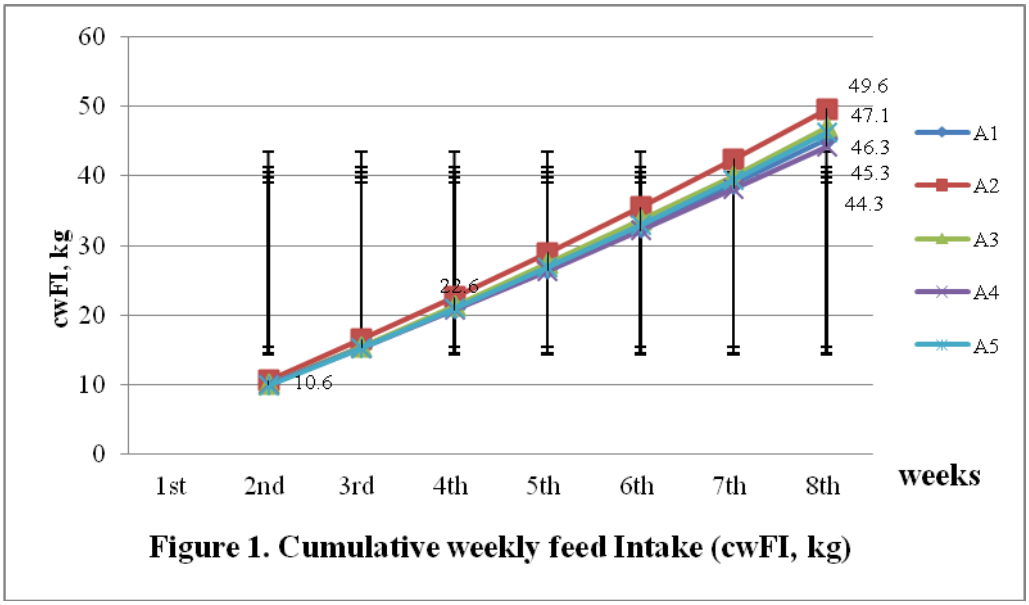

Figure 1. Cumulative weekly feed Intake (cwFI, kg)

Fig. 1 shows the weekly cumulative feed intake among all animal groups. Even though FI at the end of the 1st week was the same among groups it is shown that with the beginning of the 3rd week, 2nd group started to consume feeds (16.5 kg) by 8% more than all others and continued to attain this increase in all weeks of the experiment.

At the end of 1st month of the experiment animals were consuming 20.9 kg, 22.6, 21.3, 20.7 and 20.9 kg in groups A1, A2, A3, A4 and A5 respectively. Besides, it was recorded a decrease in feed consumption in group A4 with 100% inclusion of FBS to ration in all consecutive weeks beginning from 4th week by 0.8% and ending by 4.3 % in comparison with the results obtained in group A5 with 100% SBM inclusion. Moreover this tendency was also observed at the end of the trial in group A1 (75% SBM: 25% FBS) attaining the amount of 45.3 kg Vs 49.6, 47.1, 46.3 kg in groups A2, A3 and A5, respectively.

Looking deeper at the results obtained it was noticed that at the end of the 1st week of the experiment a significant increase ($P<0.05$) in body gain for group A2 (225 g/day) was observed in comparison with A4, A1, A5 and A3 attaining the levels of 106.7 g/day, 131.7, 166.7 and 173.3 g/day, respectively. Although in the 2nd week there was a small decrease (1.5%) in dLBWG in animal group A2 but still the gain was higher ($P<0.05$) than any other

group by 50.4 %, 34.6 %, 23.3 % and 15.8 in A4, A1, A5 and A3, respectively. Even though the health status of animals in all groups was acceptable with no signs of malnutrition and infectious diseases this decrease in dLBWG continued in A2 where it became stable beginning from week six, attaining the level of 183.3 g/day. Results obtained at the end of the experiment showed ($P<0.05$) an overall LBWG of 6.5 ± 0.3 kg/head in group A4 followed by A1 (8.5 ± 0.2), A3 (10.8 ± 0.9) and A2 (10.9 ± 1.1 kg/head). Although, body gain in A5 (9.9 ± 0.8 kg/head) was higher than A1 (8.5 ± 0.2 kg/head) but this increase was insignificant ($P>0.05$).

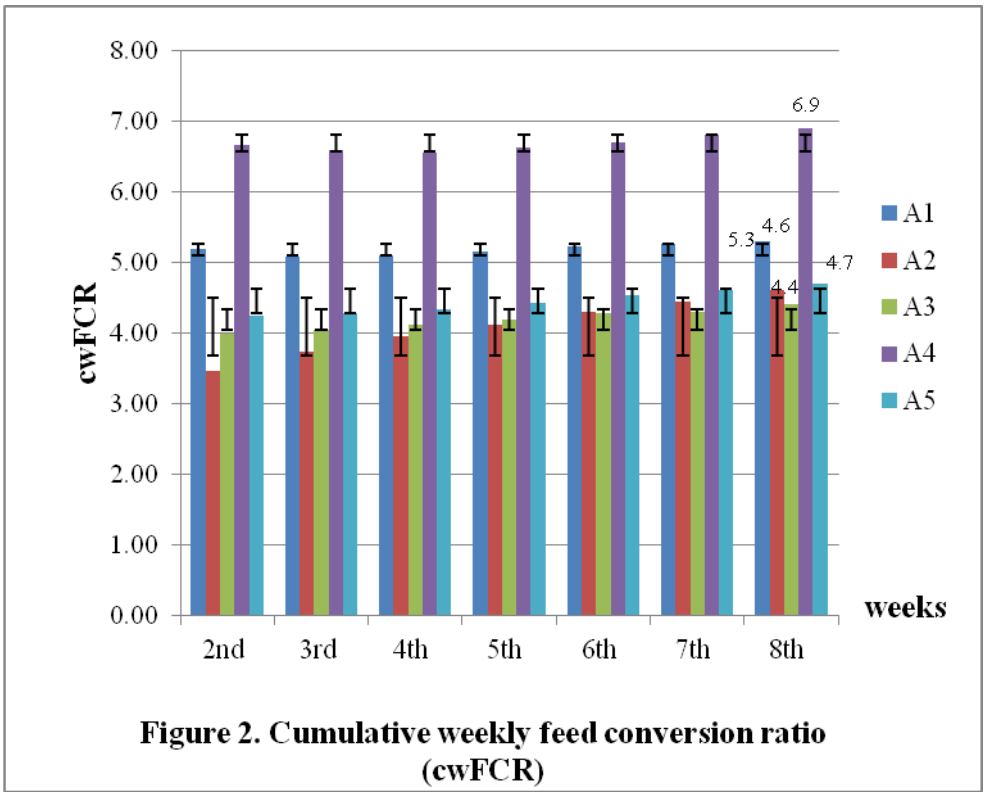

Figure 2. Cumulative weekly feed conversion ratio (cwFCR)

Fig. 2 illustrates the over-all cumulative FCR among experimental groups. The most effective FCR value ($P<0.05$) was recorded in A2 animals (4.6 ± 0.45) in comparison with A1 (5.3 ± 0.14) and A4 (6.9 ± 0.39). Moreover, the least FCR value ($P<0.05$) was observed in animal group A4 (6.9 ± 0.39) in comparison with groups. This can be explained by consuming more feeds to convert them to body weight gain and at the same time getting less live body weights due maybe to the overall effect of antinutritional factors found in fava bean seeds which was included as a sole legume ingredient (100 % FBS) in the basic ration fed to A4 lambs. Moreover, more efficient results were achieved in groups A2 and A3 whose animals were fed a combination of SBM: FBS in different proportions. This can be explained by the findings reported by Miller (1980) that fava bean protein is highly soluble in the rumen and rapidly degraded. Whereas, Emiola and Gous (2011) agreed that Fava bean feeding at various levels did not affect digestibility. However, Fulpagare (1993) concluded that as the level of fava bean increase (from 25 to 100%) in the diet of lambs, the digestibility of dry matter (Ether extract and crude fiber) increase, while that of nitrogen-free extracts (NFE) decreases.

After calculating the cost ($) of FI and LBWG it was found that feeding rations containing 100% FBS exclusive of SBM and 25% FBS in combination with 75% SBM to Awassi lambs is totally unfeasible as in group A4 (1.82 $/1 kg of LBWG) and A1 (1.50 $/1 kg of LBWG). The most efficient and feasible use of FBS was obtained in groups A3 (25 % SBM: 75 % FBS) and A2 (50 % SBM: 50 % FBS) where there cost price was the lowest, 1.19 $/1 kg of LBWG and 1.27 $/1 kg of LBWG, respectively.

Conclusion and recommendations

To simplify our discussion it was concluded, that there are opportunities for researchers to increase animal productivity through the application of appropriate technologies, particularly in production systems, nutrition and feeding potential used of local feed resources for ruminants. Researchers have emphasized the utmost importance of using local feed resources as the key driving force to increase the productivity of animals in Asia (Wanapat, 2009; Wanapat *et al*., 2011).

As it was observed, neither in all our findings including dry fava seed meal (FSM) coarsely grind in combination with the traditional soybean meal (SBM) has no adverse effect neither on live body weight gain (LBWG) and feed intake (FI) nor on feed conversion ratio (FCR). For that reason we recommend a combination of 50% SBM: 50% FBS (as in group A2) or 25% SBM: 75 % FBM (as in group A3) to be included in concentrate rations resulting in higher live body weight gains and feed conversion rate as well as profit. Further investigation is needed to detect the influence of such combinations on mutton quality (chemical and physical) of lambs and goats as well.

Abstract

The fattening study was carried out during May- July of 2017 in "Ghattas goat farm" located in Bziza, North-Lebanon, for 10 weeks and involved 15 intact male kids of the local "Baladi" goat breed after weaning. The trial included a 2-week adaptation period to the diet followed by 8 weeks of fattening by feeding five experimental diets. The goats were at 13-14 weeks of age and had at the beginning of the study 14.90 ± 0.259 Kg of live body weight (LBW). Each animal group Kids (n=3 replicates) was fed with one of the five dietary treatments: Ag1- FBS (Faba bean seeds) partially replaced 25% of the soybean meal (SBM); Ag2 - FBS partially replaced 50% of the legumes (SBM); Ag3- FBS partially replaced 75% of the legumes (SBM); Ag4 - FBS totally replaced 100% of the legumes (SBM) and Ag5 (control) – this ration was composed of 100 % SBM. Apparent feed intake (aFI), live body weight gain (LBWG) and apparent feed conversion ratio (aFCR) were calculated weekly. It was found that dry fava seed meal (FBS) coarsely grind in combination with the traditional soybean meal (SBM) had no adverse effects either on live body weight gain (LBWG) and feed intake (FI) or on feed conversion ratio (FCR). A combination of 25% SBM: 75% FBS (as in-group Ag3) to be included in concentrate ratios resulted in higher live body weight gains and feed retention as well as profit.

Keywords: *Awassi lambs; Faba beans; soybean; body performance.*

Introduction

Faba beans though are less consumed in western countries as human food, it is considered as one of the main sources of cheap protein and energy in Africa, parts of Asia and Latin America, where most people cannot afford meat sources of protein (Duc, 1997; Haciseferogullari *et al*., 2003). The crop is also becoming increasingly important in Saudi Arabia diets due to the high lysine content of the seed, which encourages the use of faba bean as a protein supplement for cereals (El-Fiel *et al*., 2002; Alghamdi, 2003). The need for alternative protein sources to soybean meal (SBM) in domestic animal feeding has recently gained focus. The main reasons include the attempt to limit SBM import from extra-EU countries, which represents a negative voice of the commercial balance; an effort to decrease costs of animal production and contemporarily reduce the loss of N compounds in the environment and the search to prevent the presence of GMO (genetically modified) in the food chain (Wilkins and Jones, 2000; Mordenti and De Castro, 2005; Mordenti *et al.*, 2007). Among the possible protein sources, lupins, peas and faba beans were successfully used in ruminants and non ruminants (Burel *et al.*, 2000; Bonomi, 2005; Masoero *et al.*, 2006; Vandoni *et al.*, 2007). Outstanding among other legumes, faba bean plays a critical role in crop rotations. The nutritional value of faba bean has always been traditionally attributed to its high protein content, which ranges from 27 to 34% (Duc, 1997; Haciseferogullari *et al*., 2003) depending on genotypes. As reported by Hossain and Mortuza (2006) most of these proteins comprise of globulins (79%), albumins (7%) and glutelins (6%). The aim of our experiment was to inspect the influence of replacing totally or partially soybean meal with

faba beans in rations fed to local "Baladi" weaned kid goats on health and some traits of body performance as well as economical feasibility. To our knowledge, the present study is among the firsts to focus on the effect of feeding FBS on body performance in local goat "Baladi" breed in fattening production.

Material and methods

This study was carried out with the approval of an Ethical Review Process and under the Animals (Scientific Procedures) Act 1986. The trial was conducted during May-June months-2017 for eight consecutive weeks on fifteen weaned male kids of local "Baladi" goat kids in Bziza at "Ghattas animal farm" in North-Lebanon, 100 km from Beirut. The experimental animals were distributed randomly into five groups by 3 animals each under typical ecological and management conditions of environment (air speed, humidity and temperature) and fed five experimental rations as shown in Table 1. Good quality wheat straw was fed *ad libitum*; clean fresh water and mineral blocks (lickers) were available all the time inside the animal pens (2 x 2 m^2)**.** Kids with 13-14 weeks of age were used having an average live body weight (LBW) at the beginning of the trial (data collection) of 14.90±0.259Kg. During the preparatory period (2 weeks) of adaptation the animals were ear tagged and vaccinated against Anthrax and FMD; Albendazole was administered as prevention for digestive tract parasites. Veterinary inspection was repeated every week where intramuscular injections of multivitamin dozes (A, D & E) were performed. Each animal-group was fed free choice forage feeds (about 1 kg of wheat straw) and around half kg of the experimental mix-rations. Ag1- FBS (Faba bean seeds) partially replaced 25% of the soybean meal (SBM); Ag2 - FBS partially replaced 50% of the legumes (SBM); Ag3- FBS partially replaced 75% of the legumes (SBM); Ag4 - FBS totally replaced 100% of the legumes (SBM) and Ag5 (control-basic ration- BR) – totally composed of 100 % SBM. All rations were isocaloric (2.9 Kcal/kg ME) and adjusted to the same level of (CP) crude protein (17%) as recommended by NRC (1981) and based on cotton seed meal (CSM), wheat bran and yellow corn, fed continuously with different ratios of Soybean meal (SBM): Dry grind Faba bean seeds (FBS) for the whole experimental period. Data obtained was analyzed using the analysis of variance (ANOVA) procedure of Sigmastat v.3.5 (Jandel corp. 2004) with $P<0.05$ statistical significance of treatment effects. Live body weight gain of each animal (LBWG/head), Feed intake of each animal-group (FI/group) and apparent feed intake of each lamb (aFI/head) and food conversion ratio of each group (FCR/group) and aFCR/head, were weighed and calculated weekly. Animals were fed on the base of 3% of live body weight recalculated as an average after weighing all animals at the beginning of each following week. Interaction of treatment means was tested using the All Pairwise Multiple Comparison Procedures (Duncan's Method) at 5% significance level. Mean±SD (Mean values±Standard Deviation) was used in all obtained statistical studies. Cost price of LBWG obtained ($/1 kg of meat produced) was calculated to explore the feasibility of the study. This level of CP and energy was selected on propose to make it easier to compare the results obtained with those achieved in another fattening trial on Awassi lambs that will study the physical and chemical quality of meat in both trials. Animals were assigned to the following five experimental rations as shown in table 1 below.

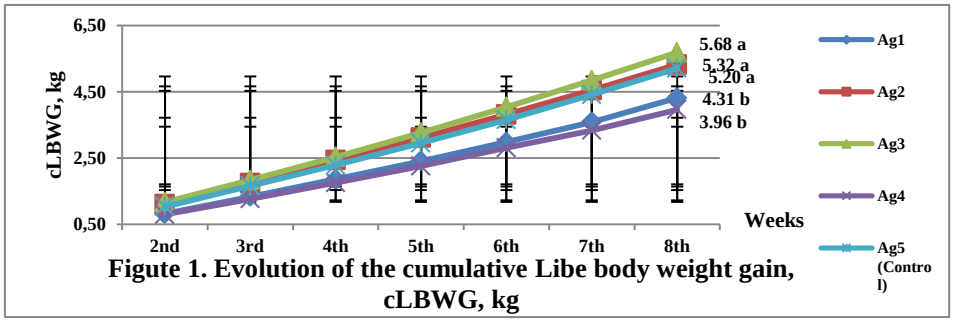
Results and Discussion

The difference in the initial live body weight (LBW) of all experimental animals (14.90±0.26Kg) were statistically non-significant ($P>0.05$) calibrating from 14.77±0.32kg in Ag5 group to 15.03±0.21kg as in-group Ag1.

Table 1. Composition of the experimental rations (% as fed basis) fed to each animal-group with their cost-prices ($/ton)

		Ag1	Ag2	Ag3	Ag4	Ag5 (Control)
Cost price of Ingredients ($/ton)	Ingredients	75% SBM+ 25%FBS	50% SBM+ 50%FBS	25% SBM+ 75%FBS	100% FBS	100% SBM (Basic ration-BR)
600	SBM	11.1	7.4	3.7	0.0	14.8
325	CSM	7.4	10.0	13.0	15.8	5.1
350	FBS	3.7	7.4	11.1	14.8	0.0
150	Wheat bran	16.0	15.0	12.7	12.3	14.7
250	corn	61.7	60.1	59.4	57.1	65.4
	Total	100.0	100.0	100.0	100.0	100.0
	CP	16.8	16.8	16.8	16.8	16.8
	ME Mcal/kg	2.9	2.9	2.9	2.9	2.9
	Cost price of rations ($/ton)	282	276	271	264	291

As for health, no problems were noticed and the animals were in good health. No signs of indigestion or diarrhea or any blood signs in manure were observed. Moreover, the appetite as we noticed in all groups was acceptable where no residues or left behind concentrate mixtures were collected. The amount of concentrate mix fed to animals did not exceed 30 kg/animal group for the whole period of the trial. At the end of 1st week, the apparent daily feed intake (adFI) per animal in all groups averaged to 450g, whereas at the end of 8th week this average value increased to 550-600g. The overall accumulation of feed intake for the whole period of the trial (cFI/head) in-group Ag4 was 27.88kg. Whereas, animals of Ag3 consumed the largest amount (29.58kg). This might be related to the fact that rations fed to animal-group Ag4 did not contain SBM and only 100 % FBS. As SBM increases in rations we observe an increase in feed intake as in Ag1 (28.53 kg), Ag2 (29.24 kg) and Ag3 (29.58 kg). Most probably the inclusion of big amounts in rations fed to goat kids has a negative effect on feed consumption relating this to the anti-nutritional factors contained in Faba bean. Figure 1 shows that, at the end of the trial group Ag3, whose animals fed a ration containing 25% SBM and 75% FBS gained the highest weight gain (LBWG) attaining the level of 5.68±0.49kg ($P<0.05$) in comparison with Ag4 (3.96±0.29kg), and Ag1 (4.31±0.25kg) and insignificantly ($P>0.05$) with Ag5 (5.20±0.75kg) and Ag2 (5.32±0.44kg). Antongiovanni *et al.* (2002), Martinez *et al*. (2004) and Morbidini *et al*. (2005) obtained results similar to ours on young growing lambs fed faba bean seeds (50-60% of the diet) as the sole protein source in concentrate mix increasing daily weight gain, demonstrating the already high protein value of faba beans for growing lambs.



Figute 1. Evolution of the cumulative Libe body weight gain, cLBWG, kg

ab Difference in the mean values with different letters is statistically significant (P<0.05)

Figure 2 illustrates the apparent FCR. The most efficient feed conversion rate (aFCR/head) was recorded in Ag3 animals (5.23±0.45) which was significant (P<0.05) with Ag1 (6.63±0.38) and Ag4 (7.06±0.51) and insignificant (P>0.05) with Ag2 (5.53±0.44) and Ag5 (5.69±0.81).

This can be explained by the overall effect of antinutritional factors found in faba bean seeds which was included as a sole legume ingredient (100 % FBS) in the basic ration fed to Ag4 goat kids. Moreover, results that are more efficient were achieved in groups Ag2 and Ag3 whose animals were fed a combination of SBM: FBS in different proportions.

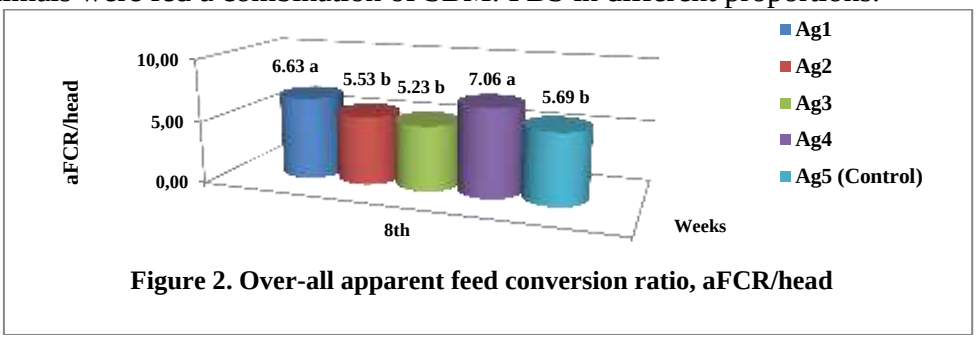


Figure 2. Over-all apparent feed conversion ratio, aFCR/head

ab Difference in the mean values with different letters is statistically significant (P<0.05)

This can be explained by the findings reported by Miller (1980) that faba bean protein is highly soluble in the rumen and rapidly degraded. Whereas, Emiola and Gous (2011) agreed that Faba bean feeding at various levels did not affect digestibility. However, Fulpagare (1993) concluded that as the level of fava bean increase (from 25 to 100%) in the diet of kids, the digestibility of dry matter (Ether extract and crude fiber) increase, while that of nitrogen-free extracts (NFE) decreases.

Duke (1981) suggested the fact that to reduce reliance on imported soybean meal (SBM) in temperate environments, faba bean may be alternative protein sources for small ruminant diets. Faba bean is used as an important source of protein rich food in developing countries and as both food and feed for animals in industrialized countries. Rations containing no SBM like in group Ag4 have negative effect on conversion of meat by eating more feeds and gaining less weight. On the contrast treatment, Ag3 whose animals were fed rations containing only 25% of SBM with 75 % FBS has maximum positive effect on conversion of feeds to meat, this can be explained by the findings reported by Miller (1980) that faba bean protein is highly soluble in the rumen. Whereas, Emiola and Gous (2011) agreed that Faba bean feeding at various levels did not affect digestibility. However, Fulpagare (1993) reported that as the level of faba bean increases (from 25 to 100%) in the diet of animals, the digestibility of dry matter (Ether extract and crude fiber) increase, while that of nitrogen-free extracts (NFE) decreases. Although in the trial conducted by Brand *et al*. (1995) performance was not reduced when faba beans were included at 0.2 kg of the diet, which was in contrast with our findings. Nevertheless, Results obtained by Guillaume (1977), Reddy *et al*. (1985), Wiseman & Cole (1988), Marquardt (1989), Jansman *et al*. (1995) and Knox *et al*. (1995) were in agreement with our findings. Where performance has been reduced by the inclusion of faba beans this has been attributed to the content of condensed tannins and non-starch polysaccharides (NSP) in the seeds. After calculating the cost ($) of FI and LBWG it was found that feeding rations containing 75% SBM: 25% FBS (Ag1) and 50% SBM: 50% FBS (Ag2) to Awassi lambs is especially unfeasible attaining the levels of 1.93 and 1.78 $/1 kg of LBWG, respectively. The most efficient and feasible use of FBS was obtained in groups Ag3 (25 % SBM: 75 % FBS) and Ag4 (50 % SBM: 50 % FBS) where there cost price was the lowest, 1.65 and 1.67 $/1 kg of LBWG, respectively.

Conclusion and Recommendation

To simplify our discussion it was concluded, that there are opportunities for researchers to increase animal productivity through the application of appropriate technologies, particularly in production systems, nutrition and feeding potential used of local feed resources for ruminants. Researchers have emphasized the utmost importance of using local feed resources as the key driving force to increase the productivity of animals in Asia (Wanapat, 2009; Wanapat *et al*., 2011). As it was observed neither in all our findings that included dry faba seed meal (FBS) coarsely grind in combination with the traditional soybean meal (SBM) has no adverse effect neither live body weight gain (LBWG) and feed intake (FI) nor on feed conversion ratio (FCR). We recommend a combination of 25% SBM: 75% FBS (as in-group Ag3) to be included in concentrate rations resulting in higher live body weight gains and feed retention as well as profit.

Abstract

An experiment was conducted in 2017 to test the effect of using thyme, peppermint and their combination in the broiler diet on the performance of the birds. 250-one day old unsexed Ross chicks were divided randomly into five groups. For the first 19 days, all chicks were fed with the same starter basal diet (BD) without antioxidants and antibiotics. At age of 20 days, groups were subdivided into three replicates. Group I was fed on a basal diet free of any antibiotics and antioxidant, group II was fed on a basal diet and 15mg/kg of virginiamycin and commercial antioxidant, group III was fed on a basal diet without antibiotics and antioxidants supplied with 10g/kg peppermint meal, group IV was fed on BD without antibiotics and antioxidants supplied with 10g/kg thyme meal, group V was fed on BD without antibiotics and antioxidants supplied with a mixture of 5g/kg peppermint and 5g/kg thyme meals. As a result of the experiment all groups showed higher results compared to group I that have been fed BD without any additives. However group III recorded the highest live body weight (1219.4g) only through the growing period. Based on the overall period of the experiment, from day 1 till slaughter age, the feed conversion ratio (FCR) did not indicate any significant difference between the different groups. However, group III recorded the most effecient FCR (1.27) and group I had the worse (1.45). In conclusion, this experiment showed promising potential of thyme and peppermint as natural growth promoters.

Introduction

Farrell (2013) reported that, due to the ever increasing demand, the poultry sector is probably the fastest growing market between live stocks especially in the last 15 years in countries of all different income levels. During the past few decades, Petracci *et al.* (2015) also observed a notable increase in the demand for poultry meat due to its low cost, good nutritional profile and suitability for further processing. However, antibiotics used in food animals for treatment, disease prevention or growth promotion, allows resistant bacteria and resistant genes to spread from food animals to humans through the food chain. This is why the use of antibiotics as growth promoters is being banned in several countries and natural product to replace these growth promoters were subject to many studies and experiments. Herbs and spices had shown strong potential as alternatives to antibiotics. Many plant products and their constituents have a broad antimicrobial activity and antioxidant properties. Scientists discovered that the performance of broiler production could be enhanced by the appetizing and stimulating effect of herbs and their extracts on the animal digestive system (Salih and Gurbuz, 2015). Therefore, the aim of this study is to investigate the impact of natural herbs (Peppermint and Thyme) as phytogenic compounds on feed intake, growth rate, feed conversion ratio, carcass production, breast cuts and physical quality of some edible internal visceral organs on broiler production during the growth period.

Materials and methods

A total of 250 one day-old unsexed broiler chicks (Ross breed) were used for 31 days in an opened poultry house in Lebanon. The birds were housed on floor and routinely managed as any other commercial broiler flock. Chicks were randomly allotted into 5 treatments by 50 in each until slaughter (10 birds/1m^2). Chicks in 1st phase (starter period 1-19 days) were kept in an area fenced with a circular cardboard (40 cm height) and littered with wood shavings and equipped with bell drinkers and feed troughs. Water and feed were offered *ad libitum*. A continuous light program was provided by incandescent 75- Watt Tungesten pulp lamps to achieve light intensity between 5-10 lux at floor level. All diets were formulated to meet minimum nutrient requirements established by the NRC (1994). Vitamin and mineral Premix were provided to basic diet (BD). The birds were vaccinated at hatching and growing period due to a programmed schedule against Marek's and Newcastle diseases, Gumboro and Infectious Bronchitis. General health status of the birds was checked daily and number of dead chicks was recorded per pen at 19 and 31 days of age. Antibiotic-free and antioxidant-free BD in mash form based on yellow corn-soybean meal mixture (230 g CP/kg and 13.1 MJ ME/kg), was offered *ad libitum* to all chick groups in the 1st starter phase (0-19 days) whereas, grower diets (2nd phase, growth period: 20-31 days) were fed with 210 g CP/kg and 13.4 MJ ME/kg distributed as follow:

- Control diet (I) - BD antibiotics-free and antioxidants-free;
- Control diet (II) - BD with antibiotics and antioxidants supplementations;
- Group (III) - as in control diet I supplemented with 10g/kg peppermint meal;
- Group (IV) - as in control diet I supplemented with 10g/kg thyme meal;
- Group (V) - as in control diet I supplemented with a mixture of 5g/kg peppermint and 5g/kg thyme meals.

Average live body weight (LBW) at 19 days of age was calculated by weighing from each group 3 batches by 3 birds each, where the average from each batch was recorded and then the total average of the 3 batches was registered. At 31 days of age, 3 batches by 3 birds from every replicate were weighed before and after slaughter by vein incision till complete bleeding after which the feather was manually plucked and the troops eviscerated to get carcass weight. Breasts (left and right) were cut and then heart and liver removed and weighed. Feed intake (FI), rate of body weight gain (LBWG) and feed conversion ratio (FCR) were calculated at the end of each feeding period (19 and 31 days of age). One way analysis of variance (ANOVA) of the results was applied to evaluate the statistical differences between the treatments using "Sigmastat software V. 3.5". The results were presented as Mean values ± SD. Significant effects were further explored using Tukey's multiple range tests to assert the interaction among treatment means. A significance level of $P<0.05$ was used.

Results and Discussion

The mortality in the first period varied from 3.9% in group V to 5.9% in groups I and II and 7.8% in groups III and IV. Since all the birds were fed the same antibiotic-free and antioxidant-free basal diet, mortality rate can be attributed to management and breeding factors. 100% livability was observed at the end of the second physiological phase in groups III and IV followed by group V (98%) and I (97.9%). The highest mortality rate (%) was attained in treatment group II (4.2%) fed with antibiotics-antioxidants basal diets. The average feed intake (FI) at 19 days of age (end of starter period) of the broiler chickens was 657.14g where no feed rejection was noticed, and remaining was negligible. The appetite of the birds was good and the same for all birds of all groups. No significant difference was noted between the different replicates, which may reflect that the distribution of all treatments was not affected by environmental or external elements that might interfere in the performance of the birds in replicates (wind, sun light, temperature, humidity). For the first 19 days of age

where all birds where on the same starter basal diet, the highest and least efficient use (P>0.05) of feeding basal diet also known as feed conversion ratio (FCR) was observed in group III (1.4) followed by group II (1.33), group IV (1.27) and group I (1.22). Group V showed the lowest FCR (1.18) in the mean values. The FCR calculated in the period from the 20th day until the end of the experiment showed significant difference (P<0.05) between treatments of the group I (average of the 3 replicates: 1.58) and group III fed with the addition of peppermint (1.11), but did not differ from the groups II (1.30), IV (1.31) and V (1.57). These results confirmed the ones from Abdulkarimi *et.al* (2011), as they noted that FCR improved by adding thyme in drinking water, and matched with the results of El-Ghousein *et al.* (2009) that formulated diets by adding 0.5, 1.0, 1.5 and 2.0% of crushed thyme. Rahimi *et.al* (2011) showed similar results as the addition of plant extracts showed significant difference in broiler performance. This could be due to the volatile oil components of thyme (thymol, carvacolo, borneol and geraniol). Thymol is the most important and primary volatile oil of thyme. Those oils and components of thyme affect the performance of the digestive system by enhancing the secretion of enzymes and endogen (amylase and chemotripsin). By this, the absorption rate of the intestine will increase and will positively affect the FCR and general performance of the birds (Feizi *et.al*, 2013). On the overall period of the experiment, from day 1 till slaughter age (Fig. 1), FCR did not indicate any significant difference between the different groups. However, group III did register the lowest FCR (1.27) and the control group had the highest FCR (1.45).

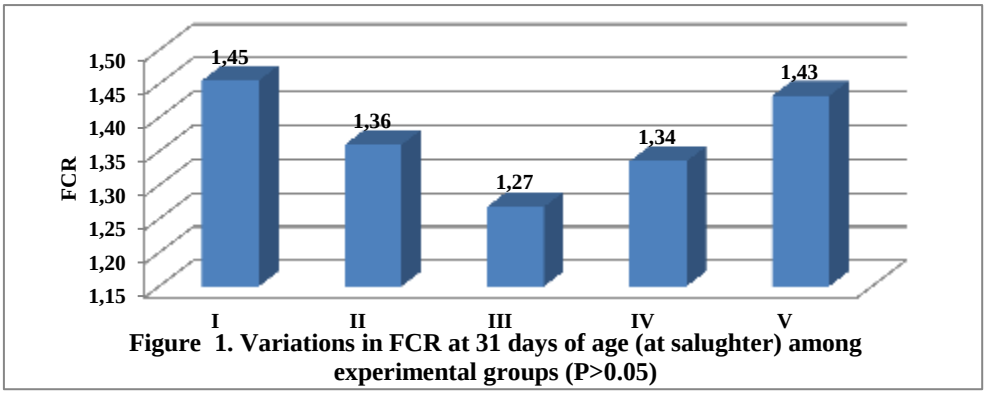

Figure 1. Variations in FCR at 31 days of age (at salughter) among experimental groups (P>0.05)

These results match with the experimental out coming of Hernandez *et.al.* (2004) and Bölükbaşi *et.al.* (2006) that both concluded that the addition of thyme and herbals did not affect significantly the performance of broiler chickens. In contradiction, Al-kassie (2009) reported significant difference between different groups and the addition of thyme. The average weight of one-day old chick was 42.02 ± 0.103g with no significant difference (P>0.05) among the five experimental groups. No significant difference was found between all groups at 19 days of age. However, in the mean values of all replicates for each group, the birds of group V recorded the highest live body weight on average 562.5g. At 31 days of age-End of growth period (slaughter), no significant difference was indicated between the five groups (P>0.05). All groups showed better average LBW (Fig. 2) compared to group I (1132.8g) that have been fed a basal diet without any additives, where group III (with the addition of peppermint) recorded the highest live body weight on average 1219.4g followed by group II (1200g), group V (1192.8g) and group IV (1171.7g).

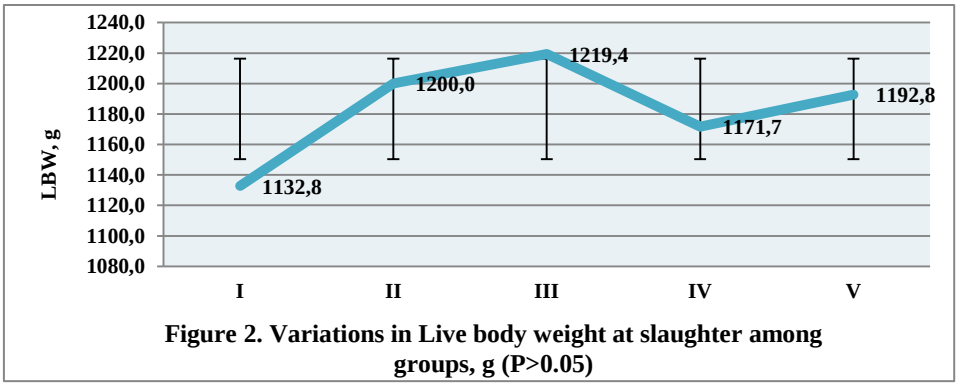

Figure 2. Variations in Live body weight at slaughter among groups, g (P>0.05)

At the end of the starter period, live body weight gain (LBWG) did not differ significantly among the average of replicate groups (P>0.05). However group V recorded the highest values of LBWG (562.5g) at 19 days of age. For the growth period, group III showed a better weight gain throughout the whole experiment (748.7g) and the control group (I) had the lowest mean values among the groups (591.2g). The net weight after slaughter (Fig. 3) without blood, feather, heads, legs and viscera did not show any significant difference between the groups. However, group II fed with an addition of antibiotics recorded the highest average 75.5 % compared to the other groups (around 72%).

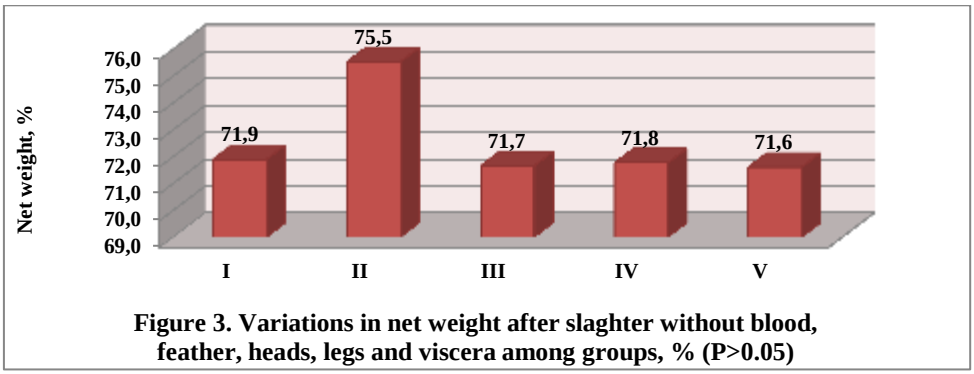

Figure 3. Variations in net weight after slaghter without blood, feather, heads, legs and viscera among groups, % (P>0.05)

The mean values of the five groups for the weight of the edible organs (liver and heart) of the slaughtered birds recorded almost similar percentage to the net weight; 3.9%, 3.9, 4.0, 3.7 and 3.9% for groups I, II, III, IV and V respectively. The variation in breast weight (left+right) after slaughter (Fig. 4) among the average of replicate-groups according to the percentage to net weight did not show significant difference between groups (22%, 21.7, 21.3, 21.2 and 21% to net weight in groups III, V, II, I, IV respectively).

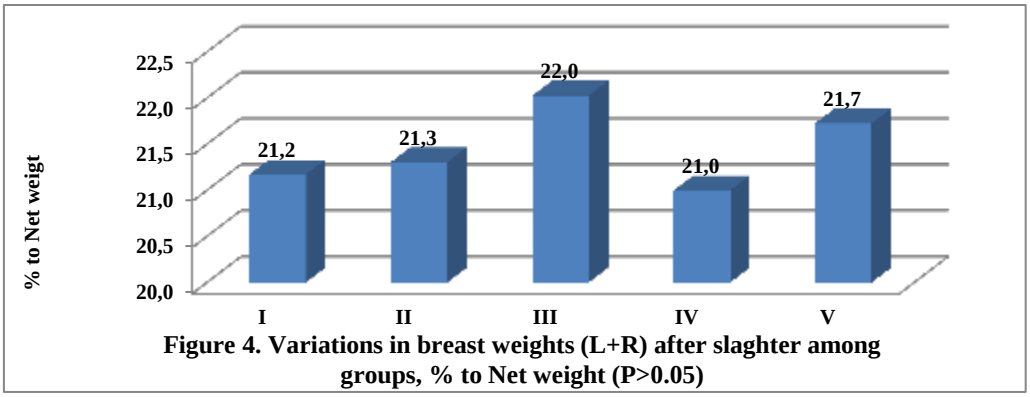

Figure 4. Variations in breast weights (L+R) after slaghter among groups, % to Net weight (P>0.05)

These outcomes differ from the results of Al-Kassie *et al*. (2010) that showed a significant difference between the average live body weight, live body weight gain, weight of edible organs and breast weight.

Conclusion

The results of this study demonstrated that all groups showed higher results compared to group I that have been fed BD without any additives. However group III recorded the highest live body weight only through the growing period. Based on the overall period of the experiment, from day 1 till slaughter age, the FCR did not indicate any significant difference between the different groups. However, group III recorded the most efficent FCR and group I had the worse. In conclusion, this experiment showed promising potential of thyme and peppermint as natural growth promoters.

Abstract

Two hundred fifty day-old broilers (Ross breed) were divided into five equal treatment-groups fed five assigned diets: Control Group CG-I (antioxidants-free and antibiotics-free basic diets -BD), CG-II (BD supplemented with antioxidants and antibiotics only, group-VI (1% Rosemary dry meal added to BD), group-VII (1% Chamomile flowers dry meal added to BD) and group- VIII (1% mixture of 0.5% Chamomile and 0.5% Rosemary). Average live body weight (LBW) at 19 days of age was calculated by weighing from each group 3 batches by 3 birds each, where the average from each batch was recorded and then the total average of the 3 batches was registered. At 31 days of age, 3 batches by 3 birds from every group were weighed before and after slaughter by vein incision till complete bleeding after which the feather was manually plucked and the troops eviscerated to get carcass weight. Breasts (left and right) were cut and then heart and liver removed and weighed. The highest and the lowest Feed Intake (FI) averages ($P<0.05$) were noticed in groups VII (1020±26.5) and VI (833.3±58.6 g/bird) where birds were fed on BD with 1% herb dry meal mix, respectively. Better numerical result of Live body Weight (LBW) at slaughter was achieved in group VI (1121.1 ± 79.5 g). Better numerical results in LBWGain was obtained in groups VI followed by II, VIII, VII, and I by 719.5±60.15, 704.2±97.63, 672±2.93, 642.5±173.3 and 591.2±46.85 g, respectively. The best rate of LBWG regarding feed intake was significantly ($P<0.05$) observed at slaughter in group VI (1.25±0.05). Best % NW (net weight) to slaughter weight was achieved in treatment II (75.5±1.2%) followed by groups VII (72.3±1.6), I (71.9±3.1), VI (71.6±2.3) and VIII (68.7±8.5%). Identical results of liver + heart (%) to NW were ranging between 3.9±0.56 and 3.1±0.86%. Breast weights (%) to NW were insignificantly different ($P>0.05$) and almost the same, ranging from 21.9±0.96% to 21.2±0.64%. The results showed that 1% Chamomile and 1% Rosemary could be considered as a potential growth promoters for poultry.

Introduction

Nowadays, the aim of the poultry industry is to maximize the health and well-being of the birds and minimize the impact of the industry on the environment. The broiler meat should be of satisfactory nutritive quality and acceptable to most consumers with respect to price and its organoleptic traits. The use of feed additives has been an important part of achieving this success since they improve the efficiency of the bird's growth and/or laying capacity, prevent disease and improve feed utilization. However, in poultry diets, these additives primarily included antimicrobials, antioxidants, emulsifiers, binders, pH control agents and enzymes. Iji *et al*. (2001), Issa and Abo Omar (2012) noted that the use of antibiotics as growth promoters is facing serious criticism. There are some important reasons that restrict the use of antibiotics such as the drug resistance in bacteria and the drug residues in meat (CAFA, 1997). To overcome the poor performance and increase susceptibility to diseases resulted from removal of antibiotics from birds diets, attempts were made to find other alternatives. Moreover, after

the European Union (Castanon, 2007) banned the use of antibiotics as growth promoters, researches were held to find alternatives that would be efficient in poultry. Herbs and their extracts showed potential feed additives and natural alternatives as replacements in growing flocks, especially under conditions of average management and quality (Cross *et al*, 2003; Lewis *et al*., 2003; Hernandez *et al.*, 2004). Odoemelam *et al*. (2013) observed that there are strong indications that herbs, spices and their products exert antioxidative, antimicrobial and growth promoting effects in livestock. Therefore, the aim of this trial is to study the impact of feeding broiler chicks basal rations free of antibiotics and antioxidants mixed with Rosemary dry meal, Chamomile flowers dry meal and their combination on body performance during growth period. The feed intake, growth rate, feed conversion ratio, carcass production, breast cuts and physical quality of broiler meat were measured.

Materials and methods

This study was carried out with the approval of an Ethical Review Process and under the Animals (Scientific Procedures) Act 1986. A total of 250 one day-old unsexed broiler chicks (Ross breed) were used for 31 days in an opened poultry house in Lebanon. The birds were housed on floor and routinely managed as any other commercial broiler flock. Chicks were randomly allotted into 5 treatments by 50 in each until slaughter (10 birds/1m^2). Chicks in 1st phase (starter period 1-19 days) were kept in an area fenced with a circular cardboard (40 cm height) and littered with wood shavings and equipped with bell drinkers and feed troughs. Water and feed were offered *ad libitum*. A continuous light program was provided by incandescent 75- Watt Tungesten pulp lamps to achieve light intensity between 5-10 lux at floor level. All diets were formulated to meet minimum nutrient requirements established by the NRC (1994). Vitamin and mineral Premix were provided to basic diet (BD). The birds were vaccinated at hatching and growing period due to a programmed schedule against Marek's and Newcastle diseases, Gumboro and Infectious Bronchitis. General health status of the birds was checked daily and number of dead chicks was recorded per pen at 19 and 31 days of age. Antibiotic-free and antioxidant-free BD in mash form based on yellow corn-soybean meal mixture (230 g CP/kg and 13.1 MJ ME/kg), was offered *ad libitum* to all chick groups in the 1st starter phase (0-19 days); whereas, grower diets (2nd phase, growth period: 20-31 days) were fed with 210 g CP/kg and 13.4 MJ ME/kg distributed as follow:

- Control diet (I) - BD antibiotics-free and antioxidants-free;
- Control diet (II) - BD with antibiotics and antioxidants supplementations;
- Group (VI) - as in control diet I supplemented with 1% Rosemary dry meal;
- Group (VII) - as in control diet I supplemented with 1% Chamomile dry flowers meal;
- Group (VIII) - as in control diet I supplemented with 1% of mixed meals (0.5% Rosemary dry meal+0.5% chamomile dry flowers meal).

Average live body weight (LBW) at 19 days of age was calculated by weighing from each group 3 batches by 3 birds each, where the average from each batch was recorded and then the total average of the 3 batches was registered. At 31 days of age, 3 batches by 3 birds from every replicate were weighed before and after slaughter by vein incision till complete bleeding after which the feather was manually plucked and the troops eviscerated to get carcass weight. Breasts (left and right) were cut and then heart and liver removed and weighed. Feed intake (FI), rate of body weight gain (LBWG) and feed conversion ratio (FCR) were calculated at the end of each feeding period (19 and 31 days of age). Statistical analyses were conducted using "Sigmastat V. 3.5" (Systat Software, 2007) to evaluate significant differences between treatments and replicate means. Significant effects were further explored using Tukey's multiple range tests to ascertain differences among treatment means. A significance level of $P<0.05$ was used. Results are illustrated as means (X) ±Standard Deviation (SD).

Results and discussion

Daily observations showed no problems in chicks health. The birds had good stature, very few leg weaknesses and showed no symptoms of diseases or feed deficiencies. The highest rate of mortality during the 1st phase was in groups II and VI (6%) followed by group I (5.9%). The lowest level of 2% was recorded in groups VII and VIII. Since all the birds were fed the same antibiotic-free and antioxidant-free basal diet, mortality rate can be attributed to management and breeding factors. Yassin *et al*. (2009) concluded that there is interrelation between 1st week mortality at broiler farms and management factors at breeder farms (like the breeder age, strain, and feed company of the breeder farms) and at hatcheries (like egg storage management, hatching management, and season). Additionally, the potential of a chick to survive the first week is directly related to the quality of the day-old broiler. The day-old chick quality depends on the genetic line of the breeders, breeder age, egg weight, egg storage conditions and duration, and incubation conditions such as temperature, humidity, gas levels, and altitude (Peebles *et al*., 1999; Vieira and Moran, 1999; Decuypere *et al*., 2001; Tona *et al*., 2004, 2005). Mortality was lower during 2nd phase (growing period) in groups II (4.2%) and I (2.1%) and higher in groups VI (6.4%), and the same as in 1st phase for groups VII and VIII by 2%. This reduction in broilers' mortalities could be explained by improvement in birds general performance and better build up of the immunity. The overall mortality (%) for both periods (1-31 days of age) averaged to 10, 12, 7.8, 4 and 4% in groups II, VI, I, VII and VIII, respectively. FI, g/bird was calculated as average for the five groups and was equal to 657.14 g/bird for the 1st phase- starter period. During the 2nd phase- growth period (20-31 days), average FI/bird of different replicates was calculated in each group resulting in almost equal ($P>0.05$) amounts of feeds (910-930 g/bird) in groups VIII, II and I. The highest and the lowest averages ($P<0.05$) of FI was noticed in group VII (1020±26.5 g/bird) and VI (833.3±58.6 g/bird) whose birds were fed basal diet with 1% Chamomile and 1% Rosemary dry meals, respectively. Feed consumption was significantly ($P<0.05$) increased (VI, VII) in the grower phase. It may be attributed to flavoring effects of 1% Rosemary (VI) and 1% Chamomile (VII) which improve the palatability of feed due to the chemical components and flavor of the chamomile flower as compared to I and II (control groups). These results are in accordance with those of Bassett (2000), Langhout (2000), Kamel (2001), Williams and Losa (2001) and Hernandez *et al*. (2004) who found that feed intake was increased with addition of essential oils derived from spices and herbs. In addition, this improvement in feed consumption may be due to the appetizing effect of active ingredient (borneol) in rosemary (Cabuk *et al*., 2003) and Chamomile (azulene, flavonoid and coumarin glycosides and fatty acids) giving anti-inflammatory, antiseptic, carminative, diaphoretic, sedative properties (Panda, 2005). Chamomile flowers inhibit the harmful intestinal microorganisms, thus counter acting excessive growth (Kolacz *et al.,* 1997). At 19 days of age (end of starter period), the variation in the average LBW was insignificant ($P>0.05$). Moreover, at 31 days of age (end of growth period), no significant differences was observed too ($P>0.05$) among replicates of each treatment where, the lowest LBW obtained was in group VII whereas, the highest average was in group I attaining the levels 1030g and 1186.7g respectively. In addition, the mean values obtained show that among all groups, better results ($P>0.05$) were achieved in birds LBW of group VI (1121.1±79.5g) followed by groups II (1200±104.1g), I (1132.8±47g), and VIII (1116.7±54.9g). The results in group VI may be due to active compounds that are presented in rosemary green meal inhibiting the excessive growth of harmful intestinal microorganisms; this may positively affect poultry health and productivity. This is in support with results obtained by Kolacz *et al*. (1997), AL-Kassie (2008), Osman *et al*. (2010), Sarker *et al*. (2010) that showed a significant improvement of LBW due to the main constituents of the herbs and their essential oils which are responsible for the bulk of the antimicrobial activity (Abaza *et al.,* 2003; Cross *et al*., 2007). It is worthy to mention that the

highest LBWG was achieved in group I whose birds were fed antobiotics-free and antioxidants-free basel diet and the lowest in group II where birds received basal diet supplemented with antibiotics and antioxidants. Data obtained on LBWG at 31 days (during the growth period) of age of replicates among all groups did not show any significant difference (P>0.05), but the highest average (816.7 g) was in group II and the lowest (444.2 g) in group VII. Better numerical results in LBWG was obtained in groups VI followed by II, VIII, VII and I by 719.5±60.15g, 704.2±97.63g, 672±2.93g, 642.5±173.3g, and 591.2±46.85g, respectively. These results agree with the obtained data achieved by Spernakova *et al*. (2007) who reported that the addition of rosemary powder at 500 mg/kg in poultry diets gave higher LBWG compared to an unsupplemented control group. At 19 days, apparent mean values of FCR/bird among all treatments had no significant diffrences (P>0.05) whereas, the least effective supplementation was obtained in group II (1.38) and the most effective treatment in VII (1.25). The best apparent mean values of FCR among treatment-groups in ascending order (P>0.05) were observed in groups I (1.22±0.08), VII (1.25±0.11), VIII (1.27±0.08), VI (1.31±0.0001) and II (1.38±0.05) where no supplementaion of neither antibiotics nor antioxidants was added to the BD. At the end of growth period (20-31 days), the best rate of body gain to feed intake was significantly (P<0.05) observed in group VI (1.13±0.07) where Rosemary was added to BD in comparison with groups I (1.58±0.08), VII (1.74±0.18) and VIII (1.54±0.08) and insignificant (P>0.05) in group II (1.30±0.14). FCR was improved significantly (P<0.05) with the addition of Rosemary dry meal if compared to FCR of the control diets. In grower phase, there was significant reduction (p<0.05) in FCR in groups VII and VIII where chamomile flower and a mixture of Rosemary and Chamomile were added. The improvement of LBWG and FCR are due to the effect of some active compounds included in chamomile flowers which had antimicrobial, antifungal, antioxidant and anti-inflammatory effects against microorganisms (Santurio *el al*., 2007). No significant (P>0.05) difference in the percentages of carcass NW in relation to LBW at slaughter among all replicates of the same treatment. Best numerical NW% was achieved in treatment II (75.5±1.2%) followed by groups VII (72.3±1.6%), I (71.9±3.1%), VI (71.6±2.3%) and VIII (68.7±8.5%) where birds were treated with a mixture of Chamomile and Rosemary meals. No significant differences (P>0.05) was obtained in the average percentage of liver+heart in relation to LBW at slaughter among all treatments. Identical results were obtained in groups I, II and VII with a very small numerical difference between groups VII and I attaining the levels of 3.9±0.56%, 3.9±0.35%, 3.9±0.39%, 3.6±0.31% and 3.1±0.86%, respectively. The results obtained about average percentage of breast (Left+Right) weight in relation to carcass NW were insignificantly different (P>0.05) and almost the same where it calibrated from 21.9±0.96% (treatment VII) and 21.8±0.9% (treatment (VIII) to 21.2±0.64, 21.3±0.73 and 21.4±1.44 % in treatments I, II and VI, respectively. These results were similarly reported by Ayad and Naji, (2007). The addition of 1% Rosemary dry meal, 1% Chamomile flower meal and 1% mix of both meals to the BD showed no significant increase in weight of breast, liver and heart compared with other treatment group. It is suggested that such promoters might be used in broiler diets, since they do not interfere negatively on the yield of the most commercialized edible cuts (Net carcass weight, breast and liver and heart).

Conclusions

The objective of the present study was to compare the effects of the supplementation of herbal natural feed additives to soybean-corn-based broiler diets on growth performance and carcass parameters. The results of trial demonstrate that the addition of 1% Rosemary and 1% Chamomile flowers meals have a potential to enhance the performance of broiler chickens. Even though most of the traits did not show significant difference in this experiment, but still

positive results were recorded compared to the control group, which can highlight that those herbs can be included in broiler feeding rations and replace antibiotics as growth promoters. It is highly recommended to use 1% Rosemary and 1% Chamomile flowers meals as a supplementation to 100 kg of basal diets in the daily feeds of broiler chickens in the growing period.

Abstract

The data from the records obtained of the herd books of the Research Institute of Mountain Stockbreeding and Agriculture in Troyan (Bulgaria) for the pregnancy and birth of 148 goats of Bulgarian White Diary were used to determine the influence of sex and the type of birth of kids on the gestation length of the same goats. Kidding was in February and March during the period 2017-2018. Very low variation in the gestation length of the Bulgarian White Dairy goats was established, depending on the parity, the birth weight of the kid, the sex and the type of birth.There was a difference in the average gestation length between goats kidded single and goats kidded twins. The average gestation length for all single born kids was 151.8 ± 0.4 days and for the twins was 150.8 ± 0.3 days. There was no significant difference between the gestation length between males and females single born kids (151.9 ± 0.6 days for males and 151.7 ± 0.7 days for females, respectively). There was a difference of 1 day between the gestation length for the male and female twins (male 150.3 ± 0.7 days and female 151.3 ± 0.6 days, respectively). Gestation length in twins with different sex continued on average 150.9 ± 0.4 days.

Keywords: *Goats, Gestation length, Sex, Type of birth.*

Introduction

The Bulgarian white dairy goat (BWD) originates from local goats improved with Saanen bucks imported from abroad. Its breeding began in 1970 and was recognized as a breed in 1992. The Bulgarian white dairy goat represents a major part of the population of goats grown in the plains and foothill regions of Bulgaria. Because of that, the goats of this breed are of interest to the research. The gestational length (GL) is a physiological variable of economic importance in the most domestic species. (Satue et al., 2011). It is a predestined characteristic for each animal species but can vary within certain limits within the breed. The influence of nutrition on foetal development during certain months of pregnancy tends to shorten or lengthen the gestation period, but the variation due to this factor is only 1.5 days (Riera, 1982). Hafez (1993) considered that the genotype of the foetus accounts for almost two thirds of the variations in gestation length of sheep; male lambs are carried longer than female lambs, spring-born lambs longer than fall-born lambs, and singles longer than twins. The gestation length for sheep and goats varies between breeds and individuals. In sheep, the early maturing breeds and the highly prolific breeds have shorter gestation periods than the slow maturing wool breeds. According to Satue et al. (2011) the management of a flock demands precise prediction of the moment of parturition. The inability to accurately predict the timing of parturition increases additionally the expenses for labour, as well as for veterinary and there is higher risk for the animals. The aim of the present study was to determine the influence of sex and type of birth of the kids on the gestation length of the Bulgarian white goat breed.

Material and Methods

The study was conducted in a herd of goats that are raised at the Research Institute of Mountain Stockbreeding and Agriculture in Troyan, Bulgaria. The records from the herd books for the pregnancy and birth in 2017 and 2018 of 148 goats of Bulgarian White Diary breed were used.

Kidding over the years was in Febuary and March. 62 of the goats kidded single, 40 male kids and 22 female kids. 86 goats gave birth to twins, 22 goats gave birth to male twins, 16 goats gave birth to female twins and 48 goats gave birth to twins with different sex. The goats which have delivered three and more kids are excluded from the data analysis because of their little number. During the winter period (pregnancy and kidding) the animals were raised at the cattle shed and fed with ration of 1,5 kg hay, 1 kg silage and 0.5 kg of concentrated fodder per head. In the summer period the animals were grazing freely and were fed with concentrate fodder 0.4 kg per head twice daily, during their milking using milking parlour. Free access to water and salt was provided. All animals were kept together to eliminate any possible pen effect and were moved to individual pens immediately after parturition. Goats were mated "by hand" and every copulation was marked in a mating notebook. The gestation length is reported from the date of mating to the date of kidding. Right after kidding the weight of the kid is measured with digital scales and written down. The gestation length of the goats is examined against the sex and the type of birth of the kid.

Data are presented as mean value and error of the mean. The results are processed by using MS Office Excel.

Results and Discussion

The gestation length of the goats is presented on the Table 1 according to sex and type of birth.

Table 1. The gestation length of the goats according to the sex and the type of birth.

	No. of observations	Gestation period (days)	Litter weight (kg)
single birth	62	151,8 ± 0,4	4±0,1
single male	40	151,9±0,6	4,1±0,1
single female	22	151,7±0,7	3,8±0,1
twins birth	86	150,8 ± 0,3	6,7±0,1
male tweens	22	150.3 ± 0.7	6,7±0,2
female twins	16	151.3 ± 0.6	6,6±0,3
twins with different sex	48	150.9 ± 0.4	6,8±0,2

Our results show that the gestation length of the goats kidded single in comparison with the goats kidded twins is longer by 1 day. If we compared the gestation length of the goats kidded male and female single kids, we would observe that there was no difference between them. However, we could observe that there was a difference between goats kidded female twins and goats kidded male twins. Goats kidded male twins had a shorter gestation length (150,3±0,7 days) than goats kidded female twins (151,3±0,6 days). The results mentioned by Karua and Banda (1990) in their study of goat crosses with Saanen bucks show that there is no significant difference in the gestation length between males and females. Gestation length in dams kidding single kids (147.14±2.86 days) was about the same as in dams kidding multiple kids (147.09±3.05 days). Similarly, the gestation length in those kidding male kids (146.94±2.7 days) were the same as those kidding female kids (147.34±2.98 days). The results therefore were in agreement with Asdell (1929) that gestation length is not affected by

litter size and sex of kid.

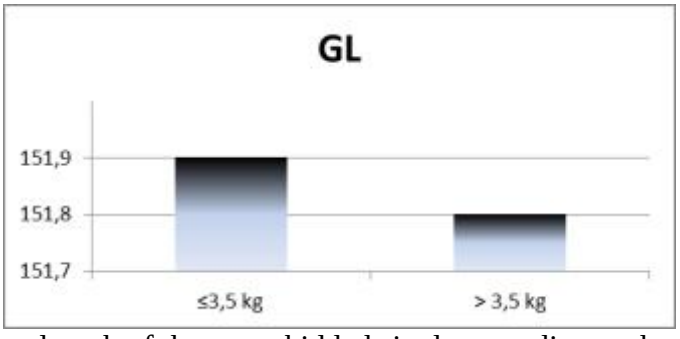

Figure 1. The gestation length of the goats kidded single according to the weight of the kids.

The gestation length of the goats kidded single with weight up to 3.5 kg and goats kidded single with weight above 3.5 kg is presented on Figure 1. As it is clear, the difference is quite negligible. This indicates that birth weight of kids does not influence on the gestation length of the goats kidded single.

Table 2. The gestation length of the goats according to the sequence of the kidding and the type of birth.

The gestation length (days)	Parity				
	I	II	III	IV	V - VII
single birth	152,2±0,8	154,2±0,7	151,6±1,6	151,6±1,1	152,2±1,1
twins birth	149,5±0,6	150,5±0,6	151,0±0,6	151,8±0,8	151,6±0,7

From the point of view of the parity (Table 2), the goats that have a second pregnancy with one kid have the longest gestation length which coincides with that found by Hoque et al. (2002) for goats of three breed groups. Goats kidded twins at the first birth had the shortest gestation length. There was no difference in gestation length between goats kidded single on the first birth and goats kidded single on the fifth birth. Our data show that with the aging (parity) of the goats kidded twins the gestation length increases and the forth kidding was 1 day longer. This trend coincides with that found by Hafez (1993) namely that the increase in the age of goats increases the gestation length. According to Asdell (1929) there was a distinct difference in the gestation length for young and older dams. This is related to the age of the dams and not to the order of the births. Gestation is shorter in the young animals than in the older according to the author.

Conclusions

It was established that the gestation length of the goats of Bulgarian White Diary breed was relatively constant value and it was observed that very low variation in the gestation length, depending on the parity, the birth weight of the kid, the sex and the type of birth.

With increasing the parity of the goats kidded twins the gestation length increased and the forth kidding was 1 day longer.

The gestation length of the goats kidded single was longer than the goats kidded twins by 1 day.

As conclusion, the results of our study can be useful for optimizing the work process in the farms.

THE IMPACT OF DIFFERENT PROTEIN CONTENT OF POLLEN ON HONEY BEE (*Apis mellifera* L.) PRODUCTIVITY

Zheko RADEV

Researcher, Belozem, Bulgaria
*Corresponding author: zhekoradev@abv.bg

Abstract

The objective of the study was to investigate the impact of the protein content of pollen on the productivity of the honey bee (*Apis mellifera* L.). The protein content of the pollen influenced the productivity of the honey bees. The productivity of the bee colonies is higher, when honey bees collect pollen with higher protein content. The protein should be taken into consideration as an essential factor influencing the productivity of honey bee colonies. The pollen collected in different periods of the year has a different protein value for honey bees. The protein content in the examined samples throughout the three seasons ranged from 13.9% to 27.8%, and the average value was 20.9%. During the period when flowering plants provide pollen with protein content over 23%, honey and pollen productivity are higher than during the period when they provide pollen with protein content less than 20.6%. There is a relationship between the nutritional value of pollen and the productivity of bee colonies. The dynamic rainfall leads to increasing the moisture content of the soil and as a result it influences the flowering intensity of a great number of plants. The dynamics of the ecological factors- rain, temperature and humidity can favor or hamper the development of different plant species.

Keywords: *Apis mellifera, honey bee, impact, protein content, productivity*.

Introduction

Pollen is the source of protein, vitamins, enzymes, lipids, minerals, sugars, water and others (Kayas, 1975; Roulston & Cane, 2000) and necessary for vital processes of the honey bees (*Apis mellifera*), (Dietz, 1975). It also contains vitamin C, vitamin B complex- folic acid, riboflavin, pantothenic acid and others (Lavrehin & Pankova, 1983; Shmeleva & Nikiforova, 1989). Protein is important for the productivity of the bee colonies (Zherebkin & Mironova, 1976; Avetisyan, 1983). According to Stanley & Linskens (1974), Herbert & Shimanuki (1978) and Loper & Berdel (1980), the amount of protein ranges from 3.8% to 40.8% with the average of about 20% for the most species. Kleinschmidt & Kondos (1977) established from 7% to 37%, Radev et al. (2014) found protein content ranged from 13.88% to 25.02% and average value 19.45%. Research work conducted by Andreev (1926), Louveaux (1958), Perelson (1962) shows that the pollen of various plant species contains different amounts of protein and it makes them different in view of their nutritious value. Research work done by Roulston et al. (2000) on the protein content in the field of 377 plants from 93 families were within the range 2.5% of *Cupressus arizonica* to 61.7% for *Dodecatheon clevalandii*. According to Liolios et al. (2015) the pollen from 54 different plants was in the range from 12.8% for pollen from *Smilax* sp. to 30.1% for that of *Fallopia type* and the average of 20.8%. Differences are often observed in the protein content of the pollen that originates from the same plants due to different environments and different climate and soil (Stanley & Linskens, 1974; Bosi & Ricciardelli D'Albore, 1975; Tyurner et al. 1972). Honey bee longevity, brood rearing and honey production are all reduced when protein availability is insufficient (Crailsheim, 1990; Herbert, 2000). There is a relationship between the nutritional value of pollen and the development, reproduction and productivity of bee colonies (Radev et al. 2014).

The purpose of this study is to identify the impact of different protein content of pollen on honey bee (*Apis mellifera* L.) productivity.

Materials and methods

Bee colonies

The study was carried out using five bee colonies, made equal during 2012-2014. The experimental part of the research was carried out in an apiary located in Belozem (42.201860,25.049330), central part of south Bulgaria. The colonies were inspected, with the following taken into account: honey productivity (kg) - was found as the difference between the weight of the full combs and the empty ones after centrifugation of the honey. The total productivity of colony was determined by the total honey collected from all the extractions. Pollen productivity (kg) - was given as the amount of pollen collected with pollen traps.

Collection of pollen

Pollen traps were placed into the bee hives and the pollen pellets were harvested every 2 days. The collection of pollen started in April and continued until September. Each sample collected was with a date. Every single month was with two reporting periods (except April 2012- only one): (First) period from 1st to 15th day of the month and (Second) period from 16th to 30/31st day of the month.

Preparing the pollen samples for analysis

The collected pollen was mixed according to the accurate period. The random sample using for analysis for each period was taken using the quarter method of sampling. By this method the pollen was spread on some paper and divided it into four equal quarters, then it was removed by using two diagonally opposite quarters. The remaining material was mixed and quartered until the sample was reduced to the desired size.

Determination of protein content

Thirty-five vials with mixed pollen collected from all the colonies were analysed. For nitrogen content determination, the pollen was analysed using the Kjeldahl method, which is separated into three steps. During the first step, digestion, a quantity of 1g of pollen was placed into the tube with 20 ml of strong sulphuric acid (H_2SO_4, 95-98%) and heated for three and half hours in the presence of a catalyst, which assists the conversion of nitrogen in proteins to ammonium ions. When the digestion was complete, the samples were removed and left to cool at room temperature. After cooling, the ammonia was distilled in the presence of NaOH and collected in a solution of boric acid (H_3BO_3, 99.5-100.5%), which was then titrated against 0.1 M HCl. The crude protein content was estimated using the factor 5.60 (Rabie et al. 1983) by the volume of HCL, which was taken by an instrument and added to the pollen. In this case the following formula applied:

Protein (%) = 0.791*V/m.
Where: V = the volume (ml) of HCl taken during the titration.
M = the amount of pollen (g).

Results and discussion

The protein content of the pollen influenced the productivity of the honey bees. During the three experimental years, it was established higher honey and pollen productivity in the period of higher protein content, and lower production in the period of lower protein content (Tab. 1), which agreed with Crailsheim (1990) and Herbert (2000) who also established, that the honey production is reduced when protein availability is insufficient. Quality and quantity of pollen collected by bees affect the productivity of the hive (Kleinschmidt & Kondos, 1978).

The production seasons with higher protein content for the three years are over 23% and the production seasons with lower protein content are less than 20.6% (Tab. 2).

Table 1. Honey and Pollen production (kg)

Year	Production season with higher protein content (kg)		Production season with lower protein content (kg)		Total honey/pollen production (kg)	
	honey	Pollen	honey	Pollen	honey	Pollen
2012	110	9.2	83	5.7	193	14.9
2013	179	6.3	82	3.7	262	10
2014	161	5.4	108	1.7	270	7.1

Table 2. Protein content (%) of pollen in different periods

	2012	2013	2014
Period of high protein content	Apr-May-Jun- 23.6%	Apr-May-Sep- 23.4%	Apr-May-Sep- 24.2%
Period of low protein content	July-Aug-Sep- 16.2%	June-July-Aug- 18.6%	June-July-Aug- 20.6%

The presented results for the three experimental years (Tab. 1) according to the results shown by the protein content (Tab. 3) are statistically significant (Anova: Single factor), namely that the bees collected the most honey and pollen when the nutritional value was higher except the pollen production for 2012. For honey production for 2012/13/14 at $p \leq 0.05$, $p=0.00$. The pollen production was significant for 2013 and 2014 (at $p \leq 0.05$, $p=0.03$ and $p=0.00$), while in 2012 it was not significant (at $p \leq 0.05$, $p=0.16$), the reason is probably the ecological factors (Fig. 1, 2 and 3).

Table 3. Protein content (%) of mixed pollen in different harvesting periods

Harvesting periods of pollen	2012	2013	2014
April 1-15		21.1	27.8
April 16-30	25	23	25.5
April (average value)	**25**	**22**	**26.7**
May 1-15	24.6	23.9	24.8
May 16-31	23.4	24.4	23
May (average value)	**24**	**24.2**	**23.9**
June 1-15	23.5	15.6	22.5
June 16-30	21.5	15.7	21.6
June (average value)	**22.5**	**15.6**	**22.1**
July 1-15	17	16	19.2
July 16-31	18.3	19.9	21
July (average value)	**17.7**	**17.9**	**20.1**
August 1-15	17.1	22.8	20.7
August 16-31	13.9	21.9	18.4
August (average value)	**15.5**	**22.4**	**19.6**
September 1-15	15.1	22.6	19.9
September 16-30	16	25.1	24.2
September (average value)	**15.6**	**23.9**	**22**

During the three years the pollen was collected by using pollen traps every second day, but the yield of honey over the years was reported during the following months: 2012- May, June, July and August; 2013/2014- May, July, August and September.

It seems that in the presence of protein content in pollen over 23% the productivity of the bee colonies is higher than in presence of protein content in pollen less than 20.6%.

According to the increase of the average annual value of the protein content in the pollen during the three years (Tab. 4) it is found that the honey productivity also increases every year (Tab. 1). Between these parameters there is a positive, high and significant correlation ($r=0.98$, $p \leq 0.05$). But between the increase of the average annual value of the protein content

in the pollen during the three years (Tab. 4) it is found that the pollen productivity decreases every year (Tab. 1). Between these parameters there is a negative, high and significant correlation (r=-0.99, p≤0.05) in the pollen productivity, the reason is probably the dynamics of the ecological factors- rain, temperature and humidity (Fig. 1, 2 and 3).

Table 4. Protein content (%) of mix bee-collected pollen in different seasons

Harvesting periods of pollen	**2012**	**2013**	**2014**
Spring	24.4	23.1	25.3
Summer	18.6	18.6	20.6
Autumn	15.6	23.9	22
X for year	**19.5**	**21.9**	**22.6**

The annual dynamics of the above-mentioned factors can be observed (Fig. 1, 2 and 3). The dynamic rainfall leads to increasing the moisture content of the soil and as a result it influences the flowering intensity of a great number of plants. In 2012 (Fig. 1) there were no days with rainfall during the summer months June and August whereas in 2013 (Fig. 2) and to a great extent in 2014 (Fig. 3) there were days with rainfall. The ecological factors can favor or hamper the development of different plant species.

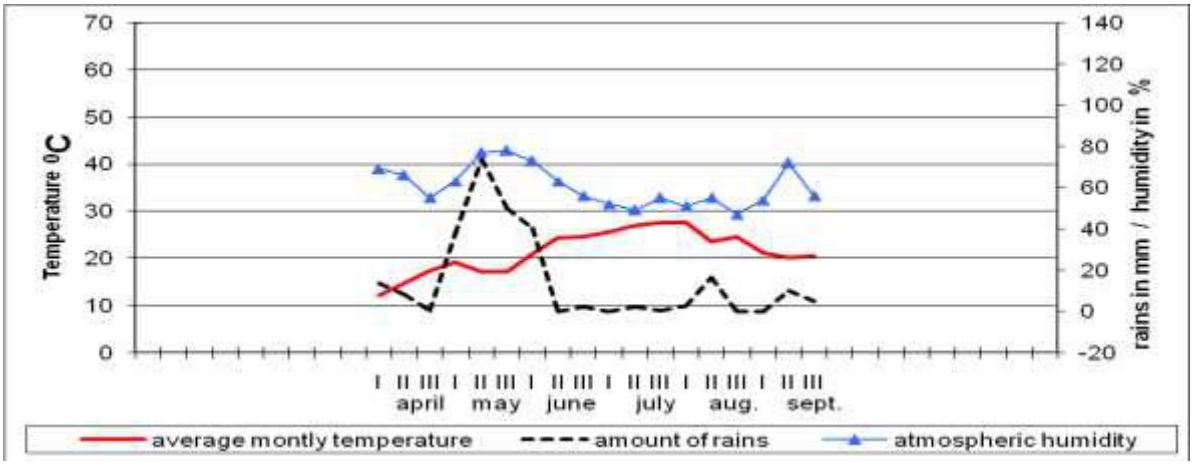

Fig. 1. Climatic characteristics of Belozem area for 2012

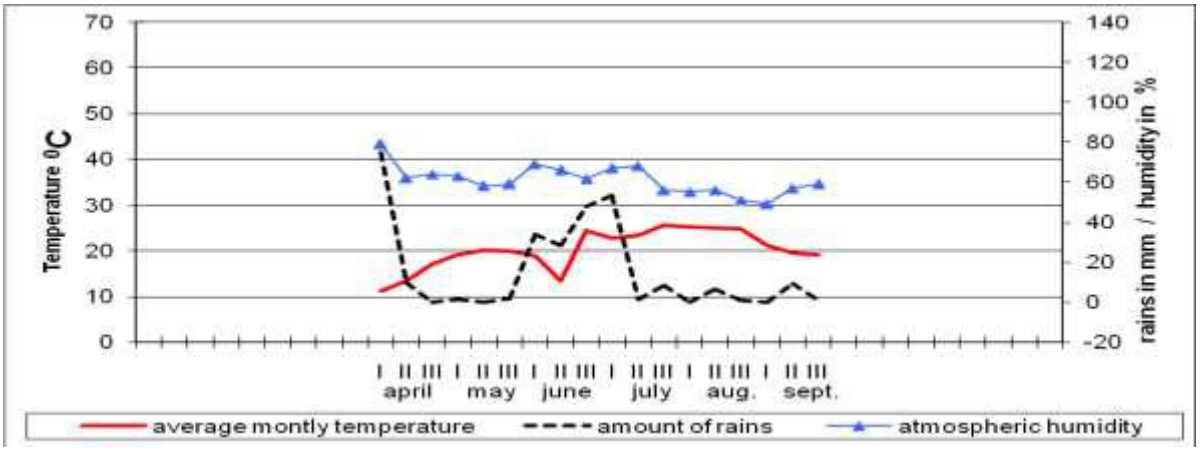

Fig. 2. Climatic characteristics of Belozem area for 2013

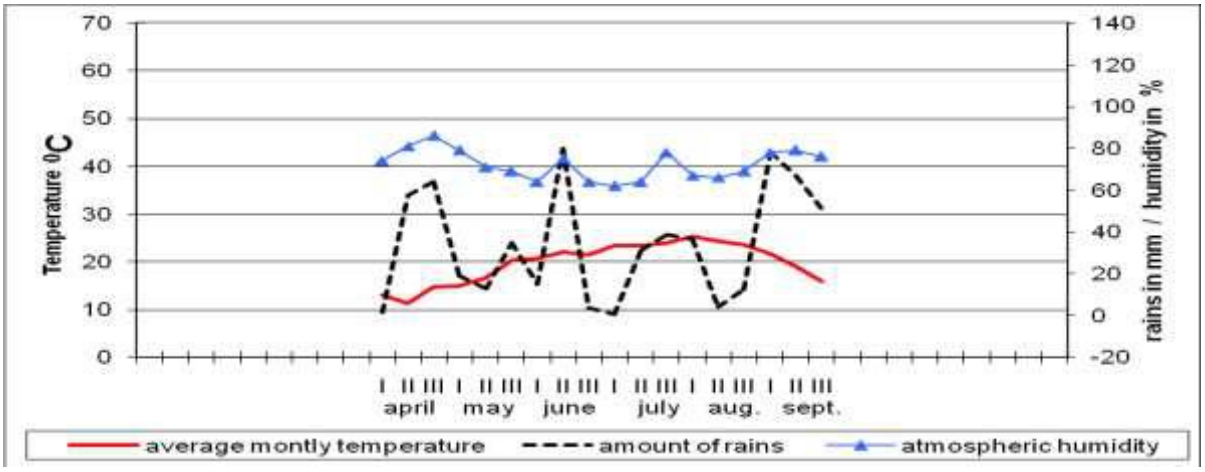

Fig. 3. Climatic characteristics of Belozem area for 2014

Conclusions

The protein content in the examined samples through the three seasons ranged from 13.9% to 27.8%, and the average value was 20.9%.

During the period when flowering plants provide pollen with protein content over 23%, honey and pollen productivity are higher than period provide pollen with protein content less than 20.6%.

There is a relationship between the nutritional value of pollen and the productivity of bee colonies.

The dynamics of the ecological factors- rain, temperature and humidity can favor or hamper the development of different plant species.

Abstract

The current study was carried out to investigate the effect of Moringa oleifera leaves supplementation on behaviour and growth performance of Nile Tilapia. Fish were classified to three groups (n=20/group, 2 replicates). First group fed on commercial diet. Second and third groups fed on 10% and 20% Moringa processed diet, respectively. Behavioural patterns, body weight, weight gain, relative growth rate, feed conversion ratio, some biochemical parameters and water quality were recorded. Results revealed that adding of Moringa by two different concentrations significantly reduced aggressive behaviour of fish in general. In addition, Moringa 20% significantly decreased body weight of fish after 10 weeks of supplementation. Moringa supplementation had no significant effect on liver enzymes, total proteins, albumins and globulins. However, fish fed with Moringa had lower serum glucose level than fish that was not fed with Moringa. Moreover, adding of Moringa in both concentrations (10 or 20%) decreased nitrite and nitrate of water in comparison with control group. Dissolved oxygen and pH of water were not affected by Moringa supplementation. It was concluded that Moringa supplementation had a favorable effect on Tilapia fish behaviour by reducing level of aggression. Also, Moringa supplementation could be used in improving water quality parameters by decreasing nitrite and nitrate levels. Generally, Moringa is nutritionally rich and can be included in fish diet at 10% levels that had no adverse effect on fish body weight.

Keywords: *Moringa oleifera, behaviour, growth performance, Nile Tilapia.*

Introduction

Fish culture is the fastest growing sector of the world's animal production by reporting an annual increase of about 10% (FAO, 1997). The Nile tilapia has its origins in Africa and is mostly farmed in tropical and sub-tropical countries. The Nile tilapia is one of the most important of the tilapia species due to its rapid growth, good survival rate in high-density populations and its disease tolerance. The tilapia species is both an omnivorous and herbivorous species, which means that it can digest both plant and animal materials. Tilapia can live in most freshwater sources, such as shallow streams, lakes, rivers and are even found living in brackish waters. The tilapia is very tolerant to poor water conditions and can endure periods with low oxygen (Francois *et al.,* 2010).

Recently, researchers have increasingly been paying attention to Moringa (Moringa oleifera Lam.). It belongs to the moringaceae family, and is considered to have its origin in the north-west region of India. Moringa oleifera (MO) can have a total dry matter (DM) yield up to 24 ton ha-1year-1 and has a crude protein (CP) content in fresh leaves varying from 193 to 246 g kg-1 DM (Sanchez *et al.,* 2006). Analytical studies have identified MO as an important source of essential nutrients; rich in protein, essential amino acids, minerals, and vitamins, with a relatively low amount of anti-nutrients (Falowo *et al.,* 2018). Moringa fresh plants have been included into the diet of different animals including fish. Moringa can be dried and used in the form of Moringa Leaf meal (MLM), 30% substitution of MLM for fish meal has been

recommended for the diet of Nile tilapia *Oreochromis niloticus* (Richter *et al.,* 2003). Furthermore, fishmeal, in the diet of *Clarias gariepinus*, can be efficiently replaced with up to 10% Moringa meal, for good growth and nutrient utilization, comparable with the fishmeal-based diet (Adewumi, 2014).

In aquaculture systems, the increasing price of feed is considered one of the most important factors that limit profitability, caused mainly by the cost of fishmeal used as a primary source of protein (McCoy, 1998). Consequently, there is a need to search for alternative protein sources for aquaculture diets. Additionally, the high cost and fluctuating quality of imported fish meal have led to the need to identify substitute protein sources for use in fish feed formulations (Olvera *et al.,* 1990).

Nowadays, plant sources have been used to replace the protein in fish meal and soybean meal, either partially or totally. Practical fish feed has been an area of focus in aquaculture nutrition research recently (Sidduraju and Becker, 2003).

This study was conducted to investigate the effect of Moringa oleifera leaves supplementation on behavioral patterns and growth performance of Nile tilapia (*Oreochromis niloticus*).

Materials and methods

The study was conducted in accordance to the regulations of Institutional Animal Care and Use Committee (IACUC), Faculty of Veterinary Medicine, University of Sadat City, Egypt and at the period from April till August, 2014. Sixty fingerlings (average weight 18.6g) were randomly divided into three groups (n=10 fish per aquarium, 100 cm length x 30 cm width x 40cm height) with two replicates per treatment. The first group fed commercial diet. The second and third groups fed 10% and 20% MO processed diet respectively. The experiment lasted for 10 weeks. Fish were fed at a rate of 3% of their body mass. The amount of food given was adjusted every two weeks after determination of new fish weights in each group.

MO leaves were collected from a Moringa farm in Sadat city and were washed with water to remove dirt, drained properly and later shade dried for seven days. Thereafter, the leaves were ground into fine powder (Bello and Nzeh, 2013). Then this powder added to wetted commercial diet by two different concentrations (10-20% of diet) and mixing them in grind meat miller. This mixture was dried in Hot air oven (BINDER, Germany) at 50°C for twenty four hours. Two different concentrations of MO processed diets were analyzed for proximate composition according to AOAC (2000) (Table 1).

Data of behavioural patterns (feeding, foraging, elimination, resting, chafing, schooling, surfacing, chasing, mouth pushing and fin tugging) were recorded by using video camera (Sony, Japan) for 10 minutes for each aquarium two times per day at morning (9:00 -11:30 am) and afternoon (2:00 - 4:30 pm); and twice weekly. Sampled behavioural categories for all fish were scanned by one observer. The behaviour of the fish in each aquarium was recorded using instantaneous sampling method at 60 seconds intervals.

Fish were taken from each aquarium for individual weight every two weeks at 0, 2, 4, 6, 8 and 10 weeks of experiment. Fish were handled by using wetted towel to avoid stress then putted in plastic container with wetted sponge on electronic weighing balance (ACCULAB, Sartorious group, Germany). According to Lee *et al.,* (2000) the following items were calculated: weight gain= Wf - Wi ; relative growth rate= (Wf - Wi)/ $^1/_2$ (Wf + Wi) X 100 and feed conversion ratio (FCR) = [dry feed fed (g)/ weight gain (g)] where Wf= final weight; Wi= initial weight.

Table 1. Proximate composition of experimental diets:

Proximate composition	Commercial diet	10% MO processed diet	20% MO processed diet
Dry matter %	93.8	92.2	94.7
Crude protein %	28.6	30.1	30.0
Crude lipid %	5.2	4.9	4.7
Crude fiber %	6.5	7.3	7.8
Ash %	7.7	7.4	7.7
Nitrogen free extract (NFE)%	45.8	42.9	44.5
Digestible energy(Kcal/Kg)	3224	3162	3199

For collection of blood samples, fish were put in 20L worm water (25°C) with Tricaine Methanoesulfonate (0.5g/10 L, Finquel, USA) for anesthesia at the end of experiment. After that blood samples were collected from direct cardiac puncture by using 3ml sterile plastic disposable syringe in test tubes without anticoagulant. The clotted blood was centrifuged at 3000 revolution per minute (rpm) for 15 min for serum separation. Sera were frozen at -20 °C until subsequent analyses. Total protein, albumin, glucose, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were estimated by spectrophotometer (Light Wave II UV/Visible Diode Array Spectrophotometer, England) according to the instructions of kits.
Water quality parameters including pH, dissolved oxygen (D.O), Nitrite (NO2) and Nitrate (NO3) were measured daily for each aquarium. Data were analyzed statistically by using SAS system (2001). The proportion of fish that performed behavioural patterns per minute was calculated. All data (behavioral patterns, growth performance, biochemical parameters and water quality parameters) were analyzed with ANOVA using a generalized linear model (GLM-procedure). Results were considered statistically significant when p-values were below 0.05.

Results and discussion

In the current study, supplementation of MO leaves at either 10% or 20% had no toxic effect on Tilapia. Additionally, MO supplementation had significantly effect on Tilapia fish behaviour and performance. The observations from this study revealed that resting and surfacing behaviours increased in fish fed with 10% and 20% MO procced diets in compared with fish fed commercial diet as shown in Table (2). A finding of interest was that aggressive behaviour levels were decreased by MO supplementation in general. Moreover, fish fed with MO showed less chasing, mouth pushing and fin tugging than control group. Therefore, MO supplementation may be having a calmness effect on fish that increased resting and suppressed aggressive activities.
Unfortunately, the literatures about effect of MO leaves on fish behaviors are rare. Bakre *et al.,* (2013) found that the extract of MO leaves caused a significant decrease in grooming and locomotion and had CNS depressant effect in mice. Therefore, MO processed diets that enhanced comfort and motionless state of fish and in the same time depressed aggression activities in this study may be attributed to suppress the central nervous system activity.

Table 2. Effect of Moringa oleifera leaves supplementation on Tilapia behaviour (LSMeans):

Behaviour (%)	Control	Moringa 10%	Moringa 20%	s.e.d	*P*-value
Ingestive:					
Feeding	25.16	22.20	25.83	2.63	NS
Foraging	22.00	21.83	24.88	3.15	NS
Elimination	7.20	7.12	7.29	0.85	NS
Comfort					
Resting	28.45^{b}	33.62^{a}	30.21^{ab}	1.66	0.03
Chafing	2.61	1.95	4.83	1.20	NS

Surfacing	4.50[b]	9.83[a]	9.29[ab]	1.85	0.04
Aggressive:					
Chasing	34.73[a]	23.45[b]	28.32[b]	1.90	0.01
Mouth pushing	11.15[a]	5.76[b]	6.87[b]	1.51	0.04
Fin tugging	34.96[a]	29.83[ab]	25.83[b]	2.32	0.006

NS: non-significant. s.e.d: standard error of difference. a-b: LS Mean with different superscripts were significantly different.

MO supplementation had undesirable effect on fish growth performance at 20% concentration. However, MO 10% concentration had no adverse effect on fish body weight (Tables 3). In addition, weight gain of fish fed blank diet was higher than fish fed with 10% and 20% MO processed food (48.48, 40.78 and 40.48, P=0.012, respectively). Also fish received 10% and 20% MO processed food had less relative growth rate than fish in control group (108.74, 113.69 and 120.71, P=0.01, respectively). Feed conversion ratio did not significantly affected by 10% or 20% MO supplementations compared with control group (1.81, 1.80 and 1.54, P>0.05, respectively). Consequently, by increasing MO levels in diets the growth parameters of tilapia fish reduced. These findings may be attributed to higher crude fiber content that found in MO processed diet in compared with commercial diet as analyzed in proximate composition of experimental diets (Table 1) that may be lower the palatability of MO processed food. These results were in accordance with Adewumi (2014) and Kittisak *et al.,* (2017) who reported that high fiber content of MO diet and decreased its acceptability were the main causes of poor growth performance of fish.

Moreover, high fiber content in diets causes dilution of the nutrients reduces digestibility, resulting in growth depression, as the diets become inconsistent. Where, fiber creates bulkiness of feed in the gut, reduces feed consumption of animals and creates regular bowel movement (Adewumi, 2012). In addition, fiber depresses utilization of feed energy and essential nutrients. This energy deficit would in turn affect other biological parameters, as well as nutrient retention and thus weight loss (Adewumi, 2014).

Table 3. Effect of Moringa oleifera leaves supplementation on Tilapia body weight (g) (LSMeans):

Week	**Control**	**Moringa 10%**	**Moringa 20%**	**s.e.d**	***P*-value**
0	18.76	18.80	18.35	0.57	NS
2	25.45	23.80	24.65	0.87	NS
4	32.89	31.05	30.06	1.17	NS
6	42.30	40.31	38.16	1.70	NS
8	52.95	50.23	48.96	1.75	NS
10	64.25[a]	57.45[ab]	55.36[b]	2.19	0.023

NS: non-significant. s.e.d: standard error of difference. a-b: LS Mean with different superscripts were significantly different.

Additionally, Richter *et al.,* (2003) showed that higher substitution of MO leaf meal with fish meal had a negative impact on the growth performance because of the presence of some anti-nutrients such as phenol, tannins, phytates and saponins. Accordingly, Eusebio *et al*., (2004) found that the presence of anti-nutrients may hinder the digestibility and utilization of dietary nutrients. Phytates reduce the bioavailability of nutrients due to formation of complexes such as a phytate–mineral/protein complex. Fish are unable to use phytate-nutrient complexes because they lack the enzyme phytase (Riche *et al.,* 2001). Besides, tannins delay the digestive process by binding to digestive enzymes such as protease resulting in a decrease in proteolytic enzyme activity, leading to reduced protein digestibility (Eusebio *et al*., 2004). Tannins also reduce the absorption of essential vitamins (Francis *et al.,* 2001). Polyphenols on the other hand, form phenolic-protein-enzyme complexes, these also decrease protein digestibility and amino acid availability.

Table 4. Effect of Moringa oleifera supplementation on biochemical parameters of Tilapia (LSMeans):

Biochemical parameters	**Control**	**Moringa 10%**	**Moringa 20%**	**s.e.d**	**P-value**
AST(U/I)	31.37	13.75	15.12	6.49	NS
ALT(U/I)	5.75	3.75	2.50	1.53	NS
Glucose (mmol/L)	180.38^{a}	119.72^{ab}	99.68^{b}	28.26	0.05
TP (g/dL)	3.47	3.61	3.37	0.21	NS
Albumin (g/dL)	1.41	1.55	1.43	0.08	NS
Globulin (g/dL)	2.06	2.06	1.95	0.21	NS

NS: non significant. s.e.d: standard error of difference. a-b: LS Mean with different superscripts were significantly different.

Using of MO in diet had no significant effect on fish biochemical parameters except fish serum glucose was only reduced (Table 4). Serum glucose was less in fish fed MO 20% than fish fed commercial diet. The reason of these recordings may be due to hypoglycemic effects of MO leaves. These findings were in agreement with Amira *et al.,* (2014) who stated that aqueous extract of MO leaves possesses potent hypoglycemic effect through the normalization of elevated hepatic pyruvate carboxylase enzyme and regeneration of damaged hepatocytes and pancreatic ß cells via its antioxidant properties.

On the other hand, Mousa *et al.,* (2008) suggested that increasing in the activities of serum liver enzymes (Aspartate aminotransferase, AST, and Alanine aminotransferase, ALT) as the level of MO leaf meal increased considerably from 20% in the diet. Elevated AST and ALT activities in fish fed 30% MO leaf meal diet and above were suggested of hepatic cellular damage leading to their leakage into circulation. However, in the current study, serum liver enzymes (ALT and AST) were not affected by MO supplementation. These differences may be attributed to the usage of MO leaves by less than 30% in this study that may be have protective role to hepatic cells (Sa´nchez-Muñoz *et al.,* 2018).

Another finding of interest was that supplementation of MO had benefit effect on water nitrite and nitrate levels. Adding of MO in both concentrations (10%-20%) decreased nitrite (1.37 and 0.87 mg/L, respectively) and nitrate (29.62 and 19.30 mg/L, respectively) of water in comparison with control group (nitrite: 1.92 and nitrate: 41.62 mg/L) (P=0.004, P=0.004, respectively). However, dissolved oxygen and pH of water were not affected by MO supplementations (P>0.05). These findings were agreed with Nand *et al.,* (2012) who found that Moringa were more effective in water purification. Additionally, Suneetha and Ravindhranath, (2012) recorded that Moringa Tinctoria leaves had bio-adsorbent ability to absorb nitrate ions in water when pH was optimized.

Conclusion

It was concluded that MO supplementation had a favorable effect on Tilapia fish behaviour. Adding of MO had a calmness effect on fish as well as reducing level of aggression. Moreover, MO supplementation could be used in improving water quality parameters by decreasing nitrite and nitrate levels. Generally, MO is nutritionally rich and can be included in fish diet at low levels that had no adverse effect on fish body weight.

Abstract

The cost of feed is of great importance for small ruminant production. The present study was conducted in Greece, exploring the potential substitution of imported soybean meal by legumes (beans) meals in sheep nutrition. Eighty ewes of the "Karagouniko" breed were split in five groups and four subgroups. In the first group nutrition was based on soy legumes (beans). In the second group nutrition was based on lupine legumes. In the third group nutrition was based on pea legumes. In the fourth group nutrition was based on vetch legumes. In the fifth group nutrition was based on broad bean legumes. Subgroups within groups consisted of: a) control subgroup with null substitution of soybean meal, b) 1/3 substitution of total nitrogen by the respective legume, c) 2/3 substitution of total nitrogen by the respective legume and d) full substitution of total nitrogen by the respective legume. Body weight was measured in the beginning and at the end of the trial period. Feed consumption and milk production were recorded daily and milk quality was analyzed weekly. No statistically significant differences were found for body weight and milk production. In qualitative characteristics of milk (protein, fat and lactose content), there were significant differences between subgroups, for vetch, broad beans, lupine, peas and soy legumes (beans). Digestibility showed statistically significant differences between subgroups, for vetch, broad beans, peas and soy legumes. The results showed that substitution of soybean meal with other locally produced legumes as main protein sources is possible, without affecting body weight and milk production. Especially, soybean meal substitution of 1/3 total nitrogen with soy beans led to increased protein and fat content and lower lactose content in milk.

Keywords: *Broad beans, Vetch, Peas, Lupine, Greece.*

Introduction

Nutrition of ruminants is based mainly on soybean (*Glycine max* L.) and maize (*Zea mays* L.). For soybean, especially, there are many restrictions in European Union, because the major quantities produced are genetically modified. Organic and traditional farmers are not allowed (and are not willing) to use GMO feed for their livestock. On the other hand, soybean production is too expensive for European farmers and thus, soybean cultivation is restricted in European Union.

As alternative nutrition sources for small ruminants, other legume beans have been proposed, by many researchers (Hadjipanayiotou 2002; Christodoulou *et al.*, 2005; Lanza *et al.*, 2011), because of their high protein content. They reported that substitution of soy bean by other legumes as a protein source, in general, did not affect milk production of small ruminants (Bonomi *et al.*, 2003; Christodoulou *et al.*, 2005; Liponi *et al.*, 2007; Renna *et al.*, 2012). In case of carcass and meat quality of lambs, these protein sources showed a rather positive

impact (Lanza *et al.*, 2011; Bonano *et al.*, 2012), indicating that other legumes could totally replace soy bean in the nutrition of small ruminants, with many benefits for the farmers raising their livestock organically or traditionally. It should be mentioned that pea legumes (*Pisum sativum* L.) are the second most important legume used globally as a substitute of soy beans (Mikic *et al.*, 2009). Pea seems to be a very promising protein source with many positive effects on small ruminants' nutrition (Bonomi *et al.*, 2003; Liponi *et al.*, 2007).
In a recent study, many different protein sources were evaluated (Zagorakis *et al*., 2015). The authors depicted that all the alternative protein sources have to be treated in order to reduce their nitrogen (N) degradability, prior to their utilization for nutrition of ruminants.
The purpose of this study was to explore the potential substitution of soybean meal by other legumes (beans) meals in sheep nutrition and the impact on digestibility, milk production and quality. The tested legumes were: soy (beans), lupine (*Lupinus albus* L.), pea vetch (*Vicia sativa* L.) and broad bean (*Vicia faba* L.) legumes (beans).

Materials and methods

The study was carried out in the farm of TEI of Thessaly, in Larissa, Greece. Eighty lactating ewes of the "Karagouniko" breed were homogeneously split in five groups and four subgroups. In the first group nutrition was based on soy legumes (beans). In the second group nutrition was based on lupine legumes. In the third group nutrition was based on pea legumes. In the fourth group nutrition was based on vetch legumes, while in the fifth group nutrition was based on broad bean legumes. The general statistical design was Latin Design 4X4 in a two-factor arrangement: plant species (groups) and feed (subgroups). Subgroups within groups consisted of: a) control subgroup with null substitution of soybean meal, b) 1/3 substitution of total nitrogen by the respective legume, c) 2/3 substitution of total nitrogen by the respective legume and, d) full substitution of total nitrogen by the respective legume. In all feeds, chrome oxide was added as a marker for digestibility measurements. The periods comprised of 21 days, i.e. 14 days for adaptation to the diets (feed) and 7 days for sampling and analyses of milk and feces. Body weight was measured in the beginning and at the end of the trial period. Feed consumption and milk production were recorded daily and milk quality was analyzed weekly. Every milk sample was refrigerated (at 4 ^{o}C) and morning/afternoon milk was mixed prior to analyses for lactose, protein, fat, ash and dry matter without fat. Feces were sampled every day and a total sample of 400 g was formed prior to drying (60^{o}C for 48h). Chrome was determined using the method Schurch, *et al*. (1950). All ewes were lactating and kept in separate cells of an area of 2.5 m^2. Daily feed was given in two meals and water was available ad libitum. Records for not-consumed-feed were kept throughout the experimental period. Table 1 presents the composition of the diets, given every day at a quantity of 1 kg per ewe. Additionally, barley straw and alfalfa hay were provided every day. General linear model was used to statistically analyze data across all factors, using SPSS ver. 17, according to Steel and Torrie (1980).

Results and discussion

Problems with feed intake and consumption of the daily rations were not recorded in any experimental group, although previous studies reported that legumes used in diets have as a result a lower feed intake due to the presence of antinutritional factors (cyanogen glycosides, alkaloids, antitrypsic factors, etc.) (Liener, 1989 in Purroy *et al*., 1992). For the other parameters recorded the results were as follows:

a) Body weight:
The results showed that there were no differences between the experimental groups of dairy ewes and experimental treatments with regard to the mean body weight of the animals, on

days 1, 14 and 21, either tested on the basis of the animal or on the basis of experimental treatment. This was expected, since ewes of the experimental groups fed rations of about the same nutritional value, as per the study design. Bonanno *et al.* (2012) reported similar growth rate for lambs fed with pea beans instead of soybean concentrate, but other past studies (Purroy *et al*. 1992) showed that a lupine diet fed to lambs caused slower growth in comparison to other legumes, and more fat deposition in comparison to a soybean cake diet. Legume seeds are considered a tasty food by ruminants and therefore there are no problems of intake or consumption, even if the beans contain antinutritional factors, resulting in full consumption of the daily amount of feed provided, by all animals.

b) Milk quantity:

There were no differences observed between the control group and the treatments using vetch, lupine, pea or soy beans (Data are not presented). This finding is different from the results of Bonanno *et al*., (2015), who reported higher yield for ewes fed a pea diet in comparison to soybean meal diet. Differences were statistically significant in the groups of broad beans in which, the administration of broad beans, resulted to a reduction in milk production, which was greater with the increase of broad beans content in the ration.

Table 2. Average milk production per experimental group

Group	Quantity
Control	$1.4998^{a} \pm 0.1408$
1/3 Broad beans group	$1.4004^{ab} \pm 0.1744$
2/3 Broad beans group	$1.3548^{ab} \pm 0.1786$
3/3 Broad beans group	$1.2841^{b} \pm 0.1118$

^{a,b} averages with different exponent differ statistically significantly ($p < 0.05$)

Although most researchers recommend the use of bean seeds in ruminants up to 30% of the ration, in this case our results are in agreement with Goelema *et al*. (1998, 1999), Yu *et al*., (2000, 2002), Selmi *et al.*, (2013), which notes that the bean seeds show increased degradation of starch and protein in the large intestine and only the heat treatment can reduce the degradation rate.

c) Milk quality:

As for the quality of the milk produced, there is a different picture depending on the legumes used. More specifically, in the case of the addition of vetch, the protein and fat content of the

milk increased with the increase of the seeds participation, while lactose content decreased. This may be due to the increase in the digestibility of the organic and the nitrogenous substances of the rations with the adding vetch. The digestibility of organic substance (DOM) and nitrogenous substances (ND) are presented in Table 3.

Table 3. Milk quality and digestibility per experimental group using vetch

Group	Protein	Fat	Lactose	DOM	ND
Control	$5.3354^{a} \pm 0.1498$	$6.5429^{a} \pm 0.1563$	$5.0164^{a} \pm 0.2525$	$91.5371^{a} \pm 1.8244$	$82.2486^{a} \pm 1.9764$
1/3 vetch group	$5.4000^{ab} \pm 0.1720$	$6.6054^{ab} \pm 0.1591$	$4.8600^{b} \pm 0.1003$	$92.0371^{ab} \pm 1.8243$	$83.6914^{b} \pm 1.2162$
2/3 vetch group	$5.4425^{b} \pm 0.1683$	$6.6425^{b} \pm 0.1525$	$4.8229^{b} \pm 0.1055$	$92.4794^{ab} \pm 1.8548$	$84.8028^{c} \pm 1.3683$
3/3 vetch group	$5.6461^{c} \pm 0.1114$	$6.7989^{c} \pm 0.1362$	$4.6604^{c} \pm 0.3193$	$92.8257^{b} \pm 1.6723$	$85.9143^{d} \pm 1.5203$

^{a,b,c} averages with different exponent differ statistically significantly ($p < 0.05$)

In the case that ewes fed a broad beans diet, an increase in lactose content and decrease in protein and fat content occurred, which is probably due to the increased rate of degradation.

Table 4. Milk quality and digestibility per experimental group using broad beans

Group	Protein	Fat	Lactose	DOM	ND
Control	$5.5411^{a} \pm 0.0855$	$6.7182^{a} \pm 0.0745$	$4.7400^{a} \pm 0.1971$	$92.1637^{a} \pm 1.8024$	$82.4146^{a} \pm 1.8851$
1/3 Broad beans group	$5.4789^{b} \pm 0.1179$	$6.6614^{b} \pm 0.1101$	$4.7989^{b} \pm 0.0757$	$91.9954^{b} \pm 1.7890$	$82.1554^{ab} \pm 1.1750$
2/3 Broad beans group	$5.4189^{c} \pm 0.1179$	$6.6214^{bc} \pm 0.1101$	$4.8389^{bc} \pm 0.0757$	$91.3878^{b} \pm 1.8436$	$81.5337^{b} \pm 1.3425$
3/3 Broad beans group	$5.3654^{c} \pm 0.0849$	$6.5718^{c} \pm 0.0827$	$4.9361^{c} \pm 0.1456$	$90.4015^{b} \pm 1.7678$	$80.5950^{c} \pm 1.4846$

^{a,b,c} averages with different exponent differ statistically significantly ($p < 0.05$)

Lupine beans treatments showed an increase in protein content of milk, a reduction in fat content and a decrease in lactose in comparison to the control group, possibly due to the progressive reduction of NDF rations by increasing the amount of beans.

Table 5. Milk quality and digestibility per experimental group using lupine beans

Group	Protein	Fat	Lactose	DOM	ND
Control	$5.3657^{a} \pm 0.0806$	$6.5907^{a} \pm 0.1114$	$4.9371^{a} \pm 0.1453$	92.1697 ± 1.7483	84.5444 ± 1.7483
1/3 Lupine beans group	$5.4282^{b} \pm 0.1116$	$6.5764^{a} \pm 0.0846$	$4.7650^{b} \pm 0.1488$	92.1441 ± 1.8244	84.6541 ± 1.2923
2/3 Lupine beans group	$5.5384^{c} \pm 0.0868$	$6.4318^{b} \pm 0.1214$	$4.8129^{b} \pm 0.1055$	92.0756 ± 1.8243	84.1516 ± 1.2922
3/3 Lupine beans group	$5.4986^{c} \pm 0.1161$	$6.3989^{b} \pm 0.1362$	$4.8307^{b} \pm 0.0744$	92.0371 ± 1.7818	83.9269 ± 1.7483

^{a,b} averages with different exponent differ statistically significantly ($p < 0.05$)

Similarly, when pea seeds were used, the protein content of the milk decreased and the fat and lactose content increased, with the exception of the group where the soybean meal was completely replaced by pea beans. Renna *et al* (2012) reported that incorporation of pa seeds in dairy ewes' diet did not affect significantly neither milk yield, nor milk fat, however variations were observed in milk fatty acid profile.

Table 6. Milk quality and digestibility per experimental group using pea beans

Group	Protein	Fat	Lactose	DOM	ND
Control	$5.4011^{ab} \pm 0.1686$	$6.6429^{b} \pm 0.1533$	$4.8621^{b} \pm 0.0982$	$91.5137^{a} \pm 1.8243$	$83.1746^{a} \pm 1.9764$
1/3 Pea beans group	$5.4493^{b} \pm 0.1638$	$6.5432^{a} \pm 0.1598$	$4.6654^{a} \pm 0.3078$	$92.1911^{a} \pm 1.8244$	$84.5054^{b} \pm 1.2162$
2/3 Pea beans group	$5.6261^{c} \pm 0.1114$	$6.6025^{ab} \pm 0.1138$	$4.8029^{b} \pm 0.1055$	$92.3791^{a} \pm 1.8548$	$84.6117^{b} \pm 1.3683$
3/3 Pea beans group	$5.3554^{a} \pm 0.1498$	$6.7589^{c} \pm 0.1362$	$5.0064^{c} \pm 0.2525$	$92.2568^{a} \pm 1.6723$	$84.2553^{b} \pm 1.5203$

^{a,b,c} averages with different exponent differ statistically significantly ($p < 0.05$)

Finally, the addition of soy beans to replace 1/3 of the soybean protein resulted in an increase in protein and fat content of milk and a reduction in lactose, and further replacement reduced all parameters due to the intense variations in nutritional value of the rations with the growing addition of the beans.

Table 7. Milk quality and digestibility per experimental group using soy beans

^{a,b,c} averages with different exponent differ statistically significantly ($p < 0.05$)

Conclusions

Nutrition of ruminants is based mainly on soybean meal and maize. However, legumes constitute competitive crops in Southern Europe and low-cost alternatives for sheep nutrition. Substitution of soybean meal with locally produced legume seeds is a viable alternative for the Greek region of Thessaly and "Karagouniko" breed, as it does not affect body weight and milk production, with the exception of broad beans that caused a reduction in milk production. Furthermore, each legume diet had a different effect on milk main components, i.e. protein, lactose and fat, therefore being able to differentiate milk composition. More specifically, vetch, lupine and soy beans diets increased protein content, which is advantageous for cheese production.

Abstract

Beekeeping is an important production branch of the agriculture and honeybees are one of the main pollinators in the world. Therefore, for the beekeepers it is crucial to have information about the state of the bee colonies. Application of information technologies in the beekeeping lead to the foundation of the Precision Beekeeping. Precision Beekeeping is based on constant data collection of bee colonies, where collected data should be transferred to a remote data centre for further data analysis. Data transmission in the field of beekeeping sometimes can be a challenging task, because beehives can be placed in rural areas without the option to get constant power supply and Internet connection. Authors of this paper chose LoRaWAN technological solution, as it allowed low energy consumption devices to communicate with Internet-connected applications over long range wireless connections for many years with only one battery. LoRaWAN network coverage and sensors were provided by Latvian company Lattelecom. Three bee colonies were equipped with LoRaWAN enabled temperature sensors. Measurements from sensors were transmitted to the LoRaWAN network gateways and servers and access to collected data was provided through the Lattelecom IoT portal web application. This research was carried out within the Horizon 2020 project SAMS "Smart Apiculture Management Services", proposing implementation of Precision Beekeeping by allowing active monitoring and remote sensing of bee colonies and beekeeping by developing appropriate ICT (Information and Communication Technologies) solutions supporting management of bee health and bee productivity.

Keywords: *Precision Beekeeping, LoRaWAN technology, Bee colony monitoring, Internet of Things.*

Introduction

In recent years fast development of Internet of Things (IoT) allows to collect data about various objects, including monitoring of living objects (Li et al. 2015). Data collection is the first stage also in the Precision Agriculture (Terry 2006) and it's branches like Precision Beekeeping (PB). Precision Beekeeping is an apiary management strategy based on the monitoring of individual bee colonies to minimise resource consumption and maximise the productivity of bees (Zacepins et al. 2015). For the data collection in Precision Beekeeping different sensors and technologies can be used (Meikle & Holst 2014). One of the issues in data collection in PB is data transfer from monitored object to the remote database or data warehouse for data storage and further analysis. As beehives usually are placed outside the urban areas, in deep forests or in rural locations, therefore connection to convenient data transmission networks (Wi-Fi, mobile networks) are limited or sometimes unavailable, as well 220V power supply for measurement devices can be unavailable. Therefore, there is a need of a new data transmission technology, which can transfer data for a long range and with low power consumption. One of the available options is to use LoRa (Long Range) technology.

LoRa stands for Long Range LPWAN (Low Power Wide Area Network) signal modulation technology proposed by Semtech (Georgiou & Raza 2017). LoRaWAN is a long-range, low-power, low-bitrate, wireless telecommunications network protocol specification, developed by

the LoRa Alliance, which uses LoRa signal modulation and is an infrastructure basis for the implementation of IoT solutions (Augustin et al. 2016). Together with long battery life, coverage is one of the most important features of the LoRaWAN solutions. Potentially communication range can achieve 10-15 km for outdoor coverage (Petäjäjärvi et al. 2016; Seye et al. 2017). Despite the potential of this technology it is not widely spread and used (Raza et al. 2016). Figure 1 below conceptually compares several data transmission technologies:

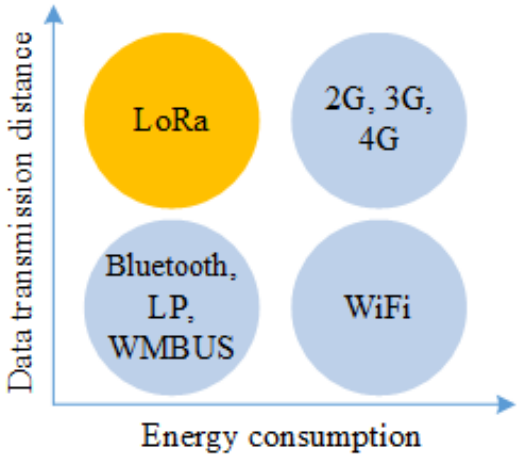

Figure 9. Comparison of data transmission technologies

Regarding agriculture sector, LoRaWAN also has huge potential. There are researches about possible implementation of that technology, for example implementation of smart irrigation (Zhao et al. 2017), soil parameter measurements (Xue-fen et al. 2017), but authors of this paper were not able to find any effort to use LoRaWAN in the beekeeping sector.

To use LoRaWAN technology it is possible to develop own infrastructure or use existing one. Many big telecommunication companies in the world provide such service, for example, Bouygues France telecommunications company has introduced LoRaWAN in 2015 and now more than 80% of the France territory is covered (http://www.objetconnecte.com/tout-savoirreseau-LoRa-bouygues). For author's research LoRaWAN infrastructure developed by Latvian company Lattelecom (https://iot.lattelecom.lv/) is used with main aim to evaluate the possibility to use it for Precision Beekeeping needs.

The Lattelecom group provides IT, telecommunication and outsourced business process solutions. Lattelecom Group is made up of five companies - SIA Lattelecom, Lattelecom BPO, Citrus Solutions and Lattelecom Technology with its subsidiary Baltic Computer Academy. The Lattelecom Group is the leading provider of electronic communications services in Latvia that offers electronic communication solutions for home, small and medium size businesses, state and municipal institutions, as well as for corporate clients.

In year 2017, Lattelecom started to develop LoRaWAN network and now is offering IoT services for municipalities and businesses for reading the utility meters, monitoring the utility infrastructure, controlling the street lights and etc. Advantages of Lattelecom network are:

- Lower cost comparing to WMBUS or 3G network;
- Low energy consumption;
- Huge amount of end devices supported by one gateway;
- Wide network coverage;
- Data transmission speed from 0.3 to 50 kbit/s.

To this moment LoRaWAN network is not covering the whole country, but is available in main cities. The capital Riga (which holds 32% of the population of Latvia, based on EUROSTAT Urban audit) has almost 99.9% network coverage (see Figure 2):

Figure 10. Lattelecom network coverage in Latvia
(source: https://www.lattelecom.lv/piedavajumi/iot/)

Concept of LoRaWAN working principle is demonstrated in Figure 3. End devices (sensors) are equipped with LoRa radio chip for a long-range data transmission. End nodes are communicating with gateways, which are connected to the Internet by the modern communication means (like fibre optics, or fast mobile internet). Those gateways are sending sensor data to the remote cloud based network server. Then developed Web application get data from the network sever to demonstrate it to the end user by the means of reports and data summaries.

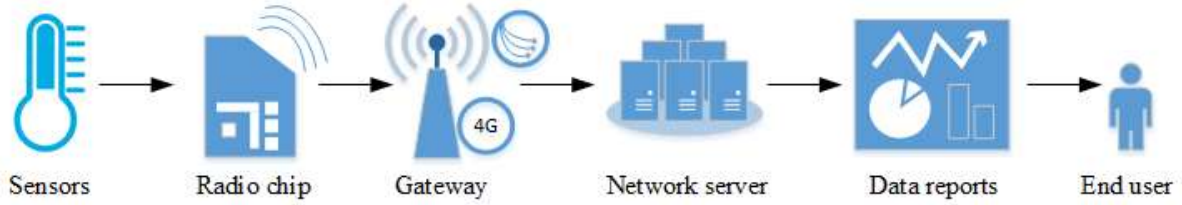

Figure 11. LoRaWAN working principle

Regarding Precision Beekeeping, there are several bee colony monitoring system architectures described (Kviesis & Zacepins 2015), in LoRaWAN scenario, each beehive (measurement node) is directly transferring the measurement data to remote network server and application using the gateway as a mediator.

Materials and methods

Based on the overall statistics beekeepers are not experienced IT specialists (not all of them), that's why installation of measurement system (measurement nodes) should not be complicated and should be done with little or no knowledge of IT. In author's case, installation of LoRa temperature sensor is trivial and user friendly – user only needs to put the sensor in the hive and mount the node to the beehive.

For authors research 3 (three) hives of *Apis mellifera mellifera* were equipped with temperature sensors for colony monitoring. Bee colonies were placed in an open environment under a hood (see Figure 4):

Figure 12. Placement of the beehives

The experiment took place at Strazdu iela 1, Jelgava, Latvia (N 56, 390, 4500 and E 23, 450, 1500). Sensors were installed on April 10, 2018. Norwegian-type hive bodies made of wood with external size 470 x 470 x 270 mm and internal size 380 x 380 x 270 mm, with a wall thickness of 45 mm, were used in the experiment. Sensors used were Adeunis Temp (see Figure 5) with references: ARF8181BA, ARF8180BA, ARF8181FA (source: https://www.adeunis.com/en/produit/temp/)).

Figure 13. Sensor Adeunis Temp

The temperature was measured every 10 minutes and data was transferred to a remote application. One temperature sensor per hive was placed above the hive body covering polyethylene foil as proposed by Stalidzans and Berzonis (Stalidzans & Berzonis 2013). Measurement units were mounted to the beehives as demonstrated in Figure 6:

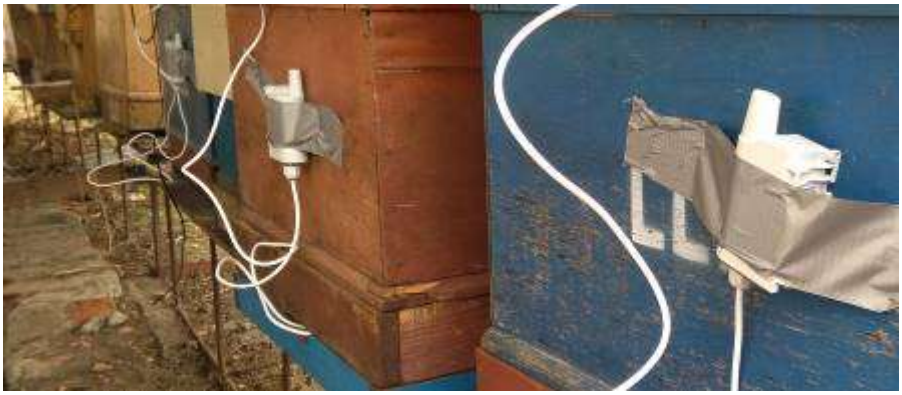

Figure 14. Beehives with mounted measurement units

Distance from the measurement point to the LoRaWAN gateway was approx. 2.4 km by the air in urban area (different obstacles, houses, trees, etc., see Fig. 7.). As a gateway Multitech MultiConnect Conduit with external antenna Taoglas OMB.868 is used.

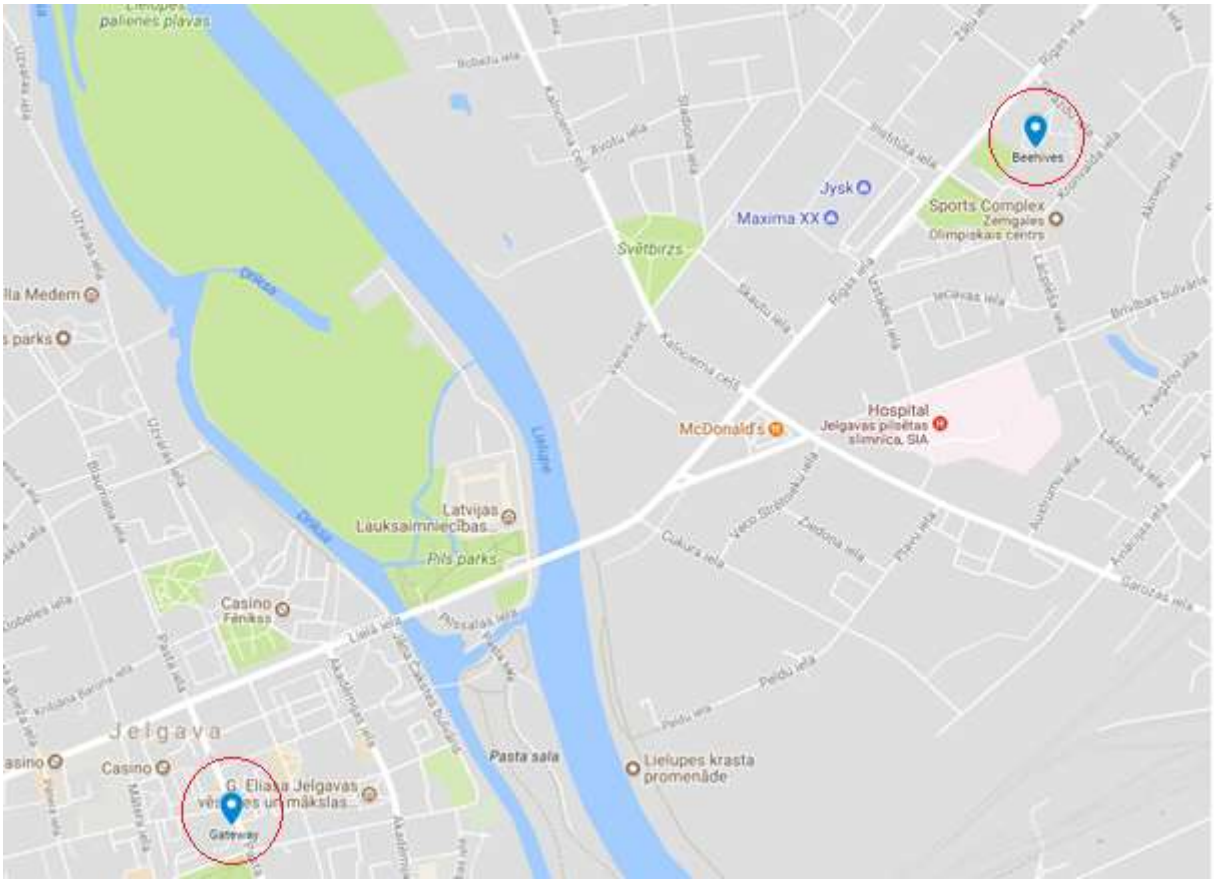

Figure 15. Location of beehives and gateway on the map

Web system for measurement visualisation

Bee colony temperature measurement data can be accessible using a Web based application (system). Web system is developed and provided by Lattelecom and is accessible by the address: https://iot.lattelecom.lv/portal/login. To get access to the measurement system administrator should register a new user and provide authorisation information (login and temporary password). After log in user can see his measurement objects (see Figure 8) and using pre-defined time periods (current month with 1 day step, last 7 days with 1 hour step,

last 24 hours with 15 min step or create custom time period) it is possible to visualise measurement data.

Figure 16. Screenshot of the web system

In addition, user can view all measurement data in table format and copy it if needed.
Usage of described above Web system is not the only option. It is possible to get access to the data warehouse and create individual system for data visualisation and analysis. This option is considered in case if more functionality is needed, for example implementing custom data analysis algorithms it is possible to define various bee colony states (death, swarming, brood rearing, etc.) and inform the beekeeper when manual inspection of bee colony is needed.

Results and Discussion

Aim of this research was to test LoRaWAN network for implementation of Precision Beekeeping. Practical experiments shows, that data transfer from the experiment beehives to the LoRa gateway was completed successfully without interruptions during the whole experiment. As distance was 2.4 km, open question is how data transfer will operate on longer distances. Within this research authors used already available infrastructure from local telecommunication company Lattelecom, but development of own infrastructure is possible too, by installing own LoRa gateways. Open question for discussion – is it economically feasible to develop own infrastructure or it is better to use existing one. This should be evaluated in each scenario and each country individually. Application of LoRa sensor for bee colony temperature monitoring is theoretically possible, but taking into account economic aspects is not so attractive, because of the measurement unit price, which is about 70 EUR per unit (2 temperature sensors per unit – out/in). However, taking into account that usually new technologies becoming more affordable after some time, authors foresee that application of LoRa sensors will be also economically feasible in the future.

Conclusions

LoRa sensors can be used for bee colony data collection for realisation of Precision Beekeeping. Advantage of LoRaWAN technology is data transmission range, which is crucial when Wi-Fi network is not available. LoRaWAN network solutions could be applicable in regions, where mobile networks have poor coverage and quality of services (e.g., Internet), for example African region, where is a good potential for Precision Beekeeping, but new technologies are not implemented so quickly.

Still Precision Beekeeping is not only limited by the temperature measurements; next important parameter is weight of the colony. Equipping scales with LoRa technology would be a good solution, because in that case amount of LoRa radio chip price will be comparable with scales price.

Acknowledgment

Scientific research, publication and presentation are supported by the Horizon 2020 Project SAMS „Smart Apiculture Management Services". This project receives funding from the Horizon 2020 European Union Research and Innovation Framework under Grant Agreement Nr.780755 – SAMS. This project receives funding from the German Federal Ministry for Economic Cooperation and Development.

Authors would like to thank LLC Lattelecom for provided sensors and LoRa infrastructure.

Abstract

The radionuclides' presence in animal feed is due both to natural radioactivity and radioactive pollution from different sources. Controls of radionuclides in animal feed will reduce the risk of radioactive hazards to animal and human health. The study was carried out in order to detect the natural radioactivity in animal feed and feed additive. Gamma spectrometer Canberra Packard with a high-purity germanium detector and Marinelli beakers (1 l capacity) were used for the samples measurement. The most prominent gamma energies observed in the spectra belonged to the naturally occurring radionuclides ^{40}K, ^{226}Ra and ^{232}Th. Other radionuclides if present occurred infrequently at low activity concentration under the measurable level. The results show that ^{40}K had the largest contribution to the specific radioactivity in all the samples. The mean activity concentration of the ^{40}K was highest in feed additive mono calcium phosphate (245.03±17.778 Bq/kg) and lowest activity concentration of the ^{40}K was measured in concentrate feed for dairy cows (23.20±2.626 Bq/kg). The average activity of the other two detected natural radionuclides in feed samples was lowest and ranged from 0.42 to 5.81 Bq/kg for ^{226}Ra and from 0.61 to 2.55 Bq/kg for ^{232}Th. The data analysis using ANOVA showed statistical significant differences in the radioactivity concentration of ^{40}K, ^{226}Ra and ^{232}Th between feed samples ($p<0.001$).

Key words: *gamma spectrometry, feeds, natural radioactivity.*

Introduction

The radioactive contamination of the animal organisms and body tissues primarily depends on the level of contamination of the food they consume, and to a lesser extent it depends on drinking water and by means of inhalation. With the use of animal feed, animals in their nutrition accumulate natural radionuclides, and to a lesser extent artificial radionuclides (^{90}Sr, ^{137}Cs, etc.). The fast industrial development and human activities in agricultural practices and livestock production significantly increase the environmental pollution, thereby leading to an increase of the concentrations of various radioactive substances such as strontium, cesium and uranium. Radionuclides have very quick migration and it is very difficult to prevent their transmission through the food chain (Petrović and Mitrović, 1994).

According Saračević (1999), the animals can be radioactively contaminated in several ways, however most commonly through nutrition or drinking water (80%).

An increasing care is dedicated to the radiation level in animal feed because ingestion through the mouth is one of the most frequent ways how radionuclides enter the living organisms. In order to increase the nutritional value of animal feed, substances containing increased levels of radionuclide activity are added, which will increase the concentration of radionuclide's in the feed. Considering that people use poultry meat and eggs as a part of their nutrition, it is necessary to monitor the levels of radioactive contamination in animal feed because it can

easily be deposited in humans through the path of radionuclides in the food chain (Hernandez et al., 2004).
Numerous researches have been performed which enable monitoring of the radioactive contamination of animal feed in order to reduce the risks that can take these quantities to humans (Carvalho et al., 2006; Casacuberta et al., 2009; Shanthi et al., 2009; Tchokossa et al., 2013).
However, in Macedonia there is a lack of data on the concentration of natural radionuclides in animal feed, namely the purpose of this paper was to assess the amount of natural radionuclides in samples of animal feed produced in Macedonia and to compare the values with already measured values of animal feed that was produced in other parts of the world. Bearing in mind that radioactive contamination in animal body tissues primarily originates from the level of contamination of the used animal feed, as well as the feeding water, a preventive measure would be to control the radioactivity of the animal feed being used, that is, if possible, it should be with a lower concentration of radioactive isotopes, which would not harm the animal organism.
Preventive measures for the reduction of the radioactive contamination of animals are also the method of land treatment which is applied for growing crops for animal feed or grazing, changes in the regime of animal management, giving binding agents or analogous products to animals and delayed slaughter of animals (Beresford and Howard, 2011).

Materials and methods

Sampling

The animal feed samples were collected on the basis of production and consumption in Macedonia. The samples were taken from several producers, and several samples were directly purchased from the market. The animal feed samples were crushed and then homogenized to a fine powder. All samples were left in hermetically sealed plastic containers with approximately 450g of sample. The containers were stored for 14 days in order to allow radium and thorium to achieve a secular balance with their (daughters) descendants.

Instrument

The samples are measured on an instrument – gamma spectrometer (Canberra Packard) with high-purity germanium detector. The measurement was performed in containers which were hermetically sealed so that ^{222}Rn produced from decay of ^{226}Ra will not result in gas leak. After the provision of time balance between the successors of ^{238}U and ^{232}Th series (21 days), these sealed samples were prepared for an analysis. The obtained spectra from the measurement were analyzed by using the program GENIE 2000. The specific activity of ^{226}Ra is calculated for energy line on 186,1 (keV) and ^{232}Th through its descendant of decay ^{228}As (second in the decayed sequence), that is, through its three gamma decay energy lines which occur on 338,4; 911,07 and 968,9 (keV).

The activities of ^{40}K were determined from its γ-line from 1460 keV. The interval of the time for calculation (counting) was 108000 seconds. The natural spectrum was recorded immediately after or before the calculation of the sample.

Activity calculation

The specific activity A (Bq/kg) is determined in accordance with the following formula by Garcia-Talavera (2003):

$$A = \frac{\frac{N}{t} - \frac{N_0}{t_0}}{\varepsilon \cdot \gamma \cdot m}$$

Where, N is clean surface of peak accumulated from a specific radionuclide in analysis of a specific sample (number of readings), N_0 is clean surface of peak accumulated from the spot of a specific radionuclide without an analysis of sample (number of readings), t is live time of accumulation of the sample spectrum (s), t_0 is live time of accumulation of the phone spectrum (s), ε is detector efficiency for a given energy (for a specific peak), γ is intensity of gamma transition in radioactive decay for a respective radionuclide (%), and m is mass of the sample (kg).

Results and discussion

The activity concentrations of ^{40}K, ^{226}Ra and ^{232}Th were assessed and they are presented in Table 1 and in Figure 1.

Table 1. Activity concentration of natural radionuclides in feed samples (Bq/kg)

Samples	n	^{40}K ($\overline{x} \pm S_{\overline{x}}$)	^{226}Ra ($\overline{x} \pm S_{\overline{x}}$)	^{232}Th ($\overline{x} \pm S_{\overline{x}}$)
Concentrate feed for pigs	5	226.13±11.911	1.81±0.269	0.61±0.086
Concentrate feed for dairy cows	5	23.20±2.626	5.81±0.982	1.99±0.281
Feed additive mono calcium phosphate	5	245.03±17.778	1.46±0.138	2.55±0.217
Maize	5	119.25±13.732	0.42±0.059	0.68±0.144
Total	20	153.40±15.542	2.37±0.411	1.46±0.164

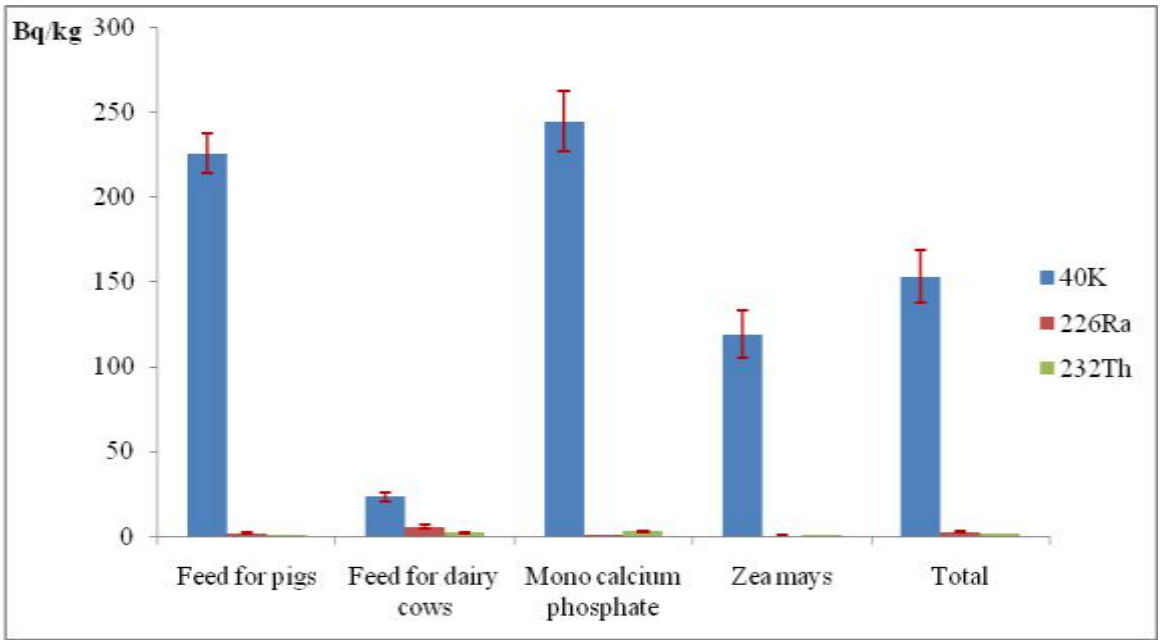

Figure 1. Activity concentration of naturally occurred radionuclides in feed samples

The results show that ^{40}K had the largest contribution to the specific radioactivity in all samples. The mean activity concentration of ^{40}K was highest in feed additive mono calcium phosphate (245.03±17.778 Bq/kg) and lowest activity concentration of ^{40}K was measured in feed concentrate for dairy cows (23.20±2.626 Bq/kg). The average activity of the other two

detected natural radionuclides in feed samples was lowest and ranged from 0.42 to 5.81 Bq/kg for ^{226}Ra and from 0.61 to 2.55 Bq/kg for ^{232}Th.

The main source of calcium and phosphorus in the concentrate for pigs is monophosphate (Ševković et al., 1991). This supplement is obtained by processing phosphorus ore, and it can also contain large amounts of uranium, thus being a potential source of radioactive contamination both for animals and people (Mitrović et al., 2011).

The results show that the measured monophosphate has a significant activity in all analyzed radionuclides. Considering the concentration of the radionuclide in the monophosphate brand, one can conclude that a large percentage of the radioactivity measured in animal feed is a result of food that contains this component. However, one cannot determine the level of radioactivity that is directly attributable to monophosphate, since the manufacturer does not specify the amount of monophosphate in nutrition. The presence of anthropogenic radionuclides was not detected, indicating that there was no contamination due to artificial radionuclides.

Conclusion

The concentrations of activity of natural radionuclides, ^{40}K, ^{226}Ra and ^{232}Th, were assessed in this study, in different samples of animal feed in the Republic of Macedonia. The results are similar with other such research. However, the values of the concentrations of the tested radionuclides are within the limits of the permitted values i.e. the transfer of such levels in animal feed and ultimately, in the human, through the radionuclide pathway, will not pose a threat when people will ultimately consume poultry meat, products and eggs of poultry fed with this feed. At the same time, systems should be established to monitor radionuclides in the main foodstuff in order to reduce human exposure to radiation through the consumption of animal products. Prevention is perhaps the best approach, and much attention needs to be paid to reduce radioactive contamination in animals and further in consumers as well. It should be emphasized that continuous monitoring of the level of natural and artificial radionuclides in animal feed is necessary in order to mitigate the amount of radioactive substances that can reach the human organism through the trophic chain.

Abstract

The concentrations of Zinc in fish from the Vardar river have been investigated in order to assess safety for consumers and the level of contamination. The selected tissues (skin, liver and muscle) of two fish species: European Chub (*Squalius cephalus*) and Common barbell (*Barbus barbus*) from Vardar river stream, Macedonia. Samples are collected in nine different points (Hot Spots) in total distance of 301 km and approximate 33 km between sampling sites. The effect environmental conditions and urban discharges on zinc accumulation in skin, muscles and liver were investigated. The metal analyses were performed using flame atomic absorption spectroscopy (AAS). The average of metal concentrations (micrograms per gram wet weight) in nine hot spots (HS) occurred in the following ranges: HS-1(skin 50.89503 – liver 30.8755 – muscles 8.829244) to HS-9 (skin 44.84977 - liver 43.03663 - muscles 13.8143.)The lowest levels of the zinc were detected in the muscles. The skin and liver were found to accumulate the highest amounts of Zn. In the case of organs, the highest levels were found, as follows: skin > liver > muscles. Further investigation of heavy metals is recommended, including a survey of fish consumption frequency among the local inhabitants.

Introduction

Fish is an important part of the human diet, but also a good indicator of trace metal pollution in the aquatic ecosystem. Fish samples are considered as one of the most indicative factors, in freshwater systems, for the estimation of trace metals pollution potential (Rashed, 2001). Organisms retain Zn, through specific binding proteins known as metallothioneins in their liver (Allen-Gil and Martynov, 1995).

Pollution of water bodies is becoming a major cause of concern with respect to human health (Jarup, 2003). Metals in waters may be of natural origin from the rocks and soil or from human activities, including industry, domestic wastewater, agricultural discharge, mine runoff, solid waste disposal and atmospheric deposition. Metals generally enter the aquatic environment through atmospheric deposition, erosion of the geological matrix, or due to anthropogenic activities caused by industrial effluents, domestic sewage, and mining wastes. Increase in the human population has greatly contributed towards the conversion of these water bodies to impending contamination sinks (Tarvainen et al., 1997; Stephen et al., 2000).

Heavy metals are well known to be non-biodegradable and when present at high concentrations, they tend to bioaccumulate (DeForest et al, 2007). Being non-biodegradable, metals can be concentrated along the food chain, producing their toxic effects at points often far away from the source of the pollution (Fernandez et al., 2000). Heavy metals can cause a variety of ailments in humans depending on the degree of exposure. These vary from minor skin irritation to severe damages of the liver, kidney, nerve tissues and circulatory system. Similarly, although zinc (Zn) is an essential requirement for good health, excess zinc can be harmful. Zn has a multitude of biological functions in the human body. It is an important

constituent of over 100 enzymes involved in a variety of fundamental metabolic processes. It is involved in the production and function of several hormones. Zinc toxicity can occur in both acute and chronic forms. Acute adverse effects of high zinc intake include nausea, vomiting, loss of appetite, abdominal cramps, diarrhea, and headaches,(Jarup, 2003; Khallaf et al., 1998).

River Vardar is the longest river in the Republic of Macedonia and Republic of Greece with distance of over 388 km, with his source in the location Vrutok and stream at the Aegean sea. The Vardar river, with its tributaries, makes up a great part of the total water resource of Macedonia. These tributaries and river Vardar are directly or indirectly connected with the mining areas for Zinc (Zn) in the locations. The river is widely used for fisheries (wild fish and fish farming), sports and recreation. Very little recent information is available regarding the contamination with metals in the Vardar river fish species. The river Vardar passes near and across the biggest cities including Gostivar, Tetovo, Skopje, Veles, Negotino, Demir Kapija and Gevgelija with possibility of environmental contamination from domestic and industrial sewage Hot point spots in Fig.1.

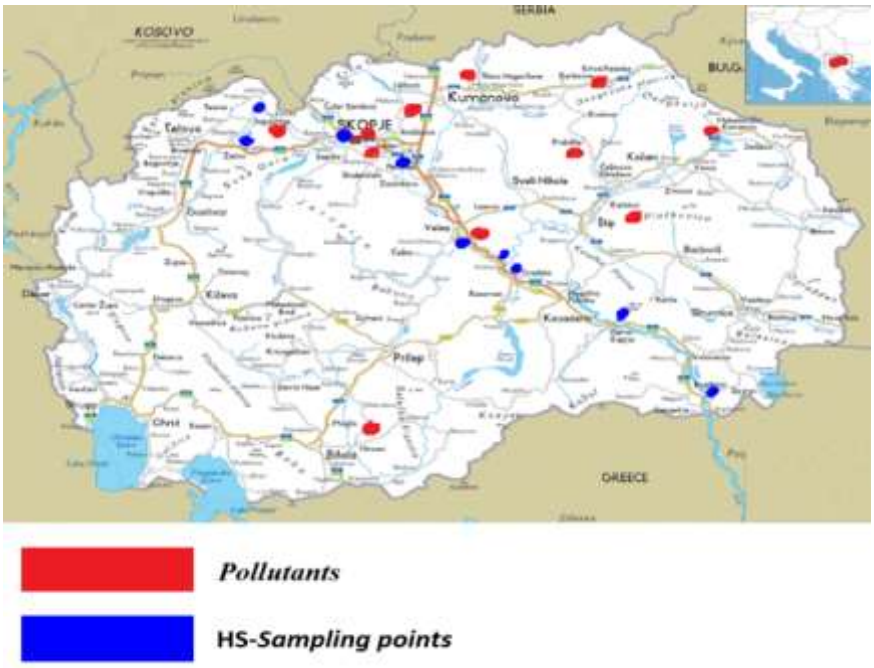

Fig.1 In the map of the Republic of Macedonia, showing hot point spots

The aim of this study is to provide information and evaluate the level of Zinc as a heavy metal in fish organs (muscle, liver and skin) from Europian Chub (*Squalius cephalus*) and Common barbel (*Barbus barbus*) fish species.

Material and methods

Samples were collected in nine (9) places with distance between them in around 33 km along the river. From each place were fishes are collected from both species with support from fishermen's.

Fish samples were transported in Pathology laboratory of the Veterinary Institute Prishtina, submitted for dissection of target organs were collected for study including skin, liver and muscle. Each sample of fish tissue has been measurement with analytical scale then set in plastic bag, marked with number which show the catching location and tissue then finally

refrigerated below the -18ºC. Total numbers of samples were sixty (60) from Europian Chub and Common barbell.

Next step was the sample and set in to the porcelain pots then the sample was heated in microwave in 105°C for 24h to drain. The next day the samples were taken out from microwave and they passed to the stove for 24h in 550°C where they were burned. After 24h the burned samples are prepare for digestion with HNO3 65%. Prepared sample after digestion are ready for reading and analyze by flame atomic absorption spectroscopy (AAS) with the Atomic absorption spectrometer produced from Thermo. All data are presented in the unit $\mu g/g^{-1}$ wet weight of a sample tissue, and are processing with comparative methods

Results and discussion

Results of this study showed that the metal concentrations accumulated in the tissue samples were in descending order of skin > liver > muscles. In the study, we found that the concentration of Zinc were different in the analyzed organs and differently in the sampling locations. The average of concentration of the Zinc in the organs (skin, liver and muscle) and the locations (nine locations) is showed in Table 1.

Table 1. Mean Heavy Metal Content ($\mu g/g^{-1}$ wet weight) in Fish skin, muscle and liver

Sampling point	Muscle	Liver	Skin
HS-1	8.82924	30.87550	50.89503
HS-2	10.25356	34.74869	36.88801
HS-3	17.63045	36.68569	59.80203
HS-4	13.39171	45.59118	41.53124
HS-5	13.16620	46.83435	42.93423
HS-6	8.74029	52.58685	40.45726
HS-7	12.19933	12.60700	46.09540
HS-8	13.17433	52.38320	39.21015
HS-9	13.81430	43.03663	44.84977

Higher Zn concentrations were found in liver tissue, while the lowest were detected in muscle tissues. This finding is in agreement with those of other studies regarding the differences between heavy-metal accumulation in fish tissues (Carpene and Vasak, 1989; Allen-Gil and Martynov,1995).

There guidelines on acceptable levels of Zn in the edible parts of fish suggested in Macedonia is according to international standards 40-100 μg/g. According to our results, there is metal contamination, but it is lower than the guidelines, in the edible part of the examined fish. The examined fish were not associated with enhanced Zn content in their muscle and were safe within the limits for human consumption.

From results we can see that we have a different Zinc concentration, and as we can see that highest level is in the HS-3 sampling site, which is the point where the river Treska is connected to the river Vardar. In the most studies of similar analyzed samples, the liver accumulate the highest concentration of Zinc in our study is shown that is the samples of skin in sampling sites HS -3 and till the HS-9, showed that fishes in the part of river Vardar from Skopje till the border with Republic of Greece accumulated higher concentration of Zinc. In previous study, increased concentrations of these hazardous substances, especially Pb and Cd, in water and sediment from the lower part of the Vardar River, influenced higher accumulations of metals in liver, gills and gonads of Gobio gobio L. (Nastova et al. 2017), concentration of Zn is not reported.

In our country the river pollution with heavy metal contaminations are in the concern because off potential thrived waste from domestic and industrial sewage, non-secured industrial landfill and mining fields. The Zn is essential elements and is carefully regulated by physiological mechanisms in most organisms (Eisler, 1988). However, they are regarded as potential hazards that can endanger both animal and human health. Knowledge of their concentrations in fish is therefore important both with respect to nature management and human consumption of fish as suggested in Amundsen et al., (1997).

Aquatic organisms have been widely used in biological monitoring and assessment of safe environmental levels of heavy metals In this study metals concentrations in the muscle of both fish species were used to investigate possible transfer of metals to human populations via fish consumption. Since accumulation of metals in the biological system is dangerous to human beings in our country, there is a need for regular or continuous monitoring of heavy metals concentrations in the aquatic environments.

In Vardar river, among all river/aquatic organisms the fish are the most interested for humans for sport activities in particular, source of food mainly for fisherman's and their families as well. Fishes are considered as indicators in river ecosystem for heavy metal contaminations with light level risk as a potential for human food consumption, because fish are in the top of aquatic food chain, heavy metal accumulation and possibly for the transfer heavy metals on the humans.

Conclusion

Our preliminary results provide information for the levels of Zn in common fish species of the Vardar river. Results will contribute to the effective monitoring of both environmental quality and the health of the organisms inhabiting the river ecosystem. According to the fish sample analyses the range of concentration with Zinc is in the lower border with the range of international standards Zn:40-100$\mu g/g^{-1}$ wet weight, and it shows that the fishes from investigated Vardar river are safe for human consumption.

Abstract

The impact of the Swedish Landrace and Large Yorkshire sire breeds (SL and LW), sires within the breed, of gender and the fattening season on the variability of pork quality traits was examined in the present study. The observed measurements were the pH value (pH_{45} and pH_{24}) of the *m. longissimus dorsi* and *m. semimembranosus*, the chemical composition (water, fat, ash and protein content), the water binding capacity, the colour and thickness of the *musculus longissimus* muscle fibers. The trial was conducted at the experimental farm and slaughterhouse of the Institute for Animal Husbandry, Zemun-Belgrade (Serbia). Sires were pure breeds: Swedish Landrace (SL, n=10) and Large White (LW, n=3). The pH value was measured in 410 offspring born in the winter, summer and autumn. Samples of *m. longissimus* originate from 50 offspring (29 samples taken from the offspring of SL sires and 21 samples of LW sires). It was found that the sire breed did not influence ($P>0.05$) the pH values of the muscles tested, but that the sires within the breed influenced ($P<0.01$) the pH_2 of the *m. semimembranosus*. The birth season of offspring shows high statistically significant impact on the pH_2 of the tested muscle ($P<0.001$), while the gender of the fatteners had no influence on the tested properties ($P>0.05$). The results show that *musculus longissimus* contained on average 73.10% of water, 24.09% of protein, 1.65% fat and 1.17% ash. The influence of the sire breed ($P<0.05$) on the water content and the influence of the sire within the breed Swedish Landrace ($P<0.05$) on the protein content were determined, while the gender of fatteners showed no impact ($P>0.05$) on the chemical composition of *m. longissimus*.

Keywords: *Genotype, Sire breed, Sex, Season, Fatteners*

Introduction

Meat quality is a complex term that is used today to describe the overall meat properties. One of the most accepted definitions of meat quality was given by Hofmann (1994), who described meat quality as the sum of all sensory, nutritive, hygienic-toxicological and technological properties of meat. Andersen *et al.* (2005) defined meat quality as a complex and multivariate feature influenced by many factors in interaction, including the conditions in which it was produced. Proteins have long been regarded as the most important component of meat. However, the importance of polyunsaturated fatty acids in meat is increasingly emphasized. Essential fatty acids found in the human brain are not found in plants only in meat. For this reason, meat is irreplaceable for humans, i.e. for normal and balanced nutrition. In this regard, the lack of polyunsaturated fatty acids in the diet presents a greater problem, from the point of view of people's health, than the lack of protein. Selection can influence the content of intramuscular fatty tissue, i.e. the content of fat in meat (Dević *and* Stamenković, 2004; Mason *et al.*, 2005). Uncastrated male animals, compared to females, have a much lower percentage of fat, according to Čepin *and* Žgur (2003) in the same diet regime. Nakev *et al.* (2016) were determined the effect the season and year of slaughter have an impact on the share of meat in the carcass sides.

The selection is a powerful tool for reducing fat content, that is, increasing the share of meat in carcass sides, also, adequate animal nutrition provides the ability to reduce fat content and

fatty acid changes. For pork the appearance of changes in the color and structure of the meat is characteristic, also the ability to retain water and other properties. Čobanović *et al.* (2017) state that the examination of the presence of liver spots on the slaughter line can be an important indicator not only for the welfare of pigs on the farm, but also for the quality of the carcasses and pig meat. Today, there are growing demands on the quality of pork in the market and, therefore, it is increasingly becoming the object of the mutual interest of the pig producers and the processing industry (processing and preserving meat and meat products) in the world. Possible prediction of the quality of pork is one of the decisive and key roles in the business success of the producer, and, in relation to this, the genetic basis becomes the primary in setting the production goals (Chan *et al*., 2002).

The aim of the conducted research was to determine the effect of sire breed, sires within the breed, gender, birth season of offspring on the quality of pig meat.

Material and Methods

The trial was conducted at the experimental farm and slaughterhouse of the Institute for Animal Husbandry, Zemun-Belgrade. Sires were pure breeds: Swedish Landrace (SL) and Large White (LW). The observed properties were the pH value (pH_{45} and pH_{24}) of the *m.longissimus* and *m.semimembranosus* of three sire breed SL (n=102; n=74 and n=36 offspring) and of three sire breed LW (n=83; n=53 and n=63 offspring). The chemical composition (water, fat, ash and protein content), the water binding capacity, the colour and thickness of the *musculus longissimus* muscle fibers. The pH value was measured in 410 offspring (207 male and 203 female offspring) born in the winter, summer and autumn. Samples of *m.longissimus* originate from 50 offspring were taken between the 13th and 14th rib (29 samples taken from the offspring of four SL sires and 21 samples of three LW sires). Data was processed by applying the adequate software package "LSMLMW and MIXMDL, PC-2 VERSION" (Harvey, 1990), i.e. by using the procedure of the Least Square Method in order to determine the significance ($P<0.05$) of systematic influences on traits of meat quality. Model included: sire breed, sires within the breed, gender, birth season of offspring and carcass side mass (linear effect).

Results and Discussion

By testing the two muscles - *musculus longissimus* (ML) and *semimembranosus* (SM), identical average values (Table 1) of pH_1 for ML and SM (pH = 6.54) were determined, while the pH value of ML for 24 hours (pH_2) decreased faster than of SM (5.70: 5.77). According to Honikel (1999), who states that the pH_{45} values of the muscles of "normal" quality are greater than 6.0 and pH_{24} values range from 5.4 to 5.85, we can say that mean values obtained in the present study are within the limits indicated, i.e. that the fatteners had muscles of normal quality. The results of our study show that the pH_2 (ML and SM) varied under the influence of the birth season ($P<0.001$) and between the sires within the breed SL ($P<0.01$) and LW ($P<0.01$) and that the other included factors did not exhibit statistically significant influence ($P>0.05$). The results obtained are contrary to the studies of a group of authors who have found that the sire breed affects the variation of the pH_1 and pH_2 values (Latorre *et al*., 2003; Josell *et al*., 2003; Radović *et al*., 2009).

In regard to the nutritional quality of pig meat, according to the previous studies (Ryu *and* Kim, 2005; Purslow, 2005; Kušec *et al.*, 2006), the content of water, proteins, fats and minerals range as follows (respectively): 60-75%; 18-21%; 1.5-5.9% and 0.8-1.2%. The obtained average values of the nutritional quality of ML in our study are within the stated limits except for the protein content (24.09%) which was higher than the values established by Mason *et al.* (2005) and Olsson *et al.* (2003) for the Swedish Landrace.

In regard to the water binding capacity (WBC), in our study (Table 3), the influence of the sire breed (P<0.01) was determined, which is in accordance with Radovic *et al.* (2009) and contrary to the research by Jukna *et al.* (2009). Our results are in agreement with Radović *et al.* (2009) who have found that the sex (gender) of fatteners did not affect the variation of WBC, but are contrary to the results of Jukna *et al.* (2009) who have determined the effect of the given factor (P<0.05). In regard to the meat colour, in our study, the variation of this property between the half-siblings of different sires of SL breed (P<0.01) was determined, which is in agreement with the research by Radović *et al.* (2009) for the influence of a sire's breed, but in contrast to the impact of sex. The obtained average value of muscle fiber thickness was in the range determined by Radović *et al.* (2009), and lower than the top value indicated by Migdal *et al.* (2005) and Makovický *et al.* (2009a, b). The thickness of the muscle fiber did not vary under the influence of the sire breed, which is contrary to the research by Radović *et al.* (2009).

Conclusions

In this study, we found that the sire breed did not influence (P>0.05) the pH values of the muscles tested, but that the sires within the breed influenced (P<0.01) the pH_2 of the *m.semimembranosus*. The birth season of offspring shows high statistically significant impact on the pH_2 of the tested muscle (P<0.001), while the gender of the fatteners had no influence on the tested properties (P>0.05). The results show that *musculus longissimus* contained on average 73.10% of water, 24.09% of protein, 1.65% fat and 1.17% ash. The influence of the

sire breed (P<0.05) on the water content and the influence of the sire within the breed - Swedish Landrace (P<0.05) on the protein content were determined, while the gender of fatteners showed no impact (P>0.05) on the chemical composition of *m. longissimus*.

Abstract

The improvement of the production characteristics of the Simmental breed in Serbia is mainly done through purebreeding. Selection is a factor without which there can be no serious results in the improvement of the genetic basis and increase in the productivity of livestock production in general. In order to realize faster improvement of production performance, of the genetic composition and increase of number of cattle in Serbia, more and more farmers have recently decided to import cattle from countries with intensive breeding of Simmental cows, primarily from Austria and Germany, i.e. from countries where the average milk production ranges from 6500 to 7000 kg with over 4% milk fat. The aim of the study wasto examine how the import of the animals influences four reproductive traits (body weight of calves at birth, age at first calving, calving interval, duration of service period) in domestic and imported populations of Simmental cows. The present study included 954 cows, with a total of 3641 completed lactations. All cows were located in the area of Toplica district, reared by individual agricultural producers (tied system) and on farms with intensive rearing (free system). On the basis of the housing system (tied and free systems) and origin (domestic and imported) animals were divided into four groups: Group 1 (animals of domestic origin, reared by individual producers/farmers); Group 2 (imported animals, reared by individual producers/farmers); Group 3 (animals of domestic origin, reared on commercial farm) and Group 4 (imported animals, reared on commercial farm). In regard to the investigated traits, the highest values were recorded in the fourth group of observed cows, while all the reproductive properties varied very significantly ($p \leq 0.001$) under the influence of the unified factor of the housing method and origin, except for the age at first calving whose variation was not statistically significant ($p > 0.05$)

Keywords: *Reproductive properties, origin, housing, Simmental breed*.

Introduction

Reproduction in modern cattle production represents a significant scientific field and a very complex stage of production. It is an area that has often been the subject of research, but it is also an area in which many unresolved and fully undefined problems occur. As such, reproduction is an important factor in intensifying cattle production, as solving problems in this area can lead to higher production of milk and meat.

Reproduction is also significant part of cattle production in which animals are provided for production of milk and meat, as well as for the renewing of herds (Mitić *et al.*, 1987).

Research on the body weight of calves at birth, as one of the fertility traits, is done for several reasons. First of all, calves that are born heavier within a single breed have a greater predisposition for faster and more efficient growth, which is particularly important for fattening breeds. However, the high birth weight of the calves is one of the main causes of heavy calving, and mortality of calves immediately after birth. In his research, Skalicki (1983) found that the average weight of male calves of German Simmental breed was 37.39 kg in the first three calvings and 35.46 kg for female calves. Similar values, the same author states for

the Austrian Simmental cattle, where the male calves had body weight at birth of 38.48 kg and the females 36.23 kg. Nikšić *et al.* (2012) analyze the results of the biological test of the bulls of the Simmental breed in Central Serbia. On a sample of 35 bulls and 3572 calves, the average weight of calves was 44.54 kg with a range from 25 to 73 kg, with very high variation ($p \leq 0.001$) under the influence of bull-sires.

During intensive rearing in the growing period, the heifer's full and physiological maturity occurs earlier. This allows for their early fertilization and the beginning of production use, which is particularly important from an economic point of view because earlier fertilization saves costs of rearing, shortens the generation interval and increases the efficiency of selection in the unit of time. Perišić *et al.* (1998), in their researches related to the reproductive and production traits of different genotypes of the Simmental breed (genotype I animals of Domestic spotted breed, 2nd genotype German Simmental breed, genotype 3rd Slovenian Simmental animals) have concluded that the age at first calving of Domestic Spotted animals was 2.1 years, German Simmental animals 2.3 years, and Slovenian 2.24 years. Đurđević (2001) has established values for the basic parameters of fertility. In his research, he examines the genetic analysis of milk yield and the reproduction of Simmental Cows, and finds that the average age for the first fertilization is 546.66 days with a variation interval of 240 to 1170, while the age at first calving is 831.94 days. In investigation of the phenotypic and genotypic variability of the production characteristics of the first Simmental breed, Pantelić (2006) states that the average age of first calving in Serbia is 778.73 days, with a standard deviation of 86.66 days and a minimum and maximum values of 620 to 1079 days.

One of the basic parameters of reproductive efficacy is the interval between two consecutive calving. This period is called the calving interval, and it should take about 12 months for Simmental cow (Petrujkić *et al.*, 1992; Miljković, 1994). However, in our production conditions, this period often lasts much longer, and as the duration of gravidity is a biological constant, the only reason for a longer calving interval is the prolonged service period (Stančić *and* Košarčić, 2007). The calving interval lasted for an average of 412 days, while Petrović (2000) in his study of the longevity of cows shows results for the duration of service period of 130.63 days and the duration of the calving interval of 416.76 days. Examining the effect of the import of breeding animals of Simmental breed from Germany to the implementation of the breeding program in the territory of the city of Kragujevac, Kostić (2014) has obtained the following results: on average, all studied have calved for the first time at an age of 780.17 days, the second time 1171.86 days, and the third time 1552.31 days. The average service period decreased with every subsequent lactation from 100.73 days, 95.43 days to 91.13 days. Domestic cows from calved for the first time earlier in comparison – by 79.13 days, the second time by 89.51 days, and the third time by 88.62 days, and all the differences are statistically significant. Statistically significant differences are also established ($p \leq 0.01$) for the duration of the service period where cows from domestic breeding show a shorter service period of 10.19 (2nd lactation) to 15.94 days (3rd lactation).

Material and Methods

Basic data on reproductive properties, as well as the origin data of all examined cows, were collected in cooperation with the "Lazar" Blace farm, which housed a part of the animals included in this research. For animals that are grown on individual farms, data on these traits were collected in cooperation with the breeding organizations, which implement the breeding program in the area of Toplica district. In this study, differences were determined in reproductive properties of cows that were imported and housed on the farm "Lazar" and those located on farms of individual agricultural producers, also differences in these properties in the imported and animals of domestic origin on the farm, as well as in individual breeders of Simmental cows on the same area.

The total number of animals and their completed lactations was divided into four groups as follows:
Group 1: animals of domestic origin grown by individual producers (n = 1526);
Group 2: imported animals grown by individual producers (n = 234);
Group 3: animals of domestic origin grown on the farm (n = 1100);
Group 4: Imported animals grown on the farm (n = 781).

When examining the impact of the unified factor of the way of holding/housing and origin, a model with a fixed unified effect of the way of holding/housing and origin (NP) was used

$Yij = \mu + NPi + eij$

- Yij: studied trait,
- μ: population average for given trait,
- NPi: fixed unified effect of the way of holding/housing and origin (i=1,2,3,4),

eij: random error.

For statistical data processing and application of the specified model, the software SPSS Statistics for Windows, Version 23.0 was used.

Results and Discussion

Table 1 shows the statistics on the body weight of calves at birth according to the housing/holding and the origin of their mothers divided into four groups, as well as the influence of these factors on the observed trait. It can be noted that the heads of the domestic origin reared on the farm (group 3) gave calves of the lowest body weight (40.10 kg), while the imprted animals (group 4) gave the calves of the highest body weight (44.78 kg). The calves of cows of domestic origin reared by individual producers (group 1) had higher body weight value (41.01 kg) than calves originating from imported cows reared by individual producers (group 2), which amounted to 40.29 kg. The results obtained with all four groups of observed are approximate to the results obtained by Nikšić et al. (2012). The unified effect of the factors of the holding/housing and the origin of animals was statistically very significant ($p \leq 0.001$) in the observed four groups of cows for the tested trait.
If the age of cows at first calving is observed by groups as shown in Table 1, it can be seen that tit was the lowest in the domestic animals rrreared by individual producers (773.73 days), somewhat higher in the first calving heifers of domestic origin reared on the farm (774.35 days), and then in the first calving heifers originating from import and reared by individual producers (778.06 days), and the longest in the case of first calving heifers from import reared on the farm (790.72 days). The age at the first calving was not significantly statistically significant ($p > 0.05$) under the influence of the combined effect of the holding/housing and origin of animals, when observing the first calving heifers divided into four groups. The values obtained for the age at first calving were significantly lower than the value stated in the study by Perišić *et al.* (1998) in German and Slovak Simmental animals, and Đurđević (2001) in Simmental cattle in Serbia, but approximately the same values for age at the first calving are reported by Perišić *et al.* (1998), Pantelić (2006) and Kostić (2014) for cows of the Simmental breed in Serbia.

N=number; $\bar{X}$=average; SD=standard deviation; SE=standard error; LB= lower border/limit; UB=upper border/limit; F=statistical value; p=significance ***- p≤0.001; ** - p≤0.01; * - p≤0.05; nz - p>0.05

Based on the results shown in Table 1, it can be concluded that the calving interval was longer in imported cows than cows of domestic origin. The calving interval of cows from import housed and reared on the farm was the longest and amounted to 405.13 days, while in case of imported animals grown by individual producers it was 394.36 days. The shortest interval between the two successive calvings was recorded in domestic animals reared by individual producers (391.52 days), and it was by eight days longer in animals of domestic origin on the farm (399.50 days).

The unified effect (holding/housing and origin) was statistically very significant (p≤0.001) for the observed four groups of cows for the test traits. The obtained results of the calving interval in all four groups of cows were significantly lower than the results obtained by Vasović (1991) and Petrović (2000).

From Table 1 it can be seen, that the service period as well as the calving interval lasted for a longer time in case of imported animals compared to the animals of domestic origin. The service period in imported animals lasted 120.15 days, in case of animals reared on the farm and 108.40 days in animals reared by individual breeders, while the domestic animals reared by individual producers had a service period of 106.58 days, and animals of the same origin reared on the farm - 114.58 days. The influence of the holding/housing and the origin was statistically very significant (p≤0.001) in the observed four groups of cows for the tested traits. The obtained results for the duration of service period were higher than the results reported by Vasović (1991), but also significantly higher than those indicated by Kostić (2014) in domestic cows. However, the results obtained are significantly lower in all four groups of cows observed than the results achieved by Petrović (2000).

Conclusions

Groups 2 and 4 of the observed cows showed longer intervals in traits the age at first calving, the duration of the calving interval, and the duration of the service period compared to groups 1 and 3, since these groups included imported animals. The assumption that the expression of the reproductive traits will be better in animals of domestic origin was starting point of the research. In all observed properties, the highest values were recorded in animals of the fourth group, but not significantly, which leads to the conclusion that the reproduction properties are not significantly damaged by the selection of the animals and the method of rearing. All of the observed reproductive traits varied very significantly ($p \leq 0.001$) under the influence of the unified factor of the way of holding/housing and origin, except for the age at first calving whose variation was not statistically significant ($p > 0.05$).

THE IMPACT OF THE NUMBER OF SCOUT AND FORAGER BEES IN SPRING ON THE STRENGTH OF HONEYBEE COLONIES IN SPRING AND AUTUMN INSPECTIONS

Abstract

The aim of this paper was to show whether the number of scout and forager bees can be an indicator of the strength of honeybee colonies. It was studied how the number of scouts and foragers in spring (March and April) influences the colony strength. Spring inspection was carried out at the beginning of April, and autumn inspection in the first decade of September. The colony strength (quantity of bees and brood) and food supplies (quantity of honey and pollen) per society were determined in each inspection. After the spring review, colonies were divided into three groups. Strong colonies had 5 frames with bees and 3 frames with brood. Medium strong colonies had 4 frames with bees and 2 to 2.5 frames with brood. Poor societies had 3 frames with bees and 2 frames with brood. The experiment was conducted in Kruševac during 2011-2012. Each group had 10 honeybee colonies that were in standard LR beehives. During March, two countings of scout and forager bees were done, and during April three countings were done. Scout bees that returned to the hive in 1 minute were counted and all forager bees that returned with the load of the pollen were counted for the same period. During the first year, the number of scouts did not reflect the strength of colonies, because the medium strong colonies had even a little more scouts and foragers than the very strong ones, while the poor were significantly behind. In the second year, scout bees did reflect the strength of colonies. The highest number of scouts (235.5) and foragers (139) was found in the strong colonies, 205.3 scouts and 107.7 foragers in the medium colonies, while poor colonies had 160 scouts and 82 foragers. In the first year, medium-strong colonies were somewhat better in autumn inspection (more bees, honey and pollen) than very strong colonies. In the second year the poor colonies reached the medium ones (higher strength and similar food supplies).

Keywords: *Honeybee colonies, colony strength, scout bees, forager bees, colony inspections*

Introduction

Frequent inspections of honey bee colonies can take a long time, especially to beekeepers who have a larger number of colonies. In addition, the frequent opening of the hives disturbs not only the colony that is being examined but also the colonies in the immediate vicinity, and sometimes the other colonies in the whole apiary. The beekeepers always wanted to be able to evaluate the strength of the colonies, but to open the hive and take out the frames as little as possible. Often this was done by looking at the floor board and what was on it, as the waste on the floor is most often grouped directly below the bees. An easier way would be to draw conclusions about the colony strength based on the number of bees that fly out or the number of bees that return to the hive. Considering that the presence of pollen in nature and its entry into the hive is very important for brood nutrition, the inclusion of the number of pollen bees would probably yield even more precise results. Farar (1936) discovered that the size of the winter honey bee population is in a positive correlation with the autumn amount of bees and

the amount of pollen. Many authors later confirmed this thesis, except for Mc Lilen (1978) who concluded that the surface under the brood was not correlated with the amount of collected or available pollen in the hive, on the day of the examination (at the daily level). This can be justified by the fact that colonies often collect more or less pollen per day, stronger colonies have more brood and have to consume larger quantities of pollen and colonies of the same strength collect different pollen at different locations (Al Tikrity *et al*., 1972). Keller *et al*. (2005) stated that the amount of collected pollen, and therefore the number of pollen in the colony, is influenced by 10 and more factors (the number of worker bees - the quantity of bees, the number of larvae - surfaces with the brood, the number of foragers (Dreller *et al*., 1999), empty space in the hive (Schmickl and Crailsheim, 2004), the removal of pollen (Lopre *et al*., 1985), surrounding vegetation, climatic factors, etc.). Eckert *et al*. (1994) artificially adjusted the amount of brood in colonies that were initially similar in terms of strength (adult bees) and food supplies (honey and pollen). A week after setting up the colonies with a high level of brood, the supply of pollen decreased. In another experiment, it has been found that colonies with more open brood have more pollen foragers, and vice versa, if the frames with open brood are replaced by frames with capped brood (from the other hive), the number of foragers decreases (Eckert *et al*., 1994). Pankiv *et al*. (1998) found that even the addition of pheromones secreted by the larvae in glass plates managed to increase the number of pollen in the colony. Several studies have attempted to establish causal relationships in the other direction, i.e. to prove that increased additions or foraging of pollen increases the area with brood and therefore the strength of the colony. Fewell and Winston (1992) found that in colonies with equal strength (bees, open and capped brood) and the amount of honey, the area with brood increased significantly by adding more pollen to the colony. The aim of this paper was to determine is there an impact of the number of scouts and the number of foragers, counted during the spring (March-April), on the colony strength in the short time period (spring inspection), as well as to discover whether this strength of the colony remains for long like this or there is a change in the later period (autumn inspection).

Material and Methods

The experiment was carried out at the apiary of the Institute for forage crops Kruševac during 2011-2012. Spring inspection was carried out at the beginning of April, and autumn inspection was in the first decade of September. In the inspections, the strength of the colonies (quantity of bees and litters) and food supplies (quantity of honey and pollen) per colony were determined. The amount of bees was determined visually based on the amount of bees that have been present on the frames. This trait is expressed in parts of the frame that are possessed by bees (1/10), and can also be expressed in percentages. By adding the amount of bees on the frames, the total quantity of bees by colony is calculated. The area under the brood was also evaluated in spring and autumn by detailed observing of each frame with an open and capped brood in the hive. The results are also expressed in parts of the frame (1/10). The area of honey and pollen were assessed in the same way and at the same time as two previous traits. After the spring inspection, the colonies were divided into three groups. Strong colonies had 5 frames with bees and 3 frames with brood. Medium strong colonies had 4 frames with bees and 2-2.5 frames with brood. Poor colonies had 3 frames with bees and 2 frames with brood. Each group had 10 honey bee colonies that were in standard LR beehives. During March, two countings of scout and forager bees were done, and during April three countings were performed. Scouts that return to the hive in 1 minute were counted and all the foragers that return with the load of the pollen were counted in the same period. At the beginning of the experiments in all colonies there were one-year-old queen bees hatched in 2010. All traits were statistically processed by the ANOVA variance analysis method on a completely random plan. Computer program STATISTICA 7.1 (StatSoft, 2006) was used for

data processing. The differences between the average values of the treatment were tested with a LSD test at a significance level of 95% ($p<0.05$).

Results and Discussion

Colonies in spring inspection had, on average, 4 frames occupied by bees and 2.3 frames with brood (Table 1). The most bees and brood were found in strong colonies and these differences were statistically significant ($p<0.05$). A somewhat different condition was determined in the spring inspection considering the amount of food, especially the amount of honey. The highest amount of honey in the first year of the spring review was found in poor colonies, slightly less in strong colonies, and the least amount was found in the medium strong colonies. Strong and medium strong colonies had almost identical amounts of pollen, and the poor ones had smaller amount of pollen, but the differences were not significant. During the counting of scouts in the first year (Table 1), the average number was 53.6 for 1 minute of counting. Medium strong colonies had the largest number of scouts, slightly smaller number was in strong colonies, and the lowest number was in poor ones. In this year, the average of 23 foragers per colony were counted. Medium strong and strong colonies were fairly uniform while the poor colonies were lagging behind considering the number of foragers. The highest percentage of pollen was found in medium strong colonies, and the differences for this trait were not statistically significant. Eckert *et al*. (1994) found that the number of pollen foragers is proportionally higher in smaller colonies than in larger ones. This finding is a compatible with the one obtained in our research and refers to medium strong and strong colonies. Jevtić (2007) found, during the pollination of alfalfa, that the percentage of pollen ranged from 27.8-40.6% in daytime countings. In the afternoon counting it has dropped considerably and ranged from 8.2 to 22.8%. Following the pollination of the red clover Jevtić *et al.*, (2013) found that the percentage of pollen in poor colonies was 27.6% and in strong ones was 29.5%. In the autumn inspection, colonies had about 8 frames filled with bees. Medium strong colonies were better than strong ones and had more bees, but they did not differ significantly, while in relation to the poor colonies, both significantly differed. Medium strong colonies had the highest amount of honey and pollen in this inspection. For the amount of honey the differences were not significant in relation to the strong colonies, and for the amount of pollen, the differences were significant (Table 1). The most brood in the autumn inspection was found in strong colonies, medium strong had a little less brood, while poor ones were far behind.

Table 1. The average number of scouts and foragers per colony and traits of colonies (occupied frames) in spring and autumn inspection in 2011

Strength	Strong	Medium strong	Poor	**Average**
Spring inspection				
Bees	4.83^{a}	3.87^{b}	3.25^{c}	**3.98**
Brood	2.67^{a}	2.31^{a}	1.88^{b}	**2.29**
Honey	3.35^{a}	2.49^{b}	3.38^{a}	**3.07**
Pollen	1.08^{ns}	1.06^{ns}	0.93^{ns}	**1.02**
Bee counting				
Scouts	56.87^{a}	57.74^{a}	46.13^{b}	**53.58**
Foragers	24.43^{a}	24.80^{a}	19.67^{b}	**22.97**
% of foragers	42.93^{ns}	43.03^{ns}	42.63^{ns}	**42.86**
Autumn inspection				
Bees	8.53^{a}	9.27^{a}	6.10^{b}	**7.97**
Brood	2.82^{a}	2.49^{a}	1.15^{b}	**2.15**
Honey	4.08^{a}	4.19^{a}	3.83^{b}	**4.03**
Pollen	0.50^{b}	0.79^{a}	0.48^{b}	**0.59**

In the second year in the spring inspection, 4.4 frames with bees were found in average, and the differences between the observed groups were significant ($p<0.05$). The identical situation (Table 2) was also determined for the second observed trait (brood size). The most brood as well as bees was found in strong colonies and the least in poor colonies. Strong companies consumed the most food, so in this inspection they had the least honey, but the most pollen. The poor colonies had the most honey, and the medium strong had the least pollen. These differences were significant ($p<0.05$). In the second year in the spring inspection, colonies had slightly more bees, brood and honey in the spring, but almost twice as low pollen compared to the previous year.

Considering the number of scouts, it was consistent with the strength determined by the inspections. The highest number of scouts was counted in strong colonies (Table 2), with 14.7% more scouts compared to medium strong and 47.6% more scouts than in the poor colonies. During the counting in the companies, the average number of foragers was 21.6. Strong colonies had 24% more foragers than medium strong and 62.8% more than poor colonies. The highest percentage of forager bees was found in strong colonies, and the lowest was in poor colonies, the differences were significant.

In the autumn inspection in the second year, poor colonies exceeded medium strong ones and had higher strength (bees and brood) while food supplies (honey and pollen) were almost identical. In this inspection, strong colonies retained their dominance for all observed traits, and the differences were statistically significant. In comparison to the previous year, the colonies had the identical amount of bees, slightly more honey (0.8 frames), but also for a whole frame less brood (56.3%) and nearly 3 times less pollen.

Table 1. The average number of scouts and foragers per colony and traits of colonies (occupied frames) in spring and autumn inspection in 2012

Strength	Strong	Medium strong	Poor	**Average**
Spring inspection				
Bees	5.55^{a}	4.32^{b}	3.24^{c}	**4.37**
Brood	2.88^{a}	2.37^{b}	1.98^{c}	**2.41**
Honey	2.95^{c}	3.22^{b}	3.56^{a}	**3.24**
Pollen	0.68^{a}	0.45^{b}	0.52^{ab}	**0.55**
Bee counting				
Scouts	47.10^{a}	41.05^{b}	31.92^{c}	**40.03**
Foragers	26.77^{a}	21.55^{b}	16.44^{c}	**21.59**
% of foragers	56.08^{a}	53.25^{b}	51.30^{c}	**53.54**
Autumn inspection				
Bees	9.43^{a}	7.00^{b}	7.48^{b}	**7.97**
Brood	1.47^{a}	1.12^{c}	1.28^{b}	**1.29**
Honey	5.25^{a}	4.57^{b}	4.58^{b}	**4.80**
Pollen	0.30^{a}	0.20^{b}	0.18^{b}	**0.23**

Conclusion

After two years of observing three groups of colonies (strong, medium strong and poor) and counting scout bees and forager bees (March-April) the following conclusions can be made:

In the first year, the number of scouts and foragers did not reflect the strength of the colonies being inspected because the medium strong companies had slightly more scouts and foragers than the strong ones, while the poor colonies were far behind. In the second year, the number of scouts and foragers did reflect the strength in the spring inspection. In the autumn inspection, in the first year, the medium strong colonies exceed strong colonies considering the amount of bees, honey and pollen. In the second year in the autumn inspection, poor

colonies exceed medium strong ones and became equal considering food supplies. Food supplies in spring inspection were as twice as large in the first year, which affected area under brood in the autumn inspection which was in the first year for 0.9 of frame higher than in the second year.

Abstract

The paper presented the results obtained by analyzing the population of pigs under selection pressure for Vojvodina during 2017. The data were collected from main breeding organization in Novi Sad. By monitoring the number of live-born piglets, the largest number was recorded in the genotype F1 generation, which amounted to 12.93 live-born pigs, while the smallest number of live-born piglets was recorded in the genotype Pietrain with the average number of live-born piglets 9.53. The largest number of weaned piglets was recorded in the genotype F1 generation of crossing between Yorkshir and Landrac 11.54, the smallest number of weaned piglets was recorded in the genotype Pietrain 8.98 piglets. Main breeding also implemented the performance test of breeding animals. The following values from performance test were recorded by female animals analysis by genotypes: the highest life gain was recorded in the 0.614 kg genotype Pietrain, and the smallest backfat thickness and side fat thickness (8.67; 9.00 mm), while the deepest ML (musculuc longissimus dorsi) was recorded in the genotype Yorkshire 70.88 mm. Performance of male animals testing determined the following values of the tested properties: the highest life gain was recorded in the Landrace (0.700 kg) genotype, while the smallest thickness of the backfat and side fat (8.00; 8.30 mm) was recorded in the genotype of Duroc, while the deepest ML was recorded in the genotype Duroc (78 mm). Calculation of the BLUP values for the measures from the performance test recorded the following variables: for a life gain of 17.311 to 79.674; thickness of the bacon from -4.454 to 6.381; thickness of side bacon from -4.529 to 6.163; ML from -33.584 to 19.439. The obtained results show that the selection pressure should continue because of the space that exists in terms of economically important features.

Introduction

Pig selection is the planned and systematic selection of the best animal for breeding, which according to the production results corresponds to producers and consumers. The selection of animals of higher production abilities of a certain quality within the pig population in which the selection is performed accumulates the genes for these properties.

The annual replacement rate on commercial farms ranges between 42 and 59% (Young at al, 2009; Koketsu, 2007), which indicates that the number of culling sows will be compensated. Therefore it is necessary to provide a sufficient number of quality breeding gilts, which will be an appropriate substitute for culling sows. By ensuring an appropriate replacement, it is necessary to devote considerable attention to the upbringing of quality breeding gilts in order to match the appropriate body weight and age in the test performance.

One way of achieving higher fertility for sows is the setting up of a pyramidal organization of pig breeding in Vojvodina. A pyramidal organization set up in Scandinavian countries can be taken for example: a nucleus farm, a production farm, a commercial farm (Lotta Rydhmer, 2005).

Subject in the implementation of the main breeding program in Vojvodina are: farmers, basic breeding organizations, regional breeding organizations, main breeding organization,

organizations with special authorization, provincial secretariat for agriculture, water management and forestry, ministry of agriculture and environmental protection.
Main breeding organization plays an important role in conserving genetic resources, genetic improvement of the population, testing of breeding animals, assessment of lean meat on the line of slaughter, as well as harmonization of the selection work with the standards of the European Union. The basic breeding goals prescribed by the main breeding organization are: increasing the productivity of domestic animals, changing and improving racial structure and preventing a reduction in the number of conditions (Main breeding Program, 2014).
Selection work of the Main breeding organization is in line with the needs of the market and moves towards the repair of economically important traits such as: life growth, backfat thickness, muscle depth (ML), all in order to increase the profitability of pig production (Radović et al., 2011).
During 2017, data were collected from the Basic breeding organizations operating in the territory of the Autonomous Province of Vojvodina. The Main breeding organization analyzed and compared the obtained data with previous years in order to test the production results of different genotypes. An analysis of the breeding value of boars using BLUP plays an important role due to the increasing use of doses from artificial insemination centers. Ranking of animals by breeding value helps in choise of boars for correction certain production trait.

Materials and methods

Research was carried out on a total of 38,169 sows that were under productivity control, 621 performance tests boars, 31,959 performance tested gilts, while the progeny test tested the breeding value of boars based on the average characteristics of their offspring. The average distribution of descendants characteristics was compared with the population average, taking into account that the selected descendants for the progeny test were from multiple litters. The test we conducted was at least 16 offspring (8 male and 8 female animals) from one boar. The total number of tested boars is 1,286, while in the work will be shown 20 boars with at least 8 male and 8 female descendants. For the analysis, the data from the performance test gilts and boars were used, and the estimation of the breeding value was carried out using the BLUP (set of linear models). The genotypes that used in the analysis were the genotype Yorkshire (Y), Landrace (L), F1 generation, the Yorkshire x Landrace (YxL), F1 generation Landrace x Yorkshire (LxY), Pietrain (P) and Duroc (D).

Results and Discussion

The number of tested boars has been declining since 2014 (Table 1), which was also recorded by Trivunović et al. (2014), as well as Radović i et al. (2015). When we compare the number of tested boars in 2014 (when the highest number of tested boars in the last five years was recorded), with 2017, the drop in the number of tested animals was 40%.
In addition to the established reduction in the number of tested boars, it is encouraging that economically important features such as backfat thickness, side bacon thickness, ML and lifetime gain have a positive five-year trend. A positive five-year trend has a major role in selecting boars for parents of the next generation. When choosing boars in addition to the listed results, the test performance should be taken as an additional parameter such as food conversion, % of meat in carcass, number of tits, constitution, size and number of litter from which it originates (Yoo and Lee, 2011).

Table 1. Results of the performance test boars

Year	Number tested boars	Body weight	Life gain kg/day	Backfat thickness, mm	Side fat thickness, mm	Deepest ML, mm
2013	812	113	0.765	17.6	18.10	77.10
2014	987	112	0.585	15.92	16.38	76.69
2015	827	107	0.569	13.90	13.70	72.60
2016	724	112.74	0.603	12.81	13.02	74.82
2017	594	110.79	0.615	11.03	11.44	75.14

By monitoring the results of the performance of tested gilts (Table 2), an increase in the number of tested gilts in the last three years in Vojvodina has been observed, which is in line with the recorded by Trivunović et al. (2014) and Radović et al. (2015). By monitoring the economically important characteristics in the performance test (thickness of the back bacon, thickness of the side bacon, ML and height of life gain), a positive trend in the development of economically important traits was identified. Tummaruk et al. (2007) recorded an approximate value of backfat thickness (12.0 mm) in their researches, while they recorded a life gain of 0.539 kg / day. Analyzing the results of the performance of the test, Amaral et al. (2010) recorded the variability of the following data: life gain from 0.600 to 0.870 kg / day, backfat thickness from 10 to 23 mm in the test sample.

Table 2. Result of performance test gilts

Year	Number tested gilts	Body weight	Life gain kg/day	Backfat thickness, mm	Side fat thickness, mm	Deepest ML, mm
2013	23,270	116.90	0.520	18.50	18.40	74.20
2014	27,747	112.90	0.520	18.90	19.00	77.60
2015	25,704	111.80	0.522	15.10	15.60	74.50
2016	27,634	109.40	0.546	13.40	13.50	73.40
2017	29,724	109.60	0.558	12.20	12.00	75.00

The analysis of the control of productivity of sows in farms in Vojvodina determined the following: the largest number of live-born piglets was found at the F1 generation animal, while the smallest number of live-born piglets were recorded in the genotype Pietrain and Duroc (Table 3). No significant differences in the number of live-born piglets were observed in F1 generators. Observing the obtained results for the number of live born piglets, a certain variability of the trait was determined: the highest number of stillborn piglets was recorded in the Pietrain genotype, while the smallest number of stillborn piglets were recorded in the genus Duroc. The obtained results are not in accordance with the research carried out by Vidović et al. (2011), where they found the average number of live-born piglets for the Landrace and Yorkshire genotypes: 14.3 and 13.9 pigs, while the number of stillborn piglets was 2.4 and 2.3 piglets.

Table 3. Control of sow productivity

Genotype	Number of sows under control	Live born piglets	Stillborn piglets	Weaned piglets
Yorkshire	7,098	11.92	1.22	10.59
YxL	11,985	12.93	0.89	11.26
Landrace	10,188	11.79	1.91	10.65
LxY	8,379	12.76	0.92	11.54
Pietrain	38	9.53	3.09	8.98
Duroc	481	9.56	0.77	9.21

The results obtained by calculating the breeding value for boars can be seen in Table 4. The best estimate of the breeding value of boar 5519 was for the property of the backfat thickness (-4.08 mm). For the side fat thickness, the best breeding value was recorded at the boar 25730 (-3.92 mm). For ML the best breeding value was recorded at boar 3998 (19.94 mm), while the best breeding value for life gain was recorded at boar 2167 (102.12 g).

Table 4. Breeding value of boars for trait from performance test of gilts and boars

Conclusion

One of the key indicators of the efficiency of pig production is the number of piglets per sow per year, the number of litters per sow per year and the number of weaned piglets per sow annually. Based on the above, it is clear that in the coming period, a higher selection pressure should be placed on the number of live born and weaned piglets on an annual basis. Also, due to the increased import of animals from abroad, it is necessary to define the criteria for importing the animals, so that the imported animals help in achieving the breeding goal in Vojvodina. The reasons for the reduced number of tested boars were expected, as the Main Breeding Organization tightened the criteria for the test of boars, increased use of boars from artificial insemination centers and increased imports of animals from abroad.

Data related to the performance test gilts are encouraging, because despite the closure of individual farms and increased imports of quality breeding offsprings, the trend of growth in the number of tested reproductive animals continues and we can consider that manufacturers

have recognized the significance of this measure. By monitoring the characteristics of the test performance, such as the thickness of the backfat and side bacon thickness, the depth of the muscle and the height of life gain, it has been determined that an appropriate selection of the abovementioned properties is carried out, and that the appropriate selection of male and female animals is made in relation to the abovementioned properties.

Abstract

The objective of this study was to identify the single nucleotide polymorphism in thyroglobulin gene (TG5), determine the genetic structure of the population and analyse its effect on beef quality traits in Slovak Pinzgau cattle. A total of 56 blood samples of Pinzgau steers were used to extract genomic DNA for animal's genotyping. The SNP genotyping of all individuals was performed by using PCR-RFLP method. Across analysed individuals the allele C was more frequent (0.64) than T allele (0.36). The sufficient level of allele impact effectiveness in population indicated mainly the value of allele effective number (1.849). The obtained values of expected (0.46) and observed heterozygosity (0.5) indicated balanced proportion of homozygous and heterozygous animals that confirmed similarly the values of Wright's F_{IS} index (-0.09). In addition, the negative value of F_{IS} index showed, that the population is not affected by the increase of inbreeding. The impact of thyroglobulin gene polymorphism on beef quality was tested by using ANOVA analysis. Four carcass traits were involved in association analysis: proportion of muscle, fat, bones, and drip loss within the beef three-rib section. Despite the fact that the statistical analysis showed only non-significant effect of TG genotypes on evaluated traits, it seems to be that the T allele is favourable for all traits under consideration. The results of present study could be affected mainly by the sample size and polygenic effects associated with expression of analysed traits.

Keywords: *Association analysis, beef quality, candidate gene, polymorphism, Thyroglobulin.*

Introduction

In beef cattle breeding, the value of the animal for both the producer and the meat industry is determined by the type and carcass traits. The study of carcass quality traits is particularly important because these traits can improve economically important factors such as carcass yield and amount of meat produced per hectare. However, the rate of genetic gain in beef cattle may be reduced mainly due to the fact that the carcass traits are measured late in life. One of the way how to solve this can be the utilization of genetic markers that has been proposed in an attempt to increase the accuracy of prediction and to reduce generation interval (de Carvalho *et al*., 2012; Fonseca *et al*., 2015).

Up to now, various studies showed that the genetic modification through genomic selection in the desired direction allow to achieve permanent and continuous progress in improving quantitative and qualitative features that are economically important in meat cattle production (Van Eenennaam, 2016; Ardicli *et al*., 2017; Mehrban *et al*., 2017). It is known that the beef quality as well as carcass traits usually show low or moderate level of heritability and are under the control of polygenic inheritance (Ogawa *et al*., 2014; Liu *et al*., 2015). Thus, progress in the genetic selection process to improve beef cattle breeds depends on the accuracy of the animals breeding value estimation (Bekseitov *et al*., 2017). The permanent progress in the field of molecular genetics make it possible to identify genes controlling the economic important traits and thus increase the accuracy of estimated breeding values. Such

candidate gene approach can be used especially if the gene is located in a region that hosts a QTL or when there is prior information on gene effect on a trait (Borges *et al*., 2014).
Tyroglobulin, a product of the TG gene, is a dimeric glycoprotein hormone synthesized by thyroid epithelial cells. It is one of the largest proteins in the body and its size is 660 kDa. Thyroglobulin is secreted by the follicular lumen and together with iodine forms a precursor for thyroid hormones, triiodothyronine (T3) and tyroxin (T4), which are involved in development and metabolism regulation and also have effects on adipocyte differentiation, growth and homeostasis of fat depots (Ailhaud *et al*., 1992; Darimont *et al*., 1993; Casas *et al*., 2005). The TG gene, encoding the thyroglobulin, is located in cattle on BTA14 and contains 37 exons. One of the first studies that analysed the polymorphism of TG gene was study of Barendse *et al*. (1997). They identified a C/T single nucleotide polymorphism (SNP) in the 5' untranslated region of the TG gene (named as TG5), which were later associated in cattle with marbling and included in commercial genotyping panels (Barendse *et al*., 1997; Casas *et al*., 2005). In addition, the TG gene is considered as functional candidate gene of post-weaning average daily gain, birth weight, and weaning weight traits (Zhang *et al*., 2015).
The aim of this study was to determine the genetic structure of population based on analysis of SNP TG5 in gene encoding thyroglobulin and to analyse its impact on beef quality traits in Slovak Pinzgau cattle.

Material and methods

A total of 56 genomic DNA samples of Slovak Pinzgau steers were included in this study. The genomic DNA was extracted from blood samples by using salting-out method following the protocol proposed by Miller *et al*. (1988). After genomic DNA extraction, the concentration and purity of each DNA sample were tested by the spectrophotometry measurement using optical density at wave length of 260 nm. To identify the TG5 polymorphism the PCR-RFLP (restriction fragment length polymorphism) method was used. Specific target segment of DNA with length 545 bp was amplified by PCR (polymerase chain reaction) using oligonucleotide primers proposed by Barendse *et al*. (1997). In the next step, the products of PCR reaction were digested using restriction enzyme *Psu*I (Fermentas) (at 37°C for 3 hours). Both the products of PCR reaction and restriction fragments were visualised by horizontal electrophoresis in 2.5 % agarose gel (200 V for 15 min) stained with fluorescent nucleic acid dye GelRed (Biotium).
The genetic structure of analysed population were determined based on the calculation of allelic and genotypic frequencies using Genalex v6.1 (Peakall and Smouse, 2012). To estimate the impact of factors such as inbreeding, artificial selection, migration or genetic drift on the population genetic structure the differences between observed and expected genotypic frequencies were tested by Chi-square test (χ^2). Moreover, several basic genetic diversity parameters (effective allele number, polymorphic information index, and molecular equivalent of pedigree based inbreeding coefficient expressed by Wright's fixation index F_{IS}) were calculated using Genalex v6.1 (Peakall and Smouse, 2012) in order to estimate the level of genetic diversity within analysed population.
To assess the impact of TG5 polymorphism on beef quality traits the GLM (one-way ANOVA) procedure adopted in SAS 9.3 was used. Four carcass traits were involved in association analysis: proportion of muscle, fat, bones, and drip loss within the beef three-rib section. Those parameters of carcass value (proportion of fat and bones) and quality of beef meat (drip loss) were measured according to Honikel (1998).

Results and discussion

The PCR-RFLP analysis revealed the presence of all three genotypes of TG5 polymorphism in analysed population of Slovak Pinzgau steers. The homozygous genotype CC was detected

based on three fragments with length 278 bp, 195bp, and 72 bp, whereas homozygous TT genotype was represented by two fragments with length 437 bp and 72 bp. The heterozygous animals was identified based on four fragments (473 bp, 278 bp, 195 bp, and 72 bp). The heterozygous CT animals were most frequent in the analysed population (50 %). The lowest frequency was found for homozygous TT animals (10.71 %), whereas the CC genotype was found in 39.29 % of animals. The C allele was in population predominant (0.643) compared to T allele (0.357). The predominance of C allele was similarly found for example in Charolais (Thaller *et al*., 2003; Casas *et al*., 2006), Holstain (Thaller *et al*., 2003) and Angus cattle (Barendse *et al*., 2004; Casas *et al*., 2006). Relatively higher frequency of T allele compared to our results was reported for simmental cattle (Rincker *et al*., 2006) and Wagyu (Van Eenennaam *et al*., 2007).

In terms of genetic diversity the high proportion of heterozygous animals in population was reflected in sufficient level of both observed (H_o=0.50) and expected heterozygosity (H_e=0.46). The balanced proportion of heterozygous and homozygous animals confirmed similarly the negative value of F_{IS} index (-0.09) that also signalized only non-significant impact of increase in inbreeding on analysed population. The expected Hardy-Weinberg equilibrium in population (based on previous parameters) confirmed also the Chi-square test that indicated only non-significant differences between observed and expected genotype frequencies (P>0.05). The effectiveness of allele impact of locus in population was expressed by two parameters: the effective allele number (N_a) and polymorphic information content (PIC). Both of this parameters indicates sufficient level of allele effectiveness in population (Na=1.849, PIC=0.354). The obtained value of PIC indicated for analysed SNP medium level of polymorphism.

Across analysed individuals the proportion of muscle within the beef three-rib section at level 60.62 ± 6.71 % was detected. The average proportion of fat was 17.38 ± 6.65 % and proportion of bones within the beef three-rib section was 21.99 ± 2.46 %. The average proportion of drip loss that referred to the quality of beef meat was found at level 2.38 ± 1.82 %. Table 1 summarizes the average values of each analysed trait with respect to the specific TG5 genotype. The obtained results indicated that the differences between the TG5 genotypes was very low. Due to this and the fact that the statistical analysis showed only non-significant effect of TG5 polymorphism on the variability of analysed traits, it can be conclude that the obtained results have only informative characters. However, compared to previous studies it seems to be that the T allele is favourable for all of analysed traits.

Table 1 Average values of analysed traits depending on the TG5 genotypes

Genotype	% of muscle	% of fat	% of bones	% of drip loss
CC	61.31±5.55	16.95±5.68	21.74±2.65	2.46±1.97
CT	59.00±7.65	18.64±7.66	22.36±2.53	2.27±1.83
TT	65.66±1.27	13.11±1.56	21.23±0.84	2.63±1.38

Conclusion

Despite the fact that our study did not confirm the role of TG gene in genetic control of carcass traits, such analyses of SNPs in genes affecting the economically important traits are still very useable for identification of genetic markers that can be applied in gene assisted selection of cattle. The results of present study could be affected mainly by the sample size and polygenic effects associated with expression of analysed traits. To obtain more reliable results in the future is therefore necessary to increase the sample size (including breeds with different genetic composition) as well as number of loci in the panel of candidate genes.

Abstract

Twenty Sicilo-Sarde ewes of local sheep were divided into two homogenous groups regarding age (5.3 vs 5.7), live weight (33.83 ± 5.63Kg vs 33.95 ± 5.58 Kg) and the rank of lactation were used to evaluate the effect of replacing corn and soya beans by white sorghum and horse beans on milk produced and quality of milk (pH, density, freezing point, fat content, protein content, lactose and fat solids). Animals were logged in two big boxes and received 1.5 kg DM / ewe / day of oat hay. Two concentrates (i) 500 g/ewe/day of concentrate that included corn (43.3%), barley (25%), soybean meal (17.7%) and mineral and vitamin supplement (4%) for the control group (RM) and (ii) a second concentrate that included white sorghum (66%), horse beans (30%) and mineral and vitamin supplement (4%) for the experimental group (RS) were used. The result showed that the diet did not affect the daily milk yield. The pH of milk was higher ($p< 0.05$) in ewes of RS group than in those of RM group. The density was affected by the diet. The freezing point was not affected. Fat content, protein content, mineral content and lactose were not affected by diet. However Solid Not Fat was affected by the diet. It is possible to replace corn and soybean by white sorghum and horse beans in the sicilo-sarde sheep.

Keywords: *Sicilo-Sarde ewes. local feed resources. milk yield and quality.*

Introduction

The ovine breeding can affect the social and economic status of people who live in arid and semi-arid regions. The development of ruminant livestock uses different sciences (nutrition. reproduction. genetics. health) need to conduct in parallel. In an integrated manner in a culture system. Sicilo-Sarde is the main dairy ovine in Tunisia. This sheep breed only thrives in the north of the country. The average milk yield of this breed is 72 l for a milking duration of 124 days on average and following a breastfeeding period of 114 days (Djemmali et al., 1995). The feeding of sheep is based on fodder with low nutritional value and little diversified and concentrate that is made from imported raw materials (corn and soybeans). Thus the increase in the price of the latter two. We must look for local primary materials to feed our livestock by covering their needs. The nutritional imbalance of the rations available to these animals, the low forage potential of these areas and the drought conditions in semi-arid to arid regions are considered the main factors hindering the development of livestock systems and threatening the sustainability of these (Ben Salem and Smith, 2008, Ben Salem, 2011).
The main objective of this study is to determine the effect of replacing corn and soya beans by white sorghum and horse beans on milk performances of sicilo- sarde sheep during lactation.

Materials and methods

Animals and management

The study was carried at the experimental station of the Higher School of Agriculture of Mateur (Tunisia) on 2010. A total of 20 ewes Sicilo-Sarde were divided into two groups

homogenous groups regarding for age (5.3 vs 5.7), live weight (33.83 ± 5.63Kg vs 33.95 ± 5.58 Kg) and the rank of lactation. Animals were logged in two similar big boxes and received 1.5 kg DM / ewe / day of oat hay. Ration was complemented by one of two concentrates: (i) 500 g/ewe/day of concentrate that included corn (43.3%). barley (25%). soybean meal (17.7%) and mineral and vitamin supplement (4%) for the control group (RM) and (ii) a second concentrate (500 g/ewe/day) that included white sorghum (66%). horse beans (30%) and mineral and vitamin supplement (4%) for the experimental group (RS) were used. Diets were iso-energetic. The daily meal was offered in two times in the morning 8h and at 14h. They were 2 week of adaptation. The repartition of control (RM) and experimental (RS) groups are presented in Table 1.

Table 1. Repartition of group.

Group	Live weight (kg)	Age (years)	Rank of lactation
Control: RM	33.83±5.63	5.3±1.25	4.3±1.25
Experimental : RS	33.95±5.58	5.7±1.15	4.6±0.96

Feed intake and Milk Production and physico-chemical parameters

The feed intake were calculated by subtracting refusal from distributed amounts. During the whole experimental period, the ewes were milked by hand 2 times per day (10 am and 3.30 pm) for daily milk yield. Every Tuesday, a physico-chemical analyses were determined for the ewe milk. The differents parameters (fat content, SNF, density, protein, mineral, lactose and freezing point) were determined by using Lactoscan (Milkotronic LTD, Serial n° 4696, Hungary). The pH was measured by pH-meter.

Results and discussions

Composition of diets

The chemical compositions of different meals are shown in table 2.

Table 2. Chemical composition of the meal (% DM basis)

Nutrient	Concentrate		hay
	C	S	
Dry matter	94.7	94.7	92
Organicmatter	91.0	88.3	92.1
Crude fibre	12.7	3.7	35.6
Crude protein	16.3	14.65	4.9

C: 10% barley; 43.3% corn; 25% wheat bran; 17.7% soybean meal and 4% CMV; S: 66% white sorghum; 30% horse bean and 4% of CMV;

The results of this analysis show that the hay is low in CP (4.9%) and rich in crude fibre (35.6%) confirming the results reported by several studies (Mahouachi and Khaldi. 1987). The CP and crude fibre concentrations in the diets containing corn were greater than diet containing sorghum.

Feed intakes and Milk Production

The mean feed intake was 1334 g DM/d for RS and 1306 g DM/d for RM. Feed intake of animals was not affected by diet. Mean daily and total milk yield was showed on table 3. Ewes of RS group produced more milk than those of control group (Fig 1). Rouissi et al (2008) and Selmi et al. (2010) reported similar findings. This can be explained by the significant degradability of horse beans proteins relative to soybean protein (Rouissi et al, 2006).

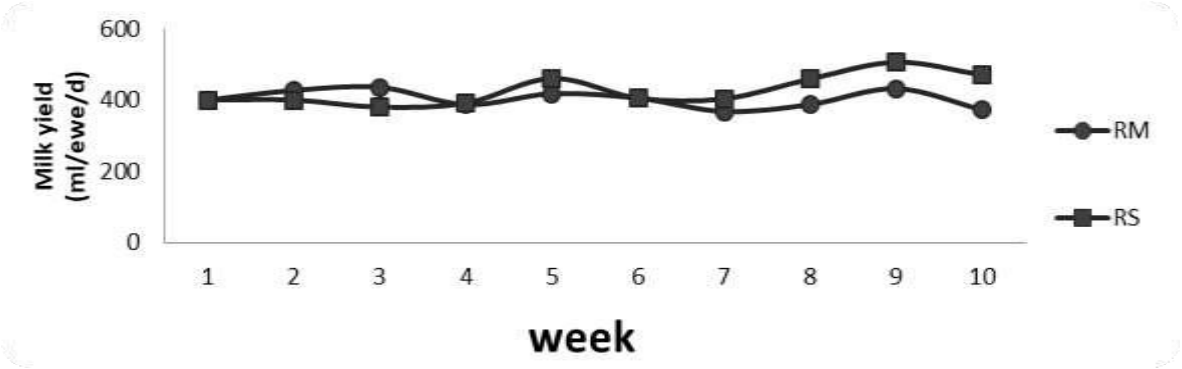

Fig 1. Weekly milk production of ewes

Table 3. Milk yield

	RM	**RS**	***Pr***
Milk yield/ewe (L)	28.22±17.15	29.94±29.72	*NS*
Milk yield/ewe (ml/d)	403.26±24.51	427.62±42.46	*NS*

NS : Non Significatif.

Milk physico-chemical parameters
pH, density and freezing point

Table 4 showed that the group RS had higher pH values than the group RM (6.61 vs 6.57). Diet affected pH significantly (P<0.001). The same result reported by Rouissi and al (2006a). the density of RS (1036.747) is higher than that of RM (1035.769). Density was affected by diet. These results agree with those reported by Assenat (1985) and Selmi et al. (2010). Freezing point was not significantly affected by diet. While the freezing point was -0,583 °C et de -0,602 °C respectively for RM and RS. The current results agree with the findings obtained by Rouissi et al (2008).

Table 4. Effects of diet on physical quality of milk of sicilo-sarde

	RM	***RS***	***Effet régime***
pH	6.57^{a}±0.040	6.61^{b}±0.049	*
Density	1035.769^{a}±0.639	1036.747^{b}±0.656	*
Freezing point, °C	-0.583±0.049	-0.602±0.053	*NS*

Means with different superscripts (a, b) within each column are significantly different (P<0.05); * = P < 0.05; NS : Non *Significatif.*

Milk fat, protein,SNF, mineral and lactose content

As shown in table 5, milk fat content was higher for RS group (7.588% vs 7.219%). Rouissi et al (2008) and Selmi et al (2010) found the same result. The milk fat content obtained in this trial is higher than that reported by Hammami et al (2008) who found an average of 5.34 to 5.83%. Milk fat content is generally negatively correlated to energy balance of ewes (Bocquier and Caja, 2001). Milk fat was significantly affected (p<0.01) with the diet. Protein is the most important fraction of milk. In fact, the protein Milk of RS is higher than the group RM (6.047% *vs* 5.865%). Diet did not affected (P>0.05) milk protein. This can be explained by the fact that the protein content of milk is positively correlated with the energy balance of

the diet. The energy supply stimulates the synthesis of microbial proteins in the rumen (Bocquier and Caja, 2001) while the diets are iso energetic (0.98 and 0.99 UFL / Kg MS respectively for RM and RS). The solid not fat was 11.372% for RS vs 11.043% for RM. The data in table 5 indicated that SNF was significantly affected by the diet. Rouissi et al (2008) observed no effect of diet on solid not fat. Table 5 showed that there was a tendency for mineral content to increase in RS group in comparison to RM group (1.026% for RS vs 0.995% for RM). However, this difference was not statistically significant between this to groups. Lactose is a sugar composed of galactose and glucose. The data represented in table 5 showed the effect of diet on lactose content. These data indicated that the lactose content is not significantly different (P> 0.05) depending on the diet (Table 5). However, lactose content of the ewes' milk in the experimental group (RS) is higher than that of the ewes in the control group (RM) (4.276% for RS and 4.159% for RM). Rouissi et al (2008) previously observed similar results.

Table 5. Effects of diet on chemical quality of milk of sicilo-sarde

	RM	***RS***	***Pr***
Fat (%)	7.21±0.41	7.58±0.69	NS
Protein (%)	5.86±0.54	6.04±0.57	NS
SNF (%)	11.04^{a}±0.18	11.37^{b}±0.21	*
Mineral (%)	0.99±0.044	1.02±0.048	NS
Lactose (%)	4.15±0.558	4.27±0.554	NS

Means with different superscripts (a, b) within each column are significantly different (P<0.05); * = P < 0.05; NS : Non *Significatif.*

Conclusion

The current study revealed that the effect of replacing corn and soya beans by white sorghum and horse beans on milk performances of sicilo- sarde sheep can improve some parameters le pH, density, and SNF but without modification significantly other parameters.

Abstract

Sicilo-Sarde is the only dairy sheep breed in the North of Africa that is mainly raised in northern Tunisia. This micro-sector contributes, through a better identification of "terroir" products, to rural development. Its milk production (MP) remains low as a result of mixed milk-meat production system with suckling period exceeding two months. Furthermore, MP in the beginning of lactation is important for both total MP and lamb growth. Dairy ewes produce about one quarter of total MP during the first month of lactation. This work aimed to estimate the suckling MP (SMP) using the method of weighing lambs before and after suckling and to determine the relationship between ewe MP and lamb growth. Ten Sicilo-Sarde ewes aged 3.90 ± 0.50 years and nursing single male lambs were used to estimate SMP during the two first months of lactation. Results obtained indicated that SMP increased with suckling duration. The means of SMP were 36.18±6.6, 57.28±10.2 and 74.80±12.2 kg respectively for week 4, 6 and 8 of suckling period. Lambs weight at 28 days (10.85±1.83 kg) and Average Daily Gain between 10 to 28 days ($ADG_{10\text{-}28;}$ 222±46 g/d) were highly correlated with SMP of week 4, 6 and 8 ($0.82 \leq r \leq 0.85$; $P<0.01$). The MP regression equations on lamb's growth traits before weaning showed that $ADG_{10\text{-}28}$ was a good trait for estimating SMP. In conclusion, Sicilo-Sarde ewe has an interesting dairy potential during suckling period that may be estimated referring to lamb growth at the first month of age.

Keywords: *Sicilo-Sarde, Suckling milk production, Lambs growth, Correlation, Regression.*

Introduction

In Tunisia, dairy sheep farming is mainly represented by the Sicilo-Sarde, only dairy breed in the North of Africa (Aloulou et *al*. 2018). Several studies have shown that the milk production level of Sicilo-Sarde ewe remains low (50-120 l/lactation: Mohamed, 2008; Meraï et *al*. 2014). This production level is lower than that of Sarda and Comisana breeds which are at the origin of this breed (158 kg per 200 lactation days and 132 kg per 150 lactation days, respectively; Haenlein, 2007). The lower milk production could be associated to a longer suckling period that generally exceeds the first three months of lactation (Djemali et *al*. 2009; Meraï et *al*. 2014). In addition, sheep dairy farming has kept a traditional management, essentially characterized by extensive feeding, hand milking and artisanal making cheese.

Milk production in early lactation period is an important factor determining for both total milk production of dairy ewe and growth rate of lambs until weaning. In fact, McDonald et *al*. (1995) reported that dairy ewes yielded about 38 and 30% of total milk production respectively during the first and second months of lactation. Also, McKusick et *al*. (2001) had reported that dairy ewes produced about 25% of total milk production in the first month of lactation. On the other hand, approximately 6 litres of milk is required to produce 1 kg of lamb body weight (Boyazoglu, 1963; Pulina et *al*., 2006).

The sources of variation in milk production level of Sicilo-Sarde during the milking period have been widely studied (Rouissi et *al*. 2008, Djemali et *al*. 2009; Meraï et *al*. 2014) and

results obtained indicate that milk production can be improved by appropriate breeding management including genetics, reproduction, animal health and nutrition techniques. However, little informations on milk production level in suckling period were available (Khaldi, 1987, Mohamed et *al*., 2008). Thus, a better evaluation of the real dairy potential of the Sicilo-Sarde ewe appears to be necessary through, an update of the knowledge of milk production level on the suckling period. Therefore, our study aims to estimate milk production level of the Sicilo-Sarde ewe during the suckling period. The second objective is to determine a relationship between suckling milk production and lamb growth before weaning.

Materials and methods

The study was conducted during spring season of 2017 at the farm of the Cooperative Unit of Agricultural Production of Methline (Bizerte), situated in the northeast of Tunisia. Ten Sicilo-Sarde ewes in second and third lactation and nursing single male lambs were used to estimate suckling milk production (SMP) on the first two months of lactation. Ewes were reared indoor and received 1.5 and 0.7 kg of oat hay and concentrate per ewe, respectively at two times daily (7 h and 16 h). Also, lambs received during the experimental period oat hay and concentrate *ad libitum*.

The measurement of SMP started on week 2 (at day 12th after lambing) to week 8th of lactation (at day 56th after lambing) and was carried out weekly during the suckling period by the weighing–suckling–weighing method. At the control day, ewes and lambs were housed in two adjacent plots of 20 m² and 12 m² respectively. The separation between the animals was done by a roasting that avoiding the access of the lambs to their mothers during the separation and keeping the visual, olfactory and auditory contact between them. The lambs were separated from their mothers at 6h for 3 hours and the first suckling was made at 9h. Lambs were weighed just before suckling using an electronic balance and allowed to suckle their mothers and then re-weighed again. The amount of milk sucked by lamb is defined as the difference between the weight of the lamb before and after suckling. In total, during the 24 hours, seven measurements of SMP were made at the rate of one measurement every 3 hours except a night measurement at six-hour interval (9 h, 12 h, 15 h, 18 h, 21 h, 3 h and 6 h). The daily SMP is equal to the sum of the quantities of milk suckled by lamb during the 24 hours. Total SMP during suckling period was calculated using the Fleishman method by the following equation:

$$\mathbf{SMP = MP1 * D1 + \sum_{i=1}^{7} \left(\frac{MPi + MP(i+1)}{2} \right) * (D(i+1) - Di) + MP8 * D8}$$

Where:

SMP: Total suckling milk production (kg); MP1: Milk production measured at the first test day; D1: Age of lamb at the first test day; MPn: Milk production measured at the nth test day (n vary from 1 to 8); D(i+1)-Di: Interval between two successive test days; MP8: milk production measured at the eighth test day; D8: Interval between last test days and weaning age.

Weight controls were used to calculate weights at 10 and 28 days (W_{10} and W_{28}, respectively) and average daily gain (ADG_{10-28}). Regression equations between dairy and growth traits were studied to establish a relationship to predict ewe SMP from lamb growth performances.

Data were analyzed with Statistical Analysis Systems (SAS, version 9.1). Pearson correlations coefficients were determined between SMP and growth performances and considered significant when $P \leq 0.05$.

Results and discussion

Results of ewe suckling milk production (SMP) and lamb growth performances are shown in Table 1. SMP increased as lactation progressed. The means of total SMP were 36.18±6.60, 57.28±10.16 and 74.80±12.15 kg respectively for week 4, 6 and 8 of suckling period. This indicated an increase of +52 and +23% in the production of milk marketed when lambs were weaned at four and six weeks, respectively, compared with weaning lambs at week eight of age. Similar findings were obtained by Khaldi (1987) and Mohamed et *al*. (2008) for the same breed. However, SMP obtained at week 6 of suckling period was greater than 49.28 kg reported by Khaldi (1987) and lower than the result (64.6 kg) of Mohamed et *al*. (2008) for ewes nursing single lamb and suckled for 42 and 45 days respectively. Thus, these differences among trials could be associated with a difference in rearing conditions (flock, month and year of lambing, parity, etc.; Djemali et *al*., 1995; Moujahed et *al*., 2009; Meraï et *al*., 2014) and probably to the method used to determine SMP. The daily SMP for ewes nursing single lamb were 1.29, 1.36 and 1.34 kg/day respectively for week 4, 6 and 8 of suckling period. These results underline an important dairy potential for this breed compared to previous studies that have shown a low level of production that does not above 100 liter per lactation (Djemali et *al*., 1995; Mohamed, 2008). This finding indicates may be that the transitive period between suckling and exclusive milking, usually accompanied by a decrease in milk production ranging from 30 to 40% (Gargouri et *al*.,1993; Marnet and Negrão, 2000), was not well mastered. Otherwise, the partial milking of ewes for a week just before weaning is recommended to avoid the milk production drop at weaning (Marnet and Negrão, 2000; McKusick et *al*., 2001). For growth performances, lambs weighted 6.87±1.16 and 10.85±1.83 kg respectively at 10 and 28 days of age. As a result lambs realized an average daily gain (ADG) of 222 g/d during the first four week of age. The relatively high value of the $ADG_{10\text{-}28}$, an excellent indicator of the dairy ability of the ewe, is mainly related to the high level of average daily milk production recorded during the suckling period that ranged from 1.29 to 1.36 kg/d. The mean of $ADG_{10\text{-}28}$ was higher than 200 and 137-140 g/d reported respectively by Khaldi (1987) and Rouissi et *al*. (2008) for single male lambs suckled by multiparous ewes.

Table 1. Ewe total milk production of week 4, 6 and 8 on suckling period and lamb growth during the first four week of age of Sicilo-Sarde dairy sheep breed

Variable	Mean	Standard deviation
Suckling Milk Production		
SMP_{w4} (kg)	36.18	6.60
SMP_{w6} (kg)	57.28	10.16
SMP_{w8} (kg)	74.80	12.15
Growth Performances		
W_{10} (kg)	6.87	1.16
W_{28} (kg)	10.85	1.83
$ADG_{10\text{-}28}$ (g/d)	222	46

SMP, suckling milk production; W, weight; w, week; ADG, Average daily gain

Pearson Correlation coefficients between traits of SMP during the suckling period and lamb growth performances at the first four week of lactation are reported in Table 2. The highest correlations were found between SMP_{w6} and SMP_{w8} ($r=0.99$, $P<0.001$) and SMP_{w4} and SMP_{w6} ($r=0.94$, $P<0.001$). Lambs weight at week 4 and $ADG_{10\text{-}28}$ were highly correlated with all SMP of week 4, 6 and 8 ($0.82 \leq r \leq 0.88$; $P<0.01$). Also, Benyoucef and Ayachi (1991) reported higher correlation between SMP and lambs growth at the first month of lactation ($r=0.83$) for Hamra ewe non-dairy sheep breed. However, the correlation coefficients between

weight at ten days and all SMP were little important and ranged from 0.57 to 0.64. Only this between W_{10} and SMP at week 8 was not significant (P>0.05).

Table 2. Pearson correlation coefficients between ewe suckling milk production and lamb growth during the first month of age in the Sicilo-Sarde dairy sheep breed

	SMP_{w6}	**SMP_{w8}**	**W_{10}**	**W_{28}**	**ADG_{10-28}**

SMP_{w6}	-	0.99 (***)	0.64 (*)	0.79 (**)	0.82 (**)
SMP_{w8}		-	0.57 (ns)	0.74 (*)	0.88 (**)
W_{10}			-	0.94 (***)	0.65 (*)
W_{28}				-	0.87 (***)

SMP, suckling milk production; W, weight; w, week; ADG, Average daily gain; ns: no significant, P> 0.05; *: P<0.05; **: P<0.0l; ***: P<0.00l

The estimating milk production at the beginning of lactation, especially during the first month of suckling by some techniques (milking, weighing of lambs, etc.) can disrupt the animals (ewes and lambs) and consequently affect the accuracy of results. Regression equations were determined to establish a relationship between SMP and lamb growth before weaning (Table 3). The regression analysis indicated that growth traits at the first week were the best criteria to predict the SMP (R^2= 70.8%). That is in agreement with the higher correlations coefficients between SMP and ADG_{10-28} determined previously (r≥0.82; P<0.01).

Table 3. Regression Coefficients of the ewe daily suckling milk productions (SMP_{w4}, $_{w6}$ and $_{w8}$) on first month lambs growth performances

	Constants	**ADG_{10-28}**	**W_{w4}**	**W_{w2}**	**R^2 (%)**

SMP, suckling milk production; W, weight; w, week; ADG, Average daily gain

Conclusion

This paper presents the results concerning the milk production of Sicilo-Sarde ewe during the suckling period. The milk production level of ewe and the lambs' growth performances obtained are acceptable and indicate an interesting dairy potential of this breed that may be not exteriorized. Thus, more appropriate breeding management, especially in relation to weaning age, earlier start of the milking period, and mastered of the transitive phase suckling/weaning/milking should be takes for a better exploit of the real vocation of this breed.

Abstract

Milking of Sicilo-Sarde dairy sheep breed in Tunisia remains always manual by calling qualified milkers who have become more and more rare. The emergence of some flocks using mechanical milking is strongly encouraged, but its use is still inefficient or inadequate. This exploratory study aimed to evaluate the technical and hygienic milking conditions in the two dairy sheep areas in the North of Tunisia. A sample of 955 Sicilo-Sarde ewes in mid and late lactation belonging to seven flocks (four public farms, three of which use machine milking in pot, and three private farms) was used to evaluate the milking conditions. The diagnosis of the milking equipment had revealed a relatively satisfactory situation of the milking machines working. The pulsation rate was between 80 and 105 cpm. Also, the average milking cadence observed for mechanical milking was relatively low (65 ewes/milker/hour), but it was acceptable for manual milking (50 ewes/milker/hour). However, farms with mechanical milking did not have a milking hallway that disturbed ewe circulation and contention during milking. For hygienic milking practices, udder preparation and teat disinfection after milking were not carried out in all farms. These results indicate that a great improvement in hygienic milking conditions must be made in dairy sheep farms. The study of the comparative impacts of mechanical milking of Sicilo-Sarda ewe on mammary health, teat integrity and milking comfort is needed to identify the appropriate settings for a best development of this system in Tunisia.

Introduction

The milk production and cheese making of sheep represent a millenary and traditional activity in the Mediterranean countries (Barillet, 1985). The Sicilo-Sarde breed is the only dairy ewe in the North African region, constitutes the basis of dairy sheep farming in Tunisia. This breed represents a micro-sector concentrated around two large production areas in the regions of Beja and Bizerte, where the potential of forage production is abundant (Djemali et *al.*, 1995; Rouissi et *al*., 2001; Mâatoug et *al*., 2015; Aloulou et *al*., 2018). Milking sheep is essentially manual and done twice daily with an interval of 12 hours. The once daily milking is adopted in late lactation, when the milk production level decreases significantly. Mechanical potting is recently adopted by some farmers who had a flock with large number of animals. Milk production is exclusively used for cheese processing. The quality of the milk as well as the cheese products is closely related to the milking conditions. The knowledge of hygienic and sanitary conditions of the ewes as well as the technical conditions of the milking have demonstrated specific relations with the milk production, and also with the improvement of the working conditions of the milker. The importance of respect the hygienic practice measures at the farm level, during milking is discussed. In this perspective, the present investigation proposes to evaluate technical and hygienic milking conditions in dairy sheep farms of the Sicilo-Sarde breed in the regions of Beja and Bizerte.

Materials and methods

Technical and hygienic diagnosis of milking conditions and breeding practices were carried out during a follow-up at milking in seven Sicilo-Sarde farms distributed as follows: five in the region of Beja: Cooperative Unit for Agricultural Production (UCPA) Gnadil, UCPA Essemen and three private farms Nour, Ben Youssef1 and Ben Youssef2) and two in the region of Bizerte: UCPA Methline and Livestock and Pastures Office (OEP) Fretissa. Four and three farms practice manual and mechanical milking pot, respectively. The follow-up was performed on a sample of 955 Sicilo-Sarde ewes in the middle and at the end of lactation.

The diagnosis of the milking equipment focuses on the general state of the milking machine and to assess the pulsation rate and the vacuum level. As for hygienic practices, the follow-up is based on cleanliness of equipment, milker and milking place for both manual and mechanical milking as well as the udder preparation and teat disinfection after milking. Also, global conditions of the milking were carried out (tranquillity, speed, completeness, hygienic ...). Various incidents observed during milking were also noted. These incidents may be related to the ewe, the milking machine, the milking place and the milker. Finally, the Practical Effectiveness of Milkers (PEM; also called milking cadence) was determined based on the following expression: PEM (ewes/milker/hour) = number of ewes milked x 60 min / total milking time (min) / number of milkers.

Total Duration of milking (TDM) was also determined.

Results and discussion

Technical and hygienic characteristics of milking machines followed

All the dairy sheep farms followed used the classical fixed milking trolley equipped with two Milking Clusters (MC) an one milking pot (MP), named Mechanical Milking Pot (MMP: 2MC + 1MT). The Technological and hygienic characteristics of followed milking machines are shown in Table 1. The diagnosis of the milking machines used revealed a satisfactory state of maintenance and running. Furthermore, a large variability of vacuum levels and pulsation rate was observed. The vacuum level is 40 and 60 kPa respectively in the region of Beja and Bizerte (Table 2). These values were different from those reported by Dubeuf (1999). This author had reported that the vacuum level for pot milking were between 33 and 36 kPa in France, 39 and 46 kPa in Italy and less than 52 kPa in Greece. Otherwise, the pulsation rate varied between 80 and 105 cpm (Table 2). These results were lower than recommended value (120 to 180 cpm; Dubeuf, 1999). For milking sheep, increased pulsation rate reduces vacuum fluctuations and thus has a better efficiency. This also makes it possible to work with a lower vacuum level, and consequently limit the risks of aggression on the udder. The choice of high pulsation rate seems limited by the performance of the pulsators (and therefore their costs). For pneumatic pulsators generally equipping milking trolley, it is advisable to choose settings between 80 and 120 cpm. This makes it necessary to choose a relatively high level of vacuum, which may be at the origin of an increase in somatic cell counts that contributing to the elevation of the risk of mastitis. The genetic improvement of the milking ability of dairy breeds is highly sought to apply a drop in vacuum levels, as practiced in France. Indeed, the morphological characteristics (udder depth, position and length of the teats ...) and physiological characteristics (ease and milking rate ...) of the udders influenced generally a particular parameters especially the vacuum level and pulsation rate. However, the material itself may differ from one country to another or between farms, which requires specific settings. To this end, the establishment of references on the aptitude of milking ewes for mechanical milking and the proposal of technical elements for the selection and adjustment of milking equipment may lead to the development of a technical referential for dairy sheep profession in Tunisia.

Table 1. Technical and hygienic situations of milking equipment on the farms followed

Characteristics	UCPA Gnadil	UCPA Essemen	UCPA Methline
Milking system	MMP1 & MMP2 (2MC + 1MP)	MMP1 (2MC + 1MP)	MMP1 (2MC + 1MP)

	MT2	105	102	80	80

MMP, Mechanical Milking Pot; MC, Milking Clusters; MP, Milking Pot; MT, Milking Trolley

As for the cleanliness of the milking equipment, cleaning is carried out after each milking and is considered satisfactory. The hygienic cleaning conditions are similar in both UCPA Gnadil and UCPA Methline. In these two farms, the cleaning is done only by water mixed with bleach, which is not enough to ensure the elimination of all microbes and dirt. The use of a product with acid detergent alternating with another alkaline is recommended for ensuring good cleaning efficiency (Chambre d'Agriculture de Bretagne, 2010). At UCPA Essemen, cleaning is only done using an alkaline detergent. This also affects the quality of cleaning, because the absence of use of an acid detergent causes the accumulation of calcium and magnesium salts (Chambre d'Agriculture de Bretagne, 2010).

For the four farms using manual milking, the place and equipment were almost similar. Manual milking is done in the sheepfold and the material used is rudimentary. The milker is satisfied with a bucket, where he collects milk and a container equipped with a filter, when he pours the milk when the bucket is full. It should be noted that the milkers neglect completely the recommended operations during milking (cleaning the teats before milking, elimination of the first milk jets, disinfecting the teats after milking ...) that can negatively affect udder health and deteriorates also the milk quality. The smooth running of the manual milking is conditioned by the respect of the ambient conditions (light and sound). These conditions are generally respected in farms using manual milking. Ewes were usually docile. However, primiparous are more agitated. The respect of a certain routine (milking time, same milker ...) is necessary to ensure a quiet milking. In a general way, except the hygienic quality of the milking which has not been not regularly respected, all the other conditions (calm, fast and complete treatment) were respected in all the farms followed.

Technical and hygienic characteristics of mechanical milking

For all the farms using milking machines, hygienic conditions were not respected. In fact, both teat cleaning before the milking and the follow-up of the order of ewes milking were not respected. At the UCPA Gnadil, the first milk jets were eliminated on ground. Also, the over milking operation was carried out only in this farm. According to Portolano et *al.* (1999), over milking is an operation to avoid in mechanical milking, because it affects negatively the udder conformation and could damage teats. Teat disinfection after milking is abandoned on all farms. However, milking was described as complete and rapid in all farms. In addition, milking is considered calm with the exception of UCPA Gnadil farm. At this farm, it should be noted: more noise (including noise from the milking machines used) thus affecting the overall sounds cape during milking; ewes were more agitated and nervous. Thus, this situation is not comfortable for the milkers.

The average practical effectiveness of milkers (PEM) in manual milking was 50 ewes/milker/hour (Table 3). This average is higher than that reported by Marion-Brilli (2014), estimated at 40 ewes/milker/hour. However, there is a difference between farms, the minimum value of the PEM is recorded on the Nour farm (43 ewes/milker/hour). This can be explained by the high number of milked ewes (303 head). For farms using mechanical milking, we also noted the absence of a milking hallway which making the organization of ewes difficult and complicated. In addition, the ewes were more agitated and nervous, which affected the quality of milking.

Table 3. Total duration of milking (min) of ewes and practical efficiency of milkers (ewes/milker/ hour) in all farms followed according to the milking system used

Farm	Number of ewes (head)		Number of milkers	TDM	PEM
	Present	Milked			
UCPA Gnadil (1) (3)	307	184	2	**152**	67
UCPA Essemen (1) (3)	216	124	1	**125**	74
UCPA Methline (2) (3)	443	155	1	**175**	53
Average mechanical milking					**65**
Nour (1) (4)	319	303	2	**213**	43
OEP Fretissa (2) (3)	234	90	1	**98**	55
Ben Youssef1 (1) (4)	66	66	1	**69**	57
Ben Youssef2 (1) (4)	33	33	1	**45**	44
Average manual milking					**50**

(1) Beja; (2) Bizerte; (3) Organized Sector; (4) Private Sector; PEM, Practical Effectiveness of Milkers; TDM, Total Duration of milking.

The higher value of PEM was recorded at Ben Youssef1 farm (57 ewes/milker/hour). This result is due to a better organization of the milking as a result of the presence of a milking hallway which facilitating the ewe circulation and their contention during milking. In addition, the milker of this farm is qualified and the size of the flock was low making thus the milking less tiring. Overall, according to the literature, the practical efficiency of milkers varied mainly with breed (milkability), milk yield and lactation stage. In this context, Delmas (1984) found that the Lacaune ewe is difficult to milk by hand (20 ewes milked / hour). Le Du (1986) reported that for dairy sheep breeds that are easy to milk, more than 60 ewes were hand milked per hour. For mechanical milking, the higher PEM was obtained at the UCPA Essemen and UCPA Gnadil, respectively, 74 and 67 ewes/milker/ hour. While, the lower PEM value was recorded at UCPA Methline (53 ewes/milker/ hour). These results can be explained by the good organization of the milking in both UCPA farms in the region of Beja with a sufficient number of workers to facilitate the circulation and contention of ewes during

milking. However, on the UCPA Methline, the milker takes care alone of all tasks during milking which making it longer and more exhausting. The good performances recorded at the UCPA Essemen are also due, in part, to the existence of a single milker, which is not the case at UCPA Gnadil. According to Piedhault et *al*. (2005), the use of a single milker is recommended to reduce the milking time.

During the following of milking process, there were several incidents that affected the total milking time, and consequently the PEM. In fact, there is no sorting of ewes by batch: all the dry, lactating, sick, healthy, aborted ewes, selected for the reform and antennas enter the place of milking. Thus, the passage of all the animals increases the TDM. In addition, all local of machine milking pot are devoid of hallway that disturbed ewe circulation and contention during milking (Photos 1 and 2). It is also noted that the volume of the pot-milker is not adapted to the milk production of the flocks. The milkers are then strained to milk into a large pot each time when the full pot-milker. Comparing the two milking systems, we found that the PEM is generally more important in farms using mechanical milking. Therefore, to improve milking conditions, in terms of time and rapidity, it is advisable to adopt mechanical milking especially for farms with large herds of animals. According to Marion-Brilli (2014), PEM in the milking parlor can reach 400 ewes/milker/hour (milking rate was about ten times more than that in manual milking).

Photo 1. Place reserved for milking ewes in the UCPA Gnadil (Beja, Tunisia)

Photo 2. Equipment for milking ewes in the UCPA Gnadil (Beja, Tunisia)

Conclusion

This work evaluated the technical and hygienic conditions of milking in the seven dairy farms of Sicilo-Sarde. These results indicate a lack of hygienic conditions during milking. Similarly, milkers do not follow the order of milking ewes, which can promote the spread of mastitis in the herd, including a mammoth sheep to a healthy one. In addition, the average of milking cadence for manual milking was adequate, while this for mechanical milking was well below the recommended milking parlor, but it is far better than that recorded in manual milking. The gradual abandonment of manual milking of ewes in favour of the generalization of mechanical milking and perhaps the gradual transition to larger and more profitable structures with equipment adapted for farms having large herds are in great demand in Tunisia for the revival of dairy micro-sector and the assurance of its sustainability, thus contributing to rural development.

Abstract

The present study was carried out to determine the effects of breeder age and relative humidity levels on egg weight loss during incubation, hatchability of total eggs and hatchability of fertile eggs in eggs of Bronz turkeys. The eggs were collected from a Bronz turkey breeder flock at 35 (young) and 66 (old) weeks of age, and were incubated in 55-60% and 61-65% humidity during the first 24 days of incubation period. After that period, the eggs were incubated under hatching conditions during hatching period. The effect of incubation humidity and breeder age on hatchability of fertile eggs, hatchability of total eggs and egg weight loss was significant ($P<0.01$). The eggs obtained from young flock showed a higher hatchability of fertile eggs and total eggs, and a lower egg weight loss during incubation when incubated at a relative humidity of 55-60%. On the other hand, similar results were observed for the eggs obtained from old flock and when incubated at a relative humidity of 61-65%.

Keywords: *Bronz turkey, Incubation humidity, Hatching characteristics, Breeder age*

Introduction

The turkey (*Meleagris gallopavo*) is one of the most important of commercial poultry species, especially in western countries, and during last decades it has gained importance as an alternative poultry production, especially to meet animal protein demand. The essential goal of turkey production is to obtain maximum hatchability and with high quality one day old poults (Anandh *et al.*, 2012). In poultry production, hatchability is an important economic parameter and affected by some factors, for example breeder age, egg quality, nutrition of breeder flock, egg handling and storage and incubation conditions e.g. incubation temperature, humidity and turning conditions (Weis *et al.*, 2011; Ipek et al., 2014; Ipek and Sözcü, 2015). Breeder hen age is an important factor that has effects on egg quality, fertility and hatchability (O'Sullivan *et al.*, 1991; İpek and Şahan, 2001; Peebles *et al.*, 2001; Nangsuay *et al.*, 2011; İpek and Sözcü, 2015). As breeders get older, egg weight shows an increment and causes a decline in hatchability (Elibol *et al.*, 2000) and increment early and late term embryonic mortalities (Elibol and Brake, 2003; Tona *et al.*, 2004; Joseph and Moran, 2005). During incubation, relative humidity also affects some important parameters such as egg weight loss, hatchability and chick hatching weight (Yahav, 2000). It is reported that a lower humidity level during incubation period results with excessive egg water loss, and subsequently embryo dehydration and moreover embryonic deaths (Reinhart and Hurnik, 1984). Also, it may affect embryo development by fluid deficit in amniotic or allontoic sacs, therefore it causes small and dehydrated chicks (van der Pol *et al.*, 2013). Furthermore, if the relative humidity is too high, there could be a shortening of incubation period and an increment in number of wet chicks with residual albumen (Taylor, 1999; Decuypere *et al.*, 2002; Tona *et al.*, 2003). The present study was carried out to determine the effects of breeder age (young and old) and relative humidity levels (standard and high) on egg weight loss during incubation, hatchability of total eggs and hatchability of fertile eggs in eggs of Bronz turkeys.

Material and Methods

The research was performed at the Research and Experimental Farm of the Department of Animal Science in Uludağ University in Turkey. A total of 480 hatching eggs (75-80 g) were collected from two Bronz turkey breeder flocks at different ages as 35 weeks (Y: young flock) and 66 weeks (O: old flock) of age. All eggs were numbered and weighed with ± 0.1 precision before incubation. Then the eggs were incubated in two fully automated, ventilated, programmable incubators at 37.5◦C and two different humidity levels as 55-60% (S: standard humidity) RH and 61-65% RH (H: high humidity) during the first 24 d of incubation. The eggs from each age group and humidity groups were randomly placed into incubator trays consisting of 40 eggs (n = 3 trays/humidity/breeder age).

During incubation period, the egg weight loss was determined between days 0-6, 7-12, 13-18, 19-24 and 0-24. On d 25 of incubation, eggs were transferred to a hatcher. The hatcher was operated at 37.0°C temperature and a 72% RH during hatching period. After the completing of hatching process, all of the hatched poults were pulled out according to standard hatchery procedures. The poults were classified into two categories as saleable poults (clean, dry, and without deformities) and culls (splayed legs, unhealed navels, and so on; Molenaar *et al.*, 2011). The percentages of saleable and cull poult were determined as a percentage of fertile eggs (Molenaar *et al.*, 2011). Unhatched eggs were opened to macroscopically determine fertility and embryonic mortality (early-term, mid-term and late-term embryonic mortalities). Mortality and fertility were calculated as the percentage of total eggs at set to fertile eggs.

Data were subjected to two-way analysis of variance (SAS Institute Inc., Cary, NC), utilizing ANOVA procedures for balanced data. The model included breeder age and relative humidity levels and interaction between them as main effects. Analysis for percentage data was conducted after an arcsine transformation of the data. Significant differences among treatment means were determined by Duncan's multiple range test. Only significant means of breeder age × relative humidity interactions were given in results. Data are presented as means ± SE. Differences were considered significant at $P < 0.05$.

Results and Discussion

The effects of breeder age and relative humidity on hatchability parameters are presented in Table 1. The initial egg weight was similar among experimental groups as 79.7 g in Y × S, 77.1 g in Y × H, 78.1 g in O × S and 76.2 g in O × H, respectively. Early, mid and late term embryonic mortalities were found to be the highest with values of 6.9%, 3.9% and 9.8%, respectively in eggs obtained from old flock and incubated at standard humidity level ($P<0.01$). The highest percentage of cull poult was found to be the highest (7.4%) in the same group. On the other hand, hatchability of fertile and total eggs were the highest in eggs obtained from young flock and incubated at standard humidity levels (87.4% and 75.0%, respectively, $P<0.01$). A higher poult hatching weight were observed in Y × S (55.8 g), Y × H (56.4 g) and O × H (56.9 g) compared to the O × S (52.1 g).

The results showed that the embryonic mortalities and hatchability were affected by both breeder hen age and relative humidity levels in bronz turkeys. The observed changes in these parameters could be related with eggshell conductance and the conductance constant that could be changed according to breeder hen age (Christensen and Nestor, 1994). Especially late term embryonic mortalities could be associated with these factors that might be combined with the relative humidity levels during incubation period. These findings are supported by previous results of Fairchild *et al.* (2002).

Table 1. The effects of breeder age and relative humidity on hatchability parameters

Parameters	Early-TEM (%)	Mid-TEM (%)	Late-TEM (%)	Percentage of cull poult (%)	HOFE (%)	HOTE (%)	PHW (g)

BA: breeder age; Y: 35 wks of age; O: 66 wks of age
RH: relative humidity; S: 55-60%; H: 61-65%

The effects of breeder age and relative humidity on egg weight loss during incubation are presented in Table 2. As seen in table 2, the highest means for egg weight loss were observed in the eggs obtained from old flock and incubated at standard humidity level during incubation period (P<0.05). It is accepted as optimum that 12-14% egg weight loss during this period in broiler and turkey eggs (Rahn *et al.*, 1981). In the study, egg weight loss between 0-24 days changed from 10.3% to 13.9% in the experimental groups.

Table 2. The effects of breeder age and relative humidity on egg weight loss (%) during incubation

O × H	2.1±0.1^{d}	2.7±0.02^{c}	3.2±0.2^{b}	2.9±0.1^{c}	11.1±04^{c}

$^{a-d}$ Means ±SEM in column that possess different superscripts differ significantly (*P<0.01;P < 0.05*)
*P<0.05, **P<0.01, NS: not significant.
BA: breeder age; Y: 35 wks of age; O: 66 wks of age
RH: relative humidity; S: 55-60%; H: 61-65%

It is known that the egg weight loss is one of the most important factors that affect embryonic death (Tiwary and Maeda, 2005). In the eggs obtained from old flock and incubated standard humidity level, observed higher embryonic mortalities could be related with a higher percentage of egg weight loss during incubation in this group.

Conclusions

In conclusion, egg weight loss during incubation, embryo's survival rate and hatchability are affected by breeder hen age and relative humidity level during incubation period in bronz turkey eggs. It can be offered that, for a maximum hatchability with a high quality poult production, the relative humidity levels should be manipulated according to breeder hen's age. A relative humidity level of 55-60% for the eggs obtained from younger flock and a relative humidity level of 61-65% for the eggs from older flocks should be recommended for a better hatchability.

Abstract

The present study was conducted to investigate the influence of the grandparent stock male - female line broiler (MF-GPS) and age of hen on egg weight, egg weight loss, hatchability, hatched chick weight and chick yields. Furthermore, the study was also conducted to determine the level of correlations between GPS male and female line and age of hen for the investigated parameters. A total of 1503 hatched egg from separate hatches were obtained by MF- GPS at 27-33 (I), 34-45 (II) and 46-64 (III) weeks of age. The data of the study obtained from a private commercial grandparent stock breeder hatchery. The eggs were incubated in an incubator at 37.5°C temperature and 84% relative humidity until 18th day of incubation. Then the eggs were transferred to a hatcher at 36.6°C temperature and 87% relative humidity until the chicks hatch. In the study, the weights of eggs and chicks were found to be similar for the male (M-GPS) and female (F-GPS) lines (P>0.05). The egg weight loss during incubation and hatchability were found to be significantly higher in F-GPS (P=0.001), while the chick yield was higher in M-GPS (P=0.001). The breeder age affected the egg weight, egg weight loss during incubation, hatchability, chick weight and chick yield (P=0.001). The interactions between the lines and the ages were significant for the hatchability (P=0.001), chick weight and chick yield (P=0.031 and P=0.017). Significant positive correlations were found between the age and egg weight (r = 0.837; P=0.001), egg weight loss (r = 0.161; P=0.001), chick weight (r = 0.783; P=0.001) and chick yield (r = 0.057; P=0.028), and for MF-GPS as well. The GPS breeder line and age of hen affected hatchability, chick weight and chick yields.

Keywords: *Grandparent stock broiler breeder line, age, egg weight loss, hatchability, chick yield.*

Introduction

Today, hatcheries with modern equipment have sufficient level of possibilities, knowledge and experience in terms of pre-incubation and incubation factors that affect the output. But the ongoing development and competition in the poultry sector requires poultry farmers to move to more technical practices in order to reach the highest level of efficiency. From this point of view, obtaining better quality of output and chick quality in hatcheries is gaining importance.

The age of hen and genotype affects hatchability, quality of chick and also growth performance of hens (Tona et al., 2004). In addition that egg weight effects incubation periods, incubation results, hatched chick weight and growth performance of birds (Witt de and Schwalbach, 2004). The weight of chicks affected by genotype, egg nutrient composition, egg weight, egg incubation conditions, egg weight loss during incubation (Wilson, 1991).

As we know egg consist albumen (60-63%), yolk (28-29%) and shell (9-11%) (Altan, 2015). The egg composition varies depend on genotype and age of hens (Vieira and Moran, 1999). During the incubation period it is necessary for succesful hatch that the weight loss in the egg is average 10-12% (Tazawa, 1980). O'Dea et al. (2004) found that weight loss and conductance of egg accreted with breeder age. Thus, egg weight accreted with breeder age. The larger eggs shell was become thinner and fractured and also more porous, it is provides more water loss and gas exchange from hen eggs (Shafey, 2002). The low egg shell quality has been caused low hatchability (Narushin and Romanov, 2002). In the hatchery this factor

should be noted, when incubated different weighed eggs to ensure ideal moisture loss for incubation (Ulmer-Franco, et al. 2010).
Chick weight is in general used for hatched chick quality evaluation (Decuypere et al., 2002). There is a correlation between egg weight and hatched chick weight in broiler chickens (Abiola et al., 2008). However, the breeder age affect chick weight and chick yield (Iqbal et al., 2016). Thus, egg weight increased with beeder age (Roque and Soares, 1994) and also chick weight (O'Dea et al., 2004). It is important for growth performance of broiler, there is a relationship between hatched chick weight and growth for broilers (Jiang and Yang, 2007).
In commercial hatcheries, eggs are obtained from different genotype and age of hens and they incubated standard incubation conditions. The number of high-quality breeder chicks obtained from GPS breeder eggs is important for hatchery. This study was aimed to investigate the influence of the grandparent stock male-female line broiler and age on egg weight, egg weight loss in incubation, hatchability, hatched chick weight and chick yields. Furthermore, the study was also conducted to determine the level of correlations between GPS male and female lines of breeders and breeder age for the investigated parameters.

Material and Methods

The data of the study obtained from a private commercial the grandparent stock hatchery in Marmara Region of Turkey. A total of 1503 hatched egg individuals were obtained by the grandparent stock male-female line broiler breeder (MF-GPS) at 27-33 (I), 34-45 (II) and 46-64 (III) weeks of age. A total of 563 separate hatches were obtained from Male Line (M-GPS) and 940 obtained from Female Line (F-GPS). The number of hatches used for different age groups respectively 164, 666 and 673 for I, II and III wks of age.
Eggs in each age group were stored for 3 to 16 days under 55% relative humidity and 18 °C. All eggs were weighed before setting into incubator. Eggs were incubated under 37.5 °C temperature and 84% relative humidity. The eggs were turned through an angle of ±45°automatically six times a day until 18^{th} day of incubation. At 18^{th} day of incubation, all eggs were weighed for determining the egg weight loss. Then eggs were transferred hatcher incubated under 36.6°C temperature and 87% relative humidity until chicks hatch. At hatch all the hatched chicks were counted and weighed. The hatchability and chick yield determined. The chick yield calculated with the formula hatched chick weight divided by egg weight at the time of setting into incubator multiplied by 100 (Iqbal et al. 2016; 2017).
Prior to statistical analysis, analyses data of egg weight loss, hatchability and chick yield were conducted after square root of arc sine transformation. The GPS line of broiler breeder and age of breeder were the main effects. The data were analysed with using a general linear model two way ANOVA (Minitab, 2013). Significant means were separated using Duncan multiple range test. Differences were considered significant at $P \leq 0.05$. The correlations between MF- GPS line and age for egg weight, egg weight loss, hatchability, chick weight, chick yield were analysed with Pearson correlation analysis (Minitab, 2013).

Results and Discussion

The effects of the grand parent stock male - female line broiler breeder and breeder age on egg weight, egg weight loss, hatchability, hatched chick weight and chick yield were given in Table 1. In the study egg weight was found to be similar for both male and female line grandparent stock of broiler (P>0.05). However, in their study Wolanski et al. (2007) suggested that strains had an impact on egg weight. In the study egg weight loss during incubation and hatchability were found higher in F-GPS broiler breeder, however egg weight loss was found low in M-GPS broiler breeder (P=0.001). That might be result of low rate egg production which attributed to the thicker egg shell in M-GPS lines.

In the study the hatched chick weight was found similar both GPS male and female lines of broiler breeders (P>0.05); despite that chick yield was found higher in M-GPS (P=0.001). The difference of hatched chicks weight of different genotype hens was not only related with egg weight differences, but also reflected genetic differences (Hardin, 1972). In their study (Wolanski et al., 2007) found that large male line had heavy eggs and chick hatch weight. Also different female lines produced different weight eggs, however, their hatch weight of chicks did not different. The chick yield of male line 70.4% and it was higher than the chick yields of commercial strains (Wolanski et al., 2007).

Tona et al. (2004), Ulmer-Franco et al. (2010), Alsobayel et al. (2013) found that hatched chick weight rising with increasing age of broiler breeders. Accordance with this findings in the study egg weight and hatched chick weight increased with breeder age (P=0.001).

The eggshell conductance was found low in young breeders eggs (Christensen et al., 2005). Accordance with them, in the study lowest egg weight loss during incubation was found in 27-33 wks of age group (P=0.001). The egg weight loss in incubation risen with parental age in duck eggs thus larger eggs have greater amount of water (El-Hanoun, 2012). However, Ulmer-Franco et al. (2010) found that young breeders' eggs had a higher percentage of weight loss than old breeders' eggs.

The united effects of low ventilation and over heat production of large eggs might be resulted increase embryo temperature and also increase embryonic mortality (Deeming, 1996) in old age breeders. Thus, in the study lowest hatchability was found in 46-64 wks of age group (P=0.001). Accordance to our results Traldi et al. (2011) reported that hatchability of eggs obtained from older breeders was 8.3% lower than eggs of younger breeders. Tona et al. (2001) found that hatchability was low in young and old aged flocks. In contrast to our findings Ulmer-Franco et al. (2010) reported that breeder age did not affect hatchability of fertile eggs.

The chick yield was interval 62 to 76% (Wilson, 1991), but the ideal chick yield is 67-68% (Aviagen, 2011). The high chick yield is an indicator of several factors that eggs were incubated at low temperature and high humidity, or incubation time short, or eggs stored long periods, or eggs obtained from very young or old breeders (Aviagen, 2011). In the study the chick yield at 34-45 wks of age group (69.99%) was found lower than that of at 27-33 wks of age (70.58%) and 46-64 wks of age (70.55%)(P=0.001). Thus Iqbal et al. (2016) found that chick yield was not influenced by egg size. But, breeder age affect chick weight and chick yield. However, Traldi et al. (2011) reported that the composition of the eggs obtained from young and adult breeders was different, but chick yield was found similar, varying between 67 and 70%.

In the study interactions between the grandparent stock male or female line broiler breeder and breeder age were found significant for hatchability (P=0.001), chick weight and chick yield (P=0.031 and P=0.017). The lowest hatchability and highest hatched chick weight was found in 46-64 wks of age group of MF-GPS of broiler breeders (P=0.001 and P=0.031). Hocking and Bernard (2000) found that breeder age not affected hatchability of male broiler breeders, but hatchability was lower in 27 to 29 wks age and 55 to 57 wks of age female broiler breeders than 35 to 37 wks of age ones. In the study the lowest chick yield was found in 34-45 wks of age group of F-GPS (P=0.017). However, there were no any significant interactions for egg weight and egg weight loss during incubation (P>0.05).

The fertility, hatchability and chick weight are related heritable traits that vary between varity and or individuals of breeds (King'ori, 2011). The correlations between the grandparent stock lines and ages of broiler for investigated parameters were given in Table 2. In the study significant positive correlations were found between breeder line and egg weight (r = 0.051; *P*=0.050), egg weight loss (r = 0.267; *P*=0.001) and significant negative correlation for chick yield (r= -0.149; *P*=0.001) for MF-GPS.

M-GPS: Male Line Grandparent stock, F-GPS: Female Line Grandparent stock
EW: Egg Weight, EWL: Egg Weight Loss, H: Hatchability, CW: Chick Weight, CY: Chick Yield

Egg weight is an important factor that affect hatched chick weight (Silversides and Scott, 2001). In the study significant positive correlations were found between breeder age and egg weight (*P*=0.001), egg weight loss (*P*=0.001 and *P*=0.037), chick weight (*P*=0.001) and significant negative correlation for hatchability (*P*=0.001) for MF-GPS, M-GPS and F-GPS. Thus, there was a strong correlation between egg weight and hatched chick weight (r = 0.90 by Bray and Iton, 1962), (r = 0.87 by Wolanski et al., 2007). There were relationships

between breeder age and egg weight (Tona et al., 2001) such that older hens lays bigger eggs (Ulmer-Franco et al. 2010) and heavier chicks (Christensen et al., 2002). But in their field's report Tona et al. (2001) indicated that there was no any significant relationship between breeder age and egg weight loss, however, there was a relationship between breeder age and hatchability. In the study there were significant positive correlations between age and chick yield for MF-GPS and F-GPS (P=0.028 and P=0.033), but except for M-GPS (P>0.05).

Conclusions

In the study eggs were obtained from different age of male and female line GPS broiler but incubated same standard incubation conditions. The results of current study indicate that the genetic stock lines affected egg weight loss, hatchability and chick yield. All investigated parameters were affected by age of chicken. In addition, the interaction between line and age on hatchability, chick weight and chick yield was found to be significant. From this point, our research provided basic information that could be useful for GPS hatcheries. Thus different line and age breeders' eggs need different incubation conditions for ensure ideal egg weight loss during incubation, so producers should be take this into consideration for better hatchability and chick yield.

Abstract

Holstein-Friesian Black-and-White cows were grouped into four treatments groups according to the analogue principle (n=4×5). Lactating dairy cows were included in the trial in the initial lactation phase with the average milk yield of 30.00 kg per day, fat content 4.10% and 3.20% protein content in milk. The analyses of the chemical composition of legume grains showed, that crude protein was higher in fodder beans than in peas, respectively 29.97% and 25.04% of dry matter. The undegraded intake protein (UIP) content also was higher in fodder beans than in peas, respectively 40.51% and 39.69% of crude protein. The highest content of starch was in peas - 48.54%, beans - 43.29% but the lowest in soybean meal - 7.62% of dry matter. Even though the daily milk yields decreased for all the cow groups during the experiment, which was normal during the lactation period, yet the milk yield decreases for the trial groups. The milk yield decreases for the experimental groups (1st and 2nd) were smaller – 0.8 kg, 1.3 kg, respectively, compared with the initial stage of the experiment ($P< 0.05$). In contrast, group 4 showed a significant decrease in the average daily energy corrected milk yield (4.9 kg), compared with the initial stage of the trial. Compared with the control group, none of the dietary interventions showed significant ($P>0.05$) deviations. The fat content of milk slightly increased, on average, by 0.04% in the 3rd and 1st groups and by 0.01% in the 2nd group, compared with the control group ($P<0.05$). The protein content of milk increased in all the experimental groups. The protein content of milk increased on average by 0.31% in the 1st group, 0.17% in the 2nd group and 0.27% in the 3rd group, compared with the control group ($P>0.05$).

Keywords: *Beans, peas, chemical composition, dairy cows, milk production and quality.*

Introduction

With many feed ingredients available to producers, protein is still a sought after nutrient, not necessarily due to a lack of availability, but the fluctuating, yet increasing costs associated with protein. One potential solution may be the botanically named *Vicia faba*, common name "faba bean". This bean is also known to have various other common names such as "horse bean", "field bean" and "broad bean". The use of alternative plant proteins in place of the soybean meal protein in diets for farmed animals aims to reduce the extra-EU soybean import and partially substitute the GMO in the food chain. Among the possible alternatives, the faba beans and peas appears interesting for dairy cow diet. The common reason for livestock producers to plant faba beans is to obtain a protein source that is homegrown and that can easily be processed on-farm, as they contain little oil. They also do not contain anti-nutritional enzymes and therefore do not need roasting. Faba beans are related to lima beans and contain approximately 30% protein (Volpelli *et al*., 2010; Heeg, 2016). Field peas are highly digestible and highly fermentable in the rumen, but have a slower starch and protein fermentation rate than several other common feeds. Therefore, fodder beans and peas be used as an important forage legume to enhance feed values for dairy ruminants, especially of importance to today's high yielding dairy cows (Jensen, 2002; Ipharraguerre and Clark, 2005). The European Union policy on the protection and enhancement of biodiversity on agricultural holdings has contributed to an increase in the area sown with legumes in Latvia.

Areas under nitrogen-fixing crops, including fodder beans or field beans and peas, are eligible for financial support regarding environment-friendly agricultural practices; consequently, the total area under field beans in Latvia in the period 2010-2016 increased approximately 11 times (from 2.8 thousand hectares to 31.4 thousand hectares) and that under peas – 7 times (from 1.2 thousand hectares to 8.9 thousand hectares). The sown areas of pulses continue to grow. In 2016, the total area of pulses increased by 32.1%, of which the area of field beans rose by 5.4 thousand hectares or 20.9% (Agriculture of Latvia, 2017). This means that the growing area under faba beans and peas in Latvia can supply agricultural animals with the necessary amount of protein as well as increase the proportion of domestic protein rich feedstuffs in the consumption of feed and reduce the production cost of livestock products, i.e. contribute to higher efficiency (Proskina and Cerina, 2017).
The objective of the present paper is to investigate the legume grains in dairy cows' feed.

Material and Methods

Trials were carried out on the farm "Upites", Allazu Parish, Allazmuiza Municipality. For the trial, four analogue (according to yield, lactation phase, live weight, fat content and protein content) treatments groups of 20 animals of Holstein-Friesian Black-and-White cows were used in the study. Feeding trial was carried out from December 2015 to February 2016, *i.e.* for 90 days. The experimental design is reported in Table 1.

Table 1. General scheme of the trial.

Group of cows	Number of cows	Feeding programme
1st trial	5	Basic feed + 10-12% *Pisum sativum*'Bruno' + 10 - 12 % *Vicia faba minora*'Lielplatone'
2nd trial	5	Basic feed + 20-24% *Pisum sativum*'Bruno'
3rdtrial	5	Basic feed + 20-24% *Vicia faba minora* 'Lielplatone'
4th control	5	Basic feed with soybean cake

The average live weight of cows in all groups were 650 kg the mean age was 3.0 lactations. The cows were in the initial phase of lactation were included in the experiment with the average yield of 30.00 kg per day, fat content 4.10% and protein content 3.20% ($P > 0.05$). The cows were kept under the tied-housing system, milked twice a day at an interval of 12 hours are kept on the same farm, under equal feeding, housing and exploitation condition. During the trial, the dairy cows received the basic feed ration which consisted, calculation per cow per day of: 40 kg silage (grass plus legume), 3 kg hay (grass plus legume), 4 kg fodder (grains), 4 kg complementary, 0.15 kg mineral additive. In the experimental period, the cows of all groups were fed the same diet except that the diet of the cows in the control group was supplemented with 1 kg soybean meal that of the 1s trial group with 1.82 kg that of the peas plus beans, that of the 2nd group with 1.9 kg peas and that of the 3rd trial group with 1.7 kg beans (Table 2).

Table 2. Dairy cows feeding during the trials.

Feedstuffs	Amount, kg	1st trial	2nd trial	3rd trial	4th control
Silage	40	40	40	40	40
Hay	3	3	3	3	3
Concentrated feed	4	4	4	4	4
Complementary feed	4	4	4	4	4
Peas plus beans	-	1.82	-	-	-
Peas	-	-	1.9	-	-
Beans	-	-	-	1.7	-
Soybean meals	-	-	-	-	1
Mineral additive	0.15	0.15	0.15	0.15	0.15
Feed ration contains:					
Dry matter, kg	-	21.60	21.70	21.50	20.80
Crude protein, g	-	3266	3261	3276	3258
NEL, MJ	-	142.7	143.8	139	137.20
Calcium, g	-	153	157	155	162
Phosphorus, g	-	82.0	83.0	85.0	82.0

The feeding ration varied according to each cows' milk yield and physiological state, and was corrected monthly depending on the results of control milk yield, dry period and state of health. When elaborating the feeding rations, we took into consideration the following: amount of feedstuffs, dry matter (DM), net energy for lactation (NEL, MJ), amount of crude protein, calcium and phosphorus (Nutrient Requirements…, 2001).

Each cows' individual milk yield and whole groups average, content of milk fat and protein was recorded, basing on the control milk yield sheets. Control of the milk yield in cows' groups was performed each day, individual milk yields were controled once a month.

A full value chemical analyses were conducted by the accredited Scientific Laboratory of the Agronomical Analyses under the Latvia University of Agriculture. Chemical analyses of the feed samples was carried out in accordance with the ISO 6498: 1998 standards, dry matter - Feed Analyses met.2.2.1.1: 1993, crude protein - LVS EN ISO 5983-2: 2009, starch - LVS EN ISO 10520:2001, crude fat - ISO 6492:1999, digestible undegraded intake protein (UIP) - calculation method, crude fibre - ISO 5498: 1981, neutral detergent fiber (NDF%) - LVS EN ISO 16472: 2006, acid detergent fiber (ADF%), net energy for lactation (NEL, MJ kg^{-1}) – LVS EN ISO 13906: 2008, crude ash - ISO 5984:2002/Cor 1:2005, calcium - LVS EN ISO 6869: 2002, phosphorus - ISO 6491: 1998 and digestibility (De Boever *et al*., 1988). Milk quality analyzes were performed determining the milk fat and protein content, the method ISO 9622-2013 (E) / IDF 141: 2013 (E).

The biometric data were analysed by a Mann-Whitney test at the significance level $\alpha = 0.05$ to identify differences in comparison with the control group (Montgomery, 2012). All statistical analyses were performed using SPSS for Windows version 20.0.

Results and Discussion

The chemical composition of fodder beans, peas and soybean meal are presented in Table 3. As can be seen from data, the content of dry matter in peas "Bruno" and fodder beans "Lielplatone" was high, 90.78% and 90.44% respectively but in soybean meal - 87.41%. Crude protein content was the highest in soybean meal - 50.61% and beans - 29.97%, while in peas - 25.04% of dry matter. Soybean meal had significantly high content of UIP - 73.99% of crude protein.

Table 3. The chemical composition of fodder beans, peas and soybean meal, on dry matter basis, % .

Item	Beans (*Vicia faba minor*) "Lielplatone"	Peas (*Pisum sativum*) "Bruno"	Soybean meal
Dry matter, %	90.44	90.78	87.41
Crude protein, %	29.97	25.04	50.61
UIP of crude protein, %	40.51	39.69	73.99
Crude fat, %	1.09	1.22	1.60
Starch, %	43.29	48.54	7.62
Crude fiber, %	9.5	7.21	3.57
NDF, %	15.79	20.58	13.98
ADF, %	11.36	9.59	6.91
NEL, MJ kg^{-1}	7.7	7.84	7.89
Crude ash, %	3.61	3.28	1.76
Ca, %	0.12	0.07	0.42
P, %	0.66	0.43	0.71
Digestibility, %	80.00	81.40	81.80

After summarizing reference data, undegraded intake protein (UIP) content in soybean meal in the rumen fluctuates within the range of 75 to 78 per cent (Singh *et al*., 2012). Relatively high percentage of UIP was also in fodder beans - 40.51%, whereas in peas it was 39.69% of the crude protein. According to Batterham and Egan (1986), the amount of UIP can make up 46% of crude protein content.

The analysis of productivity indices proved that the feeding of legumes grains showed, that the average milk production in all groups of cows during the trial was trend decreasing in Table 4. In 3 recording months' the daily milk yield decreased for all the cow groups. The greatest decrease in cow productivity was observed for the control group – by 3.98 kg of milk but a smaller decrease was observed for the 3 rd group – by 0.26 kg, of milk compared with the before the trial ($P < 0.05$).

Table 4. Cow productivity during the trials, on average, kg.

Group of cows	Before the trial	Beginning of the trial	Middle in the trial	End of the trial	Comparison between before and end values
1st trial	22.68	23.52	22.24	20.46	-2.22
2nd trial	23.48	21.58	21.76	21.38	-2.10
3rdtrial	20.74	19.70	20.28	20.48	-0.26

1st trial	0.465	0.600	0.917	0.917	0.225
2nd trial	0.917	0.347	0.917	0.754	0.138
3rdtrial	0.251	0.251	0.917	0.916	0.893
4th control	-	-	-	-	0.043 ^{S}

^{S} significant differences ($P < 0.05$)

The influence of the content of legume grains on milk quality in groups of cows is shown in Table 5 and 6. As the cows' productivity decreased during the trial and lactation period, the fat and protein contents of milk increased for the 1st, 2nd and 3rd groups, compared with 4th the control group of cows. The fat content of milk slightly increased, on average, by 0.04% for the 3rd and 1st group and by 0.01% for the 2nd group, compared with the control group, and from 0.33% to 0.37% ($P < 0.05$) compared with the before the trial. The fat content of milk decreased by 0.36% for the control group, compared with the before the trial.

Table 5. Fat content in milk during the trials on average, %.

Group of cows	Before the trial	Beginning of the trial	Middle in the trial	End of the trial	Comparison between before and end values
1st trial	4.6	4.7	4.7	4.9	0.3
2nd trial	4.7	4.6	4.5	4.9	0.2
3rdtrial	4.6	4.8	4.8	4.9	0.4
4th control	5.3	4.9	4.4	4.9	-0.4
p–value (relative to control)					
Group of cows	Before the trial	Beginning of the trial	Middle in the trial	End of the trial	*P*-value (ralative to values at the before the trial)
1st trial	0.602	0.465	0.465	1.000	0.345
2nd trial	0.465	0.251	0.917	0.917	0.686
3rdtrial	0.465	0.465	0.602	0.754	0.138
4th control	-	-	-	-	0.500

The protein content of milk increased in the 1st group (0.31%, on average) in the 2nd group (0.17% ,on average), but 3rd group (0.27%, on average) compared with the control group, and by 0.60%, 0.40% and 0.40%, respectively, compared with the before the trial ($P > 0.05$).

Table 6. Protein content in milk during the trials on average, %.

Group of cows	Before the trial	Beginning of the trial	Middle in the trial	End of the trial	Comparison between before and end values
1st trial	3.1	3.4	3.3	3.7	0.6

S significant differences ($P < 0.05$)

It is known that the cow farming technology, including cow feeding, can considerably affect milk yield. After examining the effects of different amounts of dietary legumes on productivity of dairy cows, Vander *et al*., (2008) demonstrated no significant changes when soybean flour is partially replaced by peas (150 g kg^{-1}). A similar finding was made by Tufarelli *et al*., (2012) who reported that replacing soybeans with faba beans (345 g kg^{-1}) in the diet for highly productive dairy cows (the average milk yield of 35 kg a day) did not influence the cows' productivity. According to Mordenti *et al*. (2007) pointed out that faba beans and peas (200 g kg^{-1}) incorporated into the dairy cow diet increased milk fat content but decreased milk yield.

Conclusions

Obtained results of chemical composition of legume grains the content of dry matter in peas and field beans was high, 90.78% and 90.44% respectively. Crude protein content was the highest in soybean meal - 50.61% and fodder beans - 29.97%, while in peas - 25.04% of dry matter. The highest content of starch was in peas - 48.54%, beans - 43.29% but the lowest in soybean meal - 7.62% of dry matter.

During the trial, the cow productivity indicators decreased for all the groups, which was normal during the lactation period, yet the daily milk yield decreases for the trial groups (diets comprising peas and beans) were smaller – 2.22 kg, 2.10 kg and 0.26 kg, respectively, compared with before the trial and the control group.

The fat content in milk from the 3rd group and the 1st group slightly increased, on average, by 0.04%, while that from the 2nd group – by 0.01%, compared with the 4th group. The protein content in milk increased by 0.31% for the 1st group, 0.17% for the 2nd group and 0.27% for the 3rd group, compared with the control group ($P < 0.05$).

The research results proved that the use of legumes as domestic feedstuffs for the purpose of raising the nutritional value of the feed and balancing protein in the feed ration for dairy cows is important and promising, as the legumes help better maintain the milk yield level during the lactation period and enhance the milk quality indicators.

Abstract

Great efforts have been made over the past several decades for development of improved cultivars adapted to different agro-ecological areas due to the on-going climatic changes. In order to increase further the selection gain and to accelerate breeding processes in maize, a profound knowledge is required regarding genes and genomic regions encoding for agronomically important traits. In this context, the use of haplotypes could improve selection of quantitative traits with a low heritability due to strong environmental influence. Twenty temperate drought tolerant (15) and sensitive (5) maize inbred lines from Maize Research Institute Zemun Polje (MRIZP) were subjected to SNP genotyping. Additionally, 17 maize (13) and teosinte (4) genotypes were selected for comparison from Panzea database to represent the functional diversity of maize. For SNP identification direct PCR sequencing of eight abiotic responsive candidate genes was done. A small number (3 to 8) of distinct and highly diverse haplotypes were observed in all eight (8) marker genes. Haplotype analysis based on the SNPs revealed the highest haplotype diversity in *MYBR96* (0.817) and the lowest in *MYB8* (0.3235) gene. Network analysis showed a linear relationship between haplotypes for some genes, while for the rest of genes the network graphs reflected more complex relationships between a large numbers of haplotypes. The deployment of the identified haplotypes could be a powerful complementary tool to improve accuracy and efficiency of modern breeding strategies such as marker assisted selection and genomic selection for developing drought tolerant maize genotypes.

Key words: *maize, drought, SNPs, haplotypes.*

Introduction

Global crop production is challenged by severe climatic changes like drought (Lesk *et al.*, 2016) and food demands of exponentially growing world population. It has been predicted that yields of important commodity crops need to be increased by almost 40% by the middle of 21st century (Tester and Langridge, 2010). Achieving sustainable yields of commodity crops in inconsistent environments represents a demanding task for the breeders. However, cutting-edge advances in genome analysis technologies provide high resolution molecular information which can perfect advanced quantitative genetic approaches. Low-cost genotyping tools that can capture sequence variation are now available for all agronomically important plant species (Huang and Han, 2014) and they provide an effective means for crop genetic research studies (Ganal *et al.*, 2012), such as providing a basis for genomic selection (GS) or prediction of hybrid performance.

High-throughput single nucleotide polymorphism (SNP) marker arrays or SNPs detected by DNA sequencing are the genotyping markers of choice for crop genomic research. However, their major limitation is that they provide only bi-allelic information at a locus, hence their information content compared to multi-allelic markers is low, limiting the resolution at which SNP–trait relationships can be delineated. An effective approach to surpass the biallelic limitations of SNPs is to construct haplotypes based on linkage disequilibrium (LD), one of

the most important features influencing genetic analysis of crop genomes (Qian *et al*., 2017). A haplotype is described as „two or more SNP alleles that tend to be inherited as a unit" (Bernardo, 2010). Marker-assissted selection (MAS), which has succesfully been used for mono- or oligogenic inherited traits, failed for highly quantitative traits with a low heritability due to strong environmental influence. MAS strategies proved inadequate due to statistical overestimation of QTL linked markers or complex genetic architectures for most important traits (Bernardo, 2008). That is why the concept of GS with densely spaced genome-wide markers is presently being adopted for many crop breeding programs. Genomic selection methods apply the concept that the breeding value of an individual which has not been phenotyped can be estimated purely on the basis of its genome wide marker profile. In the context of both MAS and GS, the use of haplotypes could be a powerful complementary tool to improve their accuracy and efficiency. Because of their increased information content compared to bi-allelic SNP markers, fitting haplotypes with statistically significant trait associations to phenotypes as fixed effects in GS models could further improve prediction accuracies. The use of haplotype-assisted GS should more accurately depict the complex relationships between genotypic information and phenotypes than single SNPs alone are able to do; hence, this approach could ultimately help to further increase selection gain per unit of time (Qian *et al*., 2017).

The aim of the research presented herein was to identify SNP mutations in drought candidate responsive genes in 20 drought tolerant and susceptible maize inbred lines from Maize Research Institute Zemun Polje (MRIZP) and based on the SNP information identify conserved haplotypes. Also, the nucleotide diversity in these genes between the inbreds from MRIZP collection and Panzea database was analysed.

Material and methods

Twenty temperate drought tolerant (15) and sensitive (5) maize inbred lines from MRIZP were subjected to SNP genotyping. Four sensitive and two tolerant inbreds are commercial lines used as parental lines for development in MRIZP breeding programs, while the remaining 14 are from MRIZP genebank. Additionally, a total of 17 foreign maize genotypes including tropical maize inbreds (5), teosinte lines (4), African inbred M37W and temperate maize inbreds (7) were selected from Panzea database to represent the functional diversity of maize. Most of them (without teosinte lines) have been used in crosses to develop the Nested Association Mapping (NAM) population consisting of 302 lines designed to capture the diversity of maize and to preserve historic linkage disequilibrium.

For SNP identification in 20 inbred lines from MRI direct PCR sequencing approach was applied on eight abiotic responsive candidate genes - *MYBR96* (MYB-related-transcription factor 96), *SDG110a* (histone-lysine N-methyltransferase, H3 lysine-36 and H4 lysine-20 specific), *IDP507* (protein kinase G11A), *MYB67* (myb domain protein 67) *MYB8, PCO089553b (PSF2), GA20OX1* and *DHN1*. PCR products were subjected to double stranded sequencing on ABI 3130xl platform. The raw sequencing data were base called and assembled in contigs using phred (Ewing *et al*., 1998) and phrap (Green, 1996) with default parameters. The contigs were aligned and analysed for SNP detection using BioLign software (Hall, 2001). Nucleotide sequences were converted into amino acid sequences and were compared with protein sequences (http://www.ncbi.nlm.nih.gov; http://www.panzea.org/) of the corresponding genes in maize to verify if the identified SNPs were able to produce functional mutations with amino acid changing. The sequence information is given in forward direction.

Conserved haplotypes, representing DNA sequences containing identical allelic variants at all polymorphic sites at particular locus, but originating from separate individuals, were identified visually or by application of NETWORK 5.0 software. Haplotype networks for the

whole set of 35 maize lines but separately for each gene were drawn using the same software. The network figures show the number of haplotypes observed for each gene and the SNP position which separates each haplotype from each other. Haplotype frequency is depicted by circles. Circle sizes correspond to the frequency of the corresponding haplotypes. The bigger the circle, the more genotypes are represented by that haplotype. The color in the circles corresponds to the affiliation of genotypes to the relevant collection.

Results and Discussion

Haplotype analysis of MRIZP and Panzea collections based on the SNPs from the small window size, i.e. gene window (all markers within a gene) is presented in Fig. 1. Number of identified SNPs and haplotypes, as well as haplotype diversity, for each gene is given in Table 1. The highest haplotype diversity was found in *MYBR96* (0.817) and the lowest in *MYB8* (0.3235) in the whole set of maize inbred lines (Table 1). Comparison analysis between both collections showed slightly higher level of haplotype diversity in *MYB8* (0.4902) and *MYBR96* (0.817) in MRIZP collection consisting of only temperate inbreds. The level of haplotype diversity in the rest of genes was higher in Panzea collection represented by an extremely diverse set of temperate, tropical and teosinte lines. Removal of tropical inbreds and teosinte lines led to some reduction in the level of haplotype diversity in Panzea collection, but it still remained higher in comparison to the MRIZP collection in genes *DHN1*, *IDP 507*, *MYB67* and *GA20OX1* (data not shown).

Table 1. Haplotype diversity of eight abiotic responsive candidate genes in MRIZP and PANZEA maize collections

genes	Collection (inbred lines)					
	MRIZP			PANZEA		
	SNP number	haplotype number	haplotype diversity	SNP number	haplotype number	haplotype diversity
DHN1	7	3	0.3856	18	7	0.8088
IDP507	5	3	0.3922	5	4	0.6544
MYB67	5	4	0.3987	14	7	0.7206
MYB8	4	6	0.4902	2	3	**0.3235**
MYBR96	13	6	**0.817**	16	6	0.8015
PCO089553B	3	3	0.6013	4	4	0.6397
GA20OX1	3	3	0.3856	7	7	0.6618
SDG110a	10	6	0.6993	4	5	0.7721

In this study a small number of 3 to 8 distinct and highly diverse haplotypes were observed in all eight genes in the set of 35 genotypes from both collections. These results are in accordance with those observed by Ching *et al*. (2002) for 36 elite US maize inbreds, but lower than the identified 14 haplotypes in the RTCS (rootles concerning crown and seminal roots) in 73 Chinese elite inbreds from five temperate heterotic groups and some tropic germplasm.

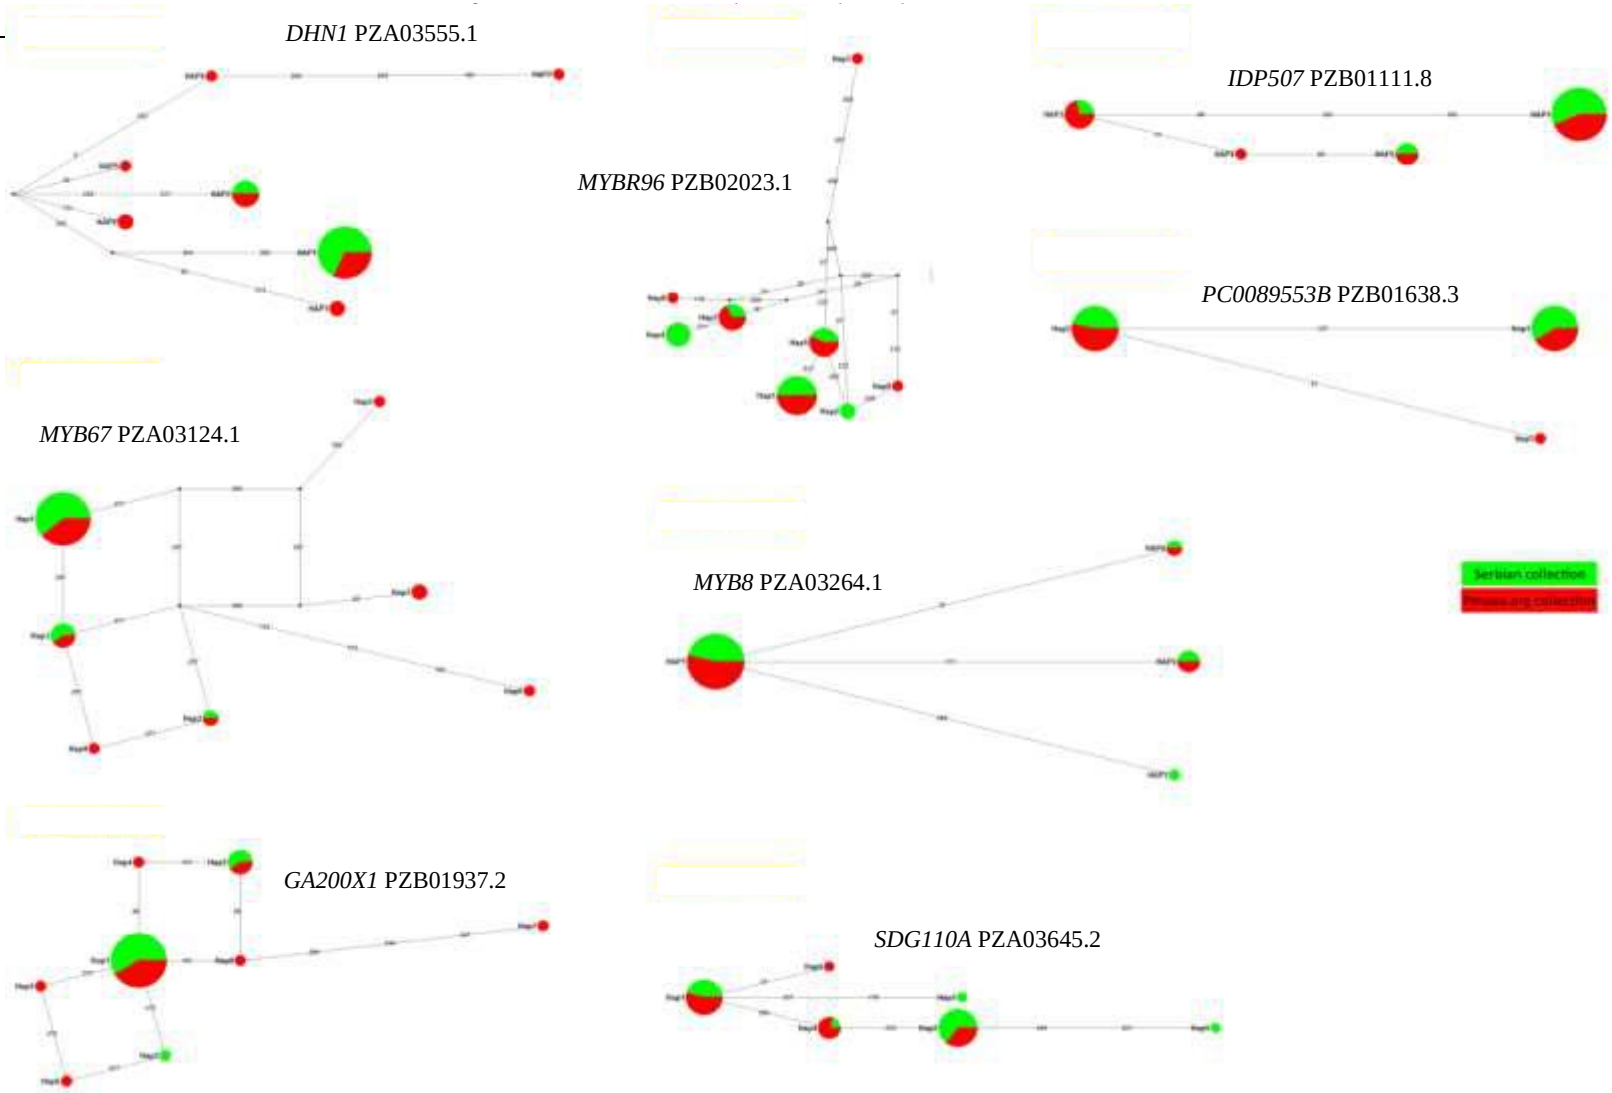

Fig. 1. Haplotype network of the eight marker genes developed on affiliation of maize genotypes to MRIZP and Panzea collections. Each circle represents a haplotype and is labeled accordingly. The two color codes, green and red in the circles represents the genotypes belonging to the two collections, MRIZP and Panzea respectively.

Network analysis showed a linear relationship between haplotypes for some genes such as *IDP507, PCO089553b, MYB8* and *SDG110a*, while for *DHN1, MYB67, MYBR96* and *GA20OX1* the network graphs reflected more complex relationships between a large number of haplotypes. This was more definitely pronounced in *MYBR96* gene where the presence of eight haplotypes was identified in the set of 35 maize genotypes. The haplotype network of *MYBR96* gene showed the presence of four major haplotypes (Hap1, Hap3, Hap4 and Hap5), which are connected to four minor ones by 1-2 SNPs. It is interesting to note, that one of the major haplotypes Hap4 is composed only of five temperate inbreds from MRIZP elite mini core collection for drought tolerance. In these lines a unique mutation (A→G transition) was observed in the acidic Ser/Thr – rich area located downstream from the SANT domain (SWI3, ADA2, N-Cor, TFIIIB DNA binding domain). This transition leads to amino acid change from Tryptophan to Alanine at the corresponding position of the protein and despite the fact that it does not affect the binding site of *MYBR96* transcription factor, this replacement might possibly reflect the spatial conformation through changing of its functional activity. To our knowledge the observed mutation is the first one reported for this position of the *MYBR96* gene as compared to the 44 other inbred lines representing the functional diversity of maize from the Panzea database (http://www.panzea.org/) (Assenov *et al*., 2013).

The simplest haplotype network consisting of only three haplotypes was observed for the marker gene *PCO0089553B (PSF2)*, one of the core genes that encode proteins which have an important role in DNA replication machinery in plants. The two major haplotypes include equal number of genotypes and are split by the marker SNP PZB01638.3 (A/T) in position 107, which is located in intron1 of the gene. This marker SNP was associated with different phenotypic traits (anthesis-silking interval, grain yield and selection index of drought tolerance) under water stress conditions at four environments in China (Hao *et al*., 2011). However, in our analysis no obvious differentiation of genotypes according to their stress response was observed.

Conclusion

Our study showed unbalanced distribution of the maize inbred lines in the analyzed haplotypes, most of which consisted of only teosinte and/or CML germplasm. The largest haplotypes consisted of lines from both MRIZP and Panzea collections. The analyzed haplotypes of the selected eight abiotic responsive genes did not comprise lines according to their level of tolerance to the drought stress, except Hap4 in *MYBR96* which was composed exclusively of five MRIZP drought tolerant lines with a unique mutation and it could be used in breeding programs for developing drought tolerant genotypes. A more profound analysis of genes expressed under drought stress in search for informative SNPs and haplotypes valuable for marker assisted or genome selection is underway.

Abstract

Thickness of wool fibres in various breeds of Pramenka sheep (Dubska and Pivska) varied; it was examined during different periods, spring and autumn, and it came from different locations – mountain Vlašić in Bosnia and Herzegovina (BandH) and Pivska mountain in Montenegro. Air temperature and the degree of insolation have a major significance on the quality of wool fibres in both Pramenka breeds. Seasonal changes, average temperature and insolation together with the age of animals and the region of the body from which samples were taken, affect the quality and the use value of wool fibres. Wool as a raw material is exposed to the activity of various insults – mechanical, thermal and chemical. The quality of wool products depends on physical and technological characteristics of the wool. The textile industry requires high-evenness of the wool primarily to reduce the sorting costs, which also increases the value of wool. Respectively, the data represents a contribution to the study of the fineness of wool fibres and their use in industry, the use for technical purposes and especially to the importance of the wool as a strategic ecological raw material.

Key words: *Dubska, Pivska Pramenka, wool fibres, micro-climate*

Introduction

In some areas the wool is the most important product of sheep, and sheep farming focuses strategically on breeds of sheep intended for production of wool, meat, milk and skin. Wool was the first textile product used by humans in Old Egypt, Palestine, Ancient Greece and Rome, Ovčarstvo (2007). Our research was a comparative study involving the Dubska and Pivska indigenous Pramenka breeds, Bosnia and Herzegovina (BandH) and Montenegro, from the aspects of the quality of wool fibres. Climate factors (air temperature and degree of insolation) had a significant impact on the quality of the wool fibres in both breeds. Comparison of the mean values of the thickness of wool fibres in May and November between Dubska and Pivska Pramenka in relation to average air temperature and degree of insolation shows certain differences.

The examinations showed that thickness of wool fibres is smaller, i.e. the fibres are thinner and finer in higher temperatures and in areas with a greater number of sunny days-hours, regardless of the Pramenka breed, the region of the body, the season – spring or autumn. In our studies, we determined an important relationship between the thickness of the wool fibres, average temperature and insolation, and taking into account also the studies by Pilling et al., (2011). This data represents a contribution to the study of the fineness of wool fibres and their use in the demanding textile industry, other industrial branches and their use for technical purposes. The significance of the wool as a strategic ecological raw material is emphasized.

Materials and methods

The samples for microscopic examinations of the skin and fibres of Dubska and Pivska Pramenka were taken during 2015. from Vlasic mountain in Bosnia and Herzegovina and Pivska mountain in Montenegro. The wool fibres for microscopic examination were taken from various parts of the body -- shoulder, rump, root of the tail-- by cutting the strands next to the skin. The samples from both locations and from different periods of time were placed in marked plastic bags until it was time to carry out microscopic examination. All impurities were cleaned in advance of microscopic examination. The samples were washed using neutral soap; they were rinsed with water, and then rinsed again with distilled water. To achieve transparency, the samples were immersed in H_2O_2-hydrogen peroxide for 24 hours, and then in xylol for 48 hours. Again, the samples were rinsed with distilled water, after which they were left to dry. The prepared samples were placed on glass slides, embedded into glycerol droplets and examined under the microscope. Measuring of thickness of the wool fibres from different parts of the body (rump, shoulder, tail root) and from different locations and periods of time -- spring-May and autumn-November – was carried out with binocular light microscope Motic 120M, under magnification of 200 and 400 times. The program that was used for measuring was Motic Image Plus 2.0ML.

Data on the average air temperature and hours of insolation was received from the Federal Hydrometeorological Institute of Bosnia and Herzegovina on 15th of October 2015, as well as the official data from the Institute's web page www.fhmzbih, and the Institute for Hydrometeorology and Seismology of Montenegro on 28th of October, 2015.

Results and discussion

Sheep farming sector in Bosnia and Herzegovina (BandH) is gradually restored – according to the FAO data, the number of sheep in 2012 was 1,515,000. The Pramenka breed makes the highest percentage of sheep population in Bosnia and Herzegovina (BandH),FAO (2012) and the wool fibres of this breed are classified between D and E. They are coarse fibres and the rest (20%) are fine fibres. (The wool in (BandH). Wool coverage of the sheep's body is also a characteristic of the breed. Coarse wool sheep, including the Pramenka sheep, are poorly covered on the stomach, legs and head and they bring smaller yields of wool per head compared to Merino breeds in which the entire body is covered with wool and some even have skin folds that significantly increase the size of the skin and therefore the amount of the wool produced Mioč et al. (2006).

In our region, Palian (1956) studied the impact of micro-climate factors, air temperature and natural, ecological and genetic factors on the types of Pramenka.

The most coarse fibres are found on the upper legs, lower back and around the root of the tail. The thinnest and the thickest fibres are on both sides of the trunk,Sheep farming (2006).

The organized purchase and wool processing would solve the ecological problem, which, we can say, is escalating, and BiH cannot become an EU member unless it resolves this issue. Working in this segment of sheep farming, we stressed the importance of wool, as a useful raw material in sheep farming in BiH, rather than waste. (Programme for Development of Agriculture in Central Bosnia Canton (2009-2015).

Comparison of the mean values of thickness of the wool fibres in the spring – month of May between Dubska and Pivska Pramenka and comparison of the average air temperature and degree of insolation show differences. It should be noted that the average air temperature in May at Babanovac Vlašić was 9.4°C, and the degree of insolation was 173.8 hours. During the same period, meteorological station at Zabljak Montenegro measured the average air temperature of 8.9°C, and the insolation was 162,5 hours. The mean value of the thickness of wool fibres in Dubska Pramenka from Vlašić mountain was generally smaller compared to the Pivska Pramenka during the same period, May 2014, regardless of the age -- three years and

above, and regardless of the region of the body that was examined. Evenness of the fleece in narrow terms represents the evenness of the wool's fineness on certain parts of the body. Fleece that is more even in terms of fineness and other properties is better for use and has a greater value, Sheep farming (2006). The indicators in this study say that the mean value of the thickness of the wool fibres from the shoulder of Dubska Pramenka was 38.14μ, and 39.14μ in Pivska Pramenka. The mean values of the thickness of the wool fibres from the rump was 43,70μ for Dubska Pramenka and 47,14μ for Pivska Pramenka. The mean value of the thickness of wool fibres from the root of the tail was 41.01μ for Dubska Pramenka and 43.60μ for Pivska Pramenka (Table 1).

Table 1.: Mean values of thickness of wool fibres of Dubska and Pivska Pramenka – month MAY

WOOL FIBERS (MAY) μm		
Region of the body	Dubska Pramenka	Pivska Pramenka
Shoulder	38,14	39,14
Rump	43,70	47,14
Tail root	41,01	43,60

Similar studies, those referring to seasonal changes: insolation and average air temperature were carried out also by Nikolić (1947).

It should be emphasized that in addition to a large supply and competitiveness of synthetic fibres, the wool has a strong and irreplaceable role in the textile industry; it is similar with fur and skin.

In Montenegro, wool and skin in the last 10-15 years have lost their economic significance. Promotion and affirmation of wool crafts and exports of raw unwashed wool have contributed to its more significant role in the past 2-3 years. We emphasize that the skin is placed successfully also as an exporting raw material.

Throughout a year, sheep require proper and high-quality diet, adequate ambient – airy and dry environment and sheep barns with covered floors, Mitić (1984). Wool becomes shorter and thinner under poor diet conditions. Sheep kept in poor zoo-hygienic conditions yield low-quality wool. Sheep pens and barns without sufficient litter, wet, muddy, tight and poorly aired environments are the biggest damaging factors to the wool and its health Mioč et al. (2000,2006).

The wool fibres are primarily qualitative parameters in production of wool and in determining its usability in further processing, however, they also represent quantitative parameters of fleece of sheep. The fibres are of uneven quality, both in terms of chemical and technical characteristics. These characteristics depend on the race i.e. breed, diet, breeding conditions, hormonal status, zoo-hygienic and climate conditions and so on, Savić et al. (2007). In his studies, Gutić et al. (2006) also emphasized the impact of the climate factors on the quality and amount of wool. Stressing that fleece is an important protection of the body against negative impacts of climate factors. Protection against severe weather conditions, moisture, increased circulation of air, wind, draft, emphasizing that the fleece plays a role in preventing heat drain and higher energy consumption in sheep.

In November 2014 – autumn, the research studies involved the same breeds of Pramenka and the same locations. The average monthly air temperature on mountain Vlasic during this period (November 2013) was 3.0 °C, and the degree of insolation was 57.9 hours. During the

same research period, but in November 2014, meteorological station Zabljak measured the average monthly air temperature of 4.9°C, and the degree of insolation was 100.9 hours.
The wool fibres, the mean value of the thickness in November for Dubska Pramenka were as follows: 65,00μ-shoulder and 56,40μ-rump. The mean values for Pivska Pramenka were shoulder:rump, 48,93μ:52,54μ. The root of the tail showed the following values of the studied parameter 57,74μ for Dubska Pramenka and 53,99μ for Pivska Pramenka (Table 2).

Table 2.:Mean values of thickness of wool fibres in Dubska and Pivska Pramenka – month NOVEMBER

WOOL FIBRES (MAY) μm		
Region of the body	Dubska Pramenka	Pivska Pramenka
Shoulder	38,14	39,14
Rump	43,70	47,14
Tail root	41,01	43,60

During both research periods we came to know that the air temperature and degree of insolation affected the thickness of the wool fibres, which were thinner and finer in case when the average air temperature and degree of insolation were higher. Our results are similar to the results of Adžić (1997). The results of our research support the breeding goals for the meat-wool production in sheep breeding in Federation of Bosnia and Herzegovina (2016).
The results of the study by Wickham and McDonald (1982) show that the sheep bred in warm and dry climate have somewhat finer wool than the sheep of the same breed bred in wetter and colder areas and at the higher latitude. The wool in younger sheep is finer than the wool in the old sheep. In almost all breeds, wool is most coarse in sheep age 5-6 years. Inadequate diet may affect the quality of the wool, especially expressed in the last quarter of gravidity and during the maximum lactation.

Conclusions

Mean values of thickness of the wool fibres in Dubska Pramenka in May were smaller compared against the Pivska Pramenka during the same period, regardless of age and region of the body.
In November, the average air temperature in Zabljak was higher than 4.9°C and so was the degree of insolation, 100.9 hours in regard to the mountain Vlašić, which affected the thickness of the wool fibres in Pivska Pramenka, as they were thinner and finer compared to the Dubska Pramenka.
Our studies show that thickness of the wool fibres varied, i.e. the wool fibres are thinner and finer in higher temperatures and in areas with a greater number of sun hours regardless of the breed, age, region of the body i.e. season.
Wool as raw material cannot be classified as most suitable for use in the textile industry because of uneven and lower quality. It can be used for production of other wool products.
Our research studies can also be applicative, and inadequate disposal of wool in the environment can be significantly reduced through a continual education of farmers, proper shearing and adequate assortment of the wool. This will increase the use of wool as an important ecological raw material, its classification for the use in various industrial branches (even in ecological civil engineering), Zametica et al. (2016).

Our research has provided a major contribution toward treating wool as an ecologically important raw material, rather than waste.

Abstract

Vegetable production in the protected area belongs to highly intensive agricultural production, and it is followed by appropriate results of production. It brings a number of advantages as opposed to the production of vegetables in the open area and is therefore very attractive for an agricultural producer. In this paper, the production of vegetables in a protected space without heating in the territory of the city of Bijeljina (Bosnia and Herzegovina) has been analyzed, as well as the specificities and possibilities for improving the business results. The results of the research indicate that the most common way of using protected area is to cultivate one line during the year, while on two farms two crops were grown in the protected area. The highest average gross margin was achieved in the production of tomatoes in the observed model. The t-test affirmed that there is a statistically significant difference in the average gross margin between the protected space with one production line and the protected space with two production lines.

Key words: *Protected area, Gross margin, Vegetables*

Introduction

Vegetable production is characterized by high labor inputs and production assets per unit of production area. However, due to the fact that the demand for this type of agricultural products is rapidly growing, there is an increase in the area under it. The reasons for the increase in demand are found in the nutritional value of most vegetables products, which makes this type of foods irreplaceable in human nutrition. Thanks to the positive aspects that the consumption of vegetables has for the human body, numerous studies recommend 400 grams of the aforementioned in human nutrition daily (Bodiroga 2015). The high intensity of vegetable production is accompanied by high production results. Thus, the production of vegetables in the open area can provide five to eight times higher value of production, while the production of vegetables in greenhouses has 190-250 times higher value than wheat (Vlahović et al., 2010). A large number of vegetable crops have high requirements for light and temperature, and as such can not be cultivated in the open field out of the season. The problem can be solved by cultivating them in different forms of protected area where this problem can be partially or completely eliminated. All the benefits of vegetable production are further enhanced by the cultivation of vegetables in a protected area (Hadelan et al., 2015). With the production in the protected area significantly higher yields compared to the open field production are accomplished and thus more favorable financial results are achieved. Vegetable crops are directly under the influence of a variety of variables such as weather variations (temperature, humidity, carbon dioxide concentration, etc.), nutrition, biotic factors and cultivation (Davioglu and Acioglu, 2017). The financial result will depend on a number of aforementioned factors, but also factors such as the type of protected space, production technology, space utilization during the year, and the like. Therefore, agricultural producers must use a production strategy that will optimize production and profitability, and economic evaluation is often used to assess the overall performance of the production system

(Saeid Mohamed et al, 2017). In this paper we are going to present the characteristics of greenhouse production in the area of Bijeljina (Bosnia and Herzegovina), economic results, as well as the differences that can be derived from the different use of protected space. The aim of the paper was to determine whether significant changes in business results can be achieved by changing the way of utilization of the protected area.

Material and the Methods

For the needs of the survey, agricultural producers from the area of Bijeljina, who are engaged in production in a protected area, were surveyed. Combining open and closed questions, all the necessary information for the defined goal of the research were sought. Households were selected randomly. Research was done in 2015. year and involved 20 farms. The minimum area that the farms should have in order to participate in the survey is 500 m² of protected space. In the survey the results of production in the protected area were observed, while the other lines on the farms were not analyzed. The financial result in production for individual lines was determined using the calculation of variable costs (Direct costings). The obtained data were processed by methods of descriptive statistical analysis. The method of testing hypotheses on the difference of arithmetic mean by using t-test is used for determining the significance of the difference between the gross margin in greenhouses with one and two realized lines annually as well as by the method of testing hypotheses on the difference of arithmetic mean by using t-test. For the purpose of statistical analysis the statistical software SPSS was used.

Results and Discussion

Nowadays, in the production of vegetables in a protected area, traditional methods of cultivation can be distinguished, which are applied in simple objects without modern irrigation systems and conditions control conditions, and modern, mostly computerized modes with complete control of plant growth and development. (Djurovka and Martinovic, 2009) The results of the research indicate that in the analyzed area there is a traditional method of cultivation with several different construction solutions used for production in the protected area. These are mostly low, semi-high, and high tunnels, but also modern greenhouses of various constructions.

High tunnels as well as modern greenhouses are the most common form of protected space in the observed sample. The production capacities of the farms, when it comes to the protected area, are given in the following table.

Table 1. Production capacity of observed holdings (protected area)

Indicators	$\bar{X}$	X_{min}	X_{max}	CV
Area under greenhouses (m²)	5033,00	500,00	40 000,00	173,42

*Source: Research by the author

From the table it can be noticed that the average area under greenhouses was 5033 m². There were high variations in surfaces under protected space, which can be concluded by observing data on minimum and maximum surfaces as well as the value of the coefficient of variation (CV).

All researched farms produce vegetables in conditions without heating. By carefully combining the crops in conditions without heating, it is possible to use the protected area completely during the year. Some of the ways to use the protected area without heating in the conditions of the continental climate, including the city of Bijeljina, is given in the following table.

Table 2. Possible combinations of crops in a protected area without heating

	Place in crop rotation	**Combination 1**	**Combination 2**	**Combination 3**	**Combination 4**
Vegetable species	Previous crops	Salad	Green onions	Spinach	Salad
	Main crops	Peppers	Tomato	Cucumber	Cucumber
	Post-crops	Green onions	Spinach	Green beans	Spinach

*Source: Bodiroga (2015) quoting Lazić et al. (2001), Kurtovic, (2008)

The results of the survey show that the households do not fully exploit the protected area and that one production line is most often realized during the year (peppers, cucumbers or tomatoes). The maximum number of production units on each farm was present two line during the year, in a different combination.

Production results on farms were determined using calculation based on variable costs (Direct costing method). Variable costs are costs whose value changes with the change in the volume of production, or the degree of utilization of the capacity of the means of production. (Sredojevic, 2015) The original name, the direct costing method does not express quite precisely its essence, since the term "direct" here implies variable costs, while in classical analytical calculations this term is used for costs that directly and in whole relate to individual lines of production but can also have the character of fixed costs. (Andric, 1998)

By applying this type of calculations, it is possible to draw conclusions as to whether revenues from individual lines can cover the costs incurred for obtaining them, while fixed costs are omitted and considered as non-evasive costs and are present when there is no production on the holding.

The basic descriptive gross margin indicators obtained as the difference between the generated income and the variable costs of individual lines are given in the following table.

Table 3. Gross margin at different lines in the protected area (KM / 100 m²)

Production line	**Average**	**Maximum**	**Minimum**	**CV %**
Tomato	973,76	1436,43	581,66	27,39
Bell pepper	522,11	783,40	223,20	37,92
Kapia type pepper	504,38	800,00	190,50	43,50
Cucumber	592,83	1536,66	224,35	51,02
Salad	100,00	100,00	100,00	-------

*Source: Research by the author

The highest average gross margin was achieved with tomatoes, while in individual cases cucumber had the highest gross margin. Salad was present only in one agricultural holding. According to the data on the realized gross margin for all surveyed farms, the average gross margin is calculated for farms which realize only one production line during the year, as well as with farms that realize two production lines during the year.

For households with one line growing in the greenhouse, the average gross margin is 742,65KM, while for farms with two production lines, growing in the same space, the value is 984,91KM. In order for the information on the difference in the gross margin of the farms in the observed sample to be applied to the entire population of farms from the observed area, the t-test was applied. The condition for applying the t-test is that both sets have equal variances, that is, their variances have to be homogeneous. (Lovric et al., 2006) Using the SPSS statistical software, the Levene test was applied in order to test the homogeneity of the population and the equivalence of the variances of the sets.

The results of the Levene test indicate that there is only few reasons to doubt the homogeneity of the population of variances, which can be concluded on the basis of the data in the following table. Since the conditions for application are fulfilled, assuming the normality of the population comes from the zero hypothesis, which reads as follows: $H_0 : \mu_1 = \mu_2$ The t-test was applied, the results of which are given in the following table.

Table 4. Output results of Levene's and t-test

Independent sample test									
Type of test	Levene's Test for Equality of Variances		t-test equality of arithmetic meanings						
Indicators	F	Sig.	T	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence Interval of the Difference	
								Lower	Upper
Equal variances assumed	1,15	0,29	-2,16	38	0,038	-242,26	112,44	-469,88	-14,65

*Source: Research by the author

From the table it can be seen that in the t-test the calculated "p" value (sig) is less than the risk of error α, so the zero hypothesis is rejected and we can say that there is a statistically significant difference between the arithmetic average of the populations. The limits of confidence interval for the arithmetic average of the population with 95% of the safety indicate that the average gross margin for greenhouses with two production lines may be higher than the average gross margin of greenhouses with one line max. 469.68 KM, and a minimum of 14.65 KM observed at the level of the entire population.

Conclusion

A number of benefits from vegetable consumption contribute to the growth of demand for this type of product on the market. Production in a protected area allows obtaining vegetables in those parts of the year when it can not be produced in the open area, which positively affects

their price and thus the financial result of production. In the analyzed area, production in the protected area is characterized by the cultivation of the most common one and maximum two production lines during the year.

The highest average gross margin observed on individual lines was recorded in tomatoes. Taking into account all lines in the sample, the average gross margin in a protected area, where only one production line is realized during the year, was 742.65KM, while in the protected area with two production lines it reached the amount of 984.91KM. Using the t test, it is concluded that there is a statistically significant difference between gross margins in these protected areas.

Finally, it can be concluded that by introducing an additional production line during the year, retaining existing technology at the same level, agricultural holdings achieve significantly more favorable business results.

FINANCIAL MANAGEMENT AND CONTROL, RISK MANAGEMENT AND DISCHARGING IRREGULARITIES IN THE AGRICULTURAL SECTOR IN BOSNIA AND HERZEGOVINA

Željana VRUĆINIĆ*

Edukos, Sevoi d.o.o. Banja Luka, Republic of Srpska, , Bosnia and Herzegovina

Abstract

Financial management and control are a comprehensive system of internal controls that are established and for which the managers of institutions are responsible, and by which, by managing risks, ensure that the budgetary and other resources will be used correctly, ethically, economically and efficiently in achieving the goals. Within the overall economy and after more than two decades after the war, Bosnia and Herzegovina agriculture is still burdened with numerous problems and does not show the vision of its own social development. By adopting several laws and establishing institutions, it gradually builds an agricultural framework, but it still remains with numerous problems due to undefined measures of support to domestic production. The aim of this study is to protect the means of loss, abuse and damage in accordance with laws and other regulations. This system includes all business transactions, and in particular those related to revenues, expenditures, assets and liability protection. The internal control system is carried out by the responsible persons of the institution and the employees of the institution. Experiences from the practice show that the key to establishing financial management and control is a timely and permanent incorporation of all knowledge and solutions, the activation of all employees in raising awareness for financial management and control. These findings were achieved through the method of direct implementation of projects on the market (local self-government, budget and extra budgetary users, state-owned trading companies and local self-government units) through financial management and control projects, strategic plan, asset register and risk management. Today, it is clear that 80% of the problems arise from 20% of the causes – that is why employees should be educated so that they can recognize them and act effectively on them.

Keywords: *mission, vision, goals, processes.*

Introduction

In BiH, the gross value added (GVA) of agriculture (together with forestry and fishing) varied in absolute terms (1.6-1.8 billion BAM) in the past period, but in general it is growing. Nevertheless, in relative terms the sector is declining (from 8.1% in 2006 to 6.2% in 2015), due to the faster growth of GVA of other, non-agricultural sectors. In doing so, agriculture has a higher significance for the Republic of Srpska than for the Federation of BiH and the Brčko District of BiH (Agency for Statistics of BiH). In the Federation of Bosnia and Herzegovina, the GVA of agriculture ranged between 707 (2006) and 857 million BAM (2015), and its share in the GDP of the Federation of BiH declined, and in 2015 it amounted 4.6%. In the Republic of Srpska, GVA of agriculture in 2015 (857 million BAM) is almost identical to its value in 2016 (897 million BAM), but in some years it exceeded 900 million BAM. The share of agriculture in the GDP of the Republic of Srpska is decreasing, and in 2015 it was 9.3%. In the Brčko District of BiH, the GVA of agriculture is increasing in absolute terms (in 2006, 52 million BAM, and in 2015 66 million BAM), and in relative terms, its share in GDP of the Brčko District of BiH declined from 14% in 2006 to 10% in 2015.

What is generally necessary for agricultural producers to generate an incentive, both at ministerial and local government levels, is to register with the one who grants incentive funds.

Therefore, in the case of the Republic of Srpska, it is necessary to register with the Ministry of Forestry, Agriculture and Water Management and update the registration every year, and then submit a request in accordance with the rules on incentives.The big problem in BiH is the diversity of farmers, that is, insufficient association, resulting in a bad organization. Only rarely sell their products through associations or cooperatives and jointly procure raw materials. All this reduces competitiveness in both the domestic and foreign markets.

Basic shortages in organizing the agricultural sector development of Bosnia and Herzegovina

In order to solve the lack of reliable information, statistical and administrative data systems for efficient management and support to the sector, it is necessary to upgrade all existing systems of services and support of the sector, at all levels, in accordance with the constitutional competences. The EU has developed standardized approaches, methods and processes to collect such information and systems that are needed to support it. It is necessary to strengthen information on agriculture, statistical and administrative systems in BiH in order to support the implementation of agricultural policies and their monitoring, and use the results for the assessment of the impact of the policy, and on that basis, make adjustments in certain measures to make them as efficient as possible. This measure will support the establishment of the basic elements of a harmonized agricultural information and administrative system in order to support the sector, and it refers to the development of improved registers of agricultural producers according to EU standards at Entity level and in the Brčko District of BiH, which will represent a platform for the eligibility for producers for future financial support (Strategic Plan for Rural Development of Bosnia and Herzegovina (2018-2021)).

Experiences from other countries show that investing in public goods - such as research and advisory services, market infrastructure, and natural resource management - yields much higher returns than subsidies, and in particular direct subsidies for production (the Agricultural Sector Policy Study in Bosnia Herzegovina, Study on trade and integration policies). At this point, however, 60 percent of BiH's agricultural consumption is focused on subsidizing production, while only a small portion of the already limited budget is allocated to services.

In order to eliminate irregularities in the agricultural sector, or any public sector the users of public funds establish financial management and control, which is implemented by policies, procedures, processes and activities with the task of providing reasonable assurance that these goals would be achieved through:

1) Business in accordance with regulations, internal acts and contracts;
2) The reality and integrity of financial and business reports;
3) Economical, efficient and effective use of funds;
4) Protection of assets and data (information).

The term and concept of internal financial control in the public sector (IFCP) has been elaborated by the European Commission in helping to understand and implement well-developed and effective control systems during the process of accession to the European Union. The goal of the system is to ensure that public funds (national and EU funds) are effectively managed and controlled (Krpan and Rukavina, 2013).

Legislative framework for financial management and control

As Bosnia and Herzegovina is divided into two entities, the legislative documents were issued at different times:

* Handbook for Financial Management and Control in the Institutions of Bosnia and Herzegovina (Ministry of Finance and Treasury of Bosnia and Herzegovina, 2014).
* Rulebook on Implementation of Financial Management and Control in the Public Sector in the Federation of Bosnia and Herzegovina (Official Gazette of the Federation of BiH, 2017).
* Law on Financial Management and Control in the Public Sector in the Federation of Bosnia and Herzegovina (Official Gazette of the Federation of BiH, 2018).
* Law on Internal Financial Control System in the Public Sector of the Republic of Srpska (Official Gazette of the Republic of Srpska, 2016).
*Instructions on the method of establishing and implementing a financial management and control system (Official Gazette of the Republic of Srpska, 2017).
*Decree on the contents of the report and the manner of reporting on the system of financial management and control (Official Gazette of the Republic of Srpska, 2017).
*Amendments to the Rulebook on the contents of the report and the manner of reporting on the financial management and control system.

Financial management and control are carried out in accordance with international standards of internal control (Article 6) of the Law using related elements:

1) Control environment,
2) Risk management,
3) Control activities,
4) Information and communication,
5) Monitoring and evaluation of the system.

Mission, vision and objectives of the work organization in the implementation of financial management and control

The mission as a term is the basic reason for the existence of a particular organization. The mission defines focus and purpose and is presented to all members of the organization, independent of the position and gives guidance in making key decisions. Since the mission is the main reason for the existence of the organization, and it consists of the scope of activities, values and goals need to be achieved, it can be said that a mission of a public sector organization consists of providing the best services to the public by efficient, effective and economical management of the public or budgetary funds.

Example of mission definition:
The mission of a public agricultural house-holding is the efficient and responsible management of jobs, through efficient and transparent work of the household in accordance with the interests and needs of the development of the domestic product and ensuring the conditions for the continuous economic and social development of the household.
The vision statement shows the direction and describes what the organization wants to achieve in the long-term, i.e. in the period from 15 to 20 years. The vision statement should be ambitious enough and realistic. The vision statement is a written document, and it is necessary to consider and approve it before it is published.
An example of defining a vision:
We want to be an efficient and transparent house holding that will, through the provision of quality and available products, enjoy the trust of stakeholders: citizens, subjects in social activities, business entities, and business partners.
The organization sets goals that provide general guidance on what needs to be done, and which are specific enough to directly relate to the organization.
They determine the clear direction of the movements and actions of the taxpayers in order to achieve the vision and mission by achieving each of them.
An example of defining goals:
- *increase participation in the domestic market,*
- *increase exports,*
- *become a recognizable brand,*
- *placing new products,*
- *sustainable development*
- *development of modern, efficient and transparent production,*
- *development of an entrepreneurial initiative based on the development of new technologies,*
- *spatial planning of the households and environmental protection,*
- *construction of communal and transport infrastructure,*
- *increase the quality of the product.*

Strategy

As one of the most important segments of financial management and control, the strategy should include: introducing a taxpayer, defining a mission and a vision from the Mission and Vision Statement on the vision, on the mission, the analysis of the situation - SWOT, defining general objectives, defining specific goals, ways of achieving goals, performance indicators, tracking and evaluation, risk management. In a strategic document or a strategic plan document, the first part refers to general introductory information. Here is included the description of the scope of the organization as well as the description of changes in organizational classification. The organization records data on agencies, institutions and other users within its jurisdiction. According to the above, defining missions and visions greatly assist in strategic planning. A well-established vision is the starting point for setting strategic goals. Therefore, the vision in strategic planning must include understanding of the problems and the existing situation, information on all existing data, as well as the perspectives of interest groups. Since from a good and well-defined vision, and also the mission, strategic goals for achieving the above will be created. The basic goal of strategic planning is to clearly identify the nature and character of the organization and sectors, the scope that it represents and manage its development in the future. Through the process of strategic planning, the units of local self-government (regional) define their goals, priorities and strategies, and define measures for assessing the success for achieving these goals (Krpan and Rukavina, 2015).

Analysis of the situation - SWOT ANALYSIS

The most widespread approach is the SWOT analysis, by which the organization identifies its advantages and weaknesses from the internal environment, and the opportunities and threats that come from the environment and can influence the work of the organization (Krpan and Rukavina, 2013).

Strengths	**Weaknesses**
• What are our strengths and quality? • What other people consider our advantages? • What advantages do we have compared to others?	• What are our weaknesses? • What do we miss? • What is done, and can be improved? • What should we develop better? • What should we avoid?
Opportunities	**Threats**
• Where are the good opportunities? • What are the interesting trends that you are aware of? • What extreme situations provide new development opportunities? • Good opportunities can come from changes in technologies, markets, changes in social practices, population profiles, and local changes.	What are the threats from the environment? What should you pay attention to? What do we have to consider? What extreme negative effects can adversely affect the work of the organization?

An example of SWOT analysis for agricultural holdings in the Republic of Srpska

STRENGTHS	**WEAKNESSES**
* Natural Resources * Human Resources * Geographical position * Agricultural potential * Developed water infrastructure * Manufacturing industry * Traffic connections * Favourable climate * Good resources for agriculture	* Outdated technology * Lack of skilled workforce * Unordered proprietary relationships that hinder adherence * Insufficient co-ordination of educational programs and needs in the labour market * Insufficient efficiency of local government (administration, courts) * Technical notion of infrastructure projects to bid for EU funds
OPPORTUNITIES	**THREATS**
* stimulative programs for small entrepreneurs * incentives for agricultural production * developing a favourable entrepreneurial climate * establishment of agricultural cooperatives and other interest associations * transfer of knowledge and technology * development of rural population * EU funds and financing of development programs and projects (in key development areas)	* Unfavourable business environment * Non-acceptance of project proposals at the national level * Non-inclusion in national programs * Globalization * Migration * Natural disasters * An expensive and inefficient state * Global economic crisis * Politically unstable environment

Conclusion

Effective elimination of irregularities in the agricultural sector and the achievement of development goals must begin with the creation and improvement of the necessary institutional and legal frameworks for the implementation of strategic objectives and measures, that is, respecting the legislative framework for the development of the sector as a whole. First of all, it is necessary to strengthen the institutional capacities, gradually introduce measures of agrarian policy, which have been implemented in European countries for a long time, strengthen cooperation and coordination of all interest groups and cooperation with countries in the region. It is clear that without a well-established legislative framework, processes and procedures, in practice, an effective control system that will guarantee the elimination of irregularities and progress in the development of agriculture will not be possible. Creating an information basis for the programming and monitoring of agrarian and rural production implies, on the one hand, institutional entrusting responsibility for this process to structures within certain public institutions or by contracting these services with other institutions and organizations. On the other hand, this implies the establishment of an adequate information system in agriculture, the basis of which would be the agricultural census, which implies further improvement and maintenance in accordance with the constitutional competences. In order to achieve these goals, it is necessary to strengthen the institutional capacities, and to improve capacities for the implementation of official controls and audit of official controls. It is of great importance to introduce consulting services that will contribute to business planning, management, productivity improvement, market linkages, efficiency, risk reduction, creation, planning and project management. In the process of planning, if we do not think about potential events that could create difficulties in achieving goals and do not consider possible measures to mitigate them, in the future, these events will be a problem for us and we will often be asked for a quick reaction, which is most often focused on the consequences. Managing the risks we are trying to solve the cause of the possible problem. To spot key risks and take appropriate control activities in a timely manner is to avoid those financial effects that will necessarily arise in order to solve problems. Therefore, when setting up the goals, business organization, making business decisions, etc. the starting point is to look at potential events that can create difficulties in achievement of goals.

THE WINE TOURISM IN BULGARIA: AN OVERVIEW AND KEY CHALLANGES

Zina SORENSEN, Albena STOYANOVA*

Bulgaria Wine Tours – Plovdiv, Bulgaria
Earth, Resources and Traditions – Plovdiv, Bulgaria
*Corresponding author: albena.stoyanova@hotmail.com

Abstract

Rural wine tourism is a way to diversify the mass-tourism product and bring more prosperity to disadvantaged rural areas. It is a very recent concept in Bulgaria but it is foreseen to grow in the future. However, there is a lack of research-based publications on wine tourism in the country in general and its potential role in sustainable rural development. The aim of this research is to explore the state of wine tourism in Bulgaria and to present the key challenges the country is facing. A threefold approach was used to collect information for this study: (I) literature review; (II) semi-structured interviews; and (III) winery visits (observation). Eleven wineries were visited and fourteen interviews with stakeholders were conducted. Relevant stakeholders to rural wine tourism development were identified as wineries, NGOs and associations, government and tourism businesses. The main challenges facing the development of the wine tourism industry are a lack of regional competitiveness, public awareness and recognition, a lack of regional and local infrastructure (roads and signage), service delivery skills, capacity and proactive attitude in wineries, a lack of tourism strategies (national, regional and local level), planning processes and governance structure, a lack of service quality assurance mechanisms and a lack of available market research. There is a strong potential for developing rural wine tourism in Bulgaria. The presence of wineries, cultural heritage attractions, nature, food and accommodation options, as well as the defined wine regions have all laid the foundation for it.

Keywords: *Agritourism***,** *Bulgaria Rural Tourism, Rural development, Tourism development Wine tourism.*

Introduction

Wine tourism is often regarded as a subset of food and wine tourism, also called culinary or gastronomy tourism. Food and wine tourism is a niche tourism product, also called special interest tourism type. In the 1970s, food and wine tourism started to develop in a more organized manner. Wine tourism was defined by Hall & Macionis (1998) as "*visitation to vineyards, wineries, wine festivals and wine shows, for which grape wine tasting and/or experiencing the attributes of a grape wine region are the prime motivating factors for visitors"*. Another definition is "*experiential tourism occurring within wine regions provides unique experiences which include wine, gastronomy, culture, the arts, education and travel*" (Dowling 1998; Saayman & van der Merwe, 2014). It must be recognized that wine tourism also involves destination planning and marketing strategy (Getz, Dowling, Carlsen & Anderson, 1999) this recognition manifests itself in the Western Ausralian Wine Strategy (2000), which defines wine tourism as*:"…travel for the purpose of experiencing wineries and wine regions and their links to lifestyle. Wine tourism encompasses both service provision and destination marketing."* According to Okech (2016), wine tourism is considered as a form of agritourism and by being seen as a distinct niche market that is gaining popularity in wine producing regions. This type of tourism demonstrates a symbiosis between tourism and agriculture that provides potential for their mutual benefit (Carmichael, 2005). The wine industry, mainly a primary industry, involves the cultivation of grapes and other fruits as raw material for wines and liquors, the making of the wine or liquor and the actual selling of the beverage products. On the other hand, the tourism industry is a tertiary industry oriented

toward providing services related to travel for recreation, leisure, sensory experience - taste, smell and sight which in combination with the destination can act as a "pull factor" (Kivela, 2006). Besides, wine tourism requires the involvement of wine producers (the wine industry), tourism agencies (the destination) and consumers. Wine tourism is both a concept and a strategy that can develop the tourism appeal of a destination. It has the potential to be a strategy that allows for better marketing opportunities for wineries, for wine regions and ultimately, for the country. It allows the wineries and other actors involved to reap financial benefits through leveraging tourism opportunities. Integrated rural development in disadvantaged rural regions is a high priority for Bulgaria. Wine production can help rural areas redesign their economies for both wine making and the hospitality associated with fine dining (Getz &Brown, 2006). In the past, rural communities played a significant role in the economic development of Bulgaria. Agriculture was a significant economic sector. Yet, in the last 20 years, there has been a shift to a service-based economy. In 2010, the gross value added to the national economy was distributed by 31.4% for the industrial sector, 5.4 % for the agrarian sector (agriculture, forestry, hunting and fisheries) and 63.2% for the services sector (Ministry of Agriculture and Food, 2011). Rural areas have suffered with declining population mainly due to urbanization and younger generations seeking better opportunities abroad. The migration of the population, abandonment of the agricultural cooperative system and lack of investment has resulted in many abandoned and dilapidated farm and residential buildings as well as an outdated and insufficient rural infrastructure. The objective of this paper is to explore the wine tourism development in Bulgaria and to describe the challenges for wine tourism implementation.

Materials and Methods

This paper is based on qualitative research method carried out in the summer of 2015 in Bulgaria. A threefold approach was used to collect information - *literature review* - articles on tourism related subject, books by leading experts in the filed of tourism planning and policy, wine and food tourism; sustainable tourism; government online portals were used such as the Ministry of Agriculture and Food (MAF) and the Ministry of Energy and Economy (MEE). Online sources relating to the Bulgarian wine sector were used such as the Executive Agency on Vine and Wine and the National Vine and Wine Chamber. *Winery visits* (*observation)* were made to eleven wineries in the southern and southeastern wine regions of Bulgaria. Their size can be classified according to wine production, winery capacity or size of vineyards namely small wineries; medium-sized wineries; and large wineries. A typical visit would involve a guided tour of the wine making facilities and a wine tasting session during which the semi-structured interview would take place. The visits were an opportunity to understand the winery visitor's experience. Fourteen *semi-structured interviews* were conducted with tour operators (three), wineries (eight) and with NGOs / private trade associations (three). Interviews with winery representatives were conducted onsite at the winery in connection with a visit. Interviews with tour operators took place at their respective offices in Sofia and Plovdiv. Interviews with NGOs and private trade organizations took place either in their respective offices or in an informal setting in a café. A participant information sheet introducing the research topic and explaining the purpose of the research was made available to interviewees. Confidentiality or anonymity was explicitly not guaranteed. The reception of the information sheet is considered informed consent of the interviewee to participate in the research. The objective of this paper is to explore wine tourism development in Bulgaria as a country with long tradition in wine making. Besides, the challenges for implemention this type of tourism business are also analysed.

Results and Discussions

Winery visitors, be they foreign or domestic, can be segmented into different categories. If asked *who visits Bulgarian wineries for tourism purposes*, the answer is: I) tour-operator organized groups; II) local residents and their friends/families; III) nearby hotel & restaurant guests; IV) wine lovers and connoisseurs; V) wine merchants, buyers or distributors; VI) industry colleagues and VII) individual walk-ins. Additionally, it is not uncommon that wineries host events on a request basis ranging from industry events, corporate events, art events, harvest related ceremonies and staff parties. An interest was expressed in the potential of the corporate segment that not only utilizes wineries as a venue to entertain clients or for internal events but is also keen to purchase large quantities of wine. According to interviewed tour operators, there is low to medium demand for visitation to wineries, wine tastings and wine tours. An increase in interest in tourism rooted in culture, heritage and food has been noticed in recent years both in Bulgaria. The country faces the challenge that it is still an unknown destination even for cultural heritage tourism and most certainly for special interest tourism such as wine tourism. The wineries interviewed reported various collaborative steps taken to seek wine tourism business such as entering into formal agreements with tour operators to bring groups in and informally working with local hotels and restaurants to promote wine tours to existing guests. While some wineries had received some regular business through their collaboration with tour operators, others expressed that very few booking requests were coming from tour operators. Wineries often attributed the lack of interest from tour operators to the remote location of the winery under the assumption that there is no interest to visit a remote winery especially if the region has nothing additional to offer such as cultural heritage sites, tourist attractions, activities, restaurants and hotels.

A lot of emphasis was placed on the location of the winery. The conclusion drawn by many wineries was that the success of wine tourism depended on the proximity of the winery to major tourist attractions and/or a city inferring that the more remote and the more isolated the winery is, the less attractive it is to visit. The appeal of the region was considered a major factor in the success of wine tourism and other forms of rural activities as well as the variety of choices available in the region. There was a wide agreement that good quality wine is a prerequisite for a thriving wine tourism industry. Most interviewed wineries were willing and to a certain extent are ready to fully embrace wine tourism, while some wineries choose to focus on their core competency that is wine making. Unwillingness to engage in wine tourism was attributed to management decisions to focus on producing quality wines and gaining global recognition age and nature. Genuine desire to succeed in wine tourism was more evident among newer, boutique wineries typically opened post year 2007. Boutique wineries were more committed to wine tourism development; tourism was considered an integral part of their business plan even prior to construction of the winery resulting in wineries that were built in a more visitor-friendly manner. In terms of being ready to welcome tourists into the winery and to provide other services, it is clear that some wineries are more ready than others. A fundamental prerequisite is space to accommodate tourists especially for wine tastings that often require a dedicated wine tasting room. Other prerequisites are clean and well-maintained equipment, fixtures and furniture in areas presented to the public and available trained personnel to take the lead on tours and wine tastings. While some wineries have a way to go before getting fundamental prerequisites in place, others are ready to welcome guests. It is important to acknowledge that wineries have historically been focused mainly on the production and selling of wine – not on entertaining visitors. The wine industry is currently heavily focused on producing high quality wines, regaining consumer trust, venturing into new export markets and building the reputation of Bulgarian wines. Wineries have not historically entertained paying customers visiting for leisure purposes. Wine tourism entails a change in the existing paradigm of the wine industry. Two of the wineries visited have taken a

serious interest in tourism and invested in additional facilities to facilitate more tourism. These wineries have added a hotel, spa and restaurant to their facilities essentially creating a complex like product with accommodation, dining facilities, swimming pool, wine retail, and additional activities (e.g. horseback riding) as well as offering regular wine tours. Other wineries are currently planning to or have already started to add additional facilities to their wineries such as hotels and restaurants. Several wineries expressed the intent to host visitors in a serious manner but only after all visitor facilities were completed while others ascertained that given ample lead time for instance for incoming groups, it was not a problem to shape up the winery and acquire required services such as tour guides, refreshments, music or folklore entertainment through local partnerships.

Key wine tourism challenges

Wine tourism in Bulgaria faces issues that need to be addressed. There are challenges that are both demand-side and supply-side related as well as internal and external to the winery. 1. *Lack of regional competitivenss*. Bulgaria has not yet mastered the task of effectively organizing and promoting the wine regions. It was frequently mentioned that the wineries within the region need to be better at cooperating instead of competing against each other over visitors and attention. 2. *Awareness and recognition*. A common sentiment among wineries was that Bulgaria has to fully master production of high quality wines first and ensure that the quality is acknowledged globally. While there was a wide agreement that good quality wine is a prerequisite for a thriving wine tourism industry, a contradicting point was raised that some wineries are better at making quality wines while others are better in tourism. 3. *Regional and local infrastructure: roads and signage*. The roads are highly trafficked, strategic ones are poorly maintained to the point where they pose a risk to drives and deter potential visitors. Directional road signs are also either not present at all or poorly placed. Another issue is lack of English signage making it difficult to get around as a tourist. Winery signs were also not always strategically placed. *4. Service skills, capacity and education.* Due to the lack of experience with wine tourism, there is currently a lack of service culture in wineries. Employees lack training in customer service and hospitality. Wine tours are often delegated to the oenologist on duty who is required to take time away from daily duties to give wine tours. 5. *Governance, strategies and planning.* A common concern was the lack of national and regional strategies on not only the development of wine tourism but also other rural tourism forms and how they can fit in with broader regional goals. There has not been much support from any tiers of government apart from municipalities occasionally using wineries for entertainment purposes. 6. *Service quality assurance.* Bulgaria has a reputation for varying quality not only in the wines but also in the tourism sector partially due to very low prices and sometimes wildly fluctuating prices in tourism. Another aspect is that wine tourism is so new to the country that there is still a need for the concept to mature and the quality of the tourism product to be realized. 7. *Market research and marketing efforts***.** There is a tendency for local entrepreneurs and potential business owners to act without understanding the characteristics of the market. Short-term focus impedes thinking about long-term sustainability of businesses. Furthermore, tourist expectations are not understood by people who have limited experience in the tourism industry such as wineries. There is not one entity that has taken on the responsibility to market wine tourism in one or more regions. Not the State Agency for Tourism nor the National Vine and Wine Chamber.

Conclusion

There has been no study on wine tourism in Bulgaria and this one lays the foundation for future research in this field. The results reveal that wine tourism is in very early stage of development. Efforts have been made by several actors in recent years to develop wine

tourism albeit in a non-coordinated or cooperative way. The findings of the research describe the category of tourists visiting the wineries as well as willingness of wineries to involive into tourism business. We found out that boutique wineries are more open to welcome tourists on their premises not only for a wine tour and tasting but to host events on a request, art workshops or harvest pinics than the large-scale wineries. Furthermore, special attention is paid to the key challenges that the wine tourism industry in Bulgaria is facing. Such an example is the lack of global and national awareness that Bulgaria in fact does have a budding wine tourism industry as well as interesting wineries and wine regions contributes to sluggish demand. Tourism is a service sector where training and professional approach to the guest is very important for the satisfaction of the tourist product offered. The study reveal the need for education and training to the staff employed in the wineries. Moreover, quality assurance mechanism for wine tourism should be designed in order to sell tourism product effectively. The state has not been proactive in supporting the development of wine tourism. National tourism policy does not reflect a commitment to rural tourism or gastronomic tourism. There is hardly any cooperation between the MAF, MEE (State Agency for Tourism) and Ministry of Rural Development that all have an interest in both alternative tourism development and rural development. It is clear that wine tourism alone cannot ensure socio-economic development and revive rural areas. However, in cooperation with other stakeholders, wine tourism can act as a catalyst to reach goals in rural development aspirations and national tourism product aspirations.

Abstract

Up-to-date challenges to agriculture and sustainability have led to a practical need to minimize the risks of farming activities. Emerging uncertainties, risks, and crises related to the natural environment, technology, economic and political environment as well as globalization are new challenges addressed to risk management in the agrarian sector. Important for effective risk management is its understanding by all actors in the chain of the types of risks. Some of the risks faced by agriculture are critical and require a constant search for solutions for its management. The main aim of the study is to analyze the application of risk management policy in Bulgaria. The hypothesis is that policies related to agrarian risk management will reduce the negative consequences of its occurrence and impact. The paper is divided into several parts. The first part includes a theoretical background of sources and types of risk in agriculture. The second part relates to review and assessment of the legislative framework and the existing instruments for risk management in agriculture. The analytical part is based on a survey of risk management policy in Bulgaria. The collected empirical material is a part of scientific project "Integrated risk management approach in the agricultural sector". According to the results, general conclusions and policy recommendations are made.

Keywords: *agricultural risk, risk policy management, Bulgarian agriculture.*

Introduction

Agricultural risk may vary from independent (e.g. localized hail or farmer disease) to highly correlate (e.g. market price or widespread drought) losses. Risk management in agriculture is particularly challenging, as many risks are strongly associated, which results in simultaneous damage to whole communities. The risk is the likelihood of loss or non-receipt the income that is intended to be realized through the use of capital investments in the farm (Nedelcheva, 2012). Some authors (Fleisher, 1990) expose the connection between the access to different forms of insurance and subsidies paid by the government, and as a side effect reducing the risk of agricultural activities. The author considers that by using the measurement of agriculture policy farmers would apply risk friendly practices as insurances. Very often the studies of the literature directed to risk management states that the mechanism as subsidies in crop insurance has resulted in more plantings and extensive margin (Clark, Fleming, Skees, 2003). The authors' findings state that by using risk reduction mechanisms, the farmers would be more willing to implement activities with higher risk, as well to reflect in changing technologies, type of plants, even operational areas by using different land. These practices can cause as well negative environmental impact on the environment, because it is possible higher intensity or use more prepares to reduce the risk factors in plant sector.

Risk analysis consists of its identification and evaluation. Risk identification classifies several different risk categories that agricultural holdings may encounter in production, financial, personal, price, institutional, natural, political, and others. Risk assessment can be done through a variety of methods, from more elementary subjective methods such as completing a map of risk assessment indicators to more complex methods involving different quantitative

calculations (Boehlje, Lins, 1998). Risk assessment can be done in two ways: potential and probability. The risk potential is the magnitude of the negative consequences for the holding that would occur as a result of an event, and the likelihood is the chance of a potential event occurring (Detre, Briggeman, Boehlje & Gray, 2006).
Risk management analysis and connected policy should be proposed at levels as individual component (raw material and material supply, farm, processing, transportation, distribution, region, sub-sector, food chain). As well the policy should be directed at macro level (Bashev, 2005, 2012). In the theory can be traced out the statement that farmers do not have the qualification and statistical skills to calculate adequately the risk of their activities (Nedelcheva, 2012).

Material and methods

In the paper are used several methodological approaches. First part of the article is based on research of theoretical review and is used system and historical approach of analyzing the authors' view dedicated to risk management policy. The second part includes official data of applied policies related to agrarian risk management in Bulgaria. The risks were classified in two categories: 1) plant and 2) livestock sectors. According to collected literature framework and Bulgarian policy was set up an extended structure interviews in a questionnaire aimed to evaluate the risk management policy in Bulgarian agriculture. The sample includes farmers from different subsector and the aim was to obtain a sample close to product structure distribution of Bulgarian agricultural sector. The survey was held in 2018, under scientific research project NID, NI 16/2018, Integrated risk management approach in the agricultural sector.
Respondents have described the occurred risk event in last 5 years and the impact on their activity and evaluate the most common risk factors of their activities. The used scale is an ordinal Likert scale of 1 to 5, where 1 is low influence/impact to 5 strong influence/impact. Last part of the questionnaire were open questions where interviewees shared the good practices which they apply in their business activities connected to reduction of risk impact.

Results and Discussion

Analysis and procedures of policies related to agrarian risk management in Bulgaria

Ministry of Agriculture and Food is responsible for risk management policy in Bulgaria. A special structure has been set up at the Ministry of Agriculture and Food -the Food Chain Risk Assessment Center. Their role is to assess the most significant risks in agriculture and provide mechanisms to prevent their negative impact on the sector. On the basis of the assessment carried out by the assessment center, an annual plan is prepared for the prevention of risks in agriculture with measures to influence risk management. According to their classifications, some of the risks by sectors are shown in table 1.

Table 1. Classification of agricultural risks in Bulgaria

Crop	**Livestock**	**Forestry**
Risks:	Risks:	Risks:
▪ Hail ▪ Natural disasters ▪ Fires of the roots ▪ Thunderstorms ▪ Frost ▪ Storms ▪ Earthquakes ▪ Late spring leaning	▪ Fires ▪ Natural disasters ▪ Accidents ▪ Contagious diseases ▪ Non-infectious diseases ▪ Forced destruction ▪ Slaughter by necessity ▪ Earthquakes	▪ Fires ▪ Floods ▪ Landslides ▪ Crushed forest ▪ roads ▪ Broken / torn dam walls ▪ Hail

▪ Early autumn trimming ▪ Frost and pull ▪ of crops (cereals) ▪ Diseases and diseases invasions (pests)	▪ Parasitic diseases	▪ Storms ▪ Thunderstorms ▪ Frost ▪ Oscillation ▪ Snowmobiles, avalanches ▪ Earthquakes

*Source: MAF, 2018

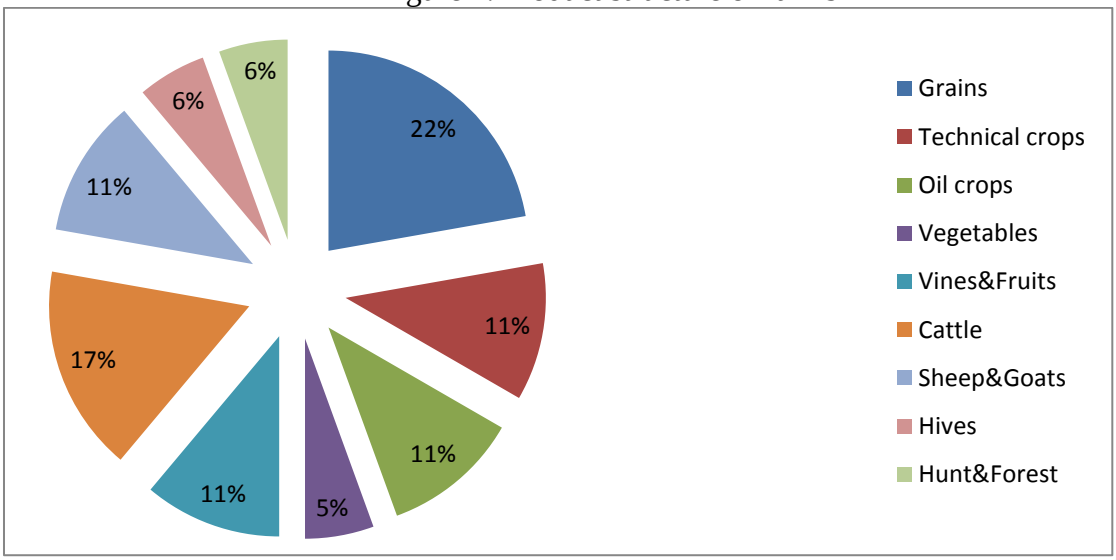
Once the risks have been identified and their likelihood and impact assessed, an appropriate response should be considered. Taking measures and actions to respond to identified and assessed risks is a very important stage in risk management. The government structure as well prepares different types of risk response (Ministry of Agriculture and Food, 2018). The following response options are possible: limitation, transfer, tolerance and ending of risk. When selecting appropriate actions/responses, account is taken of the requirement that their costs do not exceed the expected benefits. This choice also depends on the assessment of the level of residual risks the organization can accept without taking further action. Any major risk management activity needs to be documented to ensure traceability of the entire process. The documentation shall include an appropriate description of the identified risks, the appropriate response/action chosen and the personnel responsible for carrying out these actions within specified deadlines.

A risk-register is used to document the results. Ensuring the effectiveness of the risk management process requires regular and continuous systematic monitoring / monitoring at each stage and reporting periodically the identified risks and action is taken to reduce them. To carry out systematic monitoring, the risk-register shall be reviewed at least once a year.

Survey results

The surveyed farm owners have a different product structure. The distribution is shown in Figure 1. The sample includes average representatives (most common) of each sub agrarian sector presented in Bulgaria.

Figure 1. Product structure of farms



*Source: Author's elaboration based on the questionnaire survey results.

Of the sample, 11% of the farmers did not experience a risky event, financial risk accrues in 44 % of the farmers, risk of lack of personnel in crucial period- 50%, loses of actives- 40%, financial risk- 44%, other risks (22%).
External risks occurred in the past five years in the surveyed farms of plant sub sectors are presented in table 2, and livestock breeding in table 3. From table 2 and 3 can be made conclusion that the biggest share of the participants in the survey had experience risk events, which affected their activities.

Table 2. Occurred risk events last 5 years in crop sectors in Bulgaria

Hail	50%
Natural disasters	11%
Fires of the roots	20%
Thunderstorms	0%
Frost	6%
Storms	0%
Earthquakes	0%
Late spring leaning	6%
Early autumn trimming	11%
Frost and pull of crops (cereals)	44%
Diseases and diseases invasions (pests)	26%

*Source: Author's elaboration based on the questionnaire survey results.

Table 3. Occurred risk events last 5 years in livestock sectors in Bulgaria

Fires	0%
Natural disasters	6%
Accidents	11%
Contagious diseases	16%
Non-infectious diseases	40%
Forced destruction	22%
Slaughter by necessity	22%
Earthquakes	0%
Parasitic diseases	0%

*Source: Author's elaboration based on the questionnaire survey results.

In plant sectors hail is the biggest risk which has occurred, followed by frost and pull of crops. In livestock sectors non-infectious diseases occurred to 22% of the studied farms.
Of these, 67% state that their activity is risky. After the main risks were identified, the respondents assessed the weight of the factors from low risk to high risk. The results are presented in Table 4.

Table 4. Risk factors in agriculture. Self-evaluation

Reason	**Score 5 high risk to 1 low risk**
Perpetual of production	5,00
Manipulation by the middleman, lack of a mechanism of the price market.	5,00
High quality requirements for milk, /crop production diseases high mortality, animals stealing and others.	4,75
Unstable prices of fodder, veterinary services, the reseller.	4,50
Production volumes set out in the business plan and strong dependence on nature and markets.	4,50
Uncompetitive compared with colleagues from other European countries due to different subsidies received.	4,25
Often a too-close farm that self-sustains the entire cycle with its own production (fodder-stock-breeding). When there is a risk in the chain, it affects the entire farm.	4,20
Lack of qualified personnel.	4,00
Uncertainty in agriculture prevents long-term goals from being set up.	3,50

*Source: Author's elaboration based on the questionnaire survey results.

The maximum score is given to the perpetual of the production and problematic markets operating in the country. On the second place as a reason of high risk activity are pointed high quality requirement of the production. As well farmers have the opinion that high dependence of the nature make their activities with high risk. With relatively low estimation are inabilities of long term planning due to environment, lack of personnel and too close farm that self-sustains the entire cycle with its own production.

Part of the questions was dedicated to reveal the opinion of the farmer opinions connected with their own good practices in risk management. The main practices can be summarized as follows:

- Using innovative technologies which can reduce the risk from the activity;
- Closing the chain of production cycle- produce-end market;
- Farm contracting which can be used for a credit line;
- Contracts with producers of inputs and outputs;
- Diversification of the production;
- Insurances;
- Implementing better and sustainable breeds/seeds;
- Using a robotic technic;
- etc.

Some of the questions which respondents gave opinion are related to evaluation of current Bulgarian risk policy in agricultural sector. All of the respondents share the opinion that the policy is insufficient in the area of the risk management. Of them 75% are pointing that the biggest issue is connected with very complicated applying procedure , 50% of them do not know the measures which they can use to reduce the impact of risk events.

44% of the farmers applied for risk management measure to CWRS, all of them received compensatory payment. Farmers received up to 80% of the expenditures which they did, but their statement that this is not sufficient payment, as well as payment were delaying. Another conclusion from the interviews is the lack of coverage of some very specific risks, which are facing some of the sectors, as bee hives.

The proposed policy recommendation can be summarized as follows:

- Part of payment of SAPS to be connected with risk events by change of the Ordinance of SAPS;
- According to the market risk, the government to implement mechanism which will keep minimum price of the products as a milk;
- Each agricultural sector to have specific strategy;
- Help to farmers to find a proper market with decent condition for selling the animals;
- The payments for small farms to differ from these of big farms; The effect of risk to be calculated as a share of the farm;
- Training courses for farmers on the following topics: -risk management according to agricultural sector;
- possible risk policy measurements in Bulgaria;
- Etc.

Conclusions

The agrarian sector is important, dynamic and its nature can be defined as a high-risk potential event to occur. Farmers involved in the survey identify the risk of their activity and outline several different risk categories, such as production, financial, personal, price, institutional, natural, political, etc.

In Bulgaria is existing risk policy management but at this stage the farmers do not know for possible measure and mechanism. The results of the survey confirm the literature review finding that risk management policy should be proposed at levels as individual component (raw material and material supply, farm, processing, transportation, distribution, region, sub-sector, food chain).

Agriculture is evaluated as sector with a high level of risk and policy-makers should adjust the current policy due to minimize the effect of occurring and helping the agricultural sector to become sustainable one.

Acknowledgment

SUSTAINABILITY OF UNDP PROJECTS IN EGYPT: A CASE STUDY IN SIWA OASIS (SIWA ENVIRONMENTAL AMELIORATION PROJECT)

Mazen BARAKAT

Department of Rural Sociology, Faculty of Agriculture, Ain-shams University, Cairo, Egypt
*Corresponding author: mazen.m.barakat@gmail.com

Abstract

The main objective of this research paper was to evaluate the effect of one of the international projects in Egypt, in order to know the benefit of such projects and to discover the reasons of their success or failure from different point of views. Siwa Environmental Amelioration Project (SEAP) was chosen as one of the famous projects in Siwa Oasis. It worked there for two phases for 6 years in order to set sustainable development activities in the oasis through loan activities in the agricultural field, in order to raise the quality of life for the oasis people and set a perfect example for the capabilities and the good effect that such projects can do. Ven diagram and pairwise ranking matrix were used to identify the linkage between different actors involved in the project and the problems importance according to their point of view , The results showed that faced the project a lot of local obstacles faced the project and didn't help SEAP in achieving its goals. Besides, the other local NGO partner (SCDEC) was not qualified enough to take over the projects after SEAP left. Even with the success of organic agriculture production as an innovation, the problem of marketing already killed the idea, and small farmers couldn't cope with it, and it ended up by cancelling the activity.

Keywords: *sustainable agriculture, innovation.*

Introduction

According to the Egyptian definition, Siwa Oasis is considered to be the city and district of Siwa. It located in the western desert, 800 km from Cairo the capital, and 300 km from Matrouh city, the capital of the Governorate, which it is administratively, follows. Siwa was isolated for a very long time since there was no direct road to drive there.

Through all this period of time(800 years according to different studies) Siwan people were managing their land and ground water sources within ten tribes through their own special social contract and a special tribes council that arrange most of their life issues socially and economically.

Although Siwa is located in Matrouh governorate, but it would had taken 18 hours to reach it from Matrouh city and almost one day from Cairo.

In the early 80s a road was structured by the petroleum companies in order to connect Siwa Oasis with Matrouh city governorate. By that time the road was the innovation that connected Siwa to the world and helped in delivering many medical and technical services. Since that time tourism started to be a basic source of income for Siwan community, this road even gave the chance for Siwan youth to join university education.

Study problem

No doubt that many international organizations were interested to study and help to develop this isolated community in order to improve those people's life and help in developing their sustainable resources management, UNDP (United Nation Development Program) and EIECP (Egyptian Italian Environmental Cooperation Program) were the first international organizations that started projects aiming to develop the Siwan community through improving the quality of life, that's why the current study aimed to evaluate one of the famous projects

out there SEAP and its impact and sustainability with its positive or negative impact on Siwan community.

Study goals: Evaluation of SEAP in achieving its goals and Evaluating the benefits of such projects for the Siwan community

Materials and methods

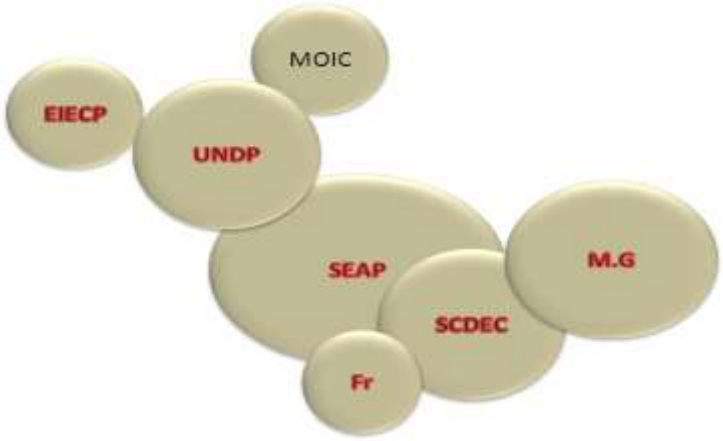
A long field visit was prepared from 1-10/4 /2016
Personal interviews were done to the key persons and informants. Group discussion technique took place with the farmers' organic agricultural group (16 people), as well as secondary SEAP' data.
Some of SEAGA (Socio Economic and Gender Analysis) tools were used according to the field study and community special traditions:
Ven diagram and Pair-wise analysis
- A ven diagram was prepared with SEAP management unit in order to know the linkage between different actors involved in the project. The importance of each actor is represented by a circle sized according to its importance, while the level of overlapping between them shows the degree of contact.
-A pair wise analysis was done three times. One with each of SEAP team, SCDEC management unit, and thirdly with the farmers as a way to identify the main problems faced and how each sees SEAP success or failure from their different point of view.

Results and discussion

UNDP with the cooperation of EIECP started in 1998 applying SEAP first phase for three years. This project aimed at developing Siwan community through giving micro credits to each Sheikh of a tribe who was responsible to recycle the loans inside his own tribe among the farmers, but by the end of the project a big dilemma started to arise since most of the loans were not given back.
SEAP project discussed with the tribes the idea of establishing an association responsible for recycling those loans, as a way to solve the problem of not paying back the loans.
The association was established in 2001 by 31 members with a management council of 13 members representing the 10 tribes (one member from each tribe) and three villages (one member from each village).The council management members' changes every six years.
In 2004 the second phase of SEAP was agreed with different perspectives between EIECP and MOIC (Ministry of international cooperation) under the supervision of UNDP
The project had three main goals

1. Turning Siwa into an international natural park.
2. Achieving sustainable agriculture development through
    a. Achieving organic agriculture system
    b. Improving local animal production
3. Using SDEC organization as a local partner to take over the activities after they will leave.

The following ven diagram in (fig 1) was used to show the linkage between different actors in SEAP, the area of the circles shows the degree of importance while the level of over lapping shows the degree of contact.



(fig 1) Ven diagram showing the linkage&
The degree of contact between actors in SEAP.

Key:
MOIC: Ministry of International Cooperation
EIECP: Egyptian Italian Environmental Cooperation Program
UNDP: United Nation Development Program
SEAP: Siwa Environmental Amelioration Project
SCDEC: Siwa Community Development and Environment Conservation
M.G : Matrouh governorate
Fr: Farmers

Meeting and group discussion results:

1. The international natural park was not applied because suddenly and with no reason the governor of Matrouh decided to be an obstacle in front of SEAP goals, he negotiated for more than one year the possibility of cutting part of the project fund for achieving a medical natural ecology which was impossible because it was not mentioned in the agreement signed before.
   That's illustrating why UNDP stopped negotiation and transferred the budget of that part to another place, leaving SEAP only with a small budget for the agriculture issues.
2. According to the agreement signed in 2003, SEAP was obliged to use consultants only from national research centers, SEAP Management suffered a lot because they were unqualified consultants and miss leaded them.
3. The project was left with a small fund to work on the second and third objectives only, according to the socio economic studies done by the specialist, SEAP management decided to start organic agriculture production by establishing a demonstration organic farm, 16 Fadden given to 16 youth fresh graduate Siwan, they were chosen carefully according to special application and within the tribes applied by SCDEC and supervised by SEAP.
   Consultants taught them about organic agriculture steps and compost preparations, drip irrigation system was installed and all infrastructures were settled dawn by SEAP and given to farmers as a loan should be paid back to SCDEC to recycle it and transfer the new innovation to other farmers
   The final highly coast product could not be sold in local markets or even in organic markets whether in Alexandria or Cairo due to the large distance and the small production for the16 feddan

Unfortunately farms removed the drip irrigation system and went back to surface irrigation system and now they are cultivating natural products for local markets and loans were never paid back.

4. The animal production specialist after two weeks of studying the Siwan conditions delivered special cows to the association in order to deliver to small farmers as a loan but the cows died directly after arriving due to high temperature and ticks. The contract with the research center for delivering the animals was canceled, SEAP management decide to build an animal demonstration farm for goats and sheep to produce animals given as loans for small farmers and women and to be managed by the association even after SEAP will leave.
   After the project was finished the association refused to take over the demonstration farm and sadly it was closed and loans were never paid back
5. Pairwise ranking matrix was used to show the most important problems

Matrix (fig 2) represent SEAP management point of view and was prepared through personal interviews.

Pairwise ranking matrix according to SEAP management		
Problem	Time preferred	rank
Matrouh governer	4	1
Inexperience specialists	3	2
Unqualified association members	2	3
Cutting fund	1	4
Farmers adopting new innovation	0	5

It was clear from SEAP management that Matrouh governor was the strongest obstacle against achieving the project goals, and on the other hand the project suffered to use certain specialists from certain place and didn't had the flexibility to choose.

Matrix (fig 3) represent SCDEC management point of view and was prepared through personal interviews

Pairwise ranking matrix according to SCDEC management		
Problems	Times prefered	ranking
Goals of SEAP were not clear	4	1
Shortage of trained people	3	2
Shortage of funding	2	3
Farmers connection	1	4
Tribes council	0	5

SCDEC is local NGO created in 2001 with the help of SEAP first phase, the association is considered to be the formal way of the tribes' council to be presented and take over responsibilities to manage the Siwan resources and to support supervise the projects applied in siwa since that the agreement of the association management council mean the agreement of the tribes

SCDEC under the tribes control failed to take over and manage the sustainable agriculture projects, we have to mention that SCDEC reputation among other projects started to fail dawn since that a lot of projects now are not interested in SCDEC to be their local NGO partner, and of course there is no other NGO in Siwa

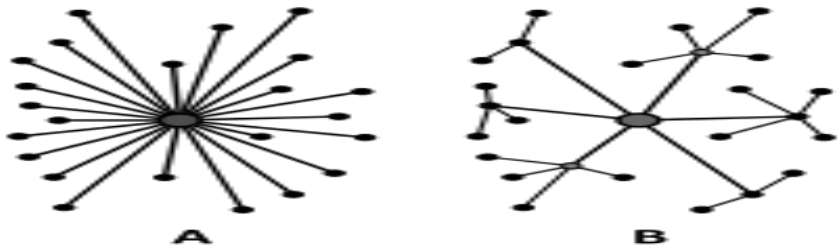
Ranking matrix (fig 4) represents the farmers' point of view

Pairwise ranking matrix according to farmers point of view		
Problems	Times prefered	ranking
Marketing problems	4	1
High costs of infra structure	3	2
Bad comunication with SCDEC	2	3
Organic certification problems	1	4
Water problems	0	5

It was clear from the group discussions with the farmers group that they faced a lot of problems in marketing especially with the high infrastructure cost which should be given back to SCDEC as a loan in order to recycle the experience and transfer the innovation to other farmers.
Since the final products was highly costly with no suitable market and no good price, they failed to continue after SEAP ended and turned to traditional agriculture products, even when they tried to build another association for organic farmers in siwa nobody supported them.

Conclusion

1. SEAP failed to achieve sustainable agriculture development in Siwa due to Matrouh governor and miss leading specialists' recommendations.
2. SCDEC as an only association in the Oasis failed to take over and manage the assets and activities left by SEAP and shut them all down.
3. The farmers couldn't cope with the organic agriculture process with no support within from tribes or Association.
4. Decentralization is the process of redistributing or dispersing functions, powers, people or things away from a central location or authority(free decionory.com, 2013), I was clear that there is a huge problem in the management system that allowed the governor of Matrouh to be an obstacle. On the other hand decentralization should be the system that international organizations apply when they are offering or designing a plan or projects to help the undeveloped countries.



(fig 5): Graphical comparison of centralized and decentralized system.

The word "centralization" came into use in France in 1794 as the post-French Revolution French Directory leadership created a new government structure. The word "decentralization" came into usage in the 1820s (Vivien A. Schmidt,2007)

Leopold Kohr, author of the 1957 book The Breakdown of Nations—known for its statement "Whenever something is wrong, something is too big"—was a major influence on E.F. Schumacher, author of the
1973 bestseller Small is Beautiful:Economics As If People Mattered(Dr. Leopold Kohr,1994).

According to a 1999 united nation development program report:

"A large number of developing and transitional countries have embarked on some form of decentralization programs. This trend is coupled with a growing interest in the role of civil society and the private sector as partners to governments in seeking new ways of service delivery...Decentralization of governance and the strengthening of local governing capacity is in part also a function of broader societal trends. These include, for example, the growing distrust of government generally, the spectacular demise of some of the most centralized regimes in the world (especially the Soviet Union) and the emerging separatist demands that seem to routinely pop up in one or another part of the world. The movement toward local accountability and greater control over one's destiny is, however, not solely the result of the negative attitude towards central government. Rather, these developments, as we have already noted, are principally being driven by a strong desire for greater participation of citizens and private sector organizations in governance ("Decentralization: A Sampling of Definitions", 1999,)

So I guess we are not trying to approach a new idea or a new system of work. This is weird really why international organizations don't apply this system in order to apply the needed projects according to the people needs especially in Egypt.

On the other hand the decentralization system is not working in Egypt in a good way because such projects usually are applied and approved according to certain agreements done between Egypt and other countries under the umbrella of UNDP and in the end it is just waist of money.

5. Community participation could be the first step of solving the centralization problem through community development associations, and NGO,S .

   The people should feel the power of social participation and the affect of their enrolment in decision making. It is unbelievable that a community Like Siwa with ten trips only works through one organization, another youth organizations should take place to gain the trust of international organizations.

Recommendations

1. Egyptian government should start a survey in such locations to build a check list for the most important project needed by local people, so that the interested international organizations can choose from them easily.
2. Since there is a signed agreement it's important that the governor should not be an obstacle for such projects, laws should be updated.
3. Siwa need badly another new association with youth educated people in order to regain the trust of international organizations again.

CLIMATE EFFECT ON RURAL TOURISM DEVELOPMENT, CASE STUDY OF GUILAN PROVINCE (IRAN)

Nasser HEYDARI POURI, Mona TAMIMI, Mehdi SHAFAGHATI*

Watershed Management Department, Forest, Range and Watershed Management Organization, Tehran, Iran
*Corresponding author: m_shafaghati70@yahoo.com

Abstract

One strategy that has been recently considered by many countries in the world, even applied and implemented in some leading to positive results and outcomes, is tourism development in potential rural areas. Rural tourism entails diverse activities conducted by tourists in rural areas. In other words, rural tourism constitutes of all the activities that the tourists might be able to undertake in a rural area with respect to its natural attractions, culture, rural traditional context, art and handicrafts, and customs which might be classified as agricultural tourism, green tourism, farm tourism, and food and hunting Agritourism. Rural tourism encourages economic growth, diverse and sustainable livelihood, commercial and industrial productivity, promotion of income opportunities in the form of multifaceted activities, creation of new markets for agricultural crop and forms the cornerstone of developing a local productive economy. In the geographical span of Iran, Guilan province has a significant and valuable tourism status. Its geographical features and unique economy of Guilan along with ancient, historical, religious and cultural monuments make this region of Iran unique and transform it to a massive hub of tourism in Iran. The main goal of this research is planning to adapt the existing context based on climate potentials in this province to develop rural tourism industry in Guilan province. This is an applied research using descriptive-analytical methodology. In this paper the province climate is determined using climate classification method and TCI climate tourism method climate zoning is inducted. Then the issue of using climate determinants to develop rural tourism economy is addressed and potentials and new ideas are identified and strategies andrequired solutions to develop rural tourism in this region are introduced.

Keywords:*Climate, Climate parameters, Rural tourism, Guilan province.*

Introduction

Many contemporary planners perceive rural tourism as a key and crucial activity in rural development and considered it from various perspectives; economists consider tourism industry as "invisible export". This industry is a vast scope activity that has important economic, social, cultural and environmental impacts. Therefore, planning for rural tourism development requires a clear understanding of the impacts and consequences perceived by the host society which ultimately leads to sustainable development in the region [5]. Rural tourism has been expanding markedly since the 1950s. Given the attractiveness of the economic consequences of tourism development, early studies during the 1960s focused more on the positive economic effects of this phenomenon. But in the 1970s, the economic consequences of tourism development have been evaluated by researchers with a wider perspective [3]. In the course of this period, there was mostly a negative approach to tourism development; so that researchers often emphasized its negative effects [2].The benefits and positive economic effects of tourism are divided into two categories of direct and indirect benefits. Direct benefits include: new employment opportunities, currency injection, improving people's living standards, sale of services and income generation, economic mobility, recruitment of young work-force; and indirect benefits include: construction boom, crafts boom, horticulture flourishing, fishing, development of services and consumable goods,

infrastructure development and improvement [10].Of course, tourism effects are not always positive and lack of monitoring on the use of tourist environments might result in destruction or cause recession in some sectors of the economy [4]. Besides the economic effects, tourism has social and cultural implications. Social impacts result from various types of tourists travelling to the region. Presence of tourists in rural areas leads to communication with local communities with significant mutual impact on cultural and social development, literacy promotion, and establishment of health care centers, promotion of women's role in often traditional societies, and promotion of social relations in remote communities [11]. Cultural impacts include changes in life style, architecture, the art and customs of the host community [7].

Material and Methods

This research is based on the applied purpose and in terms of its descriptive-analytical method, describes the climate classification of a region's climate. In this method, the climatic profile is calculated from the following equation and in this formula, P is the mean annual precipitation in millimeters and T is the annual temperature in degrees centigrade. According to the De Marton Formula, each region is classified into six types of climates, as shown in Table 1. [1, 8]. Accordingly, and the current statistics on climate zonation of the entire province were carried out (figure1)

Table (1): De Marton climatic classification

Climate	De Matron Drought Ratio (I)
Arid	>10
Semi-arid	10 – 19.9
Mediterranean	20 – 23.9
Semi-humid	24-27.9
Humid	28 – 34.9
Very Humid	35 – 54.9
Very very humid	<55

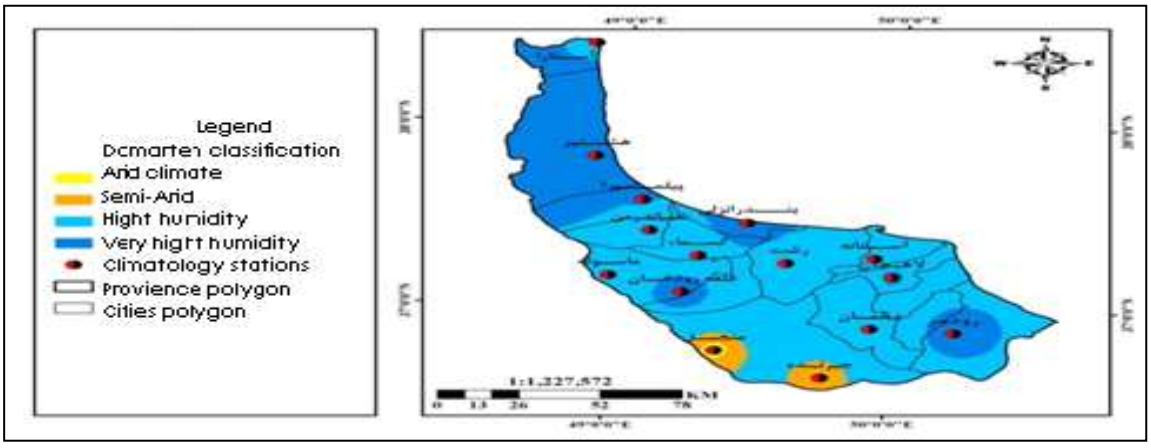

Figure (1): Climate zoning map of Guilan province by De marton method

Results and discussion

- Preparation, extraction and climatic data of synoptic stations of the study area,
- Use of climatic components in the region including temperature, precipitation, relative humidity, wind, sunny hours, number of cloudy days,

- Using EXCEL, GIS, SPSS software to map different geographic and climatic maps in the area,
- Use of different climatic indexes such as TCI to determine the appropriate climatic index of the area,
- Climatic zoning in different regions of the province using different climatic methods.

Guilan province is one of the northern provinces of the country with an area of 14711 km2. The Alborz mountain range with an average height of 3000 m is drawn like a wall in the west and south of Guilan, and this area, other than the Manjil valley, has no other dirt way to the Iranian plateau. The shortest distance of the mountain from the Caspian Sea (in the Hawiq section of the city of Talesh) is about 3 km and its maximum distance from the sea (in Imam Zadeh Hashem, Rashte-Qazvin road) is about 50 km. This province is limited to the Caspian Sea and the independent countries of Central Asia from the north, from the west to Ardebil province, south to Zanjan province and Qazvin, and east to Mazandaran province.
Based on the latest national divisions, Guilan province has 15 counties, 52 towns and 43 districts.

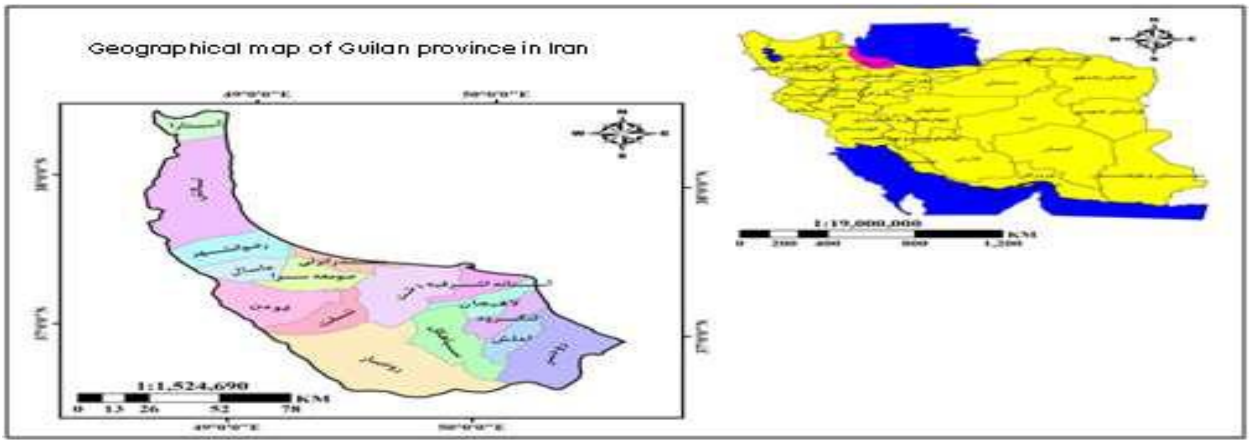

Figure (2): Geographical map of Guilan province in Iran

-Guilan Province Climate Zoning

The results of De Marcton climatic coefficient estimation in Guilan province are shown in Fig. 2. Figures 3 and 4 show the isothermal map of Guilan province using the De Marton method in two statistical periods of 1985-2000 and 2000-2015; Also, the isohyet map of Guilan province using the De Marton method in the same statistical period is presented in Figures 5 .

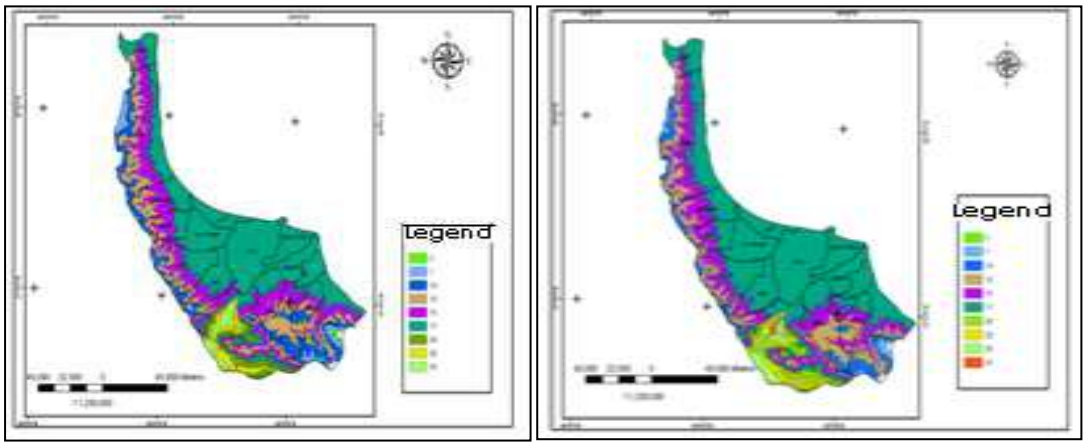

Figure (3): Isothermal map of Guilan province, De Marton method, 1985-2000 and 2000-2015

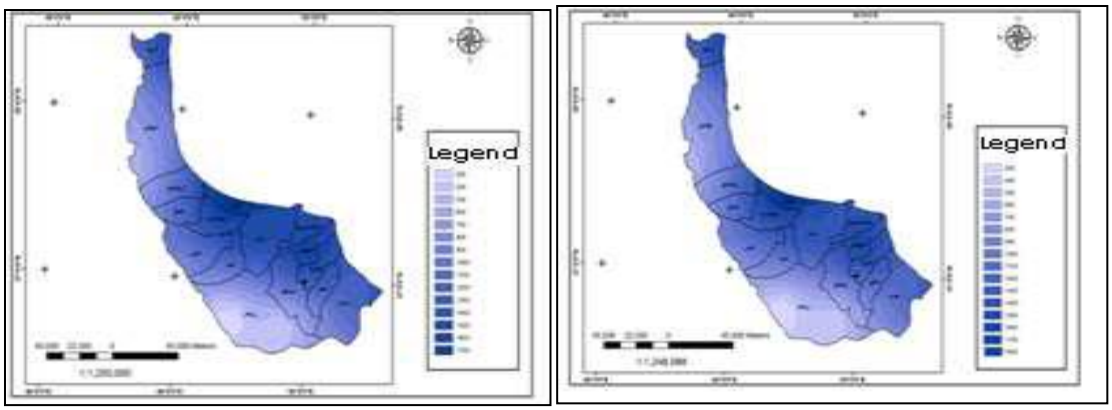

Figure (4): Isohyets map of Guilan province, De Martonmethod, 1985-2000 and 2000-2015

-TCI Climate Zoning

Figure 5 demonstrates the tourism climate status in the stations of Guilan province for the twelve months of the year. In April, the climate improves relatively. In this time of the year, the whole province shares relatively similar climate comfort index except for a number of regions in the central parts with an index of 70-79 with good conditions; other parts of the province with a range of 100-80 indexes fall within excellent and very good climatic groups.

Finally, it can be concluded that spring, late summer (early September), early autumn and March are the best time for tourism in terms of climate comfort conditions in Gilan province, and due to the climatic variation in the province and slight weather difference in the northern stations compared to the southern stations; in a general overview, the whole Guilan region is well-suited for tourism.

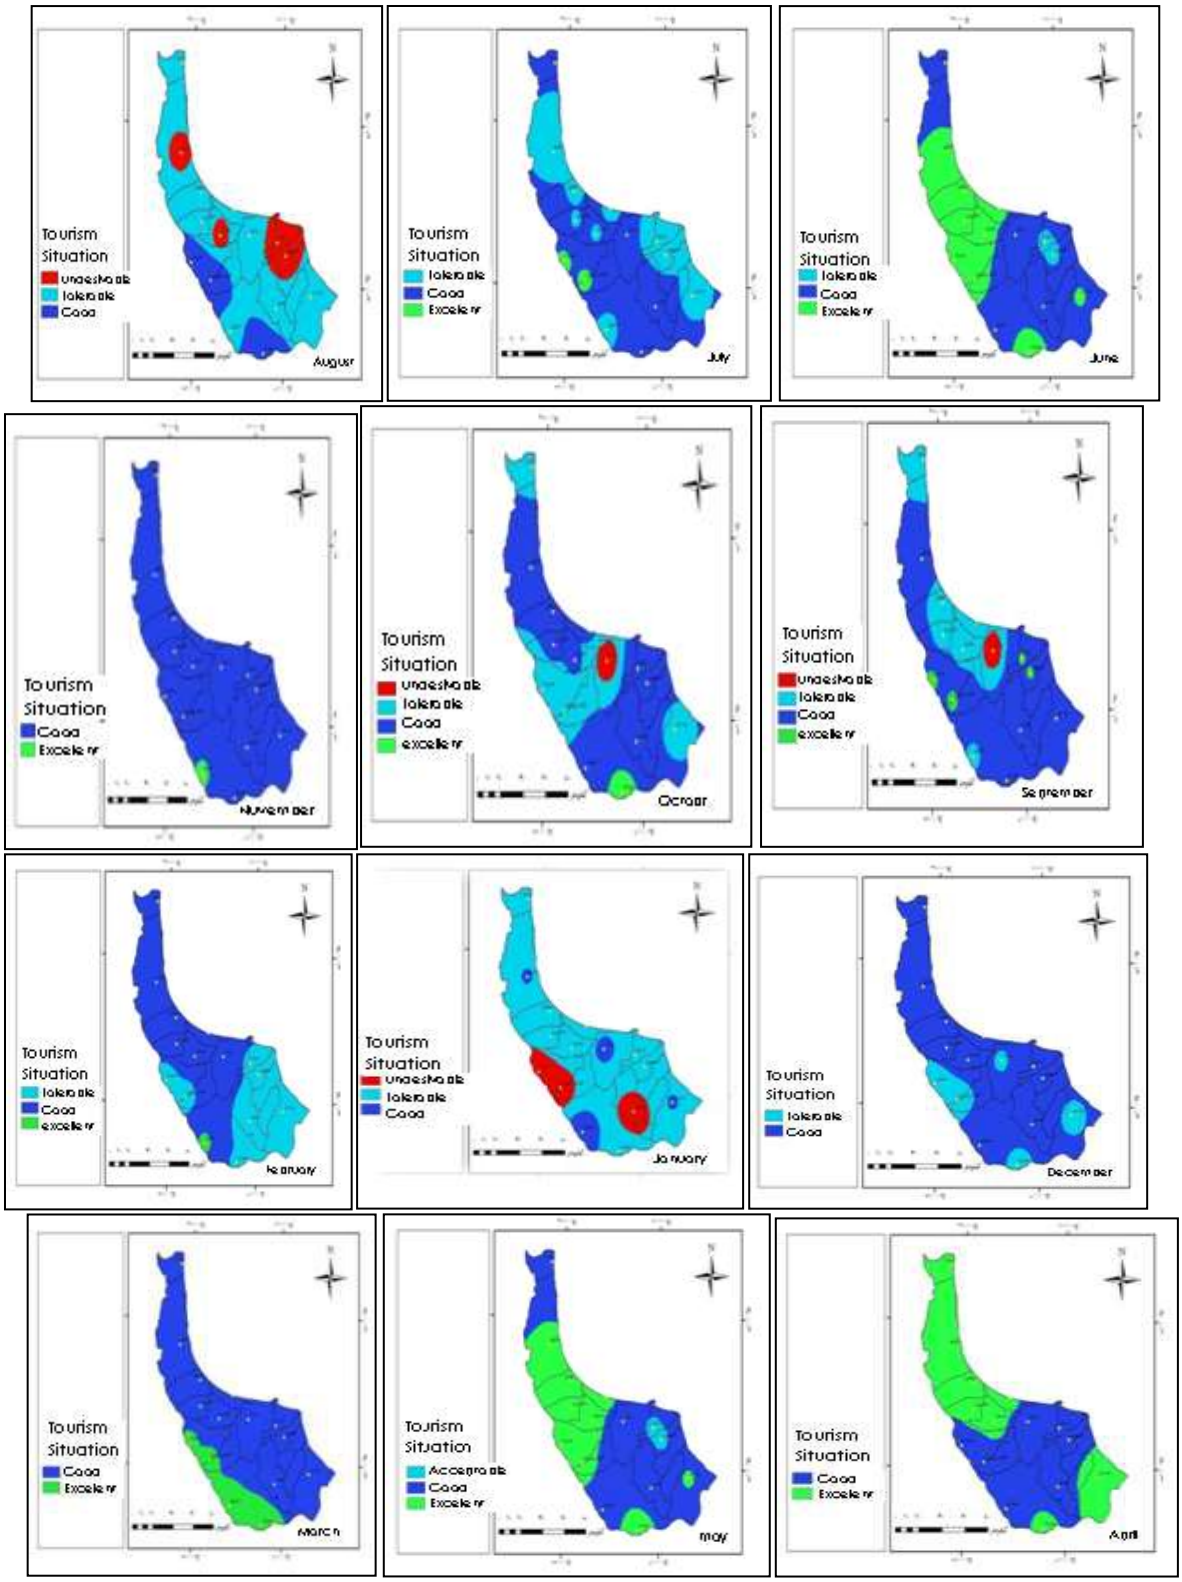

Figure (5): The climate zonation of Guilan province is based on the index TCI during the months of the year

Key Climatic Elements of Tourism in Guilan:

The differentiation level and combination of climatic elements and factors resulting from geographic variation create different climatic zones, each of which can have a particular impact [12]. Iran has been subjected to sub-tidal pressure in terms of cluster division in a dry and semi-arid region. Nonetheless different climatic conditions can be observed in Iran and the province of Gilan is no exception.

According to the studies, elements such as temperature, precipitation, humidity and wind are effective elements in tourism of the province.

In terms of temperature, according to the climate comfort estimations, spring (May and June) is the perfect; summer (July and August) is inappropriate; September is suitable; the winter and autumn (November and December) are also inappropriate for tourism.

In terms of precipitation, autumn (October and November) is unfavorable and the remaining months and seasons are favorable.

In terms of humidity, spring is favorable and the other seasons are relatively unfavorable.

New Ideas:

[1] Provision of indoor glass halls with suitable tourist facilities (tourism incubator):

The incubator literally is the device that provides the heat needed to convert eggs to chicks and supports a premature infant towards required growth and development. The question is that how this definition of incubator relates to the trade and style of tourism. An incubator or development center constitutes of one or more buildings that accommodate proper research units and facilities and benefits support services. Each incubator typically has a common space, services and advanced facilities for the benefit of creative and innovative ideas, appropriate welfare and business services, institutions and advertising companies. This idea might be implemented in Guilan province as a tourism incubator. It is with due consideration that it is this Caspian region (with moderate & humid climate) has the highest precipitation and is the greenest region of Iran where rainfall & humidity is observed in most seasons, and there are two mountainous and plain areas in this coast.

It is recommended to construct halls in special areas with required potentials and facilities to accommodate full and proper facilities for tourists to see the snow in the winter, rain in the fall, and to protect them from the summer heat and humidity where they can benefit favorable and required services. This shall contribute to tourist attraction, income generation, region introduction and creation of new ideas.

[2] Use of natural materials for climatic integration in indigenous, urban and rural communities:

Native dwellings in the north of the country with their distinct appearance, adapted from the nature and geography of the region, respond to the needs of people whose economic activities and bio-culture are different from other parts of Iran. Based on such assumption, use of structural techniques and climate-friendly designs in Gilan will improve the living conditions and decrease the amount of environmental degradation and reduce energy consumption. It is to say that the use of natural roofing material of rhubarb (rice stems), the use of wood of various native species with high resistance to humidity, as dwelling pillars and structure, use of stones in the foundation to strengthen the infrastructure, indicate that the nature provides construction materials and teaches the native communities the building techniques. Also, use of natural roofing material is suitable for temperature adjustment in buildings (the temperature is 5 degrees warmer in summer and 5 degrees cooler in winter under tiled ceilings). It also prevents burning of straws by native communities and its subsequent environmental. Use of indigenous roof structures in touristic complexes, hotels and urban buildings is vital to tourist attraction and conservation of indigenous architecture and environmental considerations.

[3] Recommendation, forecast and change of summer holidays:
May is the best and most beautiful month in Guilan province with a high potential of tourist attraction. However, the official holidays do not correspond to the season. An executive proposal is to consider summer holidays for public institutions in this season and move 10 days of summer holidays into this month and consider a Reading Week Holiday for university students. Such provisions will make it possible to benefit proper temperature, humidity, precipitation and natural scenery to attract tourists.

[4] Use of elevated railroad modern technology:
It is recommended to use modern transportation and road facilities in touristic areas such as Anzali wetland which has natural and unique attraction but suffers road facilities and buffer zones. In mountainous regions and in the foothills, road construction is difficult due to rainfall and humidity and landslide; and it will result in farm and agricultural land destruction; and construction is difficult in foothills due to gradient and forest lands.
Use of motor boats in Anzali wetland causes noise and environmental pollution and construction of roads is not cost-effective and will result in degradation; hence it is recommended to employ a more effective means which is elevated railroad for tourist transportation.

[5] Province's zoning in terms of climate role in tourism development:
Based on the geographic and climate data of Guilan province, several zones are identified. These zones vary in their altitude, topography, climate, vegetation, and crop types. Guilan province consists of the southwest lands of the Caspian Sea; Talesh and Alborz mountains; and three geographic regions: plains, foothills and mountains. The plain area (zone) ranges from 24 meters to 100 meters, accounting for about two-thirds of the province's land, and the largest population of the province resides in these areas. The second zone is at an altitude of 100 to 500 meters and is a subtropical zone, and the third zone is above 500 meters known as the mountainous zone.
For tourism planning purposes, while identifying these three zones, it is suggested to provide coastal and maritime tourism in zone one, which has warm and humid coastal or plain climates.
For the second zone, which is a forested area with a high tide, it is recommended to consider leisure or picnic tourism (short-term tourism).And for the third zone, with mountainous and semi-Mediterranean climate, bungalow tourism (summer travel of the inhabitants of the region).

[6] Optimal use of natural scenery (coastline):
Considering the climatic nature of Iran (dry and semi-arid), the province of Gilan, located next to the Caspian Sea, its unique cover, specific climatic factors, unique Caspian coastlines, different ecosystems (forests, animals), significant climate difference between the plains and the mountains and foothills; large variation in adiabatic law in mountainous areas of the province (Adiabatic decline in the climatology including temperature drop against increasing altitude; that is, a drop of 6 ° C per each 100 meters), whereas the difference in this province is 10 The 12 ° C per each 100 meter elevation makes it unique amongst other provinces.
Considering the existence of 680 km of suitable coastline and 300 rivers running from the mountains to the sea (due to melting snow and successive precipitation), these lands have a special ecosystem. Considering the possibility and potential of proper development in these lands in the tourism sector, it is recommended to take measures to equip the coastline and

construct tourist towns instead of employing destructive technologies and construction of high-end hotels to maintain the natural scenery of the coastline.

Conclusion

The tourism climate conditions at the stations of Guilan province for various months indicate that spring, late summer (early September), early fall and March are the best times in terms of comfort conditions for the arrival of tourists to Gilan province, and due to the diversity The climate in the province and the somewhat different weather of the northern stations of the province with the southern provinces of the province shows that in a general look, all areas of Gilan are considered suitable for tourism.

In the winter, the southern half and the warm semi-northern seasons are suitable for tourism activities.

The country lacks tourism industry goal and policy recognition; some of which are as follows:

[1] Lack of coordination in various decision making and planning authorities.

[2] Pessimism of authorities and local communities against tourism industry.

[3] Lack of technical and experienced experts in various segments of the tourism industry.

[4] Lack of sufficient and quality training institutions.

[5] Negative propaganda of foreign media in an effort to present and unfavorable image of the country to isolate the Islamic Iran.

[6] Lack of required facilities for the import of the industry's essential equipment & items.

[7] Limited accommodation facilities and low maintenance and renovation of such facilities and low urban and intercity hosting facilities.

[8] Lack of relevant statistical inputs and data.

Abstract

The authors, through a vision toward new paradigms, joining tradition and innovation, the approach of the Smart Communities and Smart Territories, the bottom-up new model of Territory Governance as the Territorial Management Contracts -TMC's, design a framework of model that combine the territory risk management with solution development of driving and sharing by the local populations. The proactive involvement of population in the TMC's must be managed by the economic instruments. A model to measuring the benefits recognized by the contractors it's proposed crossing the approach of DPSIR- Drivers-Pressures-States-Impacts-Responses, oriented at the Payment of the Ecosystem Services-PES, with the techniques based in the Willing to Accept-WTA such as simplification of the contingent valuation or choice experiments. The authors demonstrate that the TMC's are concrete way to commit the Local Community the ability to design their own future in a Sustainable Strategy approach. The authors present, in this way, their own large experience in the research, than in projects, teaching and training, in this innovative approach that is strictly linked with the targets of the Sustainability Age. They show also the practical case of the *"S'Ortu de Tzviriu"* in Sardinia Island where the Local Community, driving by the QEDORA Association, is ingoing trough the contracting phase, with the Municipality of San Gavino Monreale, to achieve and set up a TMC *Multifunctional Park o Happiness* of *"S'Ortu de Tzviriu".*The implementation of the case study show that the TMC's are shared and democratic repeatable models that could be adopt in all areas of the world.

Key words: *Sustainable Development, Risk Management, Preventive Management, Territorial Contracts Management, Ecosystem Services.*

Introduction

General Framework

The many domestic and international disastrous events, had in the last years and till in the current weeks, proved to us reflect the dramatic situation that is Italy but also in the prevalence of the areas of all countries.

In the face of a disaster, as the limits of politicians and technicians, at a different level, the management begins with the citizens who are forced to solve the problems solely by themselves and/or only with the presence of many courageous volunteers.

This further drama repeats the tremendous difficulty with which states never give up illuminating examples of real-ready preventive and emergency response capabilities. The unimaginable capacity of people's reaction (with their own means, with their desperation, with their own sense of common good, with real application of subsidiarity and bottom-up approach), shows that they have the skills in managing emergencies but in particularly they have awareness of the changing the approach in preventive management. This highlights that people are primarily capable to preventing and make proactive action on the territory that is the only real modality to limit these calamitous events. The financial crisis, which is still struggling in the management of public accounts, not only in Italy but around the world, suggest that the Public Authorities do not have and will not, perhaps for decades, the ability to

activate direct intervention policies in the proper and effective management of the territories. It is time then to shift the attention and methods of managing the territory, in the process of slimming the public presence, by counting the self-management capacity of Local Communities. These have always given and give wonderful examples (see all the Italian system of the Territorial Collective Assets which, among other things, affects 1,800,000 hectares according to the latest Census data in 2010) when it comes to reacting to the emergency but also to the proper prevention.

The territory at this height should be considered as a common good for which the responsibilities of preserving productive capacity, of its physical, historical, cultural, identity and integrity can, with precise rules covering all Common Goods *(Ostrom,1990,1993),* be commended to Local Communities and actors in the area (first of all between them the farmers). As everyone knows, the European Union itself is implementing, with the collaboration of the various States of the Union and the various Local Governments, the Development Programs, with various instruments covering the multiplicity of sectors and European society as a whole the period 2014-2020.

The Unique Strategic Framework emanates the various Funds (ERDF, EAFRD, ESF, etc.), which put the focus of the various strategies on economic mechanisms that encourage active participation (to the objectives of various policies) of citizens and communities, guaranteed to operate with "good practices" for achieving those goals.

This analysis leads directly to the possible use, within this framework, of tools that, through the Mechanisms of Participated Programming, the Public and Private Management Contracts for the approach of Preventing Territory Management

Territorial Contract Managements and Ecosystem Services

The idea of the Territorial Management Contracts-CGT has been conceived and analyzed since some years *(Ciani & Oth., 2012)* consists in establishing, within a well-defined regulation context, a contract between rural operators (particularly farmers) and the Institutions. Premises that promote all the necessary actions for environmental and territorial protection (drainage, cleaning of ditches, construction of dams and bridle, soil consolidation, planting and management of tree boards, management of the undergrowth, etc.) both on their properties and those bordering on each individual or group of rural operators. The actors adhering to a TMC's are engaged in carrying out the activities described above, in compliance with precise technical parameters, for which they should receive a tangible direct and/or indirect benefit that may be related to the area concerned, to the degree of risk of the area, and the monetized benefits rendered in terms of conservation/creation of ecosystem services *(Reed M.S. & Oth, 2017).* The TMC's must be "strictly localized", promoted and implemented on the basis of the specific characteristics of the territory to which they refer. The case *"S'ortu de Tziviriu"* in San Gavino Monreale represents a concrete reality on which to implement an Experimental Pilot Project of the TMC's.

The study case

The *S'Ortu de Tziviriu* project was born in August 2016 with an active citizenship action driven by the *Association of Social Promotion Qedora* which involved the inhabitants of the neighborhood adjoining the urban garden, through the realization of participatory planning meetings.

From these meetings the project took shape, which involves the construction of the first food forest of Sardinia on public area, through a continuous, periodic and structured participatory planning.

S'Ortu de Tziviriu is located in Sardinia, in San Gavino Monreale (SU) in an area owned by the ~~Municipality.~~This area was completely abandoned and was sometimes used as an illegal

landfill, constituting a significant environmental risk rather than a heritage available to citizens. The surface directly interested by the *S'Ortu de Tziviriu* is around 0.5 ha. The total area of Municipality is 8,750 ha. In territorial management level this is linked with the Pardu stream for about 5,500 meters of length where 200 meters border the *S'Ortu de Tziviriu*. The area bordering of the small river is in total lack of maintenance and very close to the historic center and civilian homes. In 2014 was affected by flooding as a result of exceptional rains occurred in Sardinia. In the current year the water level of the channel has reached the high limits.

S'Ortu de Tziviriu represents a green space for socialization, responsibility, attention to public affairs as well as for pleasure and encounter in a natural environment. On this structural and social basis, the idea of implementing the Territorial Management Contract-TMC is being set up as the *Multifunctional Park of Happiness S'Ortu de Tziviriu*.

Targets, Materials and Methods

The paper have the goal to verify in a concrete case if the theoretical approach at the governance of territory trough the Territorial Management Contract-TMC's could be implemented as the best practice to achieve, in the Sustainable Development Strategy *(Sachs, 2015; U.N., 2015)* the implementation of Smart Territories and Smart Communities*(E.U. Commission, 2012; Ciani & Oth., 2016)*

The materials used are two different types. First at all the research was directed to achieve an updating framework of reference concerning a global vision on modern and innovative territory governance. After this, consequently at the previous activities of the Qedora Social Promotion Association, was established a *Territorial Social Inclusive Laboratory-Te.S.I.La,* with three days activities in December last 2017.

The core of the activity was arranged involving S'Ortu de Tziviriu Operators and Citizen Community, with an Exercise Training for Participatory Evaluation of Ecosystem Services *(E.U., 2014)*.

The purpose of this work is the economic evaluation of the ecosystem services of S'Ortu de Tzviriu, or of all the benefits that this sit on man *(E.U., 2013).* The evaluation aims to improve the management and conservation strategies of the naturalistic and territorial common good, in accordance with the value that the citizens perceives for them *(Italian Parliament, 2015).*

For the determination of the ecosystem services value was adopted the criteria in the approach of the Willing to Pay-WTP or Willing to Accept-WTA and simulate, in a way of the of the revealed preferences of the consumers *(Reed, 2017)*

In this way was also experimented an original contribution of the research. The criterion where the benefit that citizens can assign to the ecosystem services and they conserver or create, is equal to the value that they accept as payment at the hours of work award in the context of participation in the TMC. The substitute labor market is used in this case for the purposes of evaluating the ecosystem services. For the simulation of the substitute market was create original questionnaire that is divided in three parts; the first is an introduction at the environmental and territorial question; the second is a description of the ecosystem services and their value; the third with the demand how, about the number hours of work that each participant is available to award at the TMC**,** and how much he can accept as payment for their same work. With the simple weighted arithmetic average was calculated the WTA payment of working hours by the participating Community to the experiment.

Results and discussion

The Territorial Social Inclusion Laboratory-Te.S.I.La of San Gavino Monreale has had the participation of various community stakeholders and among them 25 accepted and signed their own filled questionnaire. The following data emerged from the analysis of the same. In reference to the willingness to offer their hours for week for the 52 weeks for year, it was an average of two hours a day but for 1.6 times a week. The average remuneration expected and acceptable for one's work hour is on average 1.4 Euro. Overall it emerges that the value of one's annual work offered for activities related to the Territorial Management Contract of S'Ortu de Tziviriu is 226 Euro per year. On the basis of the methodological prerequisites adopted, it therefore emerges that the value of ecosystem services that citizens estimate that they are maintained or created for their activity within the TCM of Multifunctional Park of Happiness S'Ortu de Tziviriu is equal to € 226 per year. According to this value creation, the benefit that the TMC should assign them, through the public intervention, that could be by direct payment or indirect benefit (lowering taxes, supplying services, etc.). As a final act of the activities of the three days there was a final Conference at the end of which the participants prepared a Declaration of San Gavino that in the final part committed the Qedora Association and the Municipal Administration to sign the Declaration itself and to stipulate a Memorandum of Understanding for the implementation of the Territorial Management Contract Project for the creation of the Multifunctional Happiness Park of S'Ortu de Tziviriu in San Gavino Monreale. On May 20, 2018 the Memorandum was signed and a working group headed by the Qedora Association will have to deliver the Project Proposal within 90 days. Concerning the the concrete implementation and perspectives of the Project was prepared the SWOT analysis (Fig. 1).

Strengths	**Weakness**
Leading of the Qedora Association High sense of territorial identity Historical Linkage People Land Awareness of the problems of the area Availability for Active Participation Propensity to the Valorization of the Territory Awareness of the value of Natural Capital Local Administration Availability Previous experience of administrative bartering Territorial Value of San Gavino	Human Resources in the Municipality Not Broad Band Not adequate friendly dissemination of ICT Weak Territorial Policy at the Regional level Loss of good agricultural practices Tradition that prevails on Innovation Financial Resources National Policy and Role of Local Community Job supply / demand system Work safety regulation

Figure 1._SWOT Analysis of the Territorial Contract Management of Multifunctional Park of Happiness of S'Ortu de Tziviriu in San Gavino Monreale

Conclusions

The territory at this height must be considered a common good for which the responsibility of preserving the productive capacity of their physical, historical, cultural, identity integrity can, be referred to the Local Communities (first of all farmers).

It is way it's time to capture the New Paradigms and New Approaches that the Territory has to offer. Among the New Paradigms we can include, in addition to the four related at the Sustainable Development strategy, those as following:

- *Territory is a living entity consequently at the vision as book to be able to read;*
- *Territory is the reservoir of resources to be put into the cycle of a sustainable production system of goods and ecosystem services;*
- *Territory is an intelligent cognitive system that educates and learning with a smart use of the ICT;*
- *Territory is specificity, rarity and specialty but social inclusive*
- *Territory is "TRADI-OVATION" (intended as an acronym for "Territory, Rural Areas, through Development, Innovation, Organization, Valorization, user friendly Technology, ICT sharing, Online Networking)(Ciani, 2012, 2015). In this sense is the key word and the main theme around which any innovative process can be structured to give effective credibility and to erase the increasing disillusion that follows major international meetings, in order to move from words to actions and create the foundations for the New Model of Management and Promotion of the all Territories.*
- *Territory send us the option to Overcoming of the Labour Systemic Prison by the Free Time and the Recovering of the Environmental Space*

As everyone knows, the European Union itself in 2014 began a process to develop, with the cooperation of the various States of the Union and of the various Local Governments, Development Programs, as a whole, for the period 2014-2020.This analysis leads us directly to use as possible, within this framework, tools that provide, through the mechanisms of Participatory Planning, Management Agreements between the Public and the Private to the preventive management of the territory. On these principles underpinning the strong assurance that the Territorial Management Contracts-TMC's can truly guarantee a new season at the Country for a preservation of its territory, to be a fundamental part of people improvement the economic, environmental and social status. Territorial Management Contracts-TMC it's a proposal with a vision of the General Contract/General Program between the Local Communities and Public Administrations within which the various aspects (rivers, lakes, landscapes, forests, etc.) can and must be taking into account. If this is not the case, we will soon be in a position to launch, especially in the most innovative ways of innovation, such a set of contract hypothesis that will only lead to conflicts between the various sectors/contracts. The model of organization, evaluation of benefits to assign at the participant at the action and the choice of the better alternative of TMC's, from the theoretical point of view, in the paper have achieved strong and solid inductive and deductive consistency. The case study of the TMC of *Multifunctional Park of Happiness S'Ortu de Tziviriu* say us that we can do and for that we must do. Some concrete cases, in the other different areas, appear suitable to implement with possible others experimental Pilot Projects. The idea of TMC's is therefore to transform the weakness of every area due to high risk, into an intelligent, inclusive, sustainable, transparent, proactive, concrete opportunity. To achieve for all rural areas of the world the character of Smart Communities and Smart Territories. To abandon the Gross National Product Approach Toward the Gross National Happiness Strategy.

Abstract

Lakes of hydro-agricultural dams are technical innovations developed by the Ivorian State in the countryside of the north of the country in the 1970s. The presence of these water reservoirs has helped to boost agricultural production and to begin an extension of aquaculture activities through the construction of various fish farms. Today, however, the dam of Tiné in the sub-prefecture of Bahouakaha, like many of these works, is in a poor state of operation due to a lack of regular maintenance of its facilities. This reality negatively impacts the agricultural activities practiced in this lowlands of an area of more than 200 hectares. The objective of this study is to examine the consequences of the failure of this lake development on the cultural and halio-aquaculture activities that depend on it. The methodological approach is based on an exploitation of the documentation relating to tributary activities of fluvio-lacustrine environments. Semi-structured interviews and direct observation of the facts were also used during the field surveys. It appears that the dysfunction of the lake supply system has led to the closure of a state-built fish farm in the lowlands. Currently, a water leak due to the damage of the stop valve, at the monk tower of the dam, affects rice and vegetable productions. This situation undermines the livelihoods of user communities and threatens the food security of local populations.

Keywords: *Ivory Coast, lacustrine system, agricultural activities, fish farming, failure.*

Introduction

In its development policy for the northern part of its territory, the Ivorian State has provided it with several small artificial reservoirs for agro-pastoral activities and drinking water supply. These dam lakes are concentrated in the current regions of Bagoué, Poro and Tchologo with a high density in the department of Korhogo (37% of the reservoirs). The Northeast and Northwest have only 9% and 1% (Anonymous, 1992). Thus, although "unequally distributed throughout this geographical zone" (Da Costa et al., 2004), these hydraulic developments constitute "technical innovations" (Akindès, 2007) that have favoured the increase in agro-pastoral production and fish extension. For Le Guen (2004), the hydro-agricultural dam is adapted to this zone because it favours the cultivation of floodable land all year round, intensive rice production for self-sufficiency and substantial income for the Senoufo indigenous populations. Consequently, it is "indisputable that the agricultural and pastoral policies developed at the beginning of the 1970s" by the realization of these works "engaged the "Northerners" in new dynamics of exploitation of the terroirs" (Le Guen, *op.cit*.).

It is in this perspective that the lake of the "*mixed use*" dam (Silué, 2012) of Tiné was created. Its creation was followed by the creation of a fish farm and the development of lowland for cereal and market garden crops. Despite its capital role in the agricultural system of hundreds of rural actors, this water infrastructure suffers from the dilapidated state of its installations whose various failures threaten the sustainability of activities; hence the following concern: how does the lack of maintenance of the Tiné hydro-agricultural dam affect agricultural, halio-aquaculture and pastoral activities?

This article examines the consequences of the failures of the Tiné hydro-agricultural dam lake on rice, vegetable, fish and pastoral activities in this zone characterized by a long annual dry season. The identification of the impact of the failures of the Tiné lake system on the activities of the operators is thus presented as a decision-making aid for regular maintenance of its installations. The methodological approach for achieving the objective of this study is as follows.

Material and methods

The Tiné hydro-agricultural dam was created in 1974 by SODERIZ (Company for Rice Development) on the Kô river, a tributary of the Solomougou. It is located in the department of Korhogo, a dozen kilometers from the city (capital of the Poro region, Ivory Coast). It generated a 45 hectare lake used for irrigation of rice and market garden plots, livestock watering and halio-aquacultural production (Silué, 2012; Traoré, 1996). A lowland of more than 200 hectares developed downstream of the structure extends over the terroirs of about twenty villages over a distance of about 12 kilometers. It is exploited by several hundred rice farmers and market gardeners. The study was based on documentary research, field observation and semi-structured interviews with "key informants" (Gumuchian and Marois, 2000), involved in the operation and management of the two spatial entities analyzed (the hydro-agricultural dam and the developed lowland). Secondary data collection was done through the use of literature on activities subject to fluvio-lacustrine environments and permitted to refine the study variables. The field survey was conducted in Pégnankaha and Bahouakaha, two rural localities in the dam's area of influence. The first community is adjacent to the lake and the second, further downstream from the water reservoir, contains part of the developed lowland. It is the headquarters of the Wowêdjo cooperative, the only rice cooperative with 404 members in 12 villages, operating in the Tiné lowland. In Pégnankaha, the village chief, two notables and the former manager in charge of the stewardship of the community fish farm during its operation were interviewed. In Bahouakaha, talks were held with the cooperative's managers and three market gardeners. Discussions focused, among other things, on the types of relationships of populations to dams and lowlands, the management system put in place, the type of problems related to their management, the reasons for the dysfunctions observed, the types of activities dependent on the lake, agricultural calendars, the quantities produced per season, the purpose of production, revenues and their modes of use. Field observations, begun in January 2017 as part of a research program on "Water and socio-economic development in the Poro region", permitted to monitor the spatial dynamics of agricultural activities around the lake and in the lowland. Regular bi-monthly visits to the study sites helped to understand the evolution of the situation at different periods of the agricultural production cycles and to observe the usual cultivation practices of the stakeholders. This approach was particularly useful to apprehend the changes that occurred in the developed perimeter, between the normal operating period of the dam and the one characterized since January 2018 by the water shortage in the reservoir following the damage to the shut-off valve of the monk's tower. The processing of the data collected has led to the following results.

Results and discussion

When it was created in 1974, five main activities were directly dependent on the Tiné water reservoir: rice growing, market gardening, livestock farming, aquaculture and fishing. The first two activities are mainly practiced in the lowlands, on plots of about 35 m^2. If, for socio-cultural reasons, rice cultivation is only the business of men, market gardening brings together actors of both sexes. In addition, rice and vegetable crops are mainly produced for marketing. Only small quantities (about one fifth for rice and less for vegetable products) of production are self-consumed by farmers and their families. This observation is confirmed by Fromageot (2008) who notes that since the 1990s, the production of fresh vegetables for the cities of the Ivorian coast has spread to the Senoufo savannahs on the Ivorian-Burkinabe border. Moreover, in terms of the number of farmers, market gardening is the main activity practiced in the lowlands because almost all households are engaged in it.

The waters of the lake provide water for the herds of village cattle. Aquaculture was present there until 1983 through the construction by the State, a little more than two kilometers downstream from the dam, of a fish farm with 14 ponds as part of the extension of this activity in the region.

The development of lake fishing has benefited from the introduction, by the Tropical Forest Technical Centre (CTFT), of several dozen juveniles of *Lates niloticus* from a trial to control the tilapia population in ponds (Kouassi et al., 2007).

This diversity of activities led Silué (2012) to qualify this hydraulic development as a "multiple-use" dam compared to four other "single-use" types. These, also present in this northern region of Ivory Coast, are intended either for the irrigation of sugar cane and rice crops, or for livestock watering or drinking water supply (Silué, *op.cit*.).

The first dysfunctions of the Tiné lake system occurred in 1978, 4 years after the dam was put into service. They concerned the water supply canal of the fish farm. This structure, a little more than two kilometers long, was filled under the combined effect of erosion (due to agricultural overexploitation of the land upstream of the canal) and a lack of maintenance, resulting in the cessation of water supply, as well as farm activities in 1983. There are no figures on the production and marketing of fish from this fish farm during its years of operation. However, it is certain that the issues of promoting the activity among local populations, the spatial dissemination of farming techniques, and the production of fish for self-consumption and sale on the local market, which guided its realization, like other farms of this type built at that time (Anonymous, 1999; Gosse, 1984), could not be reached.

Despite this first setback, the dam facilities underwent only one maintenance period in 2000, during the four decades of operation. The durability of a hydraulic structure being a function of the design and construction work but also of maintenance (Lassailly-Jacob, 1984), the control stem of the shut-off valve failed due to lack of maintenance in January 2018. This mechanical failure caused the reservoir to dry out completely following a continuous flow of water from the lake in about fifteen days. The consequences of this new failure were almost immediate and perceptible at various levels: disruption of crop calendars, loss of rice and market gardening production and income, cessation of fishing activities and migration of fishermen, modification of the village livestock watering route.

The variety of rice grown in the managed lowland of Tiné is *Wita 9*, an improved seed whose production cycle is 3 months with an average yield of 7.5 tons per hectare. To do this, the irrigation of the plots depends essentially on the proper functioning of Lake Tiné, which is filled during the single winter season (May-August). The annual practice of the activity is organized in two seasonal cycles (first cycle in yellow; second cycle in green) spread over the two respective semesters of the year (Table 1).

Table 1. Annual crop calendar of the Wowêdjo rice cooperative

Sources : Field Investigations, 2017-2018 ; Silué, 2012.

In the usual operation of the dam, the availability and regulation of water distribution make it possible to irrigate all the 170 hectares of plots cultivated by rice farmers. However, the use of water for rice production is subordinate to the climatic seasons. Thus, compared to the first cycle, production in the second cycle (July-December) is less dependent on lake water. The first growing cycle takes place in 2/3 of its period from January to June, in the dry climatic season. It is, therefore, intrinsically linked to the water retained in the dam basin during the previous rainy season. On the other hand, the second cultural cycle depends much less on it. Indeed, it starts in the middle of the rainy season and is half covered by the latter whose rainfall peaks are observed in August. This situation allows a rationing of the lake, the plots also benefiting from rainwater during this period.

The vegetable production calendar (tomato, cucumber, cabbage, zucchini, salad, aubergine, etc.) is also divided into two cultivation cycles based on the two semesters of the year. The total area of the lowland used for market gardening varies from 40 hectares in the dry season to about 15 hectares in the rainy season. This reduction in cultivated area is due to the fact that during the second cycle, upland crops such as cotton, maize and groundnuts are favoured by the actors to the detriment of vegetable crops.

In addition, market gardeners are produced on plots that are not used for rice cultivation and therefore not covered by the irrigation canals of the rice plots. As a result, they are watered daily from hundreds of shallow (1.5 m) wells set up on the farms. The permanence of the lake water upstream favours the availability of well water throughout the year.

From the above, it appears that the loss of all the water from the dam due to the failure of the shut-off valve is detrimental to the rice and market gardening activities practiced in the lowlands and thus to the stakeholders. Indeed, during the first half of 2018, the irrigation of the rice plots, essential at the beginning of the first cycle, could not be done for lack of water. The soil shriveled by the long annual dry season could not be prepared for sowing as well as nurseries; hence the lack of production, thus the absence of income for farmers. For example, in 2017, with normal operation of the dam facilities, the total rice production of the Wowêdjo cooperative for all two annual cycles was 1,445 tons (850 tons in the first cycle and 680 tons in the second cycle). For the first harvest, the price per kilogram of paddy rice fixed by the State to producers ranged from 150 FCFA (0.23 €) to 175 FCFA (0.27 €). On this basis, the average market value of the Wowêdjo cooperative's first cycle production was 114 750 000 FCFA (174 935, 25 €). In the second cycle, this value was 85 000 000 FCFA (129 581,66 €); the price per kilogram having been fixed at 125 FCFA (0,19 €). As the shut-off valve has not been repaired so far, significant revenues are at stake for the hundreds of operators. Moreover, this reality largely conditions the possibilities of execution of the second cycle of the year 2018, by the hope of an abundance and regularity of rains during the annual winter season. According to the farmers, this eventuality remains hypothetical, all the more so as the rainy season only partly covers this second crop calendar and only one of the three months of the

growing cycle of the cultivated rice variety. This result shows that the lack of maintenance of hydraulic equipment is, like the lack of control of irrigation techniques by producers, one of the obstacles to achieving intensive production with biannual cultivation cycles (FAO, 2005).
The impact on market gardening activities was equally significant in the first production cycle. In the absence of lake water, the long eight-month dry season caused the watering wells to dry up. Faced with this constraint, most operators have had to deepen their wells as a means of resilience. This solution, however, proved derisory as the dry season continued. Thus, the difficulties experienced by the unavailability of water in the watering wells of crops led to the stopping of farms or poor production during the first crop cycle. However, the second cycle could be better if winter rains are sufficient to allow efficient groundwater recharge in the lowlands and permanent water availability in wells.
Usually, five artisanal Bozo fishermen, of Malian nationality, exploit the fishery resources of Lake Tiné. These professional fishermen market their production on the "fish market" (Koudou *et al*., 2015; Kouassi *et al*., 2007) in the town of Korhogo. The absence of water in the lake led to the interruption of their activities and their departure towards the Tongon gold mine reservoir located about sixty kilometers from Korhogo, their place of residence.
Since its impoundment, the Tiné dam has been the main daily watering site for cattle herds in the riverside villages. Its accidental drying up, in the middle of the dry season, forces the shepherds to modify their grazing paths towards other more distant aquatic spaces, notably those of Sédiogo (5 km), Sinématiali (12 km) and Lokpoho (18 km), already occupied by other actors. This situation is likely to give rise to the risk of conflicts with other breeders or farmers whose farms are established on these new routes or border these water points.

Conclusion

The consequences related to the failure of the Tiné hydro-agricultural dam facilities are significant and diverse. These include disruption of cropping schedules, loss of production, loss of farmers' rice and market gardening income, cessation of fishing activities, migration of fishermen and modification of livestock watering routes in riverside villages. This situation shows that the sustainability of the valorization of this water infrastructure through the permanence of agricultural, halio-aquacultural and pastoral activities can only be possible through regular maintenance actions of its installations.

Abstract

A national environmental socio-economic project was conducted In October 2017 in a rural village named Era in the north western part of Jordan . Era is considered as an agricultural and rage land area. It has good soil fertility, suitable environmental conditions in addition to relatively high rain water precipitation, which encouraged local community to work in different farming activities either planting or grazing. Last years, due to climate change and biodiversity retardation; rain fall in the area became low which reduce the amount that can be available for plant growing. Local farmers adopted traditional agricultural practices gain low income retain. This leads to shifting the farming work to wives and youth while men are usually go to their formal work in the city. It was of great important to target women and youth in training project deals with new agricultural techniques overcome the effect of climate change. A pilot cooperative project was established by the effort of local community, charity association, university consultant and funded by UNDP-Jordan. The project dealing with training 200 individuals of local communities' beneficiaries from which 70% of them are women. The project set ups for rangelands and drought management system with several practices; rainwater harvesting, soil quality analysis, area productivity improvements, adopting nil tillage or zero tillage, introduction of new planting technology; as hydroponic and aquaponics. The training of the concerned participants tailored to ensure that those trainees will be able to transfer the knowledge and skills gained to others in the community or even other interested in the near areas. The projects ensure providing the area with demonstrative pilot project which is considered as a field school for others.

Keywords: *Rage land, Biodiversity, Pilot project, Hydroponic, Water harvesting, Local communities, Rio convention*

Introduction

Jordan is one of the middle east country with a total land area of approximately 90,000 km^2. Most of the land is desert (El-Naser et al. 2014) and the country is landlocked except for a 30 km strip of coastline along the Gulf of Aqaba. It is weather characterized as arid to semi-arid with about 200 ml of average rain fall, forests covering less than 1.5% of the country's land area. Given its relative size and position in the heart of the middle east, Jordan is particularly vulnerable to external political and economic influences (Risk, 2013). Era is a rural village of about 5 km^2 area within the territory of Balqa Governorate in Jordan. It rises approximately 580-620 meters above sea level so it considered as semi Ghour area according to Jordan geographical mapping (figure 1). It is characterized by its moderate atmosphere in all seasons of the year with about 500 ml of precipitations during winter season. It is mediated between the capital city Amman and the central agricultural area of Jordan valley with a population density of about 985 individuals/km^2. The mountains surrounding Era are covered by Aleppo pine and oak trees, which have a unique aesthetic dimension and are visited by tourists in the spring. Several herb plants, including medicinal herbs used in natural therapy are present as native plants, in addition to the spread of black Iris known in Jordan as national flower which reflect high biodiversity in the area. In domestic area olive trees are dominated in addition to

various seasonal traditional crops such as wheat, barley, lentils, chickpeas, and rainfed vegetables such as zucchini, okra, onion, garlic and potatoes. A long time ago, local community work in various agricultural activities, either agriculture or grazing. Climatic variability and frequent droughts in addition to high rates of population growth further intensify the pressures on natural resources throughout the area. The most of Era men left the village to work in governmental jobs which leads to rural area immigration. The farming works in Era is mainly family work, making wives and youth participate in different farm and agricultural activities. The combined effect of these natural and anthropogenic factors has often led to the utilization of unsustainable farming practices, resulting in the continuous degradation of agricultural soils and desertification of previously productive lands. Since this area near Al-Balqa Applied University which has a strategy to play a critical rule in technology transfer and rural area development. A cooperative work between Al-Berah charity association (31°59'07.8"N 35°41'28.9"E) which is located in Era area and a researcher from Al-Balqa Applied university funded by UNDP Jordan as a modeling project for mainstreaming Rio convention provisions into national sectoral policies. The project was deals with establishing rain water harvesting system and invest the harvested water in planting. On a selected area of about one hectare the model was established and training section were applied. The main core of the project was to train local community people targeting women and youth on using harvested rainwater in hydroponic system under greenhouse conditions as one of new environmental socio-economic novel technology in rural area (Haddad, M. *et al.*, 2009) and adopting zero tillage in open field area with introduction of new foraging crops to the area. That help justifies the use of water and increase the efficiency of its use. This is a first project in Era area deals with comprehensive agronomic-environmental-economic nature, which will, therefore, be of high relevance for the agriculture sector in the rural area in Jordan.

Figure 1. Era area in which Al-Berah charity association is located 31°59'07.8"N 35°41'28.9"E.

Materials and Methods

Pilot Plant Setup: The pilot plant is located in Al-Berah association within one-hectare area. About 10 km west-southern corner of Al-Balqa applied university campus. The pilot consists of a rain water harvesting tank that is collecting the rain water from over 300 m^2 surface area of Al-Berah association building. The total capacity of the tank is about 16 m^3 of water. The collected water were oriented for the planting area, which contains a model of greenhouse hosting the hydroponic system, and an open area for bica planting *Vicia sativa*. The green house model is 9 m wide, 36 m long, and 5.5m high, made of galvanized steel pipe frame and

covered with plastic layer. Hydroponic system was established in the green house by building concrete ponds inside the greenhouse (Figure 2).

Figure 2. Green house preperation for hydroponic system (a) Ponds are made in double lines inside the greenhouse with four section per unit leading to 8 separated ponds which is filled with irrigation solution as flooding and air pump is used for aeration (b)

Ponds are coated with anti-corrosion layer, with length of 27m, width of 3 m, and height of 35 cm. The ponds are made in double lines inside the greenhouse with four section per unit leading to 8 separated ponds which is filled with irrigation solution as flooding and air pump is used for aeration (Figure 3). The open reuse area consists of an area extending for 1 hectare which is used annually for parley plantation by local farmer, he used to incorporate it with tractor then plant it with barely seeds as rain fed area. As a part of the project this area was not cultivated and planted with *V. sative* seeds as alternative method and crop for such a pastoral area.

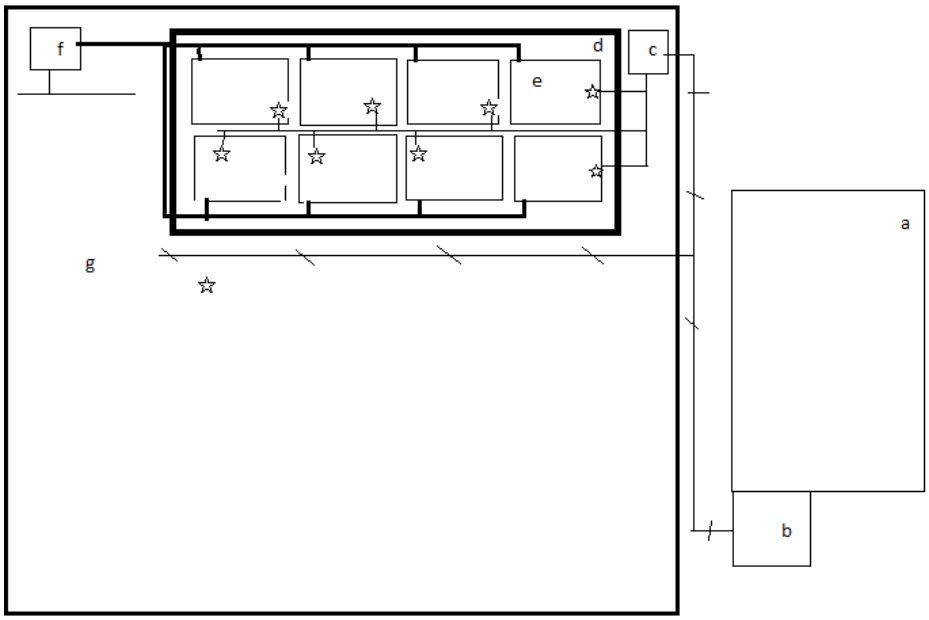

Figure 3. Schematic of Pilot Plant rain water harvesting tank, green house with Hydroponic system with horizontal channels covered with floating polystyrene sheath, which is the carrier for plastic cups filled with 1:1

perlite: petmoss containing vegetables or herpes transplants. The channels are without media allowing moist and wetting atmosphere for the roots of the plants, each channels has a pump for recycling of hydroponic solution and aeration. a: Al-Berah association building as water harvesting space b- water harvesting tank, c: hydroponic solution preparing tank, d: greenhouse e: Hydroponic channels, f: filtration and drainage tank g: open field area. Stars represent bumps for recirculation of water and aeration.

Used Plants: In the hydroponic system most of the plants was vegetables but with introducing new crops to Era area such as celery, red cabbage, and iceberg lettuce. For the open field, we also introduced new foraging crop *V. sativa* which is from legumenacy to improve soil fertility in addition to its high value as feeding crop.

Capacities developed for the conservation of rural area environment: Enhance awareness and understanding of social actors think critically on how to contribute to the sustainable development process and national development priorities to faces challenges with water and resource scarcity shortage of arable land and with accelerating desertification, soil degradation, and deforestation by engaging large numbers of local communities including youth, women, academia, and the private sector in capacity building and training sections for 6 months' period such as:

1- Water harvesting system design.

2- Adopting new agricultural methodology: zero tillage, below soil drip water irrigation and Hydroponic.

3-Chosing proper crop according to its requirements and its revenues.

4-Agricultural crop waste management.

5- Training workshop on integrated resource management in the training model.

A total number of about 200 individuals of local communities most of them are women were getting this training courses (figure 4). Each course has its own pre and post evaluation form to assist the needs and evaluate the output of the course. Monitoring and evaluating plan was conducted every two months of the project to improve the activities when required for more goals achievements. Practical training was applied for each training course under the field conditions.

Figure 4. Field visit and training on hydroponic concept for middle girl school students at Era area

Results and discussion

1. This project was its first one of its kind in Era village, it needs a condense announcement and encourage information to motivate the local community in participating in its different activities. The most important way for spreading the information about the project and its important was by using social media channels as Facebook, Wats up and Al-berah Association website. After one month of introducing the project the participating of local communities' members starts to elevated and their interest in activities became higher. Some

of the participant start adopting new activities in their farms and home gardens as water harvesting, hydroponic and recycling concepts. As a first season of the project, the total collected water in the harvesting tank was about 90 m^3. This water was used in hydroponic system which is succeeds in production of almost all the transplanted crops: celery, red cabbage, and iceberg lettuce (figure 2). Due to short production period in comparison with traditional method there was three planting rounds within 6 months of project period. We use the fourth round of planting native herbs such as thyme *Thymus vulgaris*, sage *Salvia officinalis*. The quality also of the products was very high since we did not use chemicals as pesticides or herbicides, it is considered as organic plantation (Ferguson *et al.,* 2014). Currently irrigated agriculture consumes over 60% of Jordan water budget, however severe competition between sectors for water is only expected to increase (El-Naser, Telfah, & Kilani, 2014). To maximize the efficiency of used water we are working now with consultant from Al-Balqa Applied University to connect the system with a filtration unit, which can improve the quality of the drainage water and facilitate its reusing in open field irrigation (Kumar *et al*., 2014). For field plantation, the land give good growth of vicia but it needs more time to study the difference between feeding animal on barely and that fed on vicia as main source.

2. Jordan has identified water and a number of factors including habitat degradation, pollution, and intensive use of agrochemicals threatens energy as the priority issues for development, the country's biodiversity. Furthermore, agricultural land, forests, and other protected areas are being lost to the growing urbanization and request for the inadequate resources. According to the UN Country Assessment, (UN, 2011) Given the challenges facing the country, Jordan has confirmed its commitment to improving governance and strengthening sustainable management of natural resources and the environment. The goal of this project is to deliver environmental benefits through more holistic and effective management of the natural environment to meet national socio-economic priorities. Growth and development are inclusive and sustainable, incorporating productive capacities that create employment and livelihoods for the poor. Key government and non-government actors have capacities to undertake gender-sensitive management of natural resources in a climate-resilient manner in targeted governorates. Operationalize national green economy action plan in a gender sensitive and inclusive manner. Integrate disaster risk reduction and climate change adaptation into strategies and operational plans at national and local levels. Best practices and innovative approaches for its activities include awareness-raising and education, capacity building, public policy advocacy, and business networking. Improving knowledge management, education, and awareness-raising are crucial elements in the sustainable development. Technical training and technology transfer, using research for policy-making; academia, private sector, and civil society integration to identify potential innovative to solve critical socio-economical environmental problems. Local community empowerment; emphasize their demonstration and build the capacity of local governments and communities to operationalize mainstreamed sector development plans. Horezental mainstreaming for environmental social activity will be the base point to be completed by vertical mainstreaming to rech sustainable development (Nunan, *et al.,* 2012) Resource mobilization assess long-term opportunities to mobilize resources to replicate and sustain project outcomes.

Acknowledgment

This work was a result of extensive work of Al-Berah Association with local community, the association tackle the social responsibilities for adopting the manipulation of such a project in Era village and use all its social communication to encourage local community individuals to participate in project activities. The genesis of this work would not have been possible without the dynamic and effective financial and technical support of UNDP-Jordan

specifically mr. Samy Tarabieh who guide the work for success by his valuable comments and advices. I am also expressed my thanks for Al-Balqa Applied University which facilitate my work with local community representatives in such a valuable technology transfer project.

FINANCING AND LENDING TO A FARM IN LATVIA

Aina DOBELE*, Andra ZVIRBULE

Faculty of Economics and Social Development, Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author: Aina.Dobele@llu.lv

Abstract

Financing a business encompasses all the activities necessary to provide the enterprise with finance. This represents the process of acquiring and spending funds and making investments, as well as the cash flow. Farms could use both internal and external sources of finance. The research aim was to identify the sources and amounts of finance that ensure the successful operation of farms. The research was conducted on a medium-size commercial farm "Saulaini". The farm had 190 hectares of agricultural land. The key kind of its business was milk production. The farm "Saulaini" had access to and used both kinds of finance. Since the establishment of the farm in 2001, the total investment made in the business has amounted to EUR 317.6 thousand, of which 37% was internal finance. The farm attracted external finance (approximately EUR 200 thousand) – a loan and EU funding – in order to purchase machinery. The production costs of the farm "Saulaini" exceeded its revenues and the farm made losses. However, EU support payments improved the financial performance of the farm. In 2016, the farm received EU financial support in the amount of EUR 46.7 thousand. Effective financial management on the farm contributed to its high liquidity ratio and high rate of return on capital.

Keywords: *financing, lending, farm, sources of finance, EU support payments, Latvia.*

Introduction

After developing a successful business idea, financing the business is the next most important step – the way how to acquire and invest funds in order that the enterprise can expand its economic activity.

At present, there are quite a lot of opportunities for acquiring finance to start up a new business as well as to develop existing enterprises. The key is to assess one's own abilities, then to seek creditors and investors and analyse whether it is possible to acquire national or European Union financial assistance.

Enterprise finance is a system of a legal entity's financial relations. The enterprise makes financial relations with capital owners, creditors, enterprise employees, national institutions, investors and business partners.

Financial relations have a common feature – a cash flow –, which is some kind of circulatory system for the enterprise, and the viability of the enterprise depends on the cash flow. The key task of financing an enterprise is to make a rational choice of sources of finance to finance its expenditures and achieve the desired revenue level. One of the key reasons why a well-operating enterprise needs additional finance is the expansion of its activity, requiring additional current and fixed assets.

Materials and Methods

The present research performed a review of the specific literature and used information from scientific databases (Science Direct). The research analysed the legal framework – European Union regulations and laws and Cabinet regulations of the Republic of Latvia – and acquired quantitative data from the Central Statistical Bureau (CSB) of Latvia.

To get insight into the ways of financing agricultural holdings and the amounts involved, the research employed the single case study method that allows performing in-depth examinations

of modern phenomena in real life contexts (Yin, 2013). B.Flyvbjerg (2006) believes that progress in various science disciplines has been achieved owing to particularly skilfully selected cases and an analysis of the cases. An examination of the CSB data revealed that the number of small holdings with a utilised agricultural area (UAA) of less than 50 ha decreased fast in Latvia, while the number of holdings with an UAA in the range of 100-200 ha strongly tended to increase. In the period 2010-2016, the number of such farms rose by 17%. One of the factors that affected the increase was the availability of funds for business expansion. The research performed an in-depth analysis of the amount and sources of lending to and financing for the farm "Saulaini", as the size and scope of its economic activity represented a medium commercial farm in Latvia. The farm "Saulaini" was established in 2001. The farm managed 190 hectares of agricultural land. The key kind of business of the farm was dairy farming (which was the key kind of livestock farming in Latvia), which accounted for 90% of the farm's revenue in 2016. Of the total area of the farm, 148 ha of agricultural land were used for feed production, while 42 ha were cropped with cereals and legumes.

Results and Discussion

Financing is determined by two kinds of principles – horizontal and vertical. The horizontal principle states that long-term investment has to be financed by own capital and borrowed long-term capital. However, the vertical principle prescribes that the key factors determining a ratio between own and borrowed capital are turnover stability and return on equity (Rurāne, 2005).

The sources of finance for enterprises are divided into internal and external.

Internal sources of finance are initially controlled by the management of the enterprise, the funds do not have to be acquired, as they are generated from economic activity. The internal sources of finance are as follows:

- enterprise revenues from sales;
- depreciation deductions;
- profits.

Compared with the other kinds of financing, internal financing (self-financing) has the following advantages: no cost of borrowing; no certain term of financing; an opportunity to repay a loan ahead of the schedule and reduce the amount of interest paid; own capital grows progressively; the financial security and creditworthiness of the enterprise are higher due to own capital (Saksonova, 2010).

External sources of finance are not controlled by the management of the enterprise up to the moment the funds are acquired.

The external sources of finance are as follows:

- equity financing;
- lending – all the kinds of it (incl. leasing, overdrafts etc.).

The key difference from internal financing is that the enterprise will have to pay for the borrowed capital from an external source of finance: in case of a loan – interest to a bank, while in case of equity financing – dividends to shareholders.

Agricultural enterprises in Latvia use several kinds of external financing for their development – European Union investment projects offered by the Rural Support Service (RSS), JSC Development Financial Institution ALTUM loans, loans for farmers granted by various credit institutions, as well as leases granted by machinery dealers. ALTUM is a government-owned financial institution that provides government support to some target groups in the form of financial instruments (loans, guarantees, investments in venture capital funds etc.). ALTUM offers the following programmes for farmers:

- land purchase loan programme;
- loans for purchasing current assets;

- SME growth loans;
- micro-credit programme;
- agricultural and rural development loan guarantee programme.

The data on the sources of finance used by the farm "Saulaini" in Table 1 reveal that the farm used both internal and external sources of finance. Internal financing accounted for the largest proportion of financing, even though depreciation deductions and retained profits were affected by the external financing acquired in previous years.

Source: authors' calculations based on farm "Saulaini" data

The farm used mainly internal sources of finance. In 2016, this trend began slightly changing, and the sources of both kinds of finance became equally significant.

As shown in Table 1, *European Union direct payments and national support payments* were of great importance for agricultural holdings in Latvia; the payments ensured the solvency and viability of most of the holdings. Unlike loans, this funding does not have to be paid back.

The economic performance data of the farm "Saulaini" (Table 2) indicate that the farm's production costs exceeded the revenues in the period of analysis. For this reason, support payments for both land management and agricultural products were very necessary to purchase machinery and modernise technologies. The farm could not be able to be solvent without the support payments, and its cash flow would be negative. Most of the support payments (approximately 90%) were composed of area-based payments and national decoupled and extra payments, as well as various national compensations and payments for complying with financial discipline.

Table 2 Economic performance of the farm "Saulaini" in the period 2013-2016, EUR

Indicators	**2013**	**2014**	**2015**	**2016**

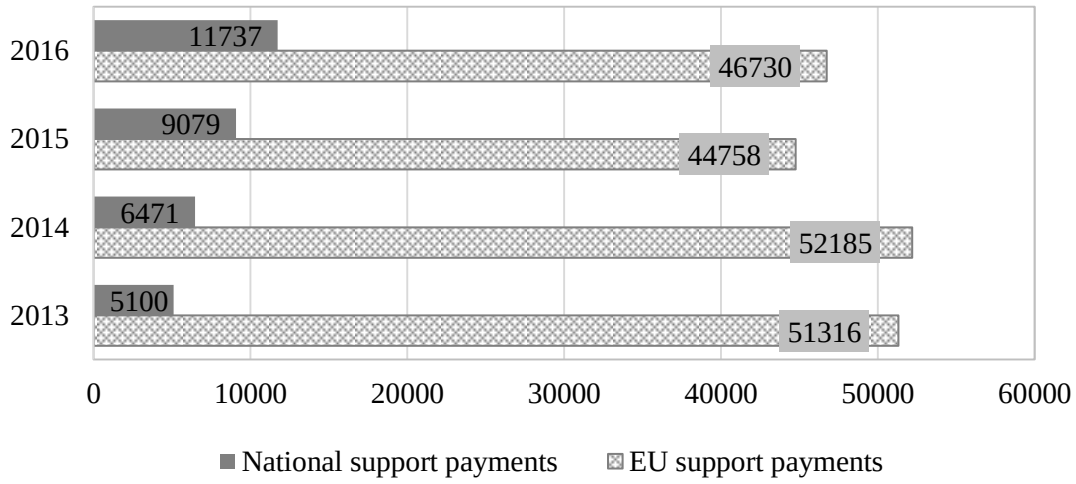
Source: authors' calculations based on farm "Saulaini" data

Area-based or direct payments represent annual national and EU financial assistance paid to farmers or forestland owners. Any natural or legal person is entitled to national and EU financial assistance that is paid for every hectare of agricultural land or forestland managed. The legislation, however, imposes obligations on the applicant, as well as makes the applicant assume responsibility for providing correct information to the Rural Support Service (RSS).
Since Latvia joined the European Union, the farm "Saulaini" has received both EU area-based payments and various national support payments.

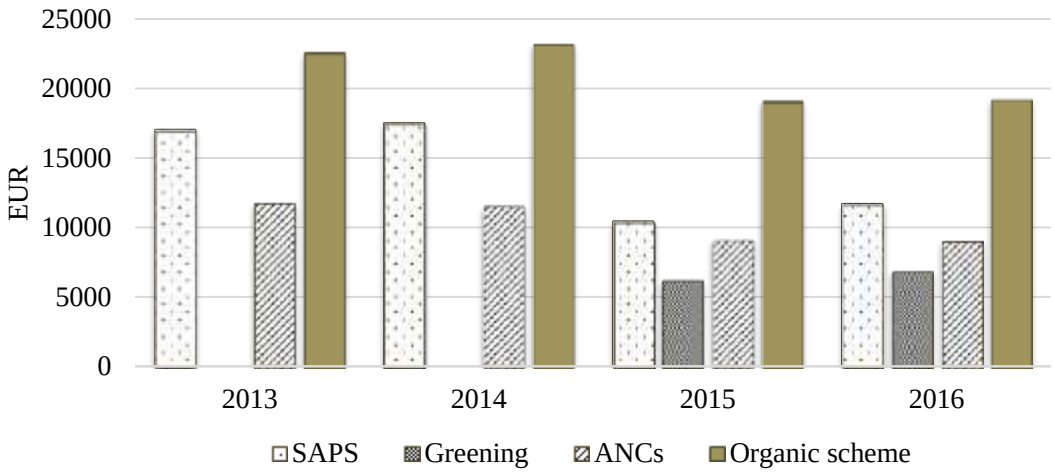
Figure 1**.** Amounts of European Union and national support received by the farm "Saulaini" in the period 2013-2016, EUR



Source: authors' construction

As shown in Figure 1, the amounts of EU area-based payments were considerably larger than those of national support payments, with small decreases in 2016 and 2016, which were determined by a decrease in the farm's land area by 10 ha. However, the amount of national support payments increased more than twofold in the period of analysis.
The farm "Saulaini" received three kinds of area-based payments: single area payments, organic farming payments and payments for areas with natural or other specific constraints. Since 2015, single area payments have been divided into two parts – the first part remained the same, whereas the other one was transformed into a new payment with a new name – the payment for agricultural practices beneficial to climate change and the environment or the green payment.

Figure 2. Breakdown of EU area-based support payments received by the farm "Saulaini" by kind of scheme in the period 2013-2016, EUR



SAPS – the Single Area Payment Scheme;
Greening – the Green Direct Payment Scheme for climate- and environment-friendly agricultural practices;
ANCs – compensatory payments for other areas with considerable natural constraints;
Organic scheme – payments for the preservation of organic farming practices and techniques.

Source: authors' construction based on farm "Saulaini" data

After the required amount of capital is identified, the farm invests it in its assets, which is a prerequisite for the expansion of the farm's business.
The need for investment is determined by a number of reasons, of which three main ones could be distinguished:
renewal of the enterprise's material and technical resources;
increase in output;
commencement of new kinds of economic activity (Leonoviča, 2005).
Using both internal and external sources of finance, the farm "Saulaini" has built up considerable material and technical resources by renovating its farm buildings and purchasing machinery. The amount of investment totalled EUR 317 thou. during the entire period of the farm.

Table 3 Breakdown of investment in farm buildings, constructions and machinery by the farm "Saulaini" by source of finance

Source of finance	**Investment, EUR**	**Breakdown of investment, %**
Internal financing	57 715	18.2
Mixed financing (farm's co-financing)	80 021	25.2
External financing	179 823	56.6
Total	**317 559**	100.0

Source: authors' calculations based on farm "Saulaini" data

An analysis of the farm's sources of finance revealed that the proportion of external financing in particular was the highest with 56.6%. The external financing was comprised of both bank

and ALTUM (development financial institution owned by the government) loans and considerable EAFRD (European Agricultural Fund for Rural Development) funding. The farm's internal financing would not be enough to make investments and build up its material and technical resources. However, as the amount of fixed assets increased, production costs in the form of depreciation deductions also increased, which made a significant effect on the economic performance of the farm but did not affect its cash flow.

Conclusion

Corporate finances is a system of relations of a business entity, which is formed by means of finance. The sources of finances for agricultural holdings as any enterprise are divided into internal and external. The largest proportion of internal finances of agricultural holdings is composed of depreciation and retained profits, yet their sizes depend on the external finances borrowed in previous years. In Latvia, external finances – EU and national support payments – are important for agricultural holdings to be operational. A very significant source of finances is European Union direct payments and national support payments. Unlike loans, this kind of finances does not have to be paid back.

GASTRONOMIC TOURISM IN LATVIA: FEATURES AND OPPORTUNITIES FOR DEVELOPMENT

Andra ZVIRBULE, Aina DOBELE

Latvia University of Life Sciences and Technologies, Faculty of Economics and Social Development, Jelgava, Latvia
*Corresponding author: andra.zvirbule@llu.lv

Abstract

As world trends show and according to the Guidelines for Tourism Development in Latvia for 2014–2020, the tourism industry represents one of the opportunities for economic growth in the country and one of the priorities of the services sector, as it makes a considerable contribution to the gross domestic product of the country and is a significant source of export revenues. The objectives of the tourism industry of Latvia are to reduce the effect of seasonality, increase the number of multi-day visitors and to contribute to the profitability of tourism products and annual increases in exports of tourism products. The research aim is to identify the most characteristic features of gastronomic tourism and to examine development opportunities for gastronomic tourism in Latvia. Specific research tasks: 1) to characterise the position and role of gastronomic tourism as well as to identify the characteristic features of it; 2) to assess the characteristic features of gastronomic tourism and the potential development of gastronomic tourism in Latvia. *Research methods used:* monographic, graphic, data grouping, analysis, synthesis. The research concluded that the most characteristic features of gastronomic tourism in Latvia were spatial stillness, regionality, the individuality of a gastronomic tourism product, the effect of seasonality, the focus on domestic tourism and the concentration of tourism activities in historical regions and ethnographic and industrial centres. To effectively contribute to the development of gastronomic tourism in Latvia, it is required to make a number of enhancements to strengthen regional gastronomic tourism, which would link the cultural and historical heritage and gastronomic tourism.

Keywords: *gastronomic tourism; kinds of gastronomic tourism, development.*

Introduction

In Latvia, just like elsewhere in the world, food is an integral component of culture, with large potential for tourism. Gastronomy as one of the mirrors of local culture has become an important resource in the tourism industry, where the leading role is played by the local culture and traditions. In Latvia, the supply of gastronomic tourism products begins representing high-quality, interesting and unique traditions of cooking, serving and eating food, which is a successful prerequisite for the expansion of gastronomic tourism in Latvia. To purposefully develop and contribute to the development of gastronomic tourism in Latvia, it is required to identify the resources and typical features that characterise and represent gastronomic tourism in Latvia as well as to ascertain development opportunities for this kind of tourism in Latvia. The Sustainable Development Strategy of Latvia until 2030 states that one of the cornerstones of sustainable national development is the use of the potential of cultural heritage for the development of creative tourism. Creative tourism is one of the ways for Latvia to use the potential of its tangible and intangible cultural heritage and cultural landscape. It is an opportunity to support the economy of local communities, to promote the preservation of the rural cultural environment, the development of craftsmanship and creative industries, particularly in rural territories. However, tourists have an opportunity to feel the culture, environment and traditions of the relevant community in an authentic location and even for a moment to have the feeling of being a local inhabitant.

The Guidelines for Tourism Development in Latvia for 2014–2020 address not only the role of tourism in national development but also highlight the significant effect of cultural tourism on the strategy for this industry. If we adhere to the definition that cultural tourism is a kind of tourism and the key purpose of travel by tourists is to get familiarised with the culture and cultural heritage of one's own nation or other nations, a number of authors stress both the cultural heritage and the diverse dimensions of cultural heritage: the tourism dimension, the dimension of utilisation of cultural heritage objects, the dimension of cultural experiences and the dimension of consumption of local products (Richards G.,2007). Modern tourists become more and more educated and experienced, and they are interested not only in visiting foreign countries and the most interesting sightseeing places there but also in getting familiarised with the local culture. One of the elements of a culture is its cuisine – national and traditional dishes and beverages and the ways of preparing and enjoying them. One of the kinds of tourism – gastronomic tourism – has emerged and developed within this element. The key purpose of travellers is to enjoy high-quality dishes and beverages of national cuisine. Gastronomic tourism activities usually occur in historical and ethnographic areas where local cultural traditions are kept alive or in areas where the art of cooking is advanced. The World Tourism Organisation states that gastronomic tourism is based on experimental taste experiences, learning from other cultures and knowledge of cooking dishes and qualities and features of the dishes. Culinary tourists partly or fully plan their travel being subordinated to learning and enjoying the local cuisine and other activities related to the peculiarities of the local cuisine and culinary heritage (World Tourism Organisation, 2012). Other authors, however, stress the association of a region's opportunities for development with gastronomic tourism that involves many opportunities for entrepreneurship and business, e.g. restaurants and hotels, cooking art schools, dish and beverage festivals and farmers' markets (Yeoman et al., 2015). The role of tourists themselves is essential, as they contribute to the development of the particular region. Therefore, it is important to make tourists in particular go to a tourism object or place in order to become gastronomic tourists and consume gastronomic tourism products – local food and dishes (Hall et al., 2007). Some authors, e.g. Kiralova and Hamarneh (Kiralova, Hamarneh, 2017), significantly complement this economic benefit by asserting that food tourism is a local phenomenon making a positive effect on the economy, employment and local cultural heritage.

Thus, research on gastronomic tourism in particular and its characteristic features would be one of the ways how the regions of Latvia could promote their tourism development strategies.

Targets, Materials and Methods

The research aim is to identify the most characteristic features of gastronomic tourism and to examine development opportunities for gastronomic tourism in Latvia. Specific research tasks: 1) to characterise the position and role of gastronomic tourism as well as to identify the characteristic features of it; 2) to assess the characteristic features of gastronomic tourism and the potential development of gastronomic tourism in Latvia.

The research used mostly information sources and research papers on the classifications and development of gastronomic tourism. The legal documents, strategies and policy documents of the Republic of Latvia were employed to identify the situation in the country.

Research methods used: monographic, graphic, data grouping, analysis and synthesis.

Results and Discussion

Role, position and characteristic features of gastronomic tourism.

An analysis of the most important trends in gastronomic tourism in the world allows concluding that one of the threats to it is globalisation that enables tourists to enjoy worldwide popular dishes in any country. Resistance movements increasingly emerge in the world owing

to globalisation, e.g. the slow food movement that views food not only from the perspective of nutritional value but also in the context of lifestyle. In recent years, the development of gastronomic tourism as regional tourism occurred owing to culinary media, social networks as well as the interest of tourists themselves in it. Travel and food has become inseparable owing to various television shows that stress the importance of tasting local and authentic dishes when traveling; culinary television shows tell their viewers about and show how to cook national dishes. Examining the behaviours of consumers, i.e. tourists, it is important to comprehend what motivates individuals to travel. Most often, the following five motivators are emphasised: physical, emotional, personal, personal development as well as social status expression and cultural motivators (Swarbrooke, Horner, 2008). All the mentioned motivators could be attributed to gastronomic tourism: the physical motivator is hunger; the emotional motivator represents all the emotions related to enjoying a dish – wellbeing, pleasure, surprise, adventure; the personal motivator is a chance to meet friends and family during the meal; the personal development motivator represents knowledge about dishes and new skills; the social status expression motivator relates to enjoying exclusive or special dishes; and the cultural motivator contributes to becoming familiarised with a new culture and nation through dishes.

However, the role of dishes in motivating tourists, according to Hjalager and Richards (2002), involves four categories of motivators: physical, cultural, interpersonal, social status expression and prestige motivators.

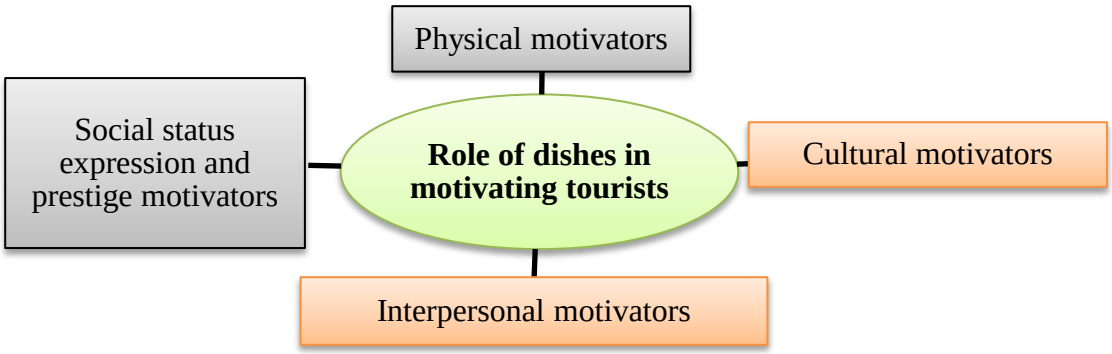

Fig. 1. Role of dishes in motivating tourists

Source: authors' construction based on Hjalager, Richards, 2002

If focusing less on the physical motivator, the cultural motivator in particular shapes gastronomic tourism, as it is an essential factor affecting the development of gastronomy and tourism. National dishes represent one of the intangible values of national culture; therefore, tasting local dishes also involves enjoying a new culture if the dishes are authentic, historical or specific to the particular culture and location. The interpersonal motivator explicitly represents a social function that takes the form of an important dimension in gastronomic tourism. Active communication and an opportunity to learn local traditions in cooking and serving dishes as well as a story about the dishes are an important tourism motivator as well.

Food tourism as a kind of special interest tourism is divided into several segments, and food tourists are defined according to some typical features: the extent of their interest in it and the importance of dishes as a motivator of travel.

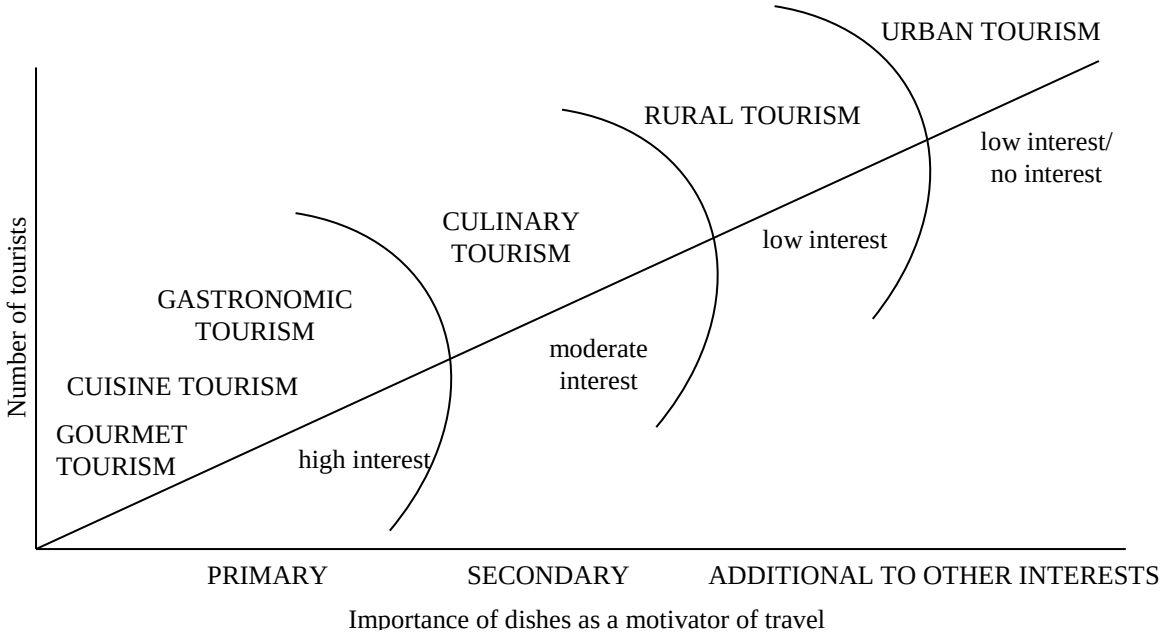

Fig. 2. Division of food tourism as a kind of special interest tourism

Source: authors' construction based on Hall et al., 2007

Food tourism is specific to the following kinds of tourism: rural and urban tourism, culinary tourism, gastronomic tourism, cuisine tourism and gourmet tourism. The interest of rural/urban tourists in food tourism is low. Food tourism as a motivation for travel is only an extra interest, which is not primary. Culinary tourists are moderately interested in food tourism, and often it is a secondary motivation for travel. Gastronomic and cuisine tourists are highly interested in food tourism, and the food as a motivation for travel is key to both kinds of tourism and play a decisive role in the choice of a destination. Gourmet tourists have the greatest interest in food tourism, as the determinant and primary motivation for travel is their interest in food. Figure 1 shows a causal association – the greater the interest in food, the smaller number of individuals are involved. For example, in rural/urban tourism, which is a popular kind of tourism, the number of tourists interested in food tourism is relatively large, while in gourmet tourism, in which the interest in food is primary and key, the number of interested tourists is small.

Characteristic features of gastronomic tourism in Latvia and the potential development of it.

According to a research study carried out in one of the regions of Latvia (Kurzeme), there were five key trends that promoted national dishes and contributed to growth in gastronomic tourism in the region:

1) increase in the standard of living (as incomes increase, consumers more often spend their money on dining outside their homes; therefore, domestic gastronomic tourism among regions emerge);
2) demographic and household changes (the concentration of households around major cities and the capital city creates opportunities to develop domestic gastronomic tourism);
3) rejection of fast food restaurants (tourists increasingly reject fast food; instead, they prefer local foods that reflect local national traditions);
4) increase in the number of multi-cultured consumers (globalisation, growth in tourism in the Baltic region increase the demand for local gastronomic tourism services along with rural and urban tourism services);
5) influence of celebrity chefs and the media (magazines, books, online magazines, television shows and the popularity and visibility of culinary shows).

An essential role in the growth of gastronomic tourism is played by the tourism target markets set by the Tourism Marketing Strategy of Latvia, which requires accurately drawing up guidelines for gastronomic and cultural tourism and examining the motivations of the tourists.

Table 1 Foreign tourism target markets set by the Tourism Marketing Strategy of Latvia

	High-priority target markets	**Priority target markets**	**Secondary target markets**	**Prospective target markets**
Countries	Lithuania, Estonia, Germany, Russia, Sweden, Finland	Norway, Denmark, Great Britain, Italy, Spain, Netherlands	Other European countries	USA, Japan, China, India

Source: Tourism Marketing Strategy of Latvia

The strategy has set Lithuania, Estonia, Germany, Russia, Sweden and Finland as high-priority foreign target markets based on the fact that most tourists arrive from these countries, as well as they stay longer at accommodation establishments in Latvia. Gastronomic tourism services are mainly focused on this target audience.

Norway, Great Britain, Italy, Denmark, Spain and the Netherlands have been set as priority target markets based on the number of incoming foreign tourists, easiness to get to Latvia as well as a suitable supply of tourism services in Latvia. All the other European countries have been set as secondary target markets where minimum marketing activities are carried out. The USA, Japan, China and India are regarded as prospective target markets; at present, there is no strong cooperation with the countries, yet in the future they could represent potential for tourism.

The Tourism Marketing Strategy of Latvia as well as several informal discussions with tourism industry professionals have suggested certain approaches to be employed to motivate tourists to visit Latvia as a destination of gastronomic tourism or make the tourists stay longer, which could be achieved by means of specific activities. The activities are as follows:

1) offering dishes as a tourist attraction (focus on cities);
2) making foods an integral component of a tourist product (special tourist routes; focus on rural tourism);
3) tasting dishes as part of tourism experiences (gourmet tourism and special activities, such as "*Taste Latvia"*);
4) stressing the role of food in the cultural heritage (cuisine tourism and rural tourism);
5) making a link between tourism and food production (synergy between tourism and entrepreneurship, with a focus on the regions of Latvia; the promotion of craftsmanship and home production).

Although tourism in Latvia tends to grow dynamically, the opportunities for gastronomic tourism could be enhanced. A series of activities have been carried out and strategic guidelines have been designed at the regional level, yet some activities are at the initial stage, e.g. developing a common tourism brand, carrying out marketing activities aimed at the target audience in particular, strengthening the role of regional tourism information centres and developing initiatives with rural entrepreneurs.

Conclusions

1. Gastronomic tourism is not only one of the kinds of tourism; it also encompasses a broad system of components: accommodation, agriculture, transport, regional food producers, rural tourism and catering enterprises.
2. The development of gastronomic tourism is shaped, on the one hand, by tourists for whom the role of dishes and the related motivation are important, while on the other hand, by a number of economic and regional factors: the standard of living, the number of multicultural consumers, cooperation with food producers and other factors.
3. At present in Latvia, gastronomic tourism is mainly based on domestic demand, yet marketing activities have been carried out to attract foreign gastronomic tourists to Latvia.
4. Further activities that allow the regions of Latvia to accurately design strategies for promoting gastronomic tourism based on the geographic location as well as the overall situation in the region should be identified and designed as well.

STRUCTURAL ANALYSIS OF SOCIO-ECONOMIC DISPARITIES IN ECONOMIC DEVELOPMENT OF THE REPUBLIC OF MOLDOVA

Olga SARBU, Liliana CIMPOIES*

Department of General Economics, State Agrarian University, Moldova
*Corresponding author: o.sarbu@uasm.md

Abstract

The concept of regional development is in fact an European idea, one of the basic principles of the EU's functioning and a main condition for administrative reform in the Member States, candidates or associate countries. In Moldova, the real development of the economy takes place asymmetrically from a regional point of view. The regional disparities in the country are due to the uneven distribution of production factors, urbanization levels, quality of technological infrastructure and institutional. The origin of such factors may result in the creation of a potential gap within the country and in the perpetuation of existing social and economic imbalances, affecting as result the economic growth. When statistical aspects and regional accounts started to be developed, the analysis of the regional dynamics in the study focused more on the identification of the convergence or divergence processes, of the concentration poles at different sectors level as services, investments, industry and agriculture. The aim of this research is to identify the existing socio-economic disparities in regions development and to analyze its impact on Moldova's economic development. Different research methods will be used in the study such as: systemic analysis, functional approaches, retrospective analysis (historical approach), diachronic analysis (analysis of changes in the structure of object over time). Methods of scientific knowledge, such as comparison method, graphical analysis and logical thinking methods, statistical analysis will allow to carry on a systemic approach of the researched problem, to identify regularities and connections in regional development and to draw conclusions and recommendations on the researched aspect.

Keywords: *agriculture, economic development, regions, regional policy Republic of Moldova.*

Introduction

Regional disparities in terms of economic development represent a challenge in the modern world. The uneven concentration of financial assets generates major inequalities in living standards between different territories. Moldova is not an exception, registering an enormous concentration of the economic potential in large cities (Chisinau, Balti). There are present major discrepancies in the standard of living between large cities and smaller localities, but also between urban and rural localities within the regions. The policies promoted in the area of Moldova's regional development start from the notification of local, inter and intra-regional disparities, stipulating the ways to minimize these disparities as an objective of the country's regional development policies. Regional development has a national and a European dimension. In the case of the development of national regional policies, the socio-economic differences between different regions require to promote concepts and programs that address the issue of regional development. Regional development has also been linked to industrial policy. In recent years, the national dimension of regional policies has dimmed, but the European dimension in this area has become more dynamic. The first regional programs at European level were initiated within the E.U., after being joined by countries that, due to a weaker level of development, caused significant disparities.

The main objectives of regional development are: achieving balanced and sustainable socio-economic development in Moldova; reducing the imbalance in socio-economic development levels between and within regions; strengthening financial, institutional and human opportunities for the socio-economic development of the regions; support the activity of local public administration authorities and local authorities, oriented towards the socio-economic development of localities and coordination of their interaction with national, sectoral and regional development strategies and programs.

Material and Methods

The given research aims to analyze the structure of the economic disparities in the development of Moldova in terms of the following criteria: the share of allocations for regional development as a share of Gross Domestic Product (GDP), the contribution of development regions to the Regional Gross Domestic Product (RGDP), the contribution of development regions in the value of agriculture, forestry and fishing as part of the RGDP. The social dimension of regional development was based on the analysis of the disparities in the quality of education, health, consumption and social relations, linked to the components of structuring or conditioning of regional differences, accessibility to services, infrastructure and employment. The data of the National Bureau of Statistics (NBS) of the Republic of Moldova to determine and analyze the indicators were used. In order to achieve the research objectives the following research methods were applied: the analytical method; method of systemic analysis; descriptive method; the synthesis method; the logical framework method used to analyze the indicators; the method of quantitative and qualitative analysis, which was applied to the analysis and interpretation of the indicators

Results and Discussion

Moldova has entered the process of transition to a market economy with significant regional imbalances caused by current production structure, being particular the predominance of the agri-food sector, the dependence of the social and economic development of small towns on a limited number of large industrial holdings. Thus, stimulating economic growth outside the largest cities, especially in rural areas that have suffered from the loss of traditional agri-food supply markets, has been one of the main challenges for the Moldovan authorities since independence.

Sustainable regional development is an imperative assumed by Moldova and confirmed by the Government through its firm commitment to equitable distribution of development opportunities across the country. This is confirmed both at the legislative level by Law No.438-XVI of 28 December 2006 on regional development adopted at the end of 2006, with subsequent amendments approved during 2010 and at the level of strategic planning, with regional development taking place in the National Development Strategies (2010-2012, 2013-2015, 2016-2020).

In order for a sector to develop efficiently, it must benefit from a strong financial support. Thus, a regional development financing system was developed within the framework of the implementation of the National Regional Development Strategy (NRDS) 2010-2012. In fact, this system or mechanism has demonstrated relative viability, flexibility and sustainability. However, this mode of financing is exclusively focused on the National Regional Development Fund (NRDF), the resources of which are insufficient compared to the needs on this dimension. For example, according to the State Budget Law from 2016, about 200 million Moldavian Lei (MDL) were allocated for NRDF, which represents almost 0.8% of its revenues or about 0.3% of GDP. It is, in fact, a small sum of what is to be done under the new NDSR project for 2016-2020, including rallying to the priority priorities for regional development (Morcotolo, 2014)

Compared to other European countries, Moldova is distinguished by a very pronounced economic polarization, so that half of its GDP is made in the capital city, which concentrates only a quarter of the country's population. The most visible evidence of this economic polarization is the concentration of economic activity, the best human resources and the best infrastructure in the largest city. The other regions in the country are even less active economically. This economic and geographical structure is clearly confirmed by a number of indicators: migration, poverty, the number and density of companies, the number of employees, the value of sales, the evolution of budgets, etc.
According to recent NBS data, one of the biggest regional discrepancy is an excessive concentration of economy in Chisinau, followed by a large difference in the Balti municipality (Table 1).

Table 1. Moldova's Gross Domestic Product by development regions, MDL

Regions	2013	2014	2015
Chisinau municipality	56.038,0	62.869.976,0	71.535.731,0
Center	15.964,9	17.973,6	19.933,0
North	18.381,9	20.519,0	21.818,7
South	9.001,7	9.704,2	10.073,7
UTA Gagauzia	2.834,8	3.064,6	3.210,1

*Source: based on data from National Bureau of Statistics, 2015-2017

The emphasis of these two cities is largely focused on structurally differentiating the factors of production that exist in these regions and the rest of the country. The indicators in the agricultural and industrial sectors are above the values registered in the service sector, which highlights the fact that the latter is concentrated in the Chisinau municipality and has a small presence in the other development regions. Thus, for Moldova two major aspects of the regional economic development are characteristic. The whole economy (with the exception of Chisinau municipality) would be specific agricultural land, while for Chisinau and partially Balti - more focused on services and manufacturing. However, the lack of statistical data and relevant analyzes has affected the good policy implementation in the field and has been reduced to a more short-term process without addressing in detail the main development factors and issues.
Besides the uneven distribution of the sectors in the regional profile, the regional economic discrepancies are confirmed also at the GDP level in territorial profile, respectively in absolute and relative terms calculated by the NBS on each territorial administrative unit and finally in the regional aspect (Figure 1)

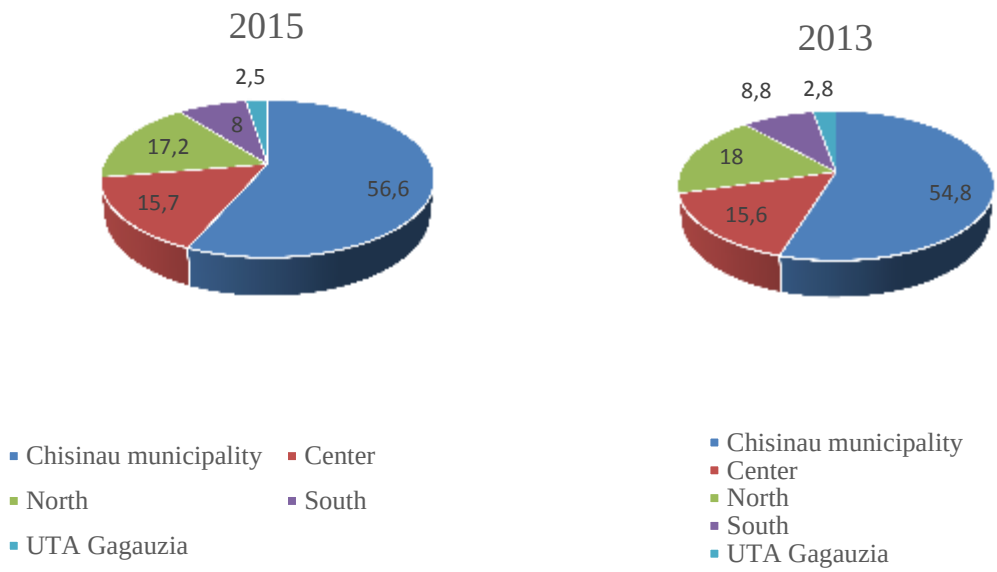

Figure 1. Development regions contribution to Moldova's GDP, Percentage
*Source: based on data from National Bureau of Statistics

About 55% of GDP is concentrated in Chisinau municipality, over 8% in Balti municipality, which is also part of the North-East Region, and UTA Gagauzia - 2.8%. In fact, a geographical concentration of the economy shows that the share of a region in a territorial profile corresponds to its share in the national economy as a whole. The geographic concentration of agriculture on a territorial or regional level is much more homogeneous than in the industrial sector. Thus, to have a similar base in the given sector, statistical data were used on each district on average fruit per hectare for the main agricultural crops in Moldova - wheat, barley, maize and sunflower. The agricultural sector, unlike the industrial one, is important for the economies of all districts. Respectively, the same statistical data show that productivity indicators in agriculture are more or less similar to those in the industrial sector. Even though the agricultural sector has recently shown contradictory tendencies to move in the same direction, regional differences in this sector remain well below those of industry, largely due to weather conditions.

Table 2. Contribution of development regions to agriculture, forestry and fishing as part of Moldova's Regional Gross Domestic Product, thousands MDL

	2013		2014		2015	
	Value, thousands MDL	Share, %	Value, thousands MDL	Share, %	Value, thousands MDL	Share, %
Total	12383120	100	14619434	100	15001568	100
Chisinau municipality	215860	1,75	319511	2,20	304463	2,03
Center	4068450	32,85	4898207	33,50	5220385	34,80
North	4383730	35,4	5137942	35,14	4968889	33,12
South	2982674	24,09	3386151	23,16	3542722	23,62
UTA Găgăuzia	732406	5,91	877623	6,00	965109	6,43

*Source: based on data fron National Bureau of Statistics

The largest value of agriculture, forestry and fishing as contribution to Regional Gross Domestic Product is obtained in the Center and Northern area (about 34%). The Southern area in the analyzed period is 23%, UTA Gagauzia - 6%, Chisinau 2% (Table 2). Among the major causes that led to the increase in disparities can be mentioned: location and scale of foreign investments in development regions, loss of competitive capacity of enterprises, both on domestic and foreign markets, due to the high moral and physical wear out of technologies and equipment (especially in regions located in the eastern part of the country) and limited access to finance for SMEs. At the same time, economic development leads to the emergence of a phenomenon manifested by the emergence and outline of areas of economic decline that is accompanied by a social decline in which there is a profound contradiction between two important factors of growth: labor and capital. The immediate consequence is rising unemployment and falling living standards in the area. Such areas are becoming underdeveloped and become potential sources of social conflict (NBS, 2016, 2017). The social dimension of regional development focuses on the analysis of the social disparities in the quality of education, health, consumption and social relations related to the components of structuring or conditioning regional differences, namely urban - rural, accessibility to services, infrastructure and employment. These taken as a whole are the basic components of the space of the economic and social development inequalities manifested at the regional level (NBS, 2015). Thus, aspects related to the social component of regional development in the Republic of Moldova can be appreciated by the estimation of the number of existing early education institutions. As shown by the most endowed calculations with such institutions are the Center, and North regions followed by the Southern region (Table 3).

Table 3. The distribution of the early education institutions by development regions, 2012-2016, number of units.

	2012	2013	2014	2015	2016
Chisinau municipality	157	159	160	160	161
North	465	473	477	484	487
Center	467	469	486	484	489

UTA Gagauzia	60	60	60	60	61
Total	1418	1440	1453	1461	1469

*Source: based on data fron National Bureau of Statistics

Not less important are the dynamics of pupils and teachers in the primary and secondary general education institutions. There is a trend of permanent decrease in the number of pupils per 10000 inhabitants in the period 2013-2017 on average in the republic, but also in the regions North, Center, South, ATU Gagauzia. Only in Chisinau the number of students per 10000 inhabitants increased from 980 in the 2013/14 study year to 1014 pupils in 2016/17. The number of pupils to a retiring teacher during the analyzed period did not suffer major changes ranging from 10 to 13 students. Differences between regions in terms of water supply and sewerage infrastructure imply specific approaches to regional development. The best equipped are the households in Chisinau, the Center region followed by the households in the North and South Regions. Thus, economic development is achieved not only to meet basic material needs but also to provide resources to improve the quality of life in health, education and a better environment.

Conclusions

Until recently, the regional economic disparities were subjectively identified, currently they are relevant and objectively, including on the basis of official statistical data. The data show differences in enormous economic development that separates the Chisinau region from the rest of the country, whose GDP per capita represents almost 60% of the rest of the country. The country's economy is highly polarized and with pronounced regional gaps. The geographical concentration of population, levers of economic growth, industrial production and services, as well as investments from all sources are located in Chisinau or its municipality. This enormous gap starts from the accumulation in the largest city of services with an intensive added value, while the industrial sector continues to develop. The agricultural sector, unlike the industrial one, is more important for the economies of all districts. Respectively, the same statistical data show that productivity indicators in agriculture are more or less similar to those in the industrial sector. Even though the agricultural sector has recently shown contradictory convergence trends, regional differences in this sector remain well below those of industry, largely due to climatic conditions. Regional development must be linked to structural reforms, and implicitly to the size of the most dynamic sectors - manufacturing and service sector. The actual structural disparities between the capital and the rest of the country indicate that in the absence of an economic structure reform of at district level for these branches, is not possible to reach a territorial development convergence. Is important to elaborate at national level a single system for monitoring all interventions within the development regions in order to properly assess their level of development and subsequently to develop sectoral development programs in the context of cohesion policies, taking into account good practices and the experiences of European countries.

SOYBEAN WAR IN PARAGUAY: THE SOYBEAN BOOM'S FLOW FROM BRAZIL TO PARAGUAY, ITS SPILLOVER EFFECTS AND STATE RESPONSES

Juan Francisco FACETTI*, Cristina CABRERA

Chair of Environmental Management and Evaluation
Dept.of Geography and Environment FIUNA- Universidad Nacional de Asuncion
*Corresponding author: jfacetti@ing.una.py

Abstract

This paper identifies the causes and effects of the soybean boom in Paraguay that took place from 1960 to 1990 when the Brazilian farmers massively migrated. The paper analyze the diverse and complex causes of this migration and agriculture land expansion. The Brazilian farmers and their descendants have easy access to financial aid, technical assistance, and technology. Institutional weakness, lack of transparency and low public participation in building policies and corruption is evident in several ways. Violent clashes between peasants and security forces ingnited as a result of displacement of peasants, massive deforestation, indiscriminate use of agrochemicals and lack of governmental assisstance. The Paraguayan government not only has not provided the necessary assisstance to the peasants for decades but also through its little to no control, facilitated the big actors' predation of natural resources and displacement of peasants. The Zero Deforestation Law was examined briefly, showing its impressive results. Enacting of the Zero Deforestation Law and the rigorous enforcement helped reduce the deforestation by 80-90 %. This reduction is a clear example that shows that when the State acts effectively in cooperation with civil society, regardless of its limitations, improvements can be experienced, benefiting thousands of citizens. The soybean crop expansion, although representing an important proportion of the Paraguayan GDP growth, must be regulated carefully considering its social-environment side effects and the violent conflicts that it may install between the actors within the society. Environmental issues must be subject to strict regulation and control to ensure the valuable resources are cared for an sustainable use.

Keywords: *Atlantic Forest of Paraguay, environmental security, deforestation, migration, soybean production.*

Introduction

The massive Brazilian migration to Paraguay started in the 1960s and continued in the next decades. The majority of the Brazilian migrants and their descendants, mostly farmers, remain until today in the Eastern region of Paraguay, bordering Brazil. Many of the pioneers had previously grown crops in Brazil in the nearby provinces such as Sao Paulo, Río Grande do Sul, Santa Catarina, and Paraná. They worked there in an environment similar to the Paraguayan: an ecosystem of subtropical forest that, once dismantled, offered a fertile soil, and a excelent climate. Therefore, the Brazilian farmers found exceptional conditions to reproduce their production system in Paraguay (Souchaud, 2007). Over the years, soybean became the flagship product, tending to monoculture and transforming the productive conditions and the environment of the region. Even though official data is scarce, thus hindering the possibility of accurately magnifying this process of migration and population, an idea can be formed based on the available data and estimations. The first areas to receive this massive immigration were the departments of Amambay and Canindeyú, but since the 1970s, most of the newcomers have established in Alto Paraná (Souchaud, 2007). 45.6 % of the Brazilian immigrants in Paraguay reside in de departments of Alto Paraná, and around 20 % in Canindeyú (Ayala Godoy, 2014). On the other hand, the demographic and economic

changes that came with the new settlers have impacted the concerning areas in numberless ways. The environmental effects of the soybean agriculture cannot be overlooked, as millions of hectares of forest have been lost. The Upper Parana Atlantic Forest was especially affected.

Material and methods

In order to better understand factors linked to the reasons of soybean expansion in Paraguay, we began with documentary research and through systematizing, tabulating, and statistically treating agronomic and demographic data from the Central Bank and Directorate for Census and Statistics. The secondary data research focused on the prices of commodities, prices of lands in Brazil and Paraguay, institutional framework of the environmental sector, corruption index in Paraguay and environmental crimes and the expansion's impacts focus on land use change in Paraguay. The crop area dataset from Paraguay was obtained from the database available at World Wildlife Fund (WWF) - Paraguay. The crop area data set from Brazil was obtained from the Series Historicas database of the Companhia Nacional de Abastecimento (CONAB) and from tradingeconomic.com. This page provides present historical data, chart and statistics. Soybeans present data and historical chart was last updated on September of 2018.The prices of lands in Paraguay were obtained from research done in paraguayan realtor web pages and interviews to certifyed appraisals. Fieldwork was then carried out between February 2016 and July 2016. In-depth interviews were carried out with indigenous farmers of the indian village of Puerto Barra in Nacunday (Mbya ethnicity), and representatives of governmental and non-governmental institutions in the departments of Caaguazu and Itapua. Non-governmental institutions included NGOs (WWF Paraguay, FeCoProd).

Results and Discussion

Causes of the Migration of Brazilian Soybean farmers to Paraguay. The causes of the migration of Brazilian farmers to Paraguay are diverse and complex. There are many aspects to it including economic factors, environmental factors as the good quality of the arable lands available in Paraguay, and institutional weakness in Paraguay, which meant less regulation and enforcement. In the following sections, these factors will be discussed.

Soil Quality. The Agricultural and Forestry Atlas of Paraguay (Vázquez, 2011) clearly shows the increasing soybean production experimented between 1991 and 2008. The cultivated area escalated from slightly above 200,000 hectares to 700,000 in Alto Paraná during this period. Meanwhile, the production grew from 500,000 tons to almost 2,000,000 tons. The mentioned Atlas shows that the best performance of the soil is precisely allocated in the departments where most of the Brazilian migrants live: Alto Paraná and Canindeyú. In some areas in these departments, the performance reached around 6 tons per hectare in 2017[15]. This increase shows the high quality of the Paraguayan soil in these areas.

Land Price Evolution in Paraguay and Brazil. The differences between Brazil and Paraguay are, in this aspect, significant, although the evolution through the years followed similar patterns. Santos Telles, *et al.* (2016) explain that since the last years of the 1960s until the first years of the 1990s, land prices in Brazil experienced successive periods of increases and stabilization. For most of this period, instability was the reality, but the prices tended to increase and on very few occasions they decreased. Croplands' prices escalated from about two thousand dollars per hectare in 1994 to almost five thousand in 2009 (Santos Telles *et al.*, 2016). Meanwhile, in Paraguay, agricultural land also experienced significant increases in its prices. The average prices climbed from 65 USD/ha. in 1995 to 1,300 USD/ha. in 2012 (Capital Campo, 2017; Salcedo, 2014). See this evolution in Table 1. Although the increase

15 The national average these years reached 3.2 tons/ha. ("Sojapar rompió nuevo record", 2017)

has been phenomenal (more than ten fold in less than 20 years), the prices remain lower than in Brazil. Nowadays, prices can range from 12,000 to 15,000 USD/ha.

Table 1. Paraguay's arable land price evolution from 1995 to 2012.

Year	USD/ha	year	USD/ha
1995	65	2004	328
1996	92	2005	388
1997	121	2006	480
1998	149	2007	658
1999	182	2008	700
2000	215	2009	768
2001	248	2010	879
2002	271	2011	1.042
2003	293	2012	1.300

Access to Agricultural Technology and Biotechnology. As Brazilians moved to Paraguay and found good quality lands at comparatively low costs, access to technology became vital to assure high productivity. This explains the transformation of agricultural production in Paraguay. Mechanization extended, and so did the sizes of the farms. Brazilians had an advantage in this aspect, having preferential access to information, technological solutions, training, consultancy services provided by EMBRAPA[16].

Currency Dynamics and its Impact on farmers' Profits. As much of the soybean production that is destined to the international market and so traded in US dollars, the exchange rate has an important influence in the price of the products and the profits made. Brazil and Paraguay experienced devaluations in their national currencies during the 1990s, facing a stronger dollar. In the first years of the new millennium, the Paraguayan Guaraní's value was three times less than its value in 1995 (BCP, 2018). The rise in local prices also reaches the soybean production. However, in this case, farmers get increased incentives due to their products' better prices in the international market (Richards *et al.*, 2012). "*From 1996 to 2002, as global prices for soybeans were stable in US dollars, in Brazilian reales, Paraguayan guaranies, and Bolivian bolivianos, prices were approaching historical heights*" (Richards *et al.*, 2012: 455).

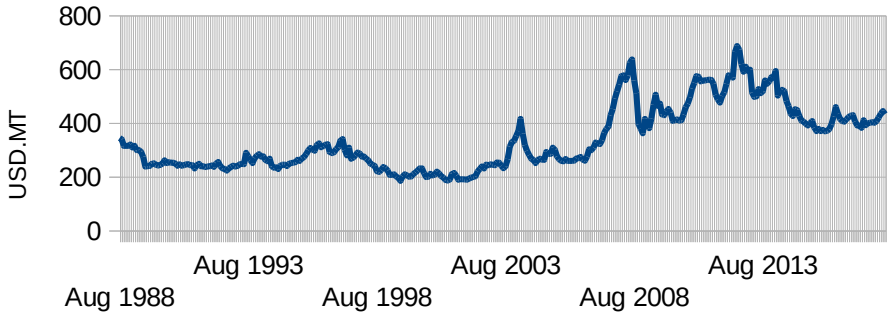
Access to Financial Support. The National Economic and Social Development Bank of Brazil (BNDES), founded in 1952, has played a critical role in financing development in diverse sectors of the Brazilian economy. Companies, rural farmers and entrepreneurs have been subject of the financing mechanisms of the BNDES for decades, and the effects have overflown Brazilian borders. After the 1950s' Government priority in industrialization, many policies oriented to the primary sector followed, leading to an essential increase in rural credit and other mechanisms of support. This resulted in a rapid expansion of crops as soybeans, whose area increased from 0.9 million ha. in 1969 to 6.4 million ha. in 1976. The increasing rates continued in the next decades (CONAB, 2018). The National System of Rural Credit, established in 1965, provide access to credit with low interest rates. The amounts available for such operations increase every year and Brazilian farmers continue to benefit from the strong policies its government is implementing (Lopes *et al*, 2016).

Prices of commodities. From the relatively low prices registered in the 1950s, the increase began to be consistent in the late 1960s. The decade of 1970 witnessed important prices' raise, reaching historic highs in the second half (TradingEconomics.com, 2018). The prices in the next decades showed a relatively stable tendency despite the increases and decreases that the

16 The *Empresa Brasileira de Pesquisa Agropecuária* (Embrapa) is a public enterprise that conducts reaserches in agriculture and cattle.

price experienced. This tendency is shown in Figure 1. The profits, continued to grow, due to the tendency in exchange rates previously described, as well as the lower production costs emerging from the new technology available and the greater productive efficiency.

Figure 1. Price evolution of soybean from 1988 to 2018.



Institutional Weakness and corruption: Although both Brazil and Paraguay have environmental laws, the levels of enforcement are very different. Having lower levels of enforcement and control by the government made it easier and cheaper to produce in Paraguay.

Weak Capacity. The Environmental Secretary (SEAM) was created in 2000 when a significant part of the process of immigration of Brazilian farmers in Paraguay and deforestation took part. The enormous expansion of soybean crops was developed for many years without any environmental regulatory control. Following the creation of the SEAM, there was, a period until its capacity is developed. This is reflected in the institution's budget over the years. In 2003 and 2004, its budget was just above one million US dollars, with low capacity for enforcement. It was only after 2011 that the budget was steadily maintained over five million US dollars, reaching a top USD 9,962,000 in 2018.

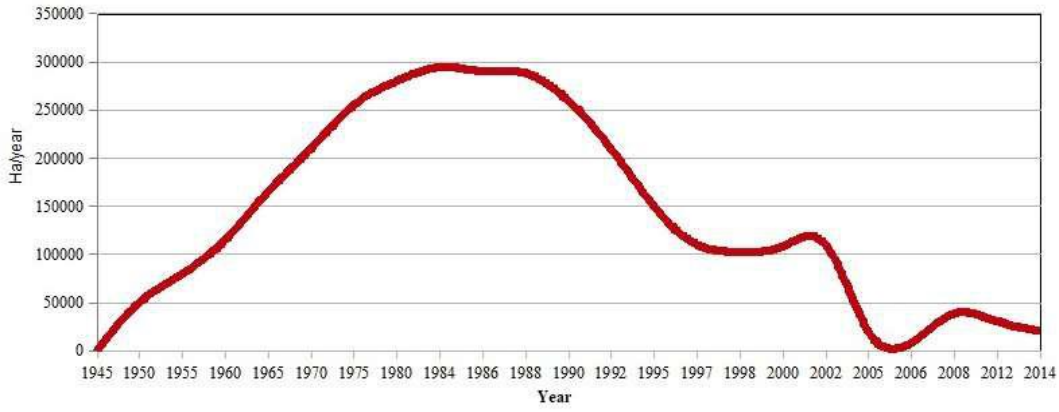
Corruption. Corruption is considered one of the most serious threats to economic processes, social development, the consolidation of democracy, regional integration and to the accessibility of the benefits of globalization. Being the government weak, resource distribution, extraction and management became fertile ground for corruption. The Corruption Perceptions Index (Transparency International, 2016) shows the magnitude of the issue. In the 2016 Index, Paraguay was placed 123 out of 176 countries. Today, the status of environmental governance is characterized by multiple problems: inadequate environmental governance structures; absence of long term planning; lack of links to the National Development Plan and to the Sustainable Development Goals; low public participation and limited availability of information to the public; the preeminence of powerful economic stakeholder groups; and nonexistent independent participation in the decision-making process. In brief, corruption is the major obstacle to environmental conservation in Latin America. (Facetti, 2010).

Environmental Effects of the Migration: Deforestation and Natural Resources Disputes. With the expansion of soybean crops across Paraguay, significant transformations occurred. This expansion of soybean crops became a direct cause of the deforestation the Eastern region of Paraguay suffered since 1960 (WWF, 2016). The deforestation rate reached an enormous 289,000 hectares in 1986. At one point, Paraguay had the second-highest deforestation rate in the world (WWF, 2013). This massively impacted the Atlantic Forest: as much as 7,000,000 hectares were lost due to its conversion into cropland (WWF, 2006). Violent clashes between peasants and security forces ingnited as a result of displacement of peasants, indiscriminate use of agrochemicals. Burning soybean crops, demonstrations, confrontations with security forces resulting in peasants injured and eleven of them killed between 2003 and 2005. As a

response, the government created a Rural Crisis Cabinet, which resulted in a proposal of Land Conversion Moratorium, a Social Pact and a series of programs implemented in the years to come.

State Responses to Environmental Conflicts: Zero Deforestation Law and its Results. There was a precise and impactful response from the State (including the civil society, through WWF-Paraguay and WWF-EPO) to the problem of deforestation through the sanctioning of the Bill Land Conversion Moratorium for the Atlantic Forest of Paraguay. The law aims to *"promote the protection, recovery, and improvement of native forest in the Eastern Region"* (Law 2524, 2004: Art. 1), by prohibiting the conversion of areas covered with the forest for an initial period of two years, which was successively extended[17]. The law was enacted in 2004, and its results were almost immediately seen. From an alarming 110,000 ha. deforested in 2002, the rates dropped to 20,000 ha. in 2005. This represents a drop between 80 and 90 % in the deforestation rates. This effect is shown in figure 2. This law while protecting the native forests has not affected the agriculture production in the region whatsoever, quite the reverse, soy production increased in the follow years (WWF, 2013). Lacerda of WWF's Global Forests Program accurately stated, "*Paraguay provides an example and an inspiration for those countries fighting against deforestation all around the world*" (WWF, 2006).

Figure 2: Evolution of the deforestation rate (Ha./year) in the Atlantic Forest of Paraguay from 1940 to 2014 (Modified from WWF, 2006)



This case study is a clear example of how resources degradation and distribution can generate violent conflicts. Many of the factors identified as primary causes of the Brazilian migration to the Eastern region of Paraguay and the correlative transformation of the landscape, the land use, and the production methods, represent remaining challenges to governance and environmental sustainability. The differentiated access Brazilian farmers have to financial aid, technical assistance, and technology, puts them in an advantageous position against Paraguayan peasants. Brazilians can produce more, due to the better technical management, technology use and the support they receive through their government and its agencies. Unless the Paraguayan government takes serious action to balance this disparity and establish an equivalent aid to local farmers, the unequal opportunities will keep pressing on the peasants, and may result in their lands sold to the bigger and stronger actors. Institutional weakness -and even the absence of it- is evident in several ways. The Paraguayan state not only did not provide the necessary technical and financial support to the peasants but also through its little enforcement facilitated the big actors' predation of natural resources. With the enacting of the Zero Deforestation Law and the rigorous enforcement that followed, the

17 The Law 5045 of 2013 extended its validity period until 2018.

rate of deforestation decreased by 80 % (reaching even more than 90 % in some years). As farfetched as it may sound, it is true, and it was achieved even despite the limited resources that the SEAM had during those years. When the State and then civil society acts effectively, regardless of its limitations, improvements can be experienced.

Conclusion

The soybean production, although representing an essential proportion of the Paraguayan GDP growth, must be regulated carefully considering its negative environmental impacts.

NATURAL CONSTRAINS VS. FARM'S ECONOMIC EFFICIENCY. EXAMPLE OF FARMS IN POLAND

Barbara WIELICZKO[1*], Agnieszka KURDYŚ-KUJAWSKA[2], Agnieszka SOMPOLSKA-RZECHUŁA[3]

Abstract

Natural conditions constitute the foundation for various forms of farming and they determine the production capabilities. They are one of numerous determinants of productivity and profitability. Various natural difficulties may have a significant impact on the economic efficiency of farming. As a consequence, it may lead to abandoning the use of land, reducing the vitality of the rural community, or changing the management system for less environmentally friendly. *The aim of the study is to identify and assess the economic diversification of farming efficiency in areas with natural constraints (ANCs).* The study was based on the Polish FADN data. The analysis included FADN farms with an economic size of 2+ ESU and the data for 2010 and 2015. The analysis covered farms located in lowland zone (I and II), mountain zone and in zone with specific difficulties. Results show significant differences in the efficiency of farming located in individual zones of natural constraints. However, there are no significant differences in the efficiency of farming between farms in the lowland zone and outside the ANCs. The production and financial results of these farms were at a similar level. In turn, the economic efficiency of farms in the mountain zone and in zone with specific difficulties was significantly different from the one of farms outside ANCs. It means that the CAP's ANC subsidies do not compensate for differences in production and financial results of farms in ANCs. To maintain agricultural activity in these areas, we should aim at increasing payments for farms from mountainous areas and from specific areas. This is an important recommendation for the CAP 2020+ that should be taken into account when considering the distribution of CAP funds. This means that the ANC subsidies introduced under the CAP do not compensate for differences in production and financial results of farms operating there, in particular in mountainous areas and the ones with specific handicaps.

Keywords: *farming efficiency, farm incomes, areas with natural constraints, ANC subsidies.*

Introduction

Support for farmers conducting agricultural production in areas with unfavourable environmental conditions has more than forty years of tradition in Europe. The EU member states through the ANC payment system implements various goals of a social, economic and environmental nature. Therefore, the methodology for determining payments, the mechanisms for their implementation and the conditions that must be met in order to obtain them differ in each country (Dax et al., 2003). The purpose of ANC payments in Poland is to provide farmers with compensation for ANCs so as to ensure continuity of agricultural land use, while maintaining the vitality of rural areas and landscape values, promote environmentally friendly agriculture and prevent rural depopulation.

According to Szabo and Grznar (2008), agricultural production in ANCs should primarily meet non-productive objectives related to nature and environmental protection and the generation of new jobs. As Bogdanov (2014) notes, over the last decade the social component of ANC payments has lost its importance, while environmental issues and the maintenance of

specific agricultural practices have become more important. This is undoubtedly connected with global problems of agriculture, including the problem of occurrence of increasingly and more extreme weather events resulting from climate change and the problem of food safety. These problems will require the introduction and improvement of existing measures to ensure continuity of production processes and support for farmers at every production level.
The high share of ANCs in Poland necessitates monitoring whether the instruments aimed at compensating for operating in these areas are effective and accurately distributed. The aim of this study is to identify and assess the economic diversification of farm management efficiency in areas with natural constraints.

Materials and methods

The study was based on FADN data. The analysis included farms with an economic size of 2 and more ESU, which in 2010 and 2015 were conducting agricultural accounting for the needs of the Polish FADN (Table1).

Table 1. Characteristics of the study sample

Specification	Years	
	2010	2015
Number of farms in the sample	11,004	12,105
Number of farms without ANC payments (N_ONW)	5,404	7,453
Share of farms without ANC payments	49.11%	61.57%
Number of farms with ANC payments (W_ONW)	5,600	4,652
Share of farms with ANC payments in the type:	50.89%	38.43%
Lowland I (W_ONW_I)	35.06%	26.43%
Lowland II (W_ONW_II)	13.30%	9.94%
With specific constrains (W_ONW_SU)	1.47%	1.36%
Mountainous (W_ONW_GO)	1.05%	0.70%

Source: own study based on FADN data.

The largest share of farms that received ANC payments were farms located in lowland zone I and II. Farms with specific constraints constituted less than 2% of all farms located in ANCs, while farms located in the mountain zone constituted about 1%. In 2010, farmers received PLN 31.02 million for operating in ANCs, while in 2015 the value of these subsidies amounted to PLN 21.57 million. The analysis included the production and economic results of farms with natural constraints, which were divided into four groups according to the ANC category. The study includes: a) farm production potential; b) production effects and; c) profitability of farms.

Results and discussion

The analysis of farms located in and outside of ANCs showed significant differences in their production potential. ANC farms were characterized by a smaller average area of agricultural land compared to non-ANC farms. The smallest were farms in mountain areas, the largest the ones in lowland. In the analysed period, the average size of mountain farms and the ones with specific constraints increased. The largest increase was recorded in mountain farms (Table 2). A grow in the average land size may lead to increased competitiveness and economic efficiency of these farms. The rise in the average area of arable land was accompanied by the increase in the share of leased land. The only exception are lowland ANC lowland farms with a decrease of 5.51% in the share of leased lands in 2015 compared to 2010. The share of permanent grassland increased. The research shows that permanent grassland is much more important in the structure of land use in ANCs. Outside ANCs, the share of permanent

grassland in the land use structure constituted on average 89% in 2010 and 12.77% in 2015. This increase may result from the need to meet the conditions associated with greening. A slight increase in the share of permanent grassland was also recorded in farms located in lowland areas. The largest share of permanent grassland was recorded in ANC mountain farms and lowland II. These are farms dominated by entities specializing in dairy cattle and herbivorous animals. In 2010, compared to 2015, there was a significant decrease in the share of permanent grassland in the structure of land use in ANC mountain farms and the ones with specific constraints. At the same time, a significant increase in the share of arable land was noted. This may result from the desire to improve profitability. This is also the result of the cattle population declining for many years, including in particular dairy cows (GUS 2016). This situation causes a reduction in the efficiency of using meadows and permanent pastures. This brings specific damages, both economic and environmental, since permanent grasslands have both production function and numerous environment protective functions (Jankowska-Huflejt, Domański, 2008). The research results indicate that farms located in ANCs are characterized by a smaller share of fallow land in the area of arable land. The smallest share of fallow land was found in lowland farms, while the largest in the case of mountain farms and the ones with specific constraints. In 2010, compared to 2015, there was a smaller share of fallow land in lowland II farms and farms with specific constraints. On the other hand, the share of fallow land in lowland and mountain farms increased. The farms lying in ANCs were characterized by a much worse quality of soils compared to non-ANC farms. This has a decisive impact on the possibility of obtaining high income from agricultural production. Farms with the lowest potential for land productivity are farms located in the ANC lowland and mountain areas. The indicator of the quality and usability of soils in these farms was half as high as in non-ANC farms. Hence, it is not surprising that in these farms, the high share arable land is formed by fallow land. Running production on weaker land makes it impossible to generate sufficient income. Low quality of soils leads to cultivation of extensive plant species, which bring lower income. Moreover, they can lead to soil degradation (Czapniewski, Niewęgłowska, Stolbova, 2008). As a consequence, it may lead to abandonment of production in these areas. The conditions in ANCs significantly affect production intensity. The highest average production costs are borne by lowland farms. In 2015, compared to 2010, the total production costs of lowland farms increased.

Table 2. Farm production potential of ANC and non-ANC farms

Years	ANC type	UAA (ha)	Share of leased UAA	Share of arable land in UAA	Share of grassland in UAA	Share of fallow land in UAA	Full-time labour (AWU)	Total production costs (PLN '000)	Production costs per ha (PLN '000)	Fertilizer cost per ha (PLN)	Soil class index

Source: own study based on FADN data.

Full-time employment in ANC farms did not differ significantly. Relatively higher employment was recorded in mountain farms. It was on the average 1.85, and in the remaining groups 1.70. Employment growth was recorded in lowland I farms. The biggest decrease in employed was seen in units with specific constraints. This could be due to a change in the organization of production. As indicated by the reduction of the average area of permanent grassland, and at the same time an increase in the average area of arable land.

The economic and financial results of the farms varied depending on their location. ANC farms were characterized by much worse results than non-ANC farms (Table 3). In the group of ANC farms, the highest value of production was achieved by lowland farms, while the lowest was obtained by mountain farms and the ones with specific constraints. In these farms the labour productivity was also the lowest. In all ANC groups, labour productivity decreased with the exception of farms with specific constraints. On the other hand, in non-ANC farms, labour productivity increased, which further deepened the difference between farms. Land productivity measured by the ratio of the value of production to the area of arable lands in ANC farms was at a lower level than in non-ANC farms. When assessing land productivity in particular types of ANCs, it should be noted that lowland and mountain farms show significantly lower land productivity than non-ANC farms. Mountain farms and the ones with specific constraints distinguished themselves by the highest change dynamics, but the land productivity decreased. ANC farms achieved a relatively lower efficiency of management compared to non-ANC farms. The lowest level of production profitability was characteristic of farms with specific constraints. In the analysed period, the production profitability in all farm groups was noticeably lower, while the largest decreases were recorded in lowland farms (around 10%). In such conditions, the use of areas of low agricultural utility in food production decreases. This raises the risk of land abandonment and losing its agricultural utility (Bański, 2008). Based on the conducted study, it can be concluded that the return on assets varies considerably depending on the location. The worse the conditions for farming, the lower the income assets generate, and therefore they are less effective. The return on equity ratio for ANC was low. In 2015, compared to 2010, it significantly deteriorated. This may mean that in the future some of these farms will cease to conduct agricultural production. As Gołaś indicates, the ability to accumulate capital by generating profits is a sine qua non condition, i.e. a decisive factor determining the continuation or cessation of economic activity in the long-term (Gołaś, 2009).

Table 3. Farm productivity indicators for ANC and non-ANC farms

Year	ANC type	Production (PLN '000)	Land productivity (PLN '000/ha)	Labour productivity (PLN '000/AWU)	Production profitability (%)	ROE (%)	ROA (%)
2010	N_ONW	229.58	19.30	149.79	131.88	1.12	9.43

Source: own study based on FADN data.

The average annual income of ANC farms was characterized by high diversity. The worse the condition for conducting agricultural production, the smaller the farm income. The income of farms from the lowland I area was closest to the non-ANC ones. The average lowland farm income is about 50% higher than the one of farms from other ANCs. The largest differences in incomes are visible for farms with specific constraints and mountain farms. In the analysed period, the income of all farm groups decreased, with the exception of farms with specific constraints (Table 4). The greatest decreases were recorded for ANC farms, including lowland ones. The difference in income between ANC and non-ANC farms decreased. In particular, in the case of mountain farms and farms with specific constraints. Research also shows that mountain farms and the ones with specific constraints were characterized by higher land profitability than lowland farms. In farms with specific constraints, the land profitability was close to the profitability ratio of non-ANC farms. This may be due to the fact that some farms

in mountain areas or the ones with specific constraints could have received ANC payments higher than the once required to compensate for the existing constrains.

Table 4. Income generation and distribution indicators for ANC and non-ANC farms

Years	ANC type	Farm income (PLN '000)	Land profitability (PLN '000/ha)	Subsidies (PLN '000)	Share of ANC payments in farm income (%)	GVA (PLN '000)	Labour productivity (PLN '000/AWU)
2010	N_ONW	95.28	5.73	-	-	134.08	50.17
	W_ONW_I	93.52	3.42	5.23	12.56	132.25	48.42
	W_ONW_II	78.75	2.69	6.37	10.09	111.39	40.98
	W_ONW_SU	60.05	4.31	5.43	10.42	88.70	33.25
	W_ONW_GO	64.17	3.58	5.55	31.35	88.36	31.96
2015	N_ONW	85.08	5.25	-	-	126.81	46.66
	W_ONW_I	76.00	2.76	4.71	11.84	115.06	40.99
	W_ONW_II	63.24	2.32	5.77	17.17	92.63	35.25
	W_ONW_SU	65.61	4.27	4.92	16.42	89.35	33.35

Source: own study based on FADN data.

The amount of ANC payments received varied depending on farm location. In 2015, compared to 2010, the average amount decreased (on average by 10%), with the exception of subsidies for mountain farms. This was due to changes in the level of payments in relation to the 2007-2013 programming period. In the period 2014-2020, the mountain ANC payment rate increased by 40%. In 2015 the share of ANC compensatory payments in farm income was on average 11.48-17.17%, while in 2010 it was 10.09-31.35%. This is the effect of introducing in 2015 a more restrictive degressivity of payments. In the analysed ANC farm groups, the land profitability was much lower than in non-ANC farms. The lowest land profitability was observed in lowland II and mountain farms. The land profitability index decreased for all ANC types. The biggest decreases were seen for lowland farms (16% on average). A slight decrease in land profitability was recorded in case of farms with specific constraints (0.93%). Labour productivity measured by net value added per person in full-time employment indicates a significant diversity between ANC and non-ANC farms. It ranged from PLN 50,170 to PLN 31,960 in 2010 and from PLN 31,960 to PLN 33,430 in 2015. A much lower level labour productivity was characteristic for farms with specific constraints and mountain ones. In the analysed period, labour productivity decreased in lowland farms, slightly increased in farms with specific constraints (0.30%) and mountain farms (4.60%). Research shows that the difference in labour productivity of non-ANC farms and mountain farms and farms with specific constraints decreases. ANC farms were characterized by diversified efficiency of inputs. Gross value added determining the increase in the value of goods produced in agricultural holdings was the lowest in mountain farms and the ones with specific constraints. In mountain farms the efficiency of inputs slightly deteriorated (a decrease in GVA by 0.28%). On the other hand, in farms with specific constraints, it increased by an average of 0.73%, while in lowland farms, it decreased significantly (by 13% - lowland I; by 16.48% - lowland II). Despite ANC compensatory payments, the ANC farms had worse efficiency than non-ANC ones. This indicates the low effectiveness of subsidies and their impact on the improvement of the economic situation of ANC farms.

Conclusion

The obtained results indicate the existence of significant differences in the efficiency of farm located in different ANCs and the lack of significant differences between farms located in the lowland zone and farms located outside the ANCs. The economic results of these farms were at a similar level, which means lowland ANCs received too high support. The economic effectiveness of farms located in mountain zone and the one with specific constraints

significantly differed from the efficiency of lowland and non-ANC farms, showing that ANC payments do not compensate for differences in production and financial results of farms from ANCs. The data indicate that the main objective of maintaining agricultural activity and stopping depopulation in mountain areas and the ones with special difficulties in the long term may not be achieved. These farms were characterized by much worse economic results than farms from other ANCs. In order to maintain production continuity within these areas a greater focus should be placed on support for mountain areas and the ones with special constraints. On the basis of the conducted research, it can be concluded that in farms receiving ANC payments in Poland in 2010-2015, the efficiency of management has not changed significantly, therefore the economic effect of ANC payments is small. Therefore, it is necessary to start work on introducing changes to the current ANC payment system in Poland.

COMPARISON OF POLISH DAIRY FARMS AGAINST SELECTED FARMS FROM OTHER EU COUNTRIES USING THE MALMQUIST INDEX

Marcin ADAMSKI

Economics of Farm Holdings Department**,** Institute of Agricultural and Food Economics - National Research Institute (Warsaw), Poland
*Corresponding author: adamski@ierigz.waw.pl

Abstract

The aim of the paper was to assess the effectiveness of Polish dairy farms (type 45) against a background of similar farms from selected European Union countries and to determine their ability to compete. The studies covered farms from the following countries: Poland, Hungary, Lithuania, Austria, Germany, Denmark, the Netherlands and France. The analysed data covered the 10-year period from 2006 to 2015. The source of research materials was data from farms from the European Farm Accountancy Data Network (FADN). In order to measure effectiveness, the Malmquist productivity index was used. In terms of the Malmquist index, the Polish farms had the lowest value (-2.9%), while the Danish farms had the highest value (2.5%). Such disproportions were mainly due to very slow changes in the technical progress of the Polish farms. In the analysed farms there was a slight decrease in productivity measured by the Malmquist index (by 0.3%). The decrease in the productivity value of the dairy farms was caused by a drop in technical progress by 0.4% with an increase in technical effectiveness by 0.2%. The slight changes in productivity were a consequence of the functioning of milk quotas in the EU. This mechanism has effectively limited the increase in milk production, so the producers could only optimize the inputs.

Keywords: *Dairy farms, effectiveness, Malmquist productivity index.*

Introduction

In Poland, in the years 2005-2015 the agricultural production increased by 73%[18]. The crop production increased by 85.5% while the livestock production by about 65%. The result was the increased share of the crop production in the commercial production by 2.8 p.p. from 38.7 in 2005 to 41.5% in 2015, with the decreased share of the livestock production by 2.8 p.p., from 61.3 to 58.5%. In the livestock production, an important role is played by farms specialising in rearing animals fed on roughage where the production of cow's milk and beef cattle. The share of this group in the commercial livestock production increased from 42 in 2005 to 46.9% in 2015. In the cattle production, the dominant position is occupied by the milk production. Its share in the analysed period was fairly stable, within the range: 32.2 – 33.8%[Gołaś 2017]. In 2016, cattle rearing in Poland was dealt with by 343.2 thousand farms, i.e. about one third of all farms with an area of 1 ha and larger [Characteristics of farms, 2017].

Poland is also a major producer of milk in the European Union. In 2017, it was fifth with the share of 7.5%, after such countries like: Germany (20.4%), France (16.2%), United Kingdom (9.6%) and the Netherlands (9.2%) [Market analyses, 2017].

The objective of the study is to assess the efficiency of the functioning of Polish dairy farms (type 45) against a background of similar farms from the selected European Union countries.

[18] Statistical Yearbook of Agriculture, CSO 2016

Materials and methods

Analysis covered the farms from: Poland, Hungary, Lithuania, Austria, Germany, Denmark, the Netherlands and France. The selection of countries was deliberate. Hungary, Lithuania and Austria have been selected because of the similar size and structure of the farms and the production intensity level. On the other hand, Germany and France have been selected as the largest producers of milk and Denmark and the Netherlands as the countries with the highest milk production intensity level.

For analysing the efficiency of dairy farms in the years 2005-2015, the input-oriented and CCR-based Malmquist productivity index has been used. As the output, the total production value has been assumed, as inputs – the labour costs (the product of working hours and the rate for paid labour on the farm), the activity costs (total costs reduced by costs of salaries and depreciation) and the value of assets. The Malmquist productivity index takes values higher than unity in the event of the increased productivity. The changes in the components of the index, i.e. changes in the efficiency in technical progress, are interpreted exactly in the same way. For the Malmquist index, the productivity is defined as a ratio of the production expressed in the given output value to all inputs applied [Coelli 1998].

The technical efficiency (changes in the technical efficiency) expresses the ratio of obtained outputs from given inputs to the possible maximum outputs achieved by selected entities. Changes in technology (changes in technical progress) determine the change in the manufacturing technique in a given period. The source of the study materials was the data of farms from the European FADN[19].

Results and discussion

Table 1 provides the costs of using own production factors: land, labour and capital in dairy farms (type 45). Despite 11 years of presence in the structures of the European Union's common market, there are still significant disparities in both the potential of farms of the so-called "Old Union" and its new members, including Poland [Kleinhanss 2015]. These differences are evidenced just by their different representation of dairy farms in the six SO classes[20]. The class 2 farms were in the field of observation only for Poland, Lithuania and Austria, while the largest farms dominated in Denmark, the Netherlands, Germany and Hungary. Attention should be paid to the persistent large differences in the level of land use costs, expressed by the amount of rent. The land use costs for the German class 3 farms were 2.6 times higher than in the Polish farms, however, we can observe a slightly higher growth rate in the newly admitted countries. Even greater differences have been observed in the case of the labour costs, by far the highest rates were applicable in the Danish farms, they exceeded the level of EUR 20 per hour, being twice as high as in the German farms and 10 times higher than the level of this rate in the Polish farms. In all the countries analysed, the costs of paid labour were growing as the economic size class increased. It should be stressed that the level of payment for farm labour was in all countries slightly lower than paid in the whole economy, the biggest differences can be observed in the lowest size classes, especially in the Polish, Austrian and French farms.

[19] The network of the farms covered by the studies.

[20] Standard output is the 5-year average production value of the specific production activity (crop or livestock) obtained during 1 year from 1 ha or from 1 animal (exclusive of: edible mushrooms – 100m^2, poultry – 100 head, bees – 1 bee colony i.e. 1 bee family), in the production conditions which are average for the given region.

[a] Average of the years 2013-2015, [b] Index of changes 2015/2010
Źródło/Source: [Ziętara, Adamski 2013, 2017]

As already mentioned, the dairy farms in the selected countries, in addition to the level of labour payment and land use costs, still differ significantly in the production scale. From the data in Table 2 it results that in 2010, on average, the dairy farm in Poland kept 5.9 cows, while the Lithuanian farm kept 4.1 cows, and in the Austrian and Hungarian - 11.3 and 21

cows, respectively. The biggest herds of cows in that year were kept in Denmark and the Netherlands, respectively: 132.2 and 74.7 cows. In Germany and France, the average herd was 45 cows. In 2013, when compared to 2010, the number of cows on the farm increased in all analysed countries (from 11% in the Netherlands to 23.8% in Hungary) apart from France, where it decreased by 10%. The differences between the countries have remained unchanged over the analysed years. In 2010, the average cow herd in the German farms was 7.8 times larger than in the Polish farms, whereas in 2013 – 7.7 times. The corresponding figures in the Danish farms in relation to the Polish farms were 24.0 and 24.4. The average cow herd size does not reflect the complexity of the phenomenon which the milk production concentration is. The more complete picture is provided by the farm structure by cow rearing scale. The share of small farms (keeping up to 9 cows) in Poland, Hungary and Lithuania was within the range from 78 to 92%. In Austria, the share of those farms was around 50%, while in other countries it was between 2.4% (Denmark) and 12.9% (Germany). In Poland, the small farms kept about 30% of the cow population, in Lithuania – about 42%, in Austria – about 16%, and in Hungary – 10%. In other countries from 0.03% (Denmark) to 1.8% (France). Poland belongs to the leading producers of milk in the European Union. With the production of 12.74 billion litres, isfourth, after countries such as: Germany, France, United Kingdom. There are also significant differences in the milk yield of cows. In 2013, the average annual milk yield of cows in Poland was similar to the yield in the Lithuanian farms, amounted to about 5,500 litres and was by about 38% lower than in the Danish farms. In other countries, the milk yield ranged from 6,400 litres (Austria) to 7,700 litres (the Netherlands).

Table 2. Number of dairy farms, cow population and milk production in the analysed countries in the years 2010 and 2013

Countries	Years	Number of dairy farms, thousand	Number of cows, thousand	Cow herd size/farm	Share of small farms[a] (%)	Share of cows in small farms (%)	Milk production, million litres	Average milk yield, litres/cow
Poland	2010	452.8	2,505.6	5.9	82.5	32.2	12.43	4,854.0
	2013	334.5	2,343.51	7.0	77.7	26.8	12.74	5,532.0

Changes in the technical efficiency of dairy farms in the selected countries

Table 3 presents the results of assessing the efficiency of the Malmquist index for dairy farms from the selected EU countries. In the years 2006-2015, the index value decreased by -0.3%, and thus not much. The index level was more affected by the decreased changes in technical progress by -0.4%, with the increasing efficiency (0.2%). The year which should be considered worst in the entire decade is 2009 when the index value decreased by 10.6% and the best year is 2010 when the index increased by 15.8%. In the whole analysed period, the index decreased 5 times (2006, 2008, 2009, 2012 and 2015) and also increased 5 times (2007, 2010, 2011, 2013 and 2014), this may indicate the high variability of the production conditions, fluctuations in the buying-in prices of milk as well as of means of production. In the analysed period, the milk production quota system was functioning, which administratively limited the increase in the production within a Member State. Therefore, the farms were able to increase the milk production by using the unused limit of another farm or to exceed the limit by incurring the risk of imposing fines. It should be noted, however, that these limitations applied on a uniform basis in all Member States, which makes it possible to compare them among themselves.

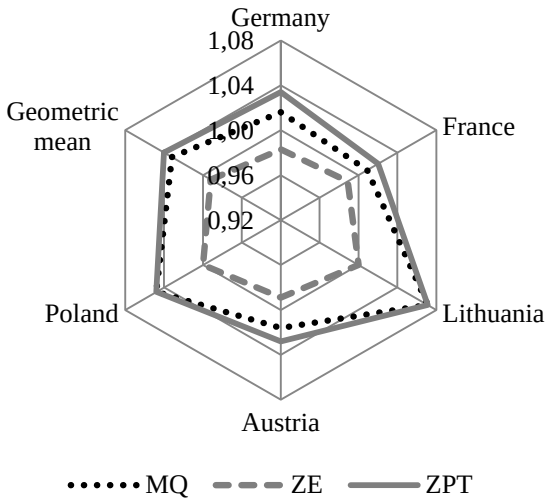
Table 3 Average Malmquist index coefficients in the years 2006-2015 for dairy farms from the selected countries, type 45

Year	Malmquist index	Changes in efficiency	Changes in technical progress
2006	0,977	1,037	0,943
2007	1,08	1,001	1,078
2008	0,954	0,986	0,968
2009	0,849	1,005	0,845
2010	1,158	0,996	1,163
2011	1,056	1,011	1,044
2012	0,982	1,001	0,981
2013	1,024	0,991	1,034
2014	1,012	1,002	1,01
2015	0,913	0,987	0,925
Geometric mean	0,997	1,002	0,996

Source: Own study based on IERIGŻ data

In the further part of the paper, we analysed the Malmquist index level in the farms of the individual EU countries from 2006 to 2015. This comparison has been carried out on the selected sufficiently representative samples from the dairy farms in three different economic size classes. In the group of the farms with the size of EUR 25-50 thousand, the MQ index value shown in Chart 1 rose by 3.2%, with the decreased efficiency of the farms in Germany, France and Austria by, respectively, 1.7%, 1.1% and 1.1%. In the farms of all countries, there has been a positive impact of changes in technical progress on the MQ index. The biggest changes in this area have been recorded in the Lithuanian and Polish farms, by 7.1% and 4.8%, respectively.

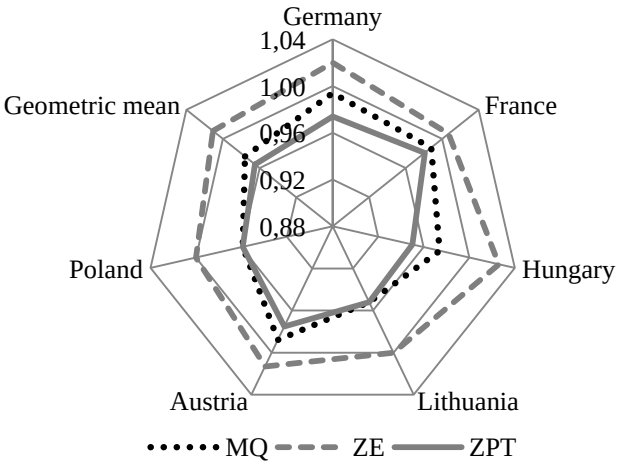
Chart 1. Malmquist index coefficient for the analysed class 3 farms, EUR 25-50 thousand in the years 2006-2015



MQ –*Malmquist Index*, ZE –*changes in efficiency*, ZPT –*changes in technical progres*
Source: Own study based on IERIGŻ data

For dairy farms in the fourth size class, with the standard output between EUR 50 and 100 thousand, the MQ productivity index decreased by 2.4% (Chart 2). This was mainly due to decreased technical progress (decrease by 3.5%) in this group, with the favourable changes in the efficiency (increase by 1.1%). Due to decreased technical progress, the MQ productivity index in the Lithuanian and Polish farms decreased by 4.8% and 4.1%, respectively. Those farms were also the weakest in terms of changes in the efficiency. This does not mean, however, that the efficiency has not improved there, but the level of this increase with respect to the Hungarian or German farms was significantly lower.

Chart 2. Malmquist index coefficients for the analysed class 4 farms, EUR 50-100 thousand in the years 2006-2015

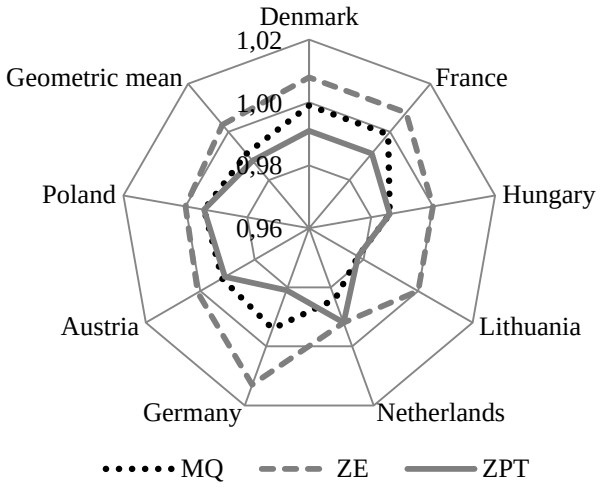


Source: Own study based on IERIGŻ data

In the case of the dairy farms with the very large production scale, classified into the fifth size class with the standard output between EUR 100 and 500 thousand (Chart 3), there has also been no increase in the productivity index. The MQ index has decreased by 0.9% in this

group. The weakest result in these terms was that of the Lithuanian, Dutch and Austrian farms, where the productivity decreased by 2.2%, 1.6% and 1.4%, respectively. Just like in the class 4 group, the decrease in the productivity resulted from decreased technical progress, with the increased efficiency. However, it should be noted that that the increased efficiency of activity in the analysed period did not apply to the Dutch farms (decreased by 0.8%), while it was highest in the German (1.3%), Danish (0.8%) and French farms (0.8%). In terms of changes in technical progress, the lowest values were obtained by the Lithuanian, German and Hungarian farms for which this index decreased by 2.2, 1.9% and 1.4, respectively.

Chart 3 Malmquist index coefficients for the analysed class 5 farms, EUR 100-500 thousand in the years 2006-2015



Source: Own study based on IERIGŻ data

Conclusions

In the period from 2006 to 2015, in the analysed farms there was a slight decrease in the Malmquist index productivity (by 0.3%). The decrease in the productivity value of the dairy farms resulted from decreased technical progress by 0.4% with the increased technical efficiency by 0.2%. The slight changes in the productivity were a consequence of the functioning of dairy quotas. As the production quoting had a limiting impact on the increase in the milk production, the decisive impact on the production output was that of the buying-in price the amount of costs incurred.

The Polish farms in terms of the average value of the Malmquist index were weakest (-2.9%), while the best were the Danish farms (2.5%). The main reasons for such disparities were too slow changes in technical progress of the Polish farms in a large part of small farms. On the other hand, these results mean that the Polish farms have great opportunities to improve their productivity.

The best, in terms of the increased productivity, were the class 3 farms with the size from EUR 25 to 50 thousand. The average index value in this group amounted to 3.2%. The leaders in this group were the Lithuanian (7.1%) and Polish (4.8%) farms. The increased productivity of those farms was due to the changes in technical progress by 4% with the decrease in the efficiency by 0.8%.

Abstract

Agriculture is the main branch of Romania's national economy, an important sector, assuring agro-food product for export, materials for the industry and also, food for population. In the growth a country, an important role plays the international trade because it express the capacity of providing certains services and to produce goods. Romania's agricultural production in 2016 compared to members states of the EU, places Romania, for both cultivated area and output for the sunflower crops, on the first place. Also, rapeseed production has recorded a continuous increasing trend in the analyzed period. The increased price is justified by demand/offer ratio. The main purpose of the paper was to analyze the foreign trade activity of Romania with oilseeds and the trends between 2007-2016. Were used statistical data referring to land surfaces sown with oilseeds, productions, the average yield per hectare, prices, import and export and also, the imports coverage degree by exports.

Keywords: *oilseeds, production, export, import, price.*

Introduction

Agriculture is an important economic sector assuring food for population, raw materials for processing industry and agro-food products for export. Its contribution to GDP is 5.6%. It registered a continuous development in the last decade, and its future depends on a modern technical endowment, investments, employment of high qualified persons, a corresponding farm structure able to assure a higher productivity, economic efficiency and competitiveness (Popescu , 2015).

The Romanian agricultural competitiveness is a debate full topic in the context of the late sectorial reforms during the country accession and convergence to the EU-28 agricultural model (Popescu et al., 2017). The agricultural sector holds a major place in the Romanian economy, with an important contribution to Gross Domestic Product (GDP) creation and also a key role in international trade. The importance of agriculture in Romanian economy results from its share in GDP, labour force and rural community's impact (Ciutacu et al., 2015). The analysis of the foreign trade activity is, like in the case of the other economical branches, of a major importance for establishing efficiency, identifying trades and the justification of specific decisions in this activity (Anghelache, 1999). The external trade has a determinant role in Romania's trade balance, for both exports and imports, especially due the accentuated dependence for the imported food products. In Romania, the land is cultivated with crops which are competitive on world market: maize, wheat, oil crops and barley. These four categories accounts for almost 80% of arable land and have high competitiveness indices of 7.94, 7.52, 3.51 and, respectively, 9.81. Triticale and tobacco are also competitive on world markets, with Balassa indices of 6.65 and, respectively, 4.8, but their shares in arable land are lower 0.87% and, respectively, 0.01. The same products: maize, wheat, oilseeds and barley account for significant shares in agro-food exports: wheat holds the main share of 19%, followed by oilseeds, with 15%, and maize with 14.3%. This structure of exports contains almost the same agro-food products as other studies report (Gheorghe et al., 2017). Vegetables and fruits are foods of plant origin with an important role in the diet, because of

their sensory characteristics and precious nutrients they contain, in the form of carbohydrates, vitamins, organic acids, mineral salts, etc. (Cîrstea et. al, 2013). As (Arghiroiu et. al, 2015) Romania was a net importing country of agricultural products. In 2013 the total trade balance has become a surplus. However, we can say that Romania has become conjectural self-sufficient, because we are surplus to only 5 of the 24 groups of agro-food products. We know a positive balance for cereals, oil seeds and oleaginous fruits, tobacco, live animals, products with raw material nature, and for the remaining agro-food groups we import massive, especially meat, sugars and sugar confectionery, fruits etc. The situation seems to be improving in recent years in terms of the total balance of trade balance, due to the major influence exerted by cereals and oil seeds and oleaginous fruits trade. An important indicator that influences the world, demand and supply is represented by the price over the international market. It has a strong informational consignment, being the basis of economic agent decisions (Angelescu et. al., 2010; Bordean et. al., 2010; Ursu, 2010). Romania's main trading partners in trade with oilseeds are the EU States members, but also we can observe that we import soya beans from Argentina, Brazil and Canada, linseeds from Turkey, India and we export sunflower in South Africa and Pakistan (Armenița Arghiroiu et. al., 2015). Romania is an important pawn over oilseeds market because it produces a significant quantity of sunflower for export. One of the main risk factors in obtaining sunflower crop with stable production is the appearance and evolution of the broomrape. In Romania, more than 60% of the sunflower cultivated area is infested with broomrape. The three more spread broomrape populations in the largest area cultivated with sunflower, are very different regarding the virulence and dissemination of the parasite The race G was definitely found in Tulcea and Constanta counties in Romania and latest surveys showed possible appearance of even more virulent race (Pacureanu et. al., 2009b). As (Pricop et. al., 2011) the race identification must be a continuous process to support farmers, by recommending sunflower hybrids based on the information concerning the parasite spread and virulence throughout the territory. The identification of the parasite physiological races also supports breeders to develop strategy for improvement programs. An evaluation should be made in this context as follows: when the domestic demand of raw materials for processing increases, exports will be reduced (www.agravista.md, 2013). As (Balasu et al., 2014) the production losses caused by soybean bacterial burning (*Pseudomonas savastanoi* pv. *Glycinea*) are major when seed treatment is ignored and the environmental conditions are favorable for the attack.

Material and Methods

In order to make this research, were used statistical data referring to land surfaces sown with oilseeds, productions, the average yield per hectare, prices, import and export and the import coverage degree by export (an indicator of economic competitiveness) (Anghelache C., 2008).

$$GA = \frac{E}{M} x100$$

GA - represents the imports coverage degree by exports;
E - values of exports;
M - values of imports.

This indicator shows the percentage of the value of imported goods covered by the value of exported goods, showing the surplus, the equilibrated or deficit trade balance.

Multiannual average (A): $A = \frac{X1 + X2 + X3 + ...Xn}{n}$;

Growth rate (%):

$$G(\%) = \frac{Xix100}{A} \quad 100$$

G (%) - Growth rate;
Xi - the main indicator used in the analysis as cultivated area, yield, production, etc.;
A - Multiannual average (A).

These data were given by FOASTAT and the National Institute of Statistic and also obtained from the Ministry of Agriculture and Rural Development.

There were also consulted a series of books, magazines and special studies in order to show as concise as possible the evolution of the oilseeds market.

Results and Discussion

As an European Union member since 2007 and a NATO member since 2004, Romania is currently one of the most dynamic large markets in Europe and plays a unique and important part in European agriculture.

Table 1. Surface evolution for the main oilseeds in Romania, during 2007-2016 (thousand ha)

Main oilseed crops cultivated in the EU are rape and turnip rape, sunflower and soya. The production was 31.1 million tonnes in the EU in 2016 which is in line with the 5-year average (– 0.8 % if compared to the 5-year average). In 2016, the rape and turnip rape seeds production was 20 million tonnes and it was the most common oilseed crop in the European Union despite its sharp decline since 2014 (-17.1%). The EU-28 sunflower seed production in 2016 was 8.8 million tons and decreased by -14.8% compared to 2014, followed by increase of 10.7% between 2015 and 2016. In 2016, the EU-28 soya production accounted for 2.5 million tons and it is steady increase since 2012 (Statistical Books, Eurostat, 2017 Edition).

In Romania, oilseeds crops register a high weight of the total cultivated area. In Table 1. is presented the evolution of oilseeds surface in Romania, between 2007- 2016. There were analyzed three oilseeds crops, such as: sunflower, rapeseed and soybean.

Between 2007-2016, the sunflower cultivated area varied between 766.0-1074.6 thousand ha. The largest surface cultivated with sunflower was of 1074.6 thousand ha, in 2013. During this year, the sunflower cultivated area increased with 14.8% than multiannual average (936.0 thousand ha). Concerning the area cultivated with rapeseed, had an oscillatory evolution, the largest surface was in 2010 with 537.3 thousand ha. In 2012 decreased over the total with 71.3% than multiannual average (366.8 thousand ha). Rapeseed has become a more and more attractive crop for farmers due to the EU subsidy (Euro 45/ha) provided since 2005 for encouraging bio fuel production (Zahiu et al., 2010). Soybean cultivated area has varied from a period to another but generally it has continuously increased from 48.8 thousand ha in 2009 to 128.1 thousand ha in 2015, with 50.7% than multiannual average (85.0 thousand ha).

Source: Romania's National Institute for Statistics Report; 2011, 2016; Own calculation.

Sunflower production has increased from 546.9 thousand tons in 2007 to 2189.3 thousand tons in 2014, with 43.0% more than the multiannual average (1530.8 thousand tons). Rapeseed production has recorded a continuous increasing trend in the analyzed period. In comparison with 361.5 thousand tons carried out in 2007, in 2016, Romania achieved 1336 thousand tons, with 79% than the multiannual average (746.4 thousand tons). Rapeseed production started increasing since 2007 at the moment when the European Union decided to expand energetic crops for bio fuel. Therefore, production performance has been determined both by the increased cultivated surface as well as by the increased yield (Table 2). Concerning the soybean production, had an oscillatory evolution during the analyzed period. In comparison with 84.3 thousand tons carried out in 2009, in 2015 and 2016, Romania achieved 262.0 thousand tons, with 65.3% more than the multiannual average (158.5 thousand tons).

The medium production of sunflower per hectare varied between 654-2187 kg/ha. In 2014, medium production of sunflower increased over the total with 35.9% in comparison with the multiannual average. Rapeseed medium production varied between 991 and 2836 kg/ha. In 2016 it recorded an increase of 43.9% than in 2007. Soybean medium production varied between 1021 and 2539 kg/ha. The large production was reached in 2014.

Table 3. shows the evolution of Romanian oilseeds export, during 2007-2016. The exported quantity of sunflower seeds varied between 382.6 and 1420.1 thousand tons. In terms of value, the year 2013 registered the highest income from sunflower seeds export (550.7 EUR millions). Rapeseed quantitative export varied between 68.2 in 2012 and 1461.9 thousand tons in 2016. The most significant soybean exported quantity was registered in 2016 with 108.9 thousand tons.

In Table 4. is presented the evolution of Romania's oilseeds imports, during 2007-2016. The quantitative import of sunflower varied between 66.6 and 1972 thousand tons, and the value oscillated between millions euro 32.5 and 138.4. Rapeseed quantitative import varied between 241.0 and 9.7 thousand tons. The quantitative import of soybean oscillated between 15.6 and 168.3 thousand tons.

Oilseeds price presented in Table 6. reflected a large variation from a year to another, but mainly a continuous increase starting from 2007. The increased price is justified by demand/offer ratio.

Conclusions

During 2007-2016, the sunflower cultivated area varied between 766.0-1074.6 thousand ha, with an increased production from 546.9 thousand tons in 2007 to 2189.3 thousand tons in 2014. The exported quantity of sunflower varied between 382.6 and 1420.1 thousand tons, the highest income from sunflower seeds export being reached in 2013 with 550.7 millions euro.
Concerning the rapeseed cultivated area, had an oscillatory evolution, the largest surface was reached in 2010 with 537.3 thousand ha. Rapeseed production has recorded a continuous increasing trend in the analyzed period, compared with 361.5 thousand tons carried out in 2007, Romania achieved in 2016, 1336 thousand tons. Rapeseed quantitative export varied between 68.2 in 2012 and 1461.9 thousand tons in 2016. Rapeseed exports had values situated between 41,8 EUR millions in 2012 and 549,0 in 2016. Soybean cultivated area has varied from a period to another but generally it has continuously increased from 48,8 thousand ha in 2009 to 128,1 thousand ha in 2015. Concerning the soybean production, in 2015 and 2016, Romania achieved 262.0 thousand tons. The most significant soybean exported quantity was registered in 2016 with 108.9 thousand tons.
Oilseeds prices reflected a large variation from one year to another but mainly a continuous increase starting from the year 2007. The imports coverage degree by exports for sunflower, varied from 324.71% in 2007 to 200.46% in 2009, to 543.81% in 2013 and 4456.41% in 2014, for rapeseed, except for 2012, the trade was low compared to the rest. For soybean, the imports coverage degree by exports varied from 19.79% in 2007 to 40.8% in 2013, as a deficit balance, to 220.87% in 2010 and 219.35% 2011 reaching a surplus.
As a conclusion, in the coming years Romania will continue to become a more and more important oilseeds producer and exporter in the European Community.

Abstract

The registration of a variety means decades of community work, studying all plant varieties created by Romanian or foreign research, without which no hectare of land can be cultivated in Romania. The system of registering new creations in the Official Catalog is based on a precise description of the variety, on the establishment of uniformity and stability following field examination of the characteristics required by the conditions required for registration. This system makes possible to evaluate all varieties under common ambient conditions. This facilitates control of the interaction between varieties and environmental conditions and it is possible to describe the candidate varieties and reference varieties under the same climatic conditions. The purpose of the test is to establish an optimal expression of the phenotype of the variety as a technical basis of assessment to establish its originality with the aim of determining the status of the variety for the new plant creation and the introduction into cultivation of varieties with valuable biological potential. The state food security is reached, among other things, by a proper system of testing, recording and multiplication of varieties, as well as certification of seed produced in accordance with the domestic and international regulations in force. By rigorous testing of maize hybrids and the recording of the performance of hybrids with resistance to unfavorable climatic conditions to diseases and pests in the Official Catalog of Romanian varieties of plants, farmers are given the advantage of obtaining large data, to cover production costs in crop production and to provide a benefit.

Keywords: *registration, testing, hybrid, corn.*

Introduction

Registering a variety means ten years of community work, of study all plant varieties created by Romanian or foreign research, without which no hectare of land can be cultivated in Romania. Testing varieties for their registration is based on the results of official examinations, covering a large number of features through which the variety is described. Field testing consists of two tests that determine the distinctiveness, uniformity and stability of the variety (test DUS) and, for field crop species, agronomic value and use (test VAU). Tests on distinctness, uniformity and stability are carried out on the basis of the Protocols of the Community Plant Variety Office (CPVO), the guidelines of the International Union for the Protection of New Varieties of Plants (U.P.O.V.). Testing varieties for registration in Romania is governed by Law no. 266/2002 on the production, processing, control and certification of quality, marketing of seeds and and planting material, as well as the registration of plant varieties – republished. The State Institute for Variety Testing and Registration (I.S.T.I.S) is the only specialized body of the Ministry of Agriculture and Rural Development and is responsible for the technical examination of the Romanian and foreign varieties for which registration is requested in the Variety Register and in the Official Catalog of Varieties (www.istis.ro). I.S.T.I.S is the only link between research institutions, where new plant varieties and seed producers are created, respectively the Romanian cultivators. Field examination is carried out in varieties testing centers.

A variety tested for registration is studied for 2 or 3 years, depending on the species, in the 24 Center for Testing Varieties (C.T.S.), which represents the entire diversity of the climatic and soil conditions of Romania and where the optimal agricultural production is achieved, the units being necessary for checking the agronomic value of the varieties. Romania's pedoclimatic conditions make it possible to ensure, in the case of crop species, comparable and competitive productions with those obtained in other European Union countries, to ensure the internal consumption needs as well as export. The performance varieties, with superior qualities, adapted to environmental conditions, are one of the means of obtaining high and stable production. The use of a biological material capable to exploit to the fullest the applied technology represent a dynamic factor for increasing production. In Romania, there is an official system for testing new plant varieties for registration in the National Official Catalog and in the European Union catalogs for marketing and / or granting legal protection.
This system makes it possible to evaluate all varieties under common ambient conditions. This facilitates control of the interaction between varieties and environmental conditions and it is possible to describe the candidate varieties and reference varieties under the same climatic conditions. Correct testing of varieties, according to international regulations, contributes to the development improvement sector by creating hybrids with high production potential and valuable physiological features, which allow the growers to achieve exceptional results. Considering the wide spread of maize both in Romania and other countries, its cultivation in the area where stress factors produce significant losses of production, an important contribution is the creation and cultivation of resistant hybrids in the view of reducing the damage. In this respect, the strategic and methodological improvements of the process of creation of inbred lines and of resistant maize hybrids can be considered of great practical interest. Due to the chemical composition of all component parts, maize is a basic forage for animal feed and a valuable raw material for industry, but it is also of particular importance to humans in some areas of culture. As a result, complex corn amelioration programs aiming at obtaining improved commercial hybrids, which correspond to the increasingly demanding market demands for production capacity and a complex of other characteristics, are carried out in all crop areas from the world (Martura et al., 2016).

Materials and Methods

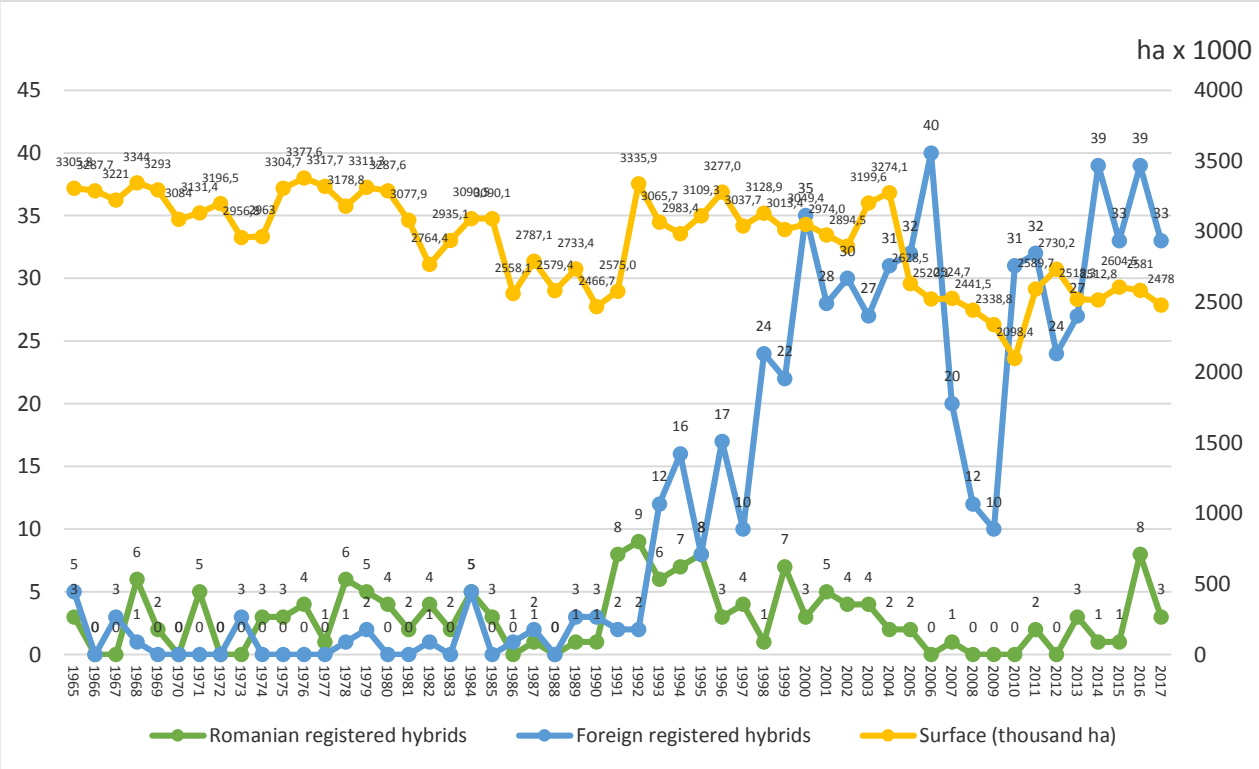
This paper is based on the analysis of the data offered by the Institute for Variety Testing and Registration, respectively the Variety Register (for the period 1965-1969), the Official List (for the period 1970-1999) and the Official Catalog of Cultivated Varieties of Romania (for the period 2000-2017).
This evolution of maize hybrids testing in Romania was carried out for the period 1965-2018, in the context of the main events in Romania, namely the 1989 Revolution and EU accession.

Results and discussions

The first systemic improvement works in Romania were made by the private, farmers Lazaar Laszlo from 1885 and M. Varady in 1902, who created two improved varieties Lapusneag and, respectively, Ardelenesc Varady. After 1910, improvement began in the state institutions, where they were created six varieties improved. Since 1930, the responsibility for the improvement of corn has returned from the Institute of Agronomic Research of Romania (I.C.R.C) established in 1928, which organized the study of the existing varieties and their zoning and created 8 new varieties (Cristea et al., 2004).
The first Romanian maize hybrid was created in 1962 at Improvement Laboratory at Research Institute for Cereals and Technical Plants-Fundulea (I.C.C.P.T) and The agricultural research resort-Turda and was approved in 1965 by the State Commission for Testing and Variety Certification in Romania (currently ISTIS) by registering it with the name HD208 (double

hybrid) in the State Register of Varieties and Hybrids of Agricultural Plants. This result was the effect of the long work done by Vladimir Mosneagă at the Institute of Agronomic Research of Romania (I.C.A.R.) in the field of inbreeding.
On this basis, it was possible to generalize the cultivation of double hybrid maize in a period of only seven years, which places Romania among the countries that have very quickly achieved the transition from the use of free-pollination varieties and local populations to hybrids between inbred lines.
The diversification of the initial material used in the creation of inbred lines, by including alongside the local varieties and populations of genotypes from other parts of the world, and gene infusions from related species, as well as the continuous improvement of breeding methods, have made it possible to make continuous progress in terms of production capacity and adaptability to the hybrids created in the next stages (http://www.incda-fundulea.ro).
The evolution of maize hybrids testing in Romania was quite oscillating, referring to 3 important periods for Romanian agriculture, namely: the communist period, the period after the revolution in December 1989 and the period after Romania's accession to the EU.

Table 1. The situation of Romanian and foreign maize hybrids registered in the Variety Register, in the Official List and in the Official Catalog during 1965-2017



The data in the table was taken from the Variety Register, the Official List and the Official Catalog of Cultivated Varieties of Romania; Own calculation.

The evolution of the recording of maize hybrids in Romania between 1965-2017, has seen a considerable fluctuation in agriculture**.** In the period 1965-1990 the number of maize hybrids tested in Romania was not significant, in 1968 and 1978 most hybrids were, respectively 7, of which one foreign and 6 Romanian. During 1969-1972 and 1974 and 1977 there was a lack of maize hybrids tested in Romania.

The hybrids recorded between 1971-1990, a period marked by the expansion of simple hybrids between inbred lines, surpassed previously created hybrids of 13-14%, and the hybrids created between 1981 and 1985 have secured a further increase of 3-4%. At the same time, other important attributes have been improved, among which the resistance to breakage, fall, drought and scorching heat and diversification of grains quality. After the Revolution of December 1989, the foreign creators of varieties have tested in Romania maize hybrids that they considered to be suitable for the pedoclimatic conditions in order to be placed on the Romanian market. Thus, since 1990, there has been a substantial increase in foreign maize hybrids tested in Romania, reaching the height in 1991, when 40 hybrid foreign maize hybrids were tested in Romania. Romania has entered the EU with an agricultural sector that shows a series of major structural differences to the landscape of European agriculture. Though blurred, the differences continue to manifest at the present time. The reason is founded: policies are not tailored to the size of a single country, but to respond as much as possible to the common needs of all. Romania, however, was largely out of the pattern of the European agricultural system, so it needed a major adjustment to get the most benefice of the European support instruments. 10 years are not enough to reform a country known since ancient times as an agricultural land. Changes have occurred, but not at the expected expected pace. Certainly, the new route - competitiveness and efficiency - that will follow the Romanian agriculture has been imprinted, and the results can not be fully evaluated at a certain moment, but they are visible in time (Albu *et all*., 2018). The highest number of maize hybrids tested in 2006, respectively 40, one year before Romania's accession to the EU.Starting with the year of Romania's accession to the European Union, respectively 2017, all foreign maize hybrids tested in Romania for registration in the Official Catalog of Romanian varieties of cultivated plants allowed the marketing of hybrids registered both on Romanian territory and on other EU Member States. During 2008-2010, there is a large decrease in the number of foreign maize hybrids tested and the lack of Romanian maize hybrids , but starting with 2011, corn hybrids begin to increase reaching the year 2016 to 47 maize hybrids, of which 8 Romanians and 39 foreigners. The potential of Romanian agriculture as well as the entry into the EU of Romania have led to the increase of the number of foreign hybrids tested in Romania, hybrids with a performance genetics that stirred the interest of the big farmers.

Due to continuous genetic progress, Romanian maize hybrids have made an essential contribution to the country's corn production, proving its competitiveness even under the strong competition of foreign hybrids.

Conclusions

Testing allows the introduction into crops only of varieties that have proven resistance to unfavorable environmental conditions in the winter, drought and heat resistance and tolerance to disease and pest attack during the test years.

The introduction of new varieties into culture encourages innovation in the field of plant variety improvement. Establishing the characteristics related to the adaptability of the tested varieties to the pedoclimatic conditions specific to the different parts of the country allows the cultivators to choose the most productive varieties within the precocity groups in the crop areas. Testing the varieties leads to the emergence of competitiveness between native and foreign varieties and influences the Romanian research for the creation of productive and quality varieties. A functional, free and competitive market for seed of the officially registered varieties is developing to ensure not only the needs but also the protection of the beneficiaries at to the European Union standards.

Testing is the basis for the development of the associative system, collaboration and partnership between seed participants of productive and qualitative high-quality varieties.

The current regulations lead to technical progress by introducing into the crop the well-proven, tested and intellectually protected varieties, as well as to the constant information of the cultivators for the widest use of the material of the new varieties.
A country's food security is provided, inter alia, by a proper system of testing, recording and multiplying varieties and certifying the seed produced in accordance with the domestic and international regulations in force.
The introduction of the best varieties into culture and their careful follow-up in the process of multiplication over the years lead to the preservation of morpho-physiological and initial quality features that are very important in achieving high-level production.
By rigorously testing new plant creations and registering only valuable varieties with resistance to adverse climatic conditions to diseases and pests in the Official Catalog, farmers are given an advantage in getting bigger productions, to cover the production costs in the respective crops and to provide a benefit.
In the current context in which modern agriculture must ensure food security for the population, it is necessary to increase the quality and quantity of agricultural production by removing all the causes that lead to the reduction of cereal crops and the improvement of agricultural techniques. A safe way to reduce crop losses is to create hybrids resistant to unfavorable environmental factors and optimize plant culture technologies to adapt them to the peculiarities of agroecosystems. Measures to mitigate the impacts of climate change, respectively to improve agricultural technologies to ensure clean air and food begin with the use of a high biological and cultural value seed resistant to abiotic and biotic stressors. The maximum level of seed quality is reached in a complex of conditions in which a number of factors are identified, with particular reference to those relating to genetic particularities and the preservation environment.
Considering the wide spread of maize both in Romania and other countries, its cultivation in the area where stress factors produce significant losses of production, an important contribution is the creation and cultivation of resistant hybrids in the view of reducing the damage. In this sense, the strategic and methodological improvements of the process of creation of inbred lines and of resistant maize hybrids can be considered of great practical interest.

Abstract

All destinations are an amalgam of tourism products aimed at providing consumers with a unique, integrated tourism experience. Destination resources and attractions, as factors of tourist offer, represent real incentive force that creates a tourist demand. The aim of this paper was to explore how key resources and attractions – physical and geographic elements of the environment, cultural heritage, opportunities for sports, leisure and recreation, accommodation facilities and their authenticity, gastronomy, general infrastructure and tourism infrastructure, safety and security - affected competitiveness of rural tourism destinations in Serbia and Hungary. Tourism experts from Serbia (163) and Hungary (175) were asked to evaluate the current condition of 24 attributes affecting the competitiveness of rural tourism destination. Likert scale of five marks was used in order to determine the effect of key resources and attractions on the competitiveness of Serbia/Hungary as a rural tourism destination. The research showed that the rural tourism sector in both countries had plenty of natural resources and special attractions. However, the accompanying services and contents were very limited and this could affect the reduction of attractiveness, and therefore the ability of the sector to highlight its potential. In the absence of ancillary infrastructure and resources, possible outcomes for the destination can range from service delivery below the expectations of visitors to major failures, thereby preventing the long-term development of the destination. The three basic elements have the potential to increase the length of stay and tourist consumption, which are: folk tradition, gastronomy and opportunities for sports and recreational activities in nature.

Keywords: *key resources and attractions, rural destination, competitiveness, Serbia, Hungary.*

Introduction

Rural tourism is one of the priorities in the tourist development of many European countries. The rural tourism market is on the rise, while at the same time the future of many rural areas is uncertain, due to changes in agricultural production or the attractiveness of urban areas due to a higher standard of living. Rural tourism is considered as one of the appropriate instruments for the revitalization of rural areas and ensuring their sustainable future through job retention or job creation, support for agricultural holdings, preserving nature, or preserving rural crafts as a tourist attraction. Destinations of rural tourism are based on a complex tourist product consisting of several partial products (accommodation, transport, food, trade, attractions, etc.) and offered as such to visitors (Roberts, Hall, Mitchell, 2003; Demonja, Ružić, 2010; Sidali, 2011). These individual tourism companies are interdependent and interconnected, and these are primarily small and medium-sized enterprises that carry the activity. Problems in rural tourism that contribute to the reduction of competitiveness are reflected through the existence of strong competition instead of cooperation among providers of tourism products and services in rural areas. Considering the importance of tourism for

rural areas, determining the factors that influence the improvement of the competitive position in the tourism market is of great importance for their further development.

Key resources and attractions – theoretical framework

All destinations are an amalgam of tourism products aimed to provide consumers with a unique, integrated tourism experience. Tourist destination products include a range of facilities and services offered at the local level, along with all socio-cultural, natural resources and public goods (Buhalis, 2000). Dwyer and Kim (2003) suggested that tourism resources and attractions should be the basis of destination competitiveness. An analysis of previous research on the attribute of the tourist destination (Buhalis, 2000; Kim, 1998) clearly indicated a wide range of attributes adopted by researchers to determine the attractiveness of tourist destinations, although some attributes are common for many research (e.g. climate, landscape, activities, accessibility). A review of literature (Seddighi, Theocharous, 2002; Navarro, 2015) found that there is no universal set of tourist attractions and resources to determine the attractiveness of a tourist destination or its competitiveness. For the purposes of this paper, the basic resources and attractions identified in the Crouch-Ritchie competitiveness model have been selected with the exception of links to emitting markets, as these elements are in line with the main research of destination attractiveness. The factor "Safety and security" was added to the group of key resources and attractions of the destination. Consequently, the "Key Resources and Attractions" is comprised of seven main factors:

1. *Physical and geographic elements of the environment* - Natural attractiveness consists of physical and geographical elements of the environment, important for rural tourism: relief, climate, hydrographic elements, plant and animal world, protected natural areas and nature parks. Especially interesting are the areas that have certain forms of relief from horizontal and vertical diversity. The climate impact is reflected in the stimulation of the development of certain forms of tourism, for example, the mountain with many snowfalls for winter, ski tourism. The flora and fauna are also important factors that attract and direct tourists to specific areas. And the animal species that are kept in some areas, increase its tourist appeal. The richness of wildlife in the forests and fish in the waters not only beautifies and makes the area interesting, but also provides opportunities for the development of various touristic contents such as hunting and fishing, observing birds, exploring, taking pictures, taking care of their maintenance and other activities.
2. *Cultural heritage* - Many cultural heritage resources, either material or non-material, include unique features that reflect their history, lifestyle or the environment, and are ideal to become tourist attractions (McKercher, Ho, du Cros, 2004). Rural culture has been, and is still, determined by specificities that help in shaping rural life style and society. Architectural heritage provides a rich source of evidence of rural culture, as well as their aesthetic values - rural houses and supporting structures reflect a way of life and a local history that has contributed to the creation of rural culture through centuries. Music, play and theater performances as part of narration can form the basis of rural social life. Religious festivals and pilgrimages are most often conducted in rural areas. The rural regions of Europe have a strong local identity, unknown to urban areas. The rich heritage of tradition and customs transmitted through centuries has a value that is valued across the continent.
3. *Opportunities for sports, leisure and recreation* - This group includes those types of attractions that are not directly related to natural or cultural characteristics and "artificial" are created, which are recreational activities and manifestations and festivals. In rural tourism, there are frequent combinations of sports and recreational activities and tourism. In this regard, they differ: (1) breaks with elements of sporting content and (2) business trips with elements of sporting content. In both of these sectors, sporting participation can be either active or passive. The most important, recreational and tourist

activities in a large number of rural environments have dramatically transformed from relatively passive to active and very important factors of natural, economic and social change.

4. *Accommodation facilities and their authenticity* - It is considered that a tourist destination with built accommodation capacities is not limited to day-tourists, but can attract visitors who will stay there for a long time (Kelly, Nankervis, 2001). In order for a tourist destination to be successful, the accommodation facilities must be available in sufficient numbers and meet the needs of the coming tourists. Apart from the adequate quality and quantity of accommodation capacities, the concept of authenticity is of great importance in rural tourism, and is intensively applied in the catering sector. The authenticity of the accommodation object is related to the material used in the construction, the architectural style, the attitude towards the environment and the appearance of the interior.

5. *Gastronomy* - Many actors in tourism (e.g. hotels, restaurants, local communities) have understood the importance of gastronomy as a driving force for tourists on one hand, and for, stimulating local, regional and national economic development on the other. Planning and conceiving of additional tourist facilities in rural areas should emphasize some functions of rural settlements, taking into account everyday activities and lifestyles of the local population. One of these activities is food preparation, i.e. local specialties, respecting the authenticity, as well as the protocol of hospitality. Gastronomy with its activities can be of great help in creating the content of the stay. These activities can be daily as: participation in the preparation of food; preparation and production of bread in a rural way; baking brandy in the night; preparing cheese and for the market, and more.

6. General infrastructure and tourism infrastructure - Infrastructure development is one of the important segments of rural policy. Well-developed infrastructure is considered to be one of the most important prerequisites for rural and overall economic development. Developed infrastructure contributes to: the economic aspect of the lives of rural communities by reducing regional inequalities and improving access to the market and, consequently, lower transport and transaction costs, increased trade exchange with other regions, and an increase in rural household income. The volume of investments in rural areas, as well as the volume of revenues from other non-agricultural branches of rural economy, such as tourism, is increasing. Lack or inadequate infrastructure (e.g. lack of tourist signaling) can diminish the atmosphere of tourists at the destination. Infrastructure is basic element in the tourism development of rural areas, so building, equipping, improving and upgrading infra and substructures should be a permanent strategic goal.

7. *Safety and security* - Safety and security are the primary condition for a successful tourist destination. To make tourists feel safe and secure before and during travel is essential for the competitiveness of tourist destinations. Negative impressions of a destination can cause a decline in tourist traffic even if the destination has high-quality tourist attractions (George, 2003). As in any other business activity, as well as rural tourism or agri-tourism, there are certain risks that must be faced by those who want to deal with this business. Risks in agritourism can be found in both the service provider and the tourists who use these services. For example, tourists who come to farm can accidentally be infected by some plant or animal diseases or, on the other hand, tourists can be the cause of death of animals or plants. In order to minimize risks, many farms create galleries from which a production process can be observed without direct contact. Risk is also growing due to conscious (deliberate) and unconscious (unintentional) tourist activities.

Materials, method and the targets of the paper

The aim of this paper is to examine the impact of key resources and attractions on competitiveness of rural destination. The authors analyzed views of stakeholders important for the development of rural tourism on the supply side in Serbia and Hungary (direct

providers of services in rural tourism, employees in tourist organizations and tourist agencies, employees in municipal and provincial services, employed in ministries, teaching staff at faculties). Tourism experts from Serbia and Hungary were asked to assess the current state of seven factors which affect/could affect the competitiveness of rural tourism destinations in Serbia/Hungary. Likert scale of five scores was used, where 1 means "very bad condition of the factor", 2="bad condition", 3="average condition", 4="very well" and 5="excellent condition of the factor". In this paper, survey research covered all those tourism experts who have the knowledge and/or experience relevant to the subject, and whose area of research and action is related to rural tourism and competitiveness of tourist destinations. In Serbia (163 experts) and Hungary (175 experts), interviewed tourism experts are as follows: teaching staff at higher education institutions, employees of the tourist organizations, employees of national and provincial institutions of importance for the development of tourism, tourism managers of travel agencies, owners of tourism enterprises in rural areas (farms, restaurants, ethno-houses, museums, wineries, souvenir shops, event organizers) and others (societies, associations, clusters). The survey was conducted in two ways - a personal interview (technique of "face to face") and by sending a questionnaire via e-mail. Selected tourism experts in Serbia and Hungary were interviewed in the period from March to May 2017. The response rate in both countries is about 60%. Statistical analysis of the data collected through the survey was done in the software statistical program SPSS 20.

Results and discussion

Table 1 presents the differences on the first scale for factors that belong to the determinants "Key resources and attractions" (arithmetic mean, standard deviation, value, and significance). At the significance level $p<0.01$, statistically significant differences were achieved with the factor "Physical and geographic elements of the environment", "Accommodation capacities and their authenticity" and "General infrastructure and tourist infrastructure".

Table 1. T-test for dependent samples - comparison of the results between Serbia and Hungary for the determinant "Key resources and attractions"

Factor	Country	Arithmetic mean	Standard deviation	Value	Significance
Physical and geographic elements of the environment	Serbia	3.5001	.55830	-7.422	.000
	Hungary	4.0058	.56773		
Cultural heritage	Serbia	3.5257	.66477	-2.184	.030
	Hungary	3.7099	.72649		
Opportunities for sports, leisure and recreation	Serbia	3.7426	.73783	-2.535	.012
	Hungary	3.9562	.65157		
Accommodation facilities and their authenticity	Serbia	3.0931	.65256	-7.602	.000
	Hungary	3.6788	.62021		
Gastronomy	Serbia	3.9669	.83267	-.002	.998
	Hungary	3.9672	.90180		
General infrastructure and tourism infrastructure	Serbia	2.9326	.70196	-9.736	.000
	Hungary	3.7117	.61785		
Safety and security	Serbia	4.0478	.75738	1.342	.181
	Hungary	3.9192	.81852		

The obtained results for factors in which there is a statistically significant difference show that the use of rivers, lakes and channels in rural tourism in Hungary is much more intensive and organized than in Serbia, and protected nature areas and nature parks are more represented in the rural tourism offer, that is, a large number of organized programs involving natural areas, as well as a series of activities organized in these areas. Also, there is a significant difference in the factor "Accommodation capacities and their authenticity", especially the difference in

the average ratings expressed between Hungary and Serbia when it comes to the authenticity of accommodation units. The tourist offers, that is, the owners of accommodation facilities in Hungary, take care that the different contents and the appearance of the building increase the attractiveness of the building. The condition, that is, the quality of basic infrastructure in Hungarian villages is better than in Serbian, while the differences between the quality of basic infrastructure in agritourism facilities is not so pronounced. In Figure 1, Serbia is the closest, according to results, in terms of gastronomy, opportunities for sport, entertainment and recreation in rural areas and cultural heritage. This is not surprising, since once part of Serbia (Vojvodina province) and Hungary share a part of history, and that a significant number of Hungarians live in the territory of Vojvodina nurturing their culture and tradition. It is interesting that the only factor of the model that has a higher average rating in Serbia than in Hungary is "Safety and security". In further research, it is necessary to examine for what reasons the safety and security in Hungary is estimated lower than in Serbia, and this advantage can be used for participation in the Hungarian rural market and for attracting their tourists.

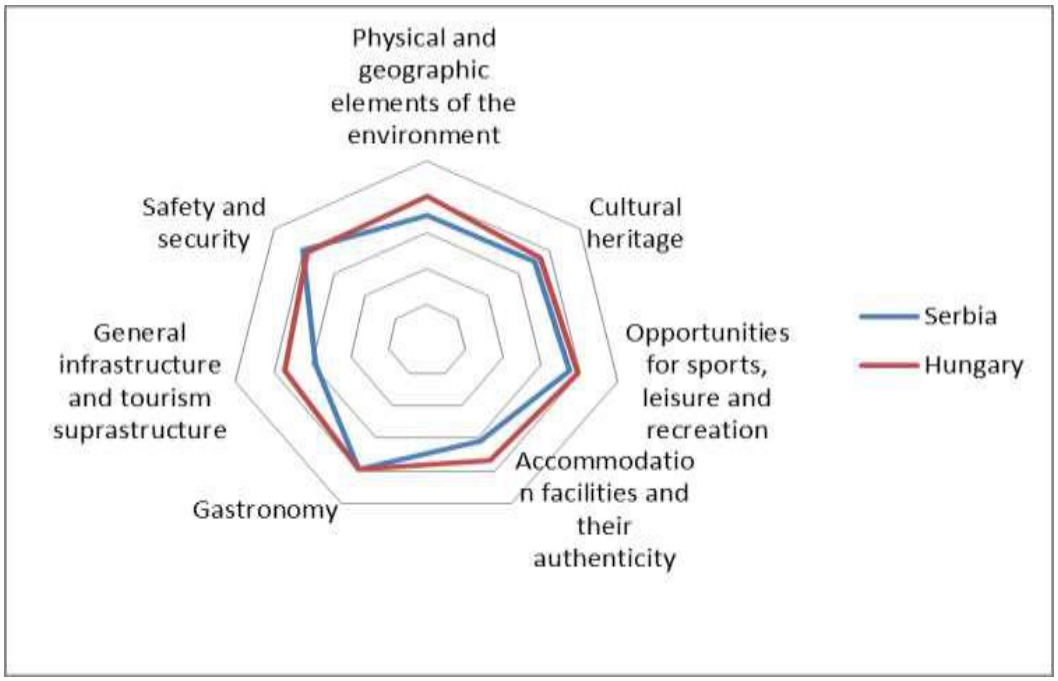

Figure 1. Performance of Serbia and Hungary for factors within the determinant "Key resources and attractions"

Conclusion

The strategy for the development of rural tourism in Serbia should have a special connection with the resources and attractions of the destination, while the priority should be given to maintaining all aspects of security and safety, the continuous improvement of services, the benefits of multicultural environment, the diversity of gastronomic products and the application of the principles of sustainability in environmental management. It is increasingly important to recognize and accept the need for resources to be managed in a sustainable way in order to be preserved for future generations. The rural tourism sector in Serbia has plenty of natural resources and special attractions. However, the accompanying services and content are very limited and this can affect the reduction of attractiveness, and therefore the ability of the sector to highlight its potential. In the absence of ancillary infrastructure and resources, possible outcomes for the destination can range from service delivery below the expectations of visitors to major failures, thereby preventing the long-term development of the destination.

The three basic elements have the potential to increase the length of stay and tourist consumption, which are folk tradition, gastronomy and opportunities for sports and recreational activities in nature. Developing key elements can stimulate visitors of rural areas of Serbia to stay longer, spend more money and participate in a wider range of activities.
The most important competitors to Serbia as a destination for rural tourism are Hungary, Croatia and Slovenia (and increasingly Romania). By comparing the results of the survey between Serbia and Hungary, it can be concluded that the level of rural tourism development in Hungary is significantly higher than in Serbia, since there is a statistically significant difference in the assessment of almost all factors (apart from factor "safety and security"). Tourism experts of Hungary do not see Serbia as their competitor, which leads to the conclusion that tourism policy holders should look at Hungary as a market that requires greater investment and significant efforts to meet the demands of their sophisticated rural tourists, which can not happen in a short period of time. In the future, Hungary should be seen as a partner and Serbian stakeholders should develop joint projects with their stakeholders, which will increase the quality of the supply of rural tourism in Serbia. At this moment, the Hungarian rural tourism market should be seen as an example of good practice. In the meantime, attention and efforts should be directed towards foreign tourist markets with a possible entry into the countries that Serbia has good traditional connections (Montenegro, Bosnia and Herzegovina, Greece, Russia).

Abstract

The parameters of potato production in Serbia, Macedonia and Entity of Republic of Srpska (Bosnia and Herzegovina) were analysed in the period 2005-16. Sown areas, yields and total production were analysed. Quantitative analysis was performed by using descriptive statistics method, and we used average annual rate of changes to discover the tendencies of changes in the analysed period. In Serbia, there were 63,646 hectares of potato in average, in Macedonia 13,402 hectares and in Republic of Srpska 14,858 hectares. Serbia showed a trend of decreasing areas of potato with average rate of -3.38% per annum, Macedonia had tendency of increasing area by the annual rate of 2.45%, and Republic of Srpska also decreased areas of potato by average yearly rate of -2%. The average potato yield was 13.4 tons per hectare in Serbia, with variation coefficient of 29.8%, in Macedonia, 13.9 t/ha (variation coefficient 6.8%) and in Republic of Srpska 11.2 t/ha (variation coefficient 12.8%). In the observed period, there was a growth tendency in yields: 0.64 in Serbia, 2.30 in Macedonia and 1.31 percent per year in Republic of Srpska. The average annual potato production in Serbia was 803,669 tons (variation coefficient of 18.1%), in Macedonia 186,770 tons (variation coefficient of 6.2%) and 166,221 tons in Republic of Srpska, (variation coefficient of 14.9%). Potato production showed tendency of growth in Macedonia, 4.79%, while it decreased in Serbia, -2.74 and in Republic of Srpska -0.72 percent per year in average.

Key words: *potato, production, Serbia, Macedonia, Republic of Srpska.*

Introduction

Truck farming represents a significant area of crop production for the agriculture in Serbia, Macedonia and Republika Srpska. The main characteristics of olericulture are:

- relatively short production process, which enables two or more crops in a year, and consequently better land use
- intensive production – large investments into irrigation and technology resulting in higher yields
- the need for manure activates cattle breading
- high level of economic effectivity as measured with the value of production and profit per hectare

The object of exploration in this paper is comparative analysis of performances of potato production in Serbia, Macedonia and Republika Srpska. Analysis of potato area harvested, potato yield per hectare and total production is performed for the period of 12 years, i.e. from 2005 to 2016. The aim of investigation is to compare yields, production of potato and its share in total crop production, and tendencies of these indicators in the analyzed countries. From comparative analysis, we can derive conclusions about the importance of potato production and positive/negative tendencies in the analyzed period; our investigation will reveal factors of these movements. The authors of this paper have been recently dealing with this problem.

Novkovic et al. (2008) analyzed vegetable production in Serbia and Vojvodina between 1981 and 2007. They found that the vegetable area is less than 300,000 hectares in Serbia. This includes 80,000 hectares in Vojvodina. In Serbia vegetables are produced on around 8.5% of total arable land, so Vojvodina lags with its 5%. On the other hand, areas under vegetables are stable, with slow tendency of growth in Serbia and decline in Vojvodina. Mutavdzic et al. (2011) analyzed the results of vegetable production in Serbia in the period 2001-2010, and these results were compared with those obtained for the previous decade (1991-2000). During these years, the production of every vegetable type increased: garlic for 2%, red pepper for over 26%, green peas for around 56%. Novkovic et al (2011) analyzed changes in sown areas, yield and total production of several important vegetable types in Vojvodina in the period 2000-2009. Due to increased yields per hectare, the total production increased, despite reductions in the total sown area. Novkovic et al. (2012) obtained similar findings about vegetable production in Republika Srpska. A great number of author has published findings concerning analyses and forecasts of production of different types of vegetables (Novkovic et al., 2012a, 2013, 2014, 2014a, 2015, 2016; Илин et al. 2014; Ivanisevic et al. 2015; Miljanovic et al. 2014; Mutavdzic et al. 2013, 2016).

Material and Methods

Quantitative explorative methods were used in this paper. Quantitative analysis included data on sown areas, yields and total potato production in Serbia, Macedonia and Republika Srpska in the period 2015-2016. The next statistics were calculated: arithmetic mean – average ($\overline{X}$) and rate of change (r).

Given the values of a time series Y with length n, the average index of change is:

$$G = \left(\frac{Y_n}{Y_1} \right)^{\frac{1}{n-1}}$$

and the average rate of change:

$$r = (G - 1)$$

where

r is the average annual rate of change

G is the average annual index of change

Y_1 is the absolute value of the first member of the time series

Y_n is the value of the last number of the time series

n is the length of the series (number of years)

Data published by official statistical bureaus of Serbia, Macedonia and Republika Srpska were used in our analyses. At first, analysis of individual data about potato-production was completed, and that was followed by comparative analysis between the Republics. Comparison was performed using the index-method; when the observed changes had opposite directions between Republics, a qualitative comparative analysis was done instead of calculation of indices.

Results and Discussion

Table 1 displays performances of potato production in Serbia. Data show that there are negative tendencies in areas under potato but on the contrary, yields were growing, which results in slower decreasing of annual production. High value of variation coefficient indicates there were serious influences of factors from nature on average yields and production. Variations in sown area are less, but still high, and this point out the fact that economic and market risks are present in this kind of production.

Table 1. *Basic data on potato production in Serbia, 2005-2016*

Production indicators	Average	Interval of variation		Variation coefficient (%)	Average rate of change (%)
		Minimum	Maximum		
Area (ha)	66,646	40,105	93,897	29.8	-3.38
Production (t)	803,669	577,966	1,015,017	18.1	-2.74
Yield (t/ha)	13.4	6.6	17.8	25.7	0.64

In Table 2, basic characteristics of potato production in Macedonia are shown. Average rates of changes are positive and similar for areas and yields, resulting in progressive tendencies in total production. Stability of potato area in Macedonia is confirmed by the fact the corresponding variation coefficient is relatively low. The variation coefficient for yields is higher but still low, showing that there is some influence of natural factors and production conditions, and in the same time, the production is intensive, meaning that external factors are well controlled.

Table 2. *Basic data on potato production in Macedonia, 2005-2016*

Production indicators	Average	Interval of variation		Variation coefficient (%)	Average rate of change (%)
		Minimum	Minimum		
Area (ha)	13,402	12,926	13,829	1.9	2.45
Production (t)	186,770	165,975	204,778	6.2	4.79
Yield (t/ha)	13.9	12.1	15.4	6.8	2.30

The results of descriptive statistics of performances of potato production in Republika Srpska are presented in table 3. There are negative tendencies in changes of potato area. Nevertheless since the yields are enlarged, decreasing in total production is lessen, the fall is minimal, with the rate of under 1% in average. The variation coefficients of the area, yields and total production are somewhere between data for lower Macedonia and higher Serbia.

Table 3. *Basic data on potato production in Republika Srpska, 2005-2016*

Production indicators	Average	Interval of variation		Variation coefficient (%)	Average rate of change (%)
		Minimum	Maximum		
Area (ha)	14,858	13,284	16,886	8.8	-2.00
Production (t)	166,221	124,144	208,447	14.9	-0.72
Yield (t/ha)	11.2	8.2	14.2	12.8	1,31

The results of comparative analysis of potato area are shown in Table 4. The largest potato area was sown in Serbia, almost five times as much as in Macedonia, and four and a half times as in Republika Srpska. Total area was decreasing in Serbia and Republika Srpska, but increasing in Macedonia.

Table 4. *Average potato area in Serbia, Macedonia and Republika Srpska 2005-2016*

Indicator	Republic			Index Macedonia = 100	
	Serbia	Macedonia	R. Srpska	Serbia	R. Srpska
Average area (ha)	66,646	13,402	14,858	497	111
Rate of change (%)	-3.38	2.45	-2.00	-	-

Average potato yield and the results of the comparative analysis are given in Table 5. In every republic, yields had growing tendencies. The largest average yield was achieved in Macedonia, while in Serbia it was for 4% lower and in Republika Srpska for 19% lower. The average growth rate of potato average yield was highest in Macedonia, and that exceeded growth rate in Serbia 3.6 times and in Republika Srpska for 75%.

Table 5. Average potato yield in Serbia, Macedonia and Republika Srpska, 2005-2016

Indicator	Republic			Index Macedonia = 100	
	Serbia	Macedonia	R. Srpska	Serbia	R. Srpska
Average yield (t/ha)	13.4	13.9	11.2	96	81
Rate of change (%)	0.64	2.30	1,31	28	57

Table 6 contains results of comparative analysis of average annual potato production. Serbia had the largest average annual potato production, which amounted to 160 thousand tons of potato per year. This quantity is 4.3 times as much as in Macedonia and 4.8 times as much as in Republika Srpska. In the same period, Serbia and Republika Srpska had negative average rates of changes of potato production, while the rate was positive in Macedonia.

Table 6. Average annual potato production in Serbia, Macedonia and Republika Srpska 2005-2016

Indicator	Republic			Index Macedonia = 100%	
	Serbia	Macedonia	R. Srpska	Serbia	R. Srpska
Average annual production (t)	803,669	186,770	166,221	430	89
Rate of change (%)	-2.74	4.79	-0.72	-	-

We can get a better insight into the importance of potato production for a country through analysis of production per capita. Results of comparative analysis of potato production per capita are shown in Table 7. The largest potato production per inhabitant had R. Srpska, the next is Serbia with 24% less production p.c. and Macedonia with 36% less production p.c.

Table 7. Average annual potato production per capita, 2005-2016

Indicator	Republic			Index Macedonia = 100%	
	Serbia	Macedonia	R. Srpska	Serbia	R. Srpska
Average annual production/Number of inhabitants (kg/p.c.)	111.8	90.9	141.6	123	158
Number of inhabitants in thousands (2011 census)	7,186	2,054	1,174	349,9	57,2

Conclusions

The results of comparative analysis of potato production in Serbia, Macedonia and Republika Srpska in the period 2005-2016 were as follows:

- The average potato area was 63,646 ha in Serbia (variation coefficient 29.8%), 13,402 ha in Macedonia (variation coefficient 1.9%) and 14,858 ha in Republika Srpska (variation coefficient 8.8%)
- The average annual rate of decline of potato area in Serbia is 3.38%, average annual rate of growth is 2.45% in Macedonia, and average annual rate of decline in Republika Srpska is 2%.
- The largest average potato yield per hectare was achieved in Macedonia with 13.9 t/ha, that was followed by Serbia with 13.4 t/ha and Republika Srpska with 11.2 t/ha.
- The greatest value of rate of growth of average potato yield was in Macedonia with 2.3%, than Republika Srpska with 1.31% and Serbia with 0.64%.
- Serbia has the largest total potato production per year (800,000 tons), the next are Macedonia (190,000 tons) and Republika Srpska (170,000 tons).
- Macedonia has the only positive rate of change of potato production (average annual rate of growth is 4.79%), while there is decline in Republika Srpska (-0.72%) and Serbia (-2.74%).
- Republika Srpska has the highest position among the three republics concerning potato production per inhabitant (142 kg p.c.), then follows Serbia (112 kg p.c.) and Macedonia (91 kg p.c.).

Abstract

Increased attention has been paid recently to the analysis of the effects of applying the concept of sustainable development in retail. In that context we have particularly considered greenhouse gases emission in retail food. This is achieved through the use of modern ecological technology in business – through the whole food value chain. The ultimate goal is to achieve the planned reductions of carbon dioxide in retail food, which positively reflects the overall performance of retailers food, environmental in particular. The costs of carbon dioxide emission reduction affect the performance of retailers food. Continuous empirical research shows that almost all global retailers food achieve a significant reduction in carbon dioxide emissions from year to year. Empirical research conducted in this paper on the example of global retailers food in the United States, Europe and the European Union, the United Kingdom, and Serbia shows significant and planned reduction of carbon dioxide emissions in retail food, especially in countries with developed market economies. This empirical research is mainly based on the analysis of the original sustainable (environmental and ecological) reports officially disclosed by selected retailers food, primarily from the countries of a developed market economies, which they started to publish with regular annual financial statements. They are now an integral part of the so-called integrated reporting on performance of global retailers food. Due to the general importance, harmonized regulations on sustainable retail food reporting are being increasingly applied as a data source for more efficient environmental management. In perspective, this will ease the comparative analysis of the carbon dioxide emission of global and other retailers food. (*Jel Classification: I10, L81, M14, M41, Q42, Q56, Q57*)

Key words: *greenhouse gas emissions, carbon dioxide, CO_2 emission sources, renewable energy sources, sustainable reporting*

Introduction

The overall goal of global retailers food is to reduce carbon dioxide emissions through the entire food value chain. The subject of research in this paper is the significance and trend of carbon dioxide emissions in retail food. The costs of carbon dioxide emission reduction are significant and affect the performance of retailers food. The problem of comprehensiveness of the research on carbon dioxide emissions in retail food is that, at the time being, there is no unified system of sustainable (environmental) reporting for all retailers. In addition, many retailers food still do not publish this report, what as a consequence, has an incomplete "comparability" of data on carbon dioxide emissions by individual retailers food. Nevertheless, knowledge of the importance and trend of carbon dioxide emissions from global retailers food is very important in order to manage overall, integrated and, in particular, environmental performance in (concrete) retail food. In view of the global, other retailers food will increasingly publish reports on sustainable development (with data on carbon dioxide emissions). In this way, they will increase its information base for more efficient management of total business, including environmental protection. This will have a positive impact on the achievement of the target profit. This paper attempts to make thorough analysis of specific issues of carbon dioxide emissions in the retail sector, firstly on the example of global

retailers food from different countries, primarily developed market economies, which, due to the general importance of the matter, publish reports on sustainable development with regular annual financial reports. This practice of global retailers food provides them with more reliable information base for efficient management of carbon dioxide emissions through the whole value chain.

Material and Methods

There is voluminous literature devoted to analyzing the way company's performance is affected by general problems and effects of carbon dioxide emission reduction through the whole food chain (Kahn, 2014; Congcong, 2016; Li, 2016; Clune, 2017; Wang et al., 2017; Ji, 2017; Linda, 2014**;** Eriksson, 2017; Lukic, 2013, 2014, 2016, 2017; Lukic et al., 2018). The general research hypothesis in this paper is that the reduction of carbon dioxide emissions positively reflects on overall (integrated, especially environmental) performance of retailers food. The methodology of the study of the given hypothesis is primarily based on the comparative analysis of the carbon dioxide emission of global selected retailers food from various comparable countries of the developed market economy.

Main data sources for the research of the treated problem in this paper are literature, articles, and, in particular, officially disclosed annual financial and sustainable reports of global retailers food. They were processed in such a way that is easy to comprehend the significance and trend of carbon dioxide emission in retail food.

Results and Discussion

The carbon dioxide emission through the entire food value chain is shown in Table 1.

Table 1. Emissions of carbon dioxide through the life cycle of food after farm

Life cycle stage post-farm gate	Number of GWP (global warming potential) values	Median ($kgCO_2$-eq/kg)	Mean ($kgCO_2$-eq/kg)	Stdev	Min ($kgCO_2$-eq/kg)	Max ($kgCO_2$-eq/kg)
Processing meats	5	0,59	0,66	0,14	0,54	0,87
Processing vegetables	15	0,06	0,07	0,04	0,01	0,013
Packaging	8	0,05	0,06	0,06	0,01	0,21
Transport to RDC (Regional Distribution Centre	21	0,09	0,13	0,19	0,02	0,95
Retail	20	0,04	0,10	0,25	0,01	1.14

Note: The table is compiled on the basis of various relevant studies.
Source: Clune et al., (2017)

The data in the given table show that, on average, emission of carbon dioxide is higher in the processing of meat than vegetables. It is also higher in transport than in retail, and is the lowest in the packaging phase. This is in line with the nature of the activities concerned. Figure 1 shows sources of carbon dioxide emission throughout the value chain, with an emphasis on Tesco's participation in carbon footprint.

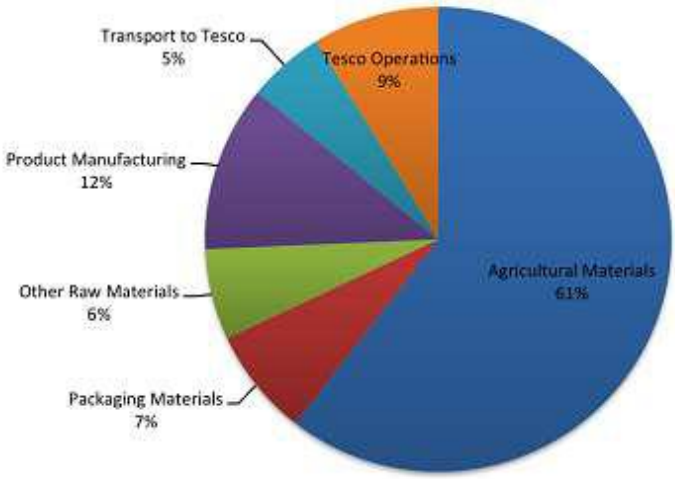

Figure 1. Emissions of carbon dioxide by source in Tesco

Source: Tesco - Our Carbon Footprint, https://www.tescoplc.com/tesco-and-society/sourcing-great-products/reducing-our-impact-on-the-environment/our-carbon-footprint/ (May 24, 2017)

Different is the carbon dioxide emissions of individual retailers food. This is shown by the results of the research in this paper.

At **Wal-Mart** (United States of America, Dominant operational format: Hypermarket / Supercenter / Superstore), a great significance is given to reducing carbon dioxide emissions (Table 2). This is achieved by: investing in renewable energy sources, reducing energy demand, improving energy efficiency, improving refrigeration in stores and maximizing the efficiency of the vehicle fleet.

Table 2. Carbon dioxide emission (Scope 1 and 2) and retail area at Wal-Mart, 2005-2014

	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
Carbon dioxide emission (million ton CO_{2e})	18,9	19,3	20,1	20,8	20,3	20,6	20,8	21,2	21,0	21,9
Retail area (million square meters)	740	805	867	921	952	985	1,037	1,072	1,102	1,134
Carbon dioxide intensity (million tons CO_{2e}/million m^2)*	0,025	0,024	0,023	0,022	0,021	0,021	0,020	0,020	0,019	0,019

Note: *Calculations performed by the author
Source: Wal-Mart Stores, Inc. 2016 Global Responsibility Report, https://cdn.corporate.walmart.com/9c/73/3f9abcef444397f2c771e081e095/2016-global-responsibility-report.pdf#page=58&zoom=auto,-130,628 (May 5, 2017)

In generating greenhouse gas emissions, Wal-Mart participates with: electricity supply 69%, refrigeration 18%, fuel transport 5.9%, fuel on the site 7% and mobile refrigerators with 0.1 % (Wal-Mart Stores, Inc. 2016 Global Responsibility Report, https://cdn.corporate.walmart.com/9c/73/3f9abcef444397f2c771e081e095/2016-global-responsibility-report.pdf#page=58&zoom=auto,-130,628 (May 5, 2017). Therefore, the main source of greenhouse gas emissions in Wal-Mart is electricity supply. With the increased application of the

ecological operation principles, Wal-Mart reduced carbon dioxide emissions from year to year, which reflects favourably on its overall performance, especially environmental.
At **Tesco** (United Kingdom, Dominant operational format: Hypermarket / Supercenter / Superstore), as with Wal-Mart, considerable attention is paid to the research and control of carbon dioxide emissions. This positively reflects on its overall performance, including the surrounding ones. In Figure 2, an illustration of the specificity of carbon dioxide emissions measurement at Tesco is shown.

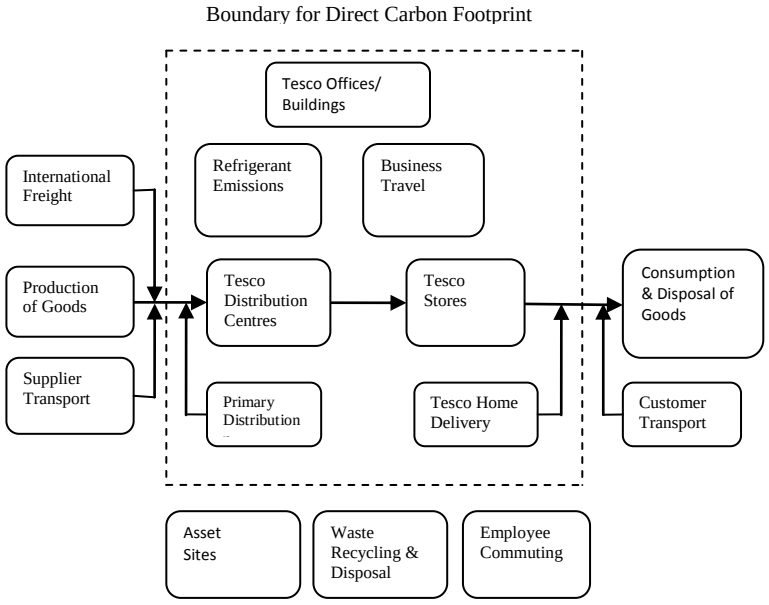

Figure 2. Tesco's emission limit

Source: Carbon Footprint 101: A Guide for Food Retailers, https://www.fmi.org/docs/sustainability/carbon-footprint-101-a-guide-for-food-retailers.pdf?sfvrsn=4#page=11&zoom=auto,-121.85 (May 10, 2017)

Therefore, Tesco participated in total emission of carbon dioxide through entire value chain with 9%. Table 3 shows ecological performances at Tesco.

Table 3. Global ecological performances at Tesco

	2016/17	2015/16	2014/15	2013/14
Carbon dioxide (million ton CO_{2e})	3,9	5,1	5,26	-
Emission of CO_2 reduction (stores and distributional centres) compared to 2006/07	40,5%	39,5%	38,3%	-
Emission of CO_2 reduction (distribution) compared to 2011/12	19,7%	17.4%	14,47%	7,8%
Direct water consumption (million m^3)	23,5	25,5	32,6	32,9

Waste percentage (food and non-food) which is recycled, used again or turn into energy	93%	88%	84%	86%

Source: Reducing our impact on the environment, https://www.tescoplc.com/tesco-and-society/sourcing-great-products/reducing-our-impact-on-the-environment/ (May 3, 2017)

The data in the given table show that the intensity of carbon dioxide emissions in Tesco is decreasing from year to year. Tesco has tendency to improve ecological performances (carbon dioxide emission reduction, direct water consumption reduction and waste treatment improvement). This reflects favourably on its market, economic and financial performances.
At **Ahold** (Germany, Dominant operational format: Supermarket), considerable attention is paid to the reduction of carbon dioxide emissions. This is shown in Table 4.

Table 4. Carbon dioxide emission at Ahold

	2008	2009	2010	2011	2012	2013	2014	2015
Carbon dioxide emissions (thousand tons)				2,176	2,106	2,107	2,090	2,019
Carbon dioxide emissions (kg CO_2/m^2 sales area)	567	574	543	507	480	473	465	420
Sources (%)								
Electricity								49%
Refrigerant appliances								29%
Fuel								12%
Gas								10%

Source: Ahold - Responsible Retailing Report 2015, https://www.aholddelhaize.com/media/1934/ahold-responsible-retailing-report-2015.pdf (May 9, 2017)

Carbon dioxide emissions at Ahold has been decreasing year after year. Since 2016, Ahold has been operating under the name of Ahold Delhaize. In view of this, Table 5 shows data on carbon dioxide emissions for Ahold Delhaize (Belgium, Dominant operational format: Supermarket) in 2016.

Table 5. Carbon dioxide emission at Ahold Delhaize

	2016 Actual	2020 Target
% reduction in CO_2 equivalent emissions per m^2 of sales area (from 2008 baseline)	-22%	-30%
Total CO_2 equivalent emissions per m^2 of sales area – location-based approach	496	n/a
Total CO_2 equivalent emissions (thousand tonnes) – location-based approach	4,505	n/a
Total Scope 1 CO_2 equivalent emissions (thousand tonnes) – location-based approach	1,940	n/a

Total Scope 2 CO_2 equivalent emissions (thousand tonnes) – location-based approach	2,420	n/a
Total Scope 3 CO_2 equivalent emissions (thousand tonnes) – location-based approach	144	n/a
Offset CO_2 equivalent emissions (thousand tonnes)	241	n/a
Avoided grid electricity CO_2 emissions (thousand tonnes)	31	n/a

Source: Ahold Delhaize Supplementary report on Sustainable Retailing performance 2016, https://www.aholddelhaize.com/media/3984/supplementary-report-on-sustainable-retailing-performance-2016.pdf (May 9, 2017)

Significant reduction in carbon dioxide emissions by 2020 (30%) is expected at Ahold Delhaize. This will be achieved by using so-called "green energy" in business operations. Sources of carbon dioxide emissions were: electricity 60%, cooling devices 31% and transport 9% (Ahold Delhaize Supplementary Report on Sustainable Retailing performance 2016, https://www.aholddelhaize.com/media/3984/supplementary-report-on -sustainable-retailing-performance-2016.pdf (May 9, 2017). Delhaize Serbia is also part of Ahold Delhaize which employs the same sustainable development strategy and environment reporting as well as company at its higher organizational level.

Conclusions

A growing number of retailers (food) in the world are increasingly publishing reports on sustainable development. By their reputation, and because of its importance, other retailers will certainly tend to publish this report in the future. It provides the basis for a comparative analysis of environmental performance in retail food from various aspects. In this report, special significance is given to trend of greenhouse gas emissions, in particular, carbon dioxide. Carbon dioxide emissions in trade, in total and by sectors, vary by country. It is significantly higher in China than in Europe or the European Union. Likewise, carbon dioxide emissions are significantly higher in trade of France, Germany and Great Britain than in Greece, Croatia, Turkey and Serbia. Carbon dioxide emissions are higher in Croatia's trade than in Serbian. These differences are due to the application of various ecological measures in business.Carbon dioxide emissions differ in individual stages of the product life cycle, retail companies and product categories. Carbon dioxide emission generators in retail companies are: electricity, transport, ventilation, heating and cooking, refrigeration, and waste. The goal of all retailers is to take appropriate measures, primarily ecological in nature, to reach a planned reduction of carbon dioxide emissions in the future. Among other things, this is achieved with the increasing use of electricity from renewable sources (so-called "green energy"), by using modern ventilation, heating and cooking systems, refrigeration units, green logistics (ecological vehicles) and more efficient waste treatment. The effect of this is to improve the overall performance of retail companies (food), especially environmental.

Abstract

Cattle production is the most important type of livestock production in Serbia. Dairy production as well as cattle fattening are usually performed at family farms which dominate in Serbian agriculture. Cattle fattening has special status within cattle production because of its long tradition and export potential for baby beef. Therefore combination of dairy production and cattle fattening is common at family farms and could improve economic performance of on farm level. Nevertheless, in recent years cattle fattening is in decline. One of the reasons is that cattle fattening is activity associated with broad range of risks. Therefore, the goal of this research is to determine how some types of risks influence profit in cattle fattening operation at family farms in Serbia. To achieve this goal, profit is calculated on the basis of revenues and costs which are determined for cattle fattening on family farm. Initially, profit is calculated for usual (expected) circumstances. Afterwards, it is analyzed how profit is influenced by changes in some important factors, such as subsidies, price of fattened cattle, price of calves for fattening and corn price. It was determined that profit was influenced the most by potential absence of subsidies, because without state support cattle fattening in Serbia would not be profitable enterprise. On the basis of scenario analysis it is possible to expect that in general cattle fattening should be profitable.

Key words: *Cattle fattening, profit, risk, family farms, subsidies.*

Introduction

Cattle fattening is one of the branches of livestock production with a long tradition in Serbia. However, there is a decreasing trend in the number of cattle so that it has fallen from 920,000 in 2014 to 893,000 in 2016. On the other hand, cattle meat production shows a trend of slight increase from 73,000 tons in 2014 to 77,000 tons in 2016 (Statistical Yearbook of the Republic of Serbia, 2017). Examining longer period (from 1985 to 2011) Dokmanović et al., (2014) determined that (comparing to the period from 1985 to 1990) production of beef decreased by 29.20% in the period from 2006 to 2011. When it comes to possibilities of beef export, there is a tradition of export from Serbia to Italy and Greece, but it has been broken for some time. At the moment, meat export does not have a significant influence within agricultural products export. However, as claimed by Bajramovic et al. (2016), Serbian beef export is larger than beef import. Problem related to cattle meat export is its low competitiveness index in relation to the EU market, while the same index for live cattle is much higher (Živkov et al., 2017). Nevertheless, the same authors claim that "The production of beef is the branch in which Central Serbia has potential to become competitive, primarily due to large pasture potentials, but also due to the access to price competitive animal feed from Vojvodina".

Research, so far, have showed that investments in this production are economically justified in Serbia (Ivanović, 2013), but if there are problems with providing cheap cattle feed these investments turn out not to be economically efficient (Marković et al., 2014). Papers of other authors indicate that cattle fattening operation is influenced by many factors. Syrucek et al. (2017) determined that the most influential parameters in cattle fattening operation were

purchase and selling prices and live weight gains of cattle. López-Paredes et al. (2017) investigated 17 important production traits influencing profitability in a large national beef cattle population, while Kopeček et al. (2009) focused on analysis of the economics of cattle fattening simulating two agricultural policy scenarios. Return and costs in small scale cattle fattening were also analyzed by Sarma and Ahmed (2011), Santana et al. (2016) and Şahin et al. (2009). Having all this in mind, the goal of this analysis is to determine revenue, costs and profit in cattle fattening operation at family farms in Serbia, as well as factors influencing profit the most.

Material and methods

Data used in this paper refer to real costs of cattle fattening at family farms operating in Pancevo municipality. In the example presented in the paper, 40 cattle are fattened in one production cycle. Cattles for fattening are male, Holstein Friesian breed, weighting in average 123 kg per head at the beginning of the fattening period and having 450 kg per head slaughter live weight (projected daily gain is 1,100 g/day). It is assumed that fattened cattle will be sold once a year. Price of calves for fattening, price of fattened cattle and feed price are taken from the STIPS database (System of Agricultural Market Information of Serbia). Amount of subsidies corresponds to current government regulations in this area. Calculation incorporating revenue and costs of cattle fattening is made in the paper. In order to make the calculation, methodology given by Gogic (2014) was used. Sensitive analysis was applied to analyze the influence of certain factors on profit in cattle fattening (various approaches to sensitivity analysis are described by Pannell, 1997), as well as scenario analysis (elaborated by Brigham and Gapenski, 1997) to perform more comprehensive risk assessment.

Results and discussion

In order to analyze economic effects of cattle fattening, a calculation containing the most important types of revenues and costs was made (Table 1).

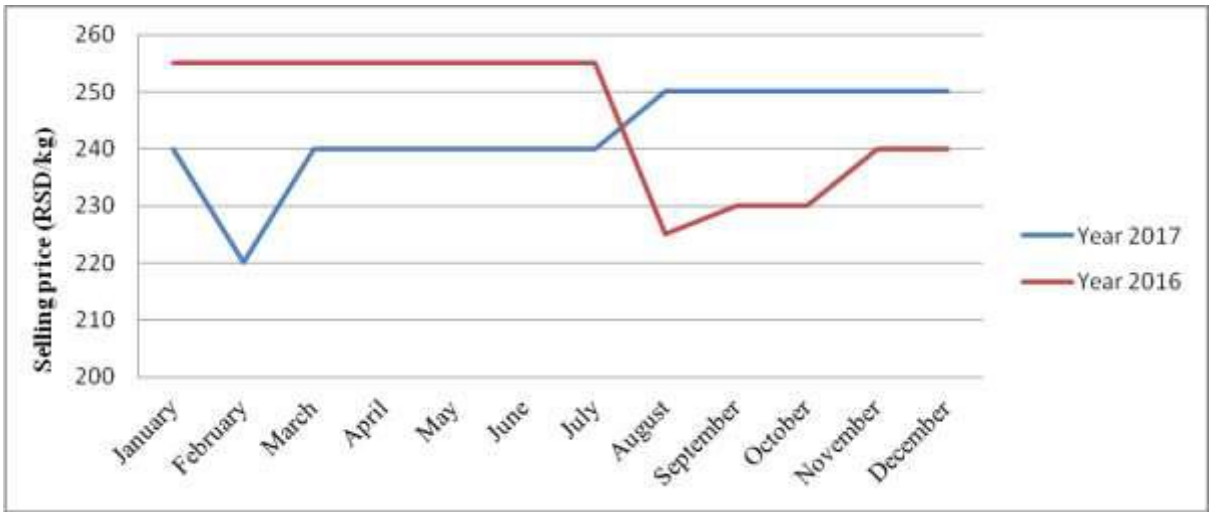
Table 1. Calculation of profit in cattle fattening operation

No.	Element of calculation	Amount (RSD)
I	Revenue	4,540,000.00
1.	Fattened cattle	4,140,000.00
2.	State subsidies	400,000.00
II	Costs	4,212,142.51
1.	Calves for fattening	1,476,000.00
2.	Feed costs	1,764,120.00
3.	Straw	360,000.00
4.	Water	25,000.00
5.	Electricity	20,000.00
6.	Veterinary and medicine	150,000.00
7.	Labor cost	300,000.00
8.	Maintenance of buildings and equipment	10,000.00
9	Depreciation	64,502.00
10	Interest	42,520.51
III	Profit	327,857.49

Source: Authors' calculation

The most important element of revenue is revenue from fattened cattle, while structure of costs is dominated by calves for fattening and total feed cost. It is determined that this is a profitable production, but it is necessary to analyze how some factors influence amount of

profit. Within total revenues of the farm, the largest part is income made by fattened cattle sale. Therefore, it is possible to question how the change of fattened cattle price influences profit of the farm. Fattened cattle price in 2016 and 2017 was between 220 RSD/kg and 255 RSD/kg in regional slaughter houses in which they are sold (Graph 1), while the price used in initial calculations was 230 RSD/kg.



Graph 1. Prices of fattened cattle in Pancevo municipality in 2016 and 2017 (RSD/kg)
Source: STIPS database

Reduction of fattened cattle price from 230 RSD/ha to a minimal achieved price of 220 RSD/kg would lead to a profit decrease from 327,857.49 RSD to 147,857.49 RSD (decrease of 54.90%). However, minimal achieved price of fattened cattle will not lead to losses in cattle fattening. The next question to be answered is if cattle fattening would be profitable without state subsidies. Basic assumption is that a farm is officially registered with appropriate state agency and receives subsidies for fattened cattle. The alternative assumption will be that a farm is not registered and does not receive subsidies (Table 2).

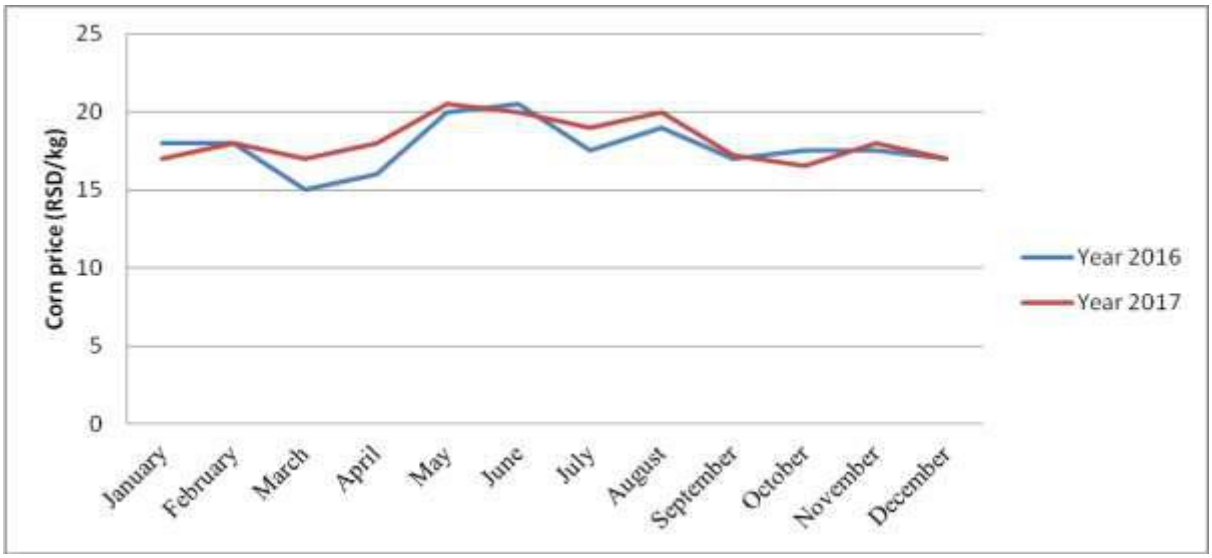
Table 2. Influence of subsidies on profit in cattle fattening

Possibility	Profit (RSD)	Decrease of profit (RSD)	Decrease of profit
With subsidies	327,857.49	-	-
Without subsidies	-72,142.51	400,000.00	122.00%

Source: Authors' calculation

Results show that cattle fattening operation without subsidies results in loss instead of profit. It indicates a significant influence of subsidies on profitability of this production. Keeping in mind a decreasing trend in cattle fattening sector, as well as very low profit per head determined in this research (8,196.00 RSD/head) decrease of subsidies would lead to a further production reduction. That is to say, the amount of subsidies (10,000.00 RSD/head) is higher than profit in this production, which means that farmers use subsidies to cover part of production costs. As it was previously stated, cattle feed costs represent the biggest part of total farm costs. Within cattle feed costs, corn costs are very important element, so fluctuations of corn price were analyzed in the same county during 2016 and 2017 (Graph 2). The highest achieved corn price in the period 2016 – 2017 was 20.50 RSD and the lowest 15.00 RSD. The basic assumption was that corn price is 18.00 RSD/kg. Therefore, it is necessary to determine profit of the farm if the corn price is equal to the highest price in the period observed. Assuming that the corn price is 20.50 RSD/kg it would lead to a profit

decrease from 327,857.49 RSD to 201,977.49 RSD (profit would be reduced for 38.39%), but the operation would remain profitable.



Graph 2. Fluctuations of corn prices in Pancevo municipality in 2016 and 2017
Source: STIPS database

Second type of costs ranked by their amount is cost of calves purchased for fattening. Prices of calves for fattening were fluctuating in 2016 and 2017 and it was necessary to determine their upper and lower limit (Graph 3). As it is showed in the graph, the highest price of calves in the market was 360 RSD/kg and the lowest one was 300 RSD/kg. Therefore, it is necessary to investigate how much the profit would reduce if the highest price of calves was used. It was determined that profit would reduce from 327.857,49 RSD to 75.857,49 RSD (the decrease would be 76.86%), but the production would remain profitable.

Source: STIPS database

Within previous sensitivity analysis basic assumption was that only one factor was changed, while all other elements of calculations remained unchanged. But, in reality, multiple elements of calculation will change at the same time. Due to that, it is possible to perform scenario analysis which involves projection of three possibilities (scenarios) for future – the best, the worst and the most likely scenario. The best scenario will represent optimistic

approach (all indicators will have the most desirable value) while the worst scenario will assume the least desirable value of all elements of calculation. The most likely scenario equals to basic assumption which is previously presented in Table 1. Within this research two scenario analysis will be performed (because both of them could happen in future), and the only difference is within the worst scenario. The first scenario analysis (Table 3) assumes that state subsidies do not exist in the worst scenario. On the other hand, the other type of scenario analysis assumes that state subsidies do exist in the worst scenario (Table 4).

Table 3. First type of scenario analysis

Scenario	Profit (RSD)	Probability of outcome (%)	Total (RSD)
Best scenario	1,071,936.49	0.25	267,984.12
Most likely scenario	327,857.49	0.50	163,928.75
Worst scenario	-792,378.51	0.25	-198,094.63
Expected profit			233,818.24

Source: Authors' calculation

Table 4. Second type of scenario analysis

Scenario	Profit (RSD)	Probability of outcome (%)	Total (RSD)
Best scenario	1,071,936.49	0.25	267,984.12
Most likely scenario	327,857.49	0.50	163,928.75
Worst scenario	-392,378.51	0.25	-98,094.63
Expected profit			333,818.24

Source: Authors' calculation

It could be seen that in both cases (having in mind three scenarios and their probability of outcome) it could be expected that cattle fattening operation would create profit.

Conclusions

This paper investigated how changes of certain types of revenues and costs influenced profit in cattle fattening at family farms. If each of the elements analyzed is observed separately, their least favorable values will lead to the profit decrease, but they will not create loss, unless there is a total abolition of state subsidies. If the best, most likely and the worst combination of factors observed (prices of fattened cattle, state subsidies, prices of corn and prices of calves) are analyzed through scenario analysis, the worst case scenario will always lead to a loss in cattle fattening activity. However, having in mind probability of occurrence of each scenario it could be expected that in general farm will make profit (even when it is assumed that subsidies did not exist as in the worst case scenario).

Abstract

The problem of financing agriculture in Serbia is constantly present and represents the biggest development limitation of this economic activity. The consequences of this problem are visible on the basis of the results of the last 2012 Census of agriculture. According to these data, most farms have four or less animals, irrigation systems cover only 3% of the total arable land, i.e. only 12% farms irrigate their land. The average age of agricultural machinery is about 20 years. A small number of farms has necessary equipment for intensive agricultural production. Out of a total of 631,552 farms, only 542 farms have greenhouses, while the cold store has only on 1,804 farms. Most agricultural entities in Serbia are not profitable, with lack of their own sources of financing, and limited access to the commercial bank loans. The financial resources of the Agrarian budget, as well as other forms of the governmental financial support are insufficient for the operational and development needs of agriculture. For the future development of Serbian agriculture it is necessary to develop new models for financing agriculture in Serbia. To this end, the authors propose the establishment of a specialized (development) agricultural bank and microcredit organizations, as well as the use of securities, financial derivatives, foreign direct investments and EU pre-accession funds.

Key words: *agriculture, financing, agricultural bank, microcredit organizations, financial derivatives.*

Introduction

In the Republic of Serbia, according to the categorization of the Organization for Economic Co-operation and Development (OECD), the rural area is considered 85% of the territory, where 55% of the total population lives. According to the results of the 2012 agricultural census, there are 631,552 agricultural farms in Serbia, with a total of 3,437,423 hectares of agricultural land. In the structure of agricultural holdings, family farms are dominant, with 99.5% of total farm numbers, and the average age of the farm holders of these farms is 59 years. The average size of farm' agricultural land is only 5.4 hectares. In addition to primary agricultural production, in other nonfarm activities are involved 78,301, or only 12% of farmers (Bogdanov & Babović, 2014).

The basic macroeconomic indicators of the importance of agriculture for the economy of a country, are: agricultural participation in the total population, participation of agriculture in total employment, participation of agriculture in gross domestic product and participation of agriculture in foreign trade. According to the data from the Labor Force Survey in Serbia for 2015, the share of employees in agriculture, forestry and fishing in the total number of employees (working age population aged 15-64) was 17%. The share of the rural population in the total population is 40.6%. Based on the data from the agricultural census in 2012, it is evident that only primary agricultural production covers 1,442,628 inhabitants, which makes up over 20% of the total population of the Republic of Serbia.

According to statistical data, the share of agriculture, forestry and fisheries in gross value added at the national economy level, expressed at current prices, was 11% in the period from

1996 to 2015. Average share of agriculture in foreign trade, i.e. in exports of goods in the period 2010-2015 was 22%. It is important to emphasize that unprocessed agricultural products prevail in exports while the products with a higher degree of processing are imported. By analyzing these indicators, it can be concluded that agriculture has great economic and social significance in Serbia.

Due to the specificity of the production cycle, low turnover of capital, low profitability, as well as the lack of own sources of financing, a constant financial and credit support in Serbian agriculture is required. Financing is the biggest and most complex problem of agriculture in the Republic of Serbia, which is constantly actual (Radović, 2009). The consequences of the unresolved financing problem are visible on the basis of the results of the last 2012 Census of agriculture. According to these data, most farms have four or less animal units, while only 522 farms have more than 100 animal units. The irrigation systems cover only 3% of the total arable land, i.e. only 12% farms are irrigating their land. The average age of agricultural machinery is about 20 years. A small number of farms has necessary equipment for the intensification of agricultural production. Only 542 farms have greenhouses and 1,804 farms have cold storage facilities.

Whether viewed in the narrow sense, as primary agricultural production, or in a wider sense, as a multifunctional agriculture, agriculture is "privileged" and has financial support in the market-developed economies. Multifunctional agriculture, in addition to primary agricultural production, includes all the activities that relate to it (food industry, trade, crafts, tourism, etc.). By solving the problems of financing multifunctional agriculture would create development opportunities, increase employment, and stop migration from rural to urban areas in the Republic of Serbia. The aim of the paper is to present financing agriculture in the previous (pre-transitional) period and the current (transitional) period, as well as to propose possible ways of financing agriculture in the Republic of Serbia.

Previous (pre-transitional) period. The economic position of agriculture analyzed through the primary distribution was very unfavorable in the entire pre-transition period due to the policy of depressed prices of agricultural products. The existence of a disparity in the price of agricultural, food and industrial products, so called a "price scissor" is from need to ensure the country's food security. It is estimated that in the 1990s in this way about $ 5 billion was "moved" out of agriculture, which permanently disrupted the economic position of agriculture. The essence of the problem of financing agriculture in the previous (pre-transitional) period was the inadequate relationship between agricultural investment through state budget allocations, and the contribution of agriculture to the creation of gross value added product (Radović, 2009). Financing of agriculture until 1994, that is, until the adoption of the Monetary System Reconstruction Program on 24th January 1994, was entirely dependent on the state, which had a decisive influence on the support directed towards financing agricultural production. The support was mainly related to financing under the beneficial loan conditions, primarily under the beneficial interest rates, and the source of credit was the primary issue many from the National Bank. Credit placements of commercial banks in the agrarian sector, which were financed from own sources of commercial banks' funds, were also under considerable influence of the state. For this period it can be said that both short-term and long-term lending to agriculture was under the state control, the funds in agriculture are administratively directed. The placements of selective loans to domestic agriculture in the 1980s and 1990s, according to the claims of some authors, were based, as this partially improved the unfavorable economic position of agricultural entities (Bjelica, 2001).

Financing of agriculture throughout the primary money emission by the National Bank was a financing method that respected the specifics of agricultural production (the seasonal character of production, the need for funds to be placed in the short term, and staying long-

tied). The price of selective loans was adjusted to the low payment capacity of agricultural entities. The disadvantage of this method of financing was primarily the insufficiency of resources for needs of the agrarian sector.

By adopting the Monetary System Reconstruction Program, on January 24, 1994, the privileged position of agriculture in terms of its financing from the primary money emission by the National Bank was abolished. With the abolition of privileged loans to agrarian sector, no other source of financing was provided, which would be an adequate replacement, and because of this, the agricultural entities were forced to borrow in very unfavorable conditions, because of the restrictive supply of money, the interest rates in the banking market were high.

Current (transitional) period. The primary way of financing agriculture in the Republic of Serbia in the transition period is the agrarian budget. The agrarian budget is a key instrument of agrarian and rural policy. As a safe and permanent source of financing for agriculture, it was established by the Decision on the formation of the agrarian budget, which was adopted in late 1995, and became an integral part of the state budget in 1996. This type of agricultural support exists in all agrarian developed countries, but also within the framework of a unified EU budget.

The share of the agrarian budget in the total state budget was the highest in 1996 (8.3%) and in 2004 (6.1%). Average participation of the agrarian in the total state budget in the period 1996-2015 was only 4.8% (Radović, 2015).

The agrarian budget has a very important qualitative dimension, as it is a key instrument for implementing the measures of agrarian policy. It should be noted that the agrarian policy in the Republic of Serbia in the whole of the past period went through sudden and inconsistent changes, which also reflected on the structural (qualitative) changes in the agricultural budget. In order to develop agriculture, it is necessary to increase the quantitative participation of the agrarian budget in the overall state budget in the coming period. Also, in its qualitative structure, greater incentives should support rural development (Vasiljevic et al., 2016).

The Republic of Slovenia can serve as a model for Serbia in terms of the continuous growth of the share of the agrarian in the total state budget in the transitional period. "Continuous growth of funds allocated from the budget of the Republic of Slovenia for agriculture in the period of transition 1996-2003 as well as the accession of this country to the European Union 2004-2010. It testifies to the need to modernize agricultural production through significant investments, to achieve higher yields, and to ensure that this production is realized with respect to all European Union standards so that Slovenian agricultural and food products will be competitive on the "European market" (Radović, 2011).

Financing of agriculture in the Republic of Serbia in the current transition period is based on financing from the provincial budget as well as from the budgets of local economic communities. Also, one of the funding sources for agricultural enterprises is subsidized loans with the support of the Ministry of Agriculture, as well as loans approved by specialized state financial institutions. These are the Development Fund of the Republic of Serbia, the Agricultural Development Fund of AP Vojvodina, the Development Fund of AP Vojvodina and the Guarantee Fund of AP Vojvodina, as well as the Development Agency of Serbia. However, given that the sources of funding are insufficient, the dominant source of financing of agricultural entities are the commercial bank' loans.

In pre Second World War period Serbia has successful tradition and developed Agricultural savings cooperatives, but according to recent Law on cooperatives (Official Gazette of the Republic of Serbia No. 112/2015) this kind of cooperatives is banned in Serbia.

Material and Methods

The conducted research is based on desktop research and methods of analysis and synthesis. Paper is primarily lean on secondary data obtained from national statistical organizations and public institutions.

Interview with relevant expert in the field of agricultural financing, as a method is used.

All results and derived conclusions are in line with the statements from the available national scientific and professional literature.

Results and Discussion

Possible sources of financing of agriculture in the Republic of Serbia are: (a) a specialized agricultural bank; (b) pre-accession funds of the European Union; (C) microcredit organizations, (d) securities and security derivatives; (E) savings institutions; (F) foreign direct investment.

A specialized agricultural bank could unify the functions of the current specialized state financial institutions, i.e. funds that exist in the Republic, province, but also at the level of almost all local municipalities in the Republic of Serbia. Also, through a specialized agricultural bank, subsidized loans could be realized by the Ministry of Agriculture through commercial banks. Given that this is a new financial institution, it is necessary to adopt a special law, which would precisely define its establishment, functioning, as well as sources of funds. This specialized development financial institution could, with the continuous supervision of the National Bank of the Republic of Serbia and with the management of placements based on the appreciation of regional and local needs and specificities, be able to provide the development possibilities of the domestic agrarian sector (Radović, 2014).

Savings institutions are increasingly active in the agricultural sector. Government subsidies of interest rates for agricultural loans proves to be effective tools for development of this financial market.

Micro-credit organizations are financial institutions with potential to actively engage in financing agriculture, as they play a significant role in supporting the development of entrepreneurship and self-employment of population categories that do not have access to the classic banking market. Therefore, these financial institutions could be an important source of funding for small family farms, which are also predominant in the structure of agricultural entities in the Republic of Serbia. The limiting factor for the application of lending through microcredit organizations in the Republic of Serbia, in the current period, is the lack of a normative framework for their functioning. Therefore, microcredit organizations must place their loans through commercial banks, which significantly increases this type of financing (Radović, 2015).

Securities and financial derivatives (futures and options) can be a significant source of financing and risk management for agriculture, but for that purpose it is necessary to establish the necessary normative framework in the Republic of Serbia, develop financial markets (primary and secondary), as well as ensure continuous information and education of agricultural entities (Kovačević & Zakić, 2016).

Pre-accession funds of the European Union are also a potential source of funding, primarily the IPARD program, but for their use, it is necessary to meet the EU's administrative requirements, as well as to provide sources for pre-financing projects, since the funds are provided on the principle of refund. To that end, it is necessary to support the state that could be realized through a specialized agricultural bank.

Pre-harvest financing as an alternative model of agricultural financing are established in Serbia and Ukraine as a pilot project for this kind of financing system in agriculture for EU[21].

[21] Both pre-harvest financing systems are developed with support of European Bank for Reconstruction and development.

Pre-harvest financing system is based on a future product, which is still in the field in the process of production, as collateral for short-term loan. The instruments of pre-harvest financing are a form of forward contracts. Contracts, by which the agricultural production is financed, in exchange for delivery of agricultural products later. This system is with great success established in Brazil in 1990s. In Serbia it was established in 2015 by the Law on pre-harvest financing, while in Ukraine pre-harvest financing is established as a pilot project in one region (Kovačević & Zakić, 2016).

Establishment of Agricultural savings cooperatives could be significant source of financing for agricultural sector in Serbia. Serbia had successful practice of agricultural savings cooperatives. For development of this kind of financial institutions legal framework in Serbia is required.

One of the possible ways of financing agriculture in the Republic of Serbia are foreign direct investments. Factors of importance for attracting foreign direct investment are: (a) characteristics of tax policy (amount of taxes and contributions to earnings of employees); (B) the quality and the cost of labor; (C) legal protection of investors and the efficiency of issuing the necessary documentation; (D) the quality of the infrastructure; (E) access to overseas markets; (F) the image and political stability of the state; (G) the development of financial markets; (H) subsidies and privileges to foreign investors (Vasiljević & Kovačević, 2014).

Conclusion

Financing of agriculture in the Republic of Serbia should be realized at the current moment with the strong financial and credit support of the state, bearing in mind the underdevelopment of this economic activity on the one hand, as well as the production resources, the importance of agriculture for the national economy and the overall employment of the population on the other. According to the results of this paper the proposal proposes the establishment of a specialized state development financial institution (specialized agricultural banks) that would prioritize the financing of agriculture and rural development in the Republic of Serbia under the beneficial conditions. This type of financing is needed because most agricultural entities in the Republic of Serbia do not have the capacity to self-finance, due to the lack of their own accumulation, and the conditions for lending on the banking market are unfavorable for them.

Agricultural savings cooperatives are important financial institutions in developed countries and it could play important function in for Serbian agricultural sector.

Possible source for the financing of agriculture in the Republic of Serbia are pre-accession funds of the European Union, microcredit organizations, securities and financial derivatives. For the purpose of their implementation, it is necessary to provide administrative conditions, as well as the appropriate legal framework. Of course, foreign direct investment is also a potential way of financing agriculture and rural development, and in order to secure them, it is necessary to have the necessary favorable conditions.

Important mechanism is pre-harvest financing system which needs to be further promoted and developed.

Abstract

More than three billions of people live in rural areas in the world. Approximately 2,5 billion of them provide for the agricultural sector. The agricultural sector is the most important element of the economic growth for most countries and especially the developing countries. The majority of the businesses in agricultural sector is conducted in family farming. Studies have been started by conducting the official introduction of the family farming in United States of America and some South American countries for the purpose of making the production of the family farmers conducting traditional production sustainable and productive. In the study, based on the definition of the family farming, the factors affecting the properties of the family businesses have been detected. Logistic regression model has been used in the determination of the factors affecting the properties of the family farming. According to the model results, agricultural income ratio, equity capital ratio, property land ratio and labor force potential, among the factors affecting the properties of family farming, have been found meaningful. The businesses in the study region are in the state of the businesses with competent income. The businesses to have an income in competent level will facilitate the budgeting for the newly met techniques and technologies and ensure the development of the businesses.

Keywords: *Family Farming, Logistic Regression, Konya.*

Introduction

Agricultural sector is the most important element of the economic growth for most countries and especially the developing countries. The developing countries form three out of four of the world agricultural production and the agricultural sector forms 30% of the GDP in most of these countries (FAO, 2013). 51% of the total population in the world and 23% of the population in Turkey form the rural population (Oğuz, 2010; TÜİK, 2014; FAO, 2014c; 2017). This population provides for the agricultural sector. The agricultural sector has a share of approximately 30 and 60% of the GDP in almost 2/3 of the underdeveloped and developing countries (Doğaner, 2016). The majority of the population working in the agricultural sector is in the position of family business (family farming). Family farming which is conducted by the family members without considering the genders, based on family labor force, sensitive to the environment, protects the environmental resources, supports the sustainable agriculture, provides high yield and quality and is dynamic has an important structure generally in the world. Family farming is a structure providing the sustainability without considering any purpose of sole profit by protecting the cultural elements as well as helping the economic development by forming labor force and income (Blekesaune, 1997; Hoppe, 2010; FAO, 2014a). 500 million out of 570 million agricultural businesses in the world are operated by the family farms and 475 million businesses have a production area less than 2 hectares (Hazell et al., 2010; FAO, 2013). However; these businesses superior in terms of number have a less area in the world in terms of agricultural area (Lowder et al., 2014). They cultivate 68% of the agricultural areas in EU countries, 85% in Asian countries, 83% in North American countries, 18% in South American countries and 62% in African countries. They produce 56% of the total agricultural production (FAO, 2014b). Studies have been started by conducting the

official introduction of the family farming in United States of America and some South American countries for the purpose of making the production of the family farmers conducting traditional production sustainable and productive. The concept "family farming" is widely used in the countries with high income such as European Union countries, some European countries and Latin America and Caribbean countries (Gras, 2009; EUROSTAT, 2010; Économie, 2011; Krasniqi, 2012; Hoppe ve MacDonald, 2013; Garner ve de la O Campos, 2014; Lowder et al., 2014). However; no definition of family farming has been commonly made in the world. According to the definition of FAO, family farming is the vegetative, animal production, fishing and forestry activities conducted by the family members without considering the gender differences with the use of family labor force. The definition of family farming in Turkey is the businesses conducting activities based on the labor force, property and administration of the family without considering the gender differences, having a field between 0-500 decare or 0-49 bovine animal existence, conducting vegetable, animal and mixed production and gaining the majority of their income from these activities (Yener, 2017; Yener and Oğuz, 2018). Besides, the definition of the family farming has been made in the city of Konya. Family farming for the city of Konya is the businesses which do not consider any gender difference, which is conducted by the family members, whose administration belongs to the owner of the business, which have a field of 0-500 decare or 0-49 bovine animal existence, which conduct vegetable, animal and mixed production, whose more than 80% of the total field amount is property land, whose 15-49 aged labor force potential is above 70%, which attains more than 85% of their total income from agriculture and whose equity capital is above 90% within the total capital (Yener, 2017; Yener and Oğuz, 2018). In this study, the factors affecting the properties of the family farming have been analyzed by taking into consideration the definition of family farming made for the city of Konya.

Materials and methods

The main material of the study consists of the primary data collected via questionnaires from the dairy farming businesses in the city of Konya. Moreover; the studies previously conducted regarding the subject and the data collected by the related institutions and organizations have been benefitted. In the study; stratified sampling method out of the simple random sampling method has been used for the purpose of increasing the accuracy of the findings collected from the businesses and providing the sufficient representation of the different parts in the population (Yamane, 1967;Güneş and Arıkan, 1985). Sample size has been calculated as 128 within 95% reliability range with 5% error margin and the businesses taking place in the sample size have been selected according to the principle of random volunteering.

Table 2. Distribution of the businesses conducting Dairy Farming according to their number of animal (Sample Size)

Business Width Groups	Sample Size (Number)
0-25	84
26-75	29
76-+	15
Total	128

Logistic regression model has been formed for the determination of the factors affecting the properties of family farming. The analysis methods that could be used in the event that the dependent variable is binary (0,1) are limited. The widely used models are Logistic Regression (LR), Probit and Linear Probability Model (Cankurt et al., 2010). Logistic regression is a method benefitted in the determination of the cause and effect relation with the explanatory variables in the event that the response variable is observed in the categorical,

binary, triplet and multiple categories. It is a regression method in which the expected values of the response variable as probability when compared to the explanatory variables (Özdamar, 1999). The assumptions foreseen for the linear regression model are distorted in the event that the dependent variable is continuous and it is a discrete variable including two or more levels and the observation variances are not equal due to the fact that the error term shows a binomial distribution. The use of logistic regression analysis is suggested because the data cannot be examined with linear regression analysis in this situation (Bagley et al., 2001).

Logistic regression model is as follows.

$$E(y_i) = \eta = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} \text{ .....} + \beta_k x_{ki}$$

If $E(y_i)$, it takes a value between $-\infty$, ∞.

Assumptions regarding the two-level logistic model are as follows:

i) $y_i \in (0,1)$, i=1,2,3,.....N

ii) $$P(y_i = 1/ \; x_i) = \frac{\exp(\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} \text{.....} \beta_k x_{ki})}{1 + \exp(\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} \text{.....} \beta_k x_{ki})}$$

iii) $y_1, y_2, \text{.....}, y_n$ are statistically independent.

iv) Independent variables are independent of one another (Aktaş and Erkuş, 2009).

The odds ratio used in the interpretation of the logistic regression model is a value attained by dividing the observation probability of the phenomenon into the non-observation probability. It is calculated as follows.

$$Odss\ Ratio = \frac{\text{Probability}}{1 - \text{Probability}}$$

Odds ratio expresses
the decrease in the event that Odds ratio<1,
that there is no relation in the event that Odds ratio=1
the increase in the event that Odds ratio>1 (Süt and Şenocak, 2007).

In the study; status of being a family business (Family Business:1, Other Business:0) has been taken as the dependent variable; and agricultural income ratio within the total income, ratio of equity capital within the capital, property land ratio within the total field, labor force potential, animal number and field have been taken as the independent variables.

The relation graphics (Scatter/Dot Charts) in SPSS program have been used in the determination of the relation between the total land amount and property land amount of the businesses conducting family farming. In addition; the relation between the total land amount and the status of producing forage crop has been determined with Chi-Square analysis.

Results and discussion

The definition of the family farming in the city of Konya has been made as the businesses which do not consider any gender difference, which is conducted by the family members, whose administration belongs to the owner of the business, which have a field of 0-500 decare or 0-49 bovine animal existence, which conduct vegetable, animal and mixed production, whose more than 80% of the total field amount is property land, whose 15-49 aged labor force potential is above 70%, which attains more than 85% of their total income from agriculture and whose equity capital is above 90% within the total capital (Yener, 2017; Yener and Oğuz, 2018). According to this definition, 50% of the businesses in the study area conduct family farming (Table 2). 45,24% of the businesses with 0-25 bovine animal existence, 48,28% of the businesses with 26-75 bovine animal existence and 80% of the businesses with 76-+ bovine animal existence conduct family farming.

Table 3. The Status of Being A Family Farming for the Businesses (Piece, %)

Business Groups	Family Businesses		Other Businesses		Total	
	Number	%	Number	%	Number	%
0-25	38	45,24	46	54,76	84	100,00
26-75	14	48,28	15	51,72	29	100,00
76-+	12	80,00	3	20,00	15	100,00
Total	64	50,00	64	50,00	128	100,00

Total income of the businesses conducting family farming is 74.113,40 $ and 91,61% of them is attained from agricultural income. Agricultural income is defined as the total of in-cash and kind values which is supplied by the business manager and his/her family from the agricultural activity attended by them with mental and physical labor force as well as their capital and whose responsibility is also undertaken by the and could be consumed by the business without narrowing down the production capacity (Talim, 1974). The agricultural income attained at the end of a production period in the agricultural businesses are expected to meet the total of the normal interest provision of the equity capital imbursed to a business in return for the labor force of the business manager and his/her family. Also; the agricultural income should be more than the total of the price calculated for the family members working in return for equity capital interest in terms of being able to give opportunities for new investments (Parlakay and Esengün, 2005). According to the notice (Notice No: 2003/20) regarding the determination of the agricultural business extent with competent income, annual processing income with competent income has been calculated as 1.783.222.746,48 $. Annual business income with competent income for 2017 has been calculated as 5.008,07 $ by taking the inflation and emitting of 6 zeros into consideration (The year 2007 has been taken as the basis) (Anonim 2013). In this respect, the businesses taking place in the study are in the status of businesses with competent income. The businesses to have an income at competent level will facilitate the separation of the budget for new techniques and technologies and will ensure the development of the businesses.

Table 4. Definitive Statistics for the Factors Affecting the Properties of Family Businesses

	Family Businesses	
	Amount	%
Agricultural Income ($)	67.891,62	91,61
Total Income ($)	74.113,40	
Equity Capital ($)	698.501,64	98,00
Total Capital ($)	712.791,69	
Property Land (da)	196,30	99,04
Total Land (da)	198,21	
Family Labor Force Potential (FLF)	967,42	71,68

According to Table 3, equity capital ratio is 98% and property land ratio is 99,04%. The average land amount in the businesses is 196,30 da and the majority of the lands are watery lands. According to the Law on Soil Protection and Land Usage no. 6537, it has been specified that the businesses with 65 da watery land and 176 da dry land for the city of Konya have an agricultural land extent with competent income (Anonim, 2014). In this respect, the businesses in the study area have agricultural lands with competent income. However; this situation is observed when the capital distributions of the businesses are considered. The capital amount and the elements forming the capital are very important in the businesses (Aksöz, 1972). The greatest share in the active capital in Turkish agricultural businesses belongs to the land capital. The reason for this is that land capital is higher than that of other capital groups. This situation is an indicator of extensive agriculture. Capital usage per unit

land is not intensive (Cinemre, 1999). The reasons for this situation could be cited as not being able to healthily detect the money capital and material capital, lands to be a tool for social prestige, farming not adopted as a life style and the land value to be far above the production capacity of the land (Cinemre et al., 1995). Family labor force potential is 71,68%. The most important cost criterion following the forage cost is the fee for permanent labor force (shepherd etc.) in the businesses conducting animal production. Family labor force potential to be high has a positive impact on the agricultural income. The increase in the agricultural income is very important in terms of the sustainability of the family farming. The land amount (da), animal number, property land ratio, capital ratio and agricultural income ratio used in the definition of family farming are the important factors affecting the family farming. For this reason; the factors affecting the properties of family farming in the study area according to the definition of the family farming for the city of Konya have been detected with Logistic regression model.

Table 5. Analysis of the Factors Affecting the Properties of Family Businesses

Name of Variable	B	SE	Wald	DF	Sig	Exp(B)
Agricultural Income Ratio	,078	,019	17,483	1	,000	1,081
Equity Capital Ratio	29,668	7,895	14,123	1	,000	7,671

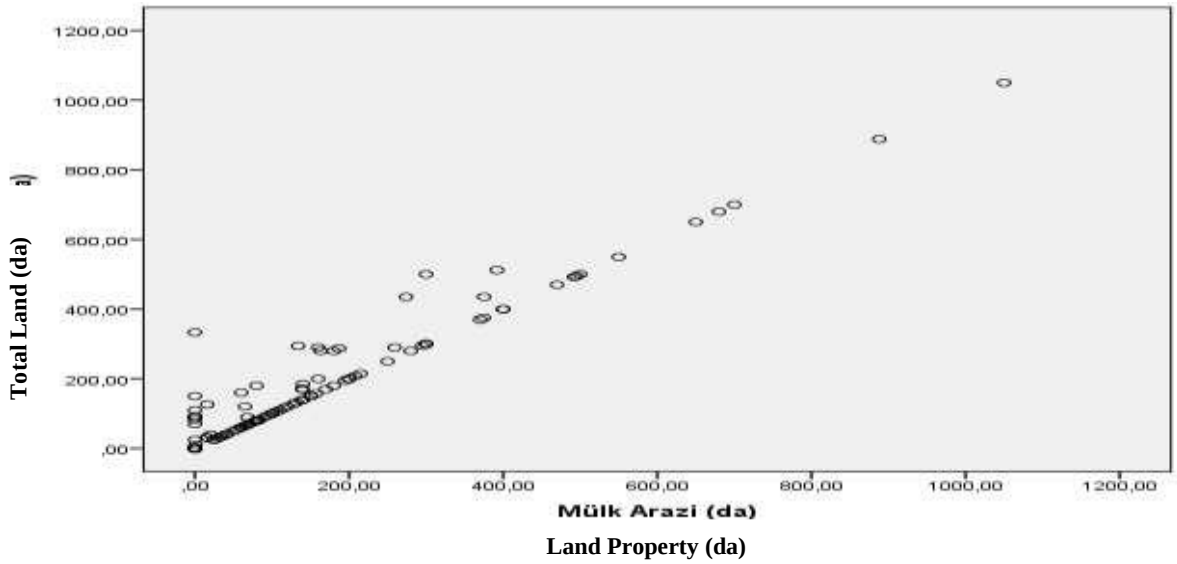
-2 LogLikelihood64,944Cox&Snell R Square 0,585 Nagelkerke R Square 0,780						

According to the results of Logistic regression model; agricultural income and equity capital ratio have been found positively meaningful at 1% importance level and labor force potential has been found positively meaningful at 10% importance level. Property land ratio has been found negatively meaningful at 10% importance level. The increase in the agricultural income among the equity capital and total income virtually belonging to the business manager and used in the agricultural production fortifies the definition of family farming. However; the importance of agricultural income has been emphasized if the family farming definitions in the world are considered (Calus ve Lauwers, 2009; Chaddad ve Jank, 2006; FAO, 2012; SAGARPA, 2012). But; as the property land ratio increases, the status of conducting family farming decreases. Small businesses conducting animal production increase their income via land renting and the big businesses increase their production area of forage plant. The production of field and horticultural plants is conducted in 55,50% of the rented lands and the production of forage plants is conducted in 44,50% of them. Therefore; a negative relation has been detected between the family farming and property land ratio in the study area. Besides, the relation between the total land and property land is given in Graphics 1.

Graphics 1. The Relation Between Total Land and Property Land



As the total land amount increases in the businesses, the property land ratio increases (Graphics 1). However; this property land is not sufficient for the forage plant production and the businesses apply to the rentin of the lands. A positive relation has been detected according to Chi-square analysis in the study area between the total land amount of the businesses and the status of the production of the forage plants (χ^2= 5233,700, p<0,01). In other words; as the total land amount increases, production area of forage plants increases. This situation is a status desired for the businesses conducting animal production. The status of the businesses for the production of forage plants on total land is 53,51%. But; this production is not sufficient and businesses apply to the renting of the lands and decrease their cost for forages. For this reason; land property ratio has been negatively meaningful. The final factor affecting the properties of the family farming is labor force potential. In contrast to the vegetable production, there is a need for permanent labor force during the production period. As the family labor force potential increases, foreign (permanent) labor force amount will decrease and this situation will increase the agricultural income. As the agricultural income rises, it will increase the desires of the businesses to use new techniques and technologies (Türkyılmaz et al., 2003; Kutlay ve Ceylan, 2008; Sezgin et al., 2010; Oğuz ve Yener, 2017). The sustainability of the family farming could only be ensured by adapting to the changing techniques and technologies for the businesses. Business income becomes very important for the businesses to be able to follow and purchase the new techniques and technologies. Besides; in similar studies, it is emphasized that the income levels of the farmers be sufficient in terms of being able to apply the modern agricultural techniques in rural areas (Kalanlar, 2005; Rogers, 2010; Ohe, 2012; Melesse ve Jemal, 2013; Ryan et al., 2014).

Conclusion

Agricultural income ratio, equity capital ratio, property land ratio and labor force potential from the factors affecting the properties of family farming have been found meaningful. The businesses in the study area are in the status of the businesses with competent income. The businesses to have an income at competent level will facilitate the separation of budget for new techniques and technologies and will ensure the development of the business. As in the average of Turkish businesses; also in the study area, the highest share among the active capital is taken by the land capital. However; the property lands of the businesses are not sufficient and the rent the lands. Besides, a negative relation has been detected between the property land ratio and family farming. The production of forage plants is conducted in

44,50% of the rented lands. This cost item will decrease as long as the production areas of forage plant expand due to the fact that the forage cost is the most important cost element in the dairy production. Furthermore; the most important cost item following the forage costs in animal production is the cost of labor force (shepherd etc.). As the family labor force potential increases, foreign labor force amount will decrease and this situation will decrease the permanent labor force cost item. Also in the model, labor force potential has been found positively meaningful. Family farming is very significant in terms of the provision of sustainability in agricultural production, food safety, prevention of the migration from rural areas to the cities and the assessment of labor force. For this reason; definitions of family farming has been made for the sustainability of the family farming in many countries. When the properties family farming is considered, it is seen that it has the same criteria in almost all over the world. There are changes only in the ratios of the criteria. The definition of family farming should be made on the basis of the countries and regions by taking these criteria into consideration and the businesses conducting family farming should be taken into account while making policies.

DEVELOPMENTS ON GEOGRAPHICAL INDICATIONS AND TRADITIONAL PRODUCT NAME REGISTRATION IN TURKEY

Gülşen KESKİN*, Nilgün GÜMÜŞAY

Republic of Turkey Ministry of Agriculture and Forestry, International Agricultural Training Center, Turkey
*Corresponding author: gulsenkeskin@gmail.com

Abstract

Interest in the origin of products and geographical indications in Turkey has recently increased in parallel with global developments. Geographical indications have the functions of preserving traditional knowledge and cultural values, combating product imitation, supporting local production and rural development, becoming a marketing tool, and guaranteeing the production methods and product standards. Traditional products, especially in underdeveloped regions, have the potential to create new employment opportunities for women and the young people and bring new initiatives for rural development. In this respect, it is of great importance to build the capacity of cooperatives and raise producer and consumer awareness and this can be achieved through both the public and the private sector. The Decree Law No:555 was implemented in Turkey as the basic regulation on the protection of geographical indications until Industrial Property Law No: 6769 came into force on January 10, 2017. The publication of the National Geographical Indication Strategy Document and the Action Plan on July 4, 2015 in the Official Gazette has been a significant development in terms of determining national policies. Turkey has a good potential for traditional products and products with geographical indications. 329 products have been registered by the Turkish Patent and Trademark Office as of April 2018, and 329 products are currently at the application stage. This study explains the current situation in Turkey on geographical indications and traditional product names and examines the practices in the application and registration process.

Keywords: *Marketing, Food quality, Rural development.*

Introduction

In global markets, it can be achieved through registered products to protect the producers of traditional/regional/local products and enrich these regions/local areas through these products and provide their sustainability. Turkey has a large export potential on existing and potential products with Geographical Indication (GI) depending on growing interest and demand in the world. Therefore, the importance of marketing strategies and registration of traditional/local food and agricultural products has been increasing in Turkey as in the world. (Çalışkan and Koç, 2012, s.211; Official Gazette, 2015). Protection by registration in these products is provided by the registration of "Geographical Indication" (GI) and "Traditional Speciality Guaranteed" (TSG). Minerals, handicrafts and industrial products as well as agricultural products and food can benefit from this protection.

The Decree Law No:555 was implemented in Turkey as the basic regulation on the protection of geographical indications until January 10, 2017 and, after this date, the Industrial Property Law No: 6769 came into force. The National Geographical Indication Strategy Document and Action Plan which are important for the determination of national policies were published in official gazette on July 4, 2015. The action plan predicts to strengthen the coordination between institutions on increasing the effectiveness of marketing strategies in order to particularly improve the institutional capacity of the relevant institutions, promote scientific studies on geographical indications, raise awareness of geographical indications in all segments of society and increase the added value of the products with geographical

indication. This will ensure the increase in registered products and good governance on geographical indications.

Turkey is a party to TRIPS Agreement, Paris Convention and Madrid Agreement for the Repression of False or Deceptive Indications of Source on Goods. Apart from these three agreements, the country accedes to some free trade agreements in which the provisions of the geographical indications are included ("Official Gazette", 2015, Gürsu, 2008). According to the Paris Convention, a separate application can be made for each country where protection is requested. It is also required to apply to the European Commission for the protection within the European Union (EU). The international registration system on GIs is expressed as Lisbon System (İloğlu, 2014).

By May 2018, Turkey has made an application to the EU Commission totally for 14 products notably Aydın Kestanesi, Inegöl Köftesi, Afyon Sucuğu, Afyon Pastırması, Taşköprü Sarımsağı, Kayseri Pastırması, Kayseri Sucuğu, Kayseri Mantısı and Bayramiç Beyazı. Antep Baklavası/Gaziantep Baklavası with the "Protected Geographical Indication" (PGI). In a similar way, Aydın İnciri and Malatya Kayısısı with "Protected Designations of Origin"(PDO). are the first products registered in the EU respectively on the dates of December 21, 2013, February 17, 2016 and July 07, 2017.

Turkey has a potential of GI approximately on 2500 products with its rich eco-system and workforce which is well-equipped with the skills and knowledge of production (Tekelioğlu et al, 2012). The preparation of the strategy document and action plan on GIs is substantial as it will enable this potential to be used together with the increase of awareness activities. Thus, the protection and recognition of these products will be provided and main producers of the products will economically be supported.

Current Situation in Geographical Indications and Traditional Speciality Guaranteed

As of the date of May 2018, Turkey has a total of 342 registered geographical indications, five of which is of foreign origin. Approximately 80% of the registered geographical indications are food and agricultural products. The meals have received PGI as the definition of TSG has not been done yet by the date of 10 January 2017 on which Industrial Property Law was adopted, (TPE, 2017a).

It has been significant improvements in the registration of geographical indications in Turkey between the years of 1996-2017. A total of 37 geographical indications were registered between 1996 and 2000, 26 of which were PGI. There was a steady increase over the following five-year periods and 84 products were registered in the last three and a half years from 2016 to this date (Graph 1). Due to the fact that the meals are given registration of PGI, 229 products (67%) in total geographical indications have received the registration of PGI.

23% of the 342 products receiving the GI registration in Turkey is made up of meals; 17% is made up of pastries/sweets/candies, and 11% is made up of fruit/vegetables/cereals group (Table 1). Other groups with a high potential of Turkey are handiworks/handicrafts and carpet/rug weaving. The country is far behind the potential in the cheese and olive oils, 4% and 2%, respectively. However, these products have a diversity originating from local and traditional characteristics and a high potential of GI.

Graph 1. Developments on registration of geographical indications

The increase in the number of applications made in recent years to the Turkish Patent and Trademark Office indicates the potential of the GI and there are 415 products in the application stage as of May 2018 (TPE, 2018). The increase in the applications filed with the EU has also gained importance and registration applications have been filed for a total of 14 products after registration of Malatya Kayısısı, Antep Baklavası and Aydın İnciri. These products are given in Table 2.

Table 2. Products in the application stage in the EU

Applications for Geographical Indications and RegistrationProcedures

Applications for geographical indication are made to the Turkish Patent and Trademark Office according to the latest regulation. The Agency evaluates geographical indications or traditional product name applications according to the Articles 33 to 37 and 39 of the Law and may request comments from related institutions and organizations for evaluating technical information. Based on this, technical comments can be sought from the Ministry of Agriculture and Forestry on food and agriculture issues. Those who have the right to apply for GI according to the Law on Industrial Property No 6769 are listed below:

1. Producer groups,
2. Public institutions and organizations related to the geographical area in which the product originates, and professional organizations in the form of public institutions,
3. Associations, foundations and cooperatives that are in the public interest or who are authorized to protect the economic interests of their members in relation to the product,
4. Producers concerned, in case that the product has only one producers and provided that this is proved.

Applications for geographical indications in Turkey are carried out mostly by commerce and industry chambers, municipalities, public institutions, local authorities and commodity exchanges (Table 3). While producer organizations in EU has an active role on geographical indications, their role in Turkey has remained limited. Up until today, producer associations and unions have made applications for five products including GiresunTombul Fındığı, Edremit Körfez Bölgesi Zeytinyağı, Güney Ege Zeytinyağları, Antep İşi and Yamula Patlıcanı and these products received GI registration. Bodrum Mandarini, Elazığ Öküz Gözü Üzümü and Tomarza Kabak Çekirdeği were registered with the producer association's channel. The difference of GI protection from brands is that it is an anonymous right that includes all the producers that produce the specific product that is included in the registry, not just the right for registrant. For this reason, it is especially crucial that cooperatives should take part in this system.

Table 3. Distribution of private/legal entities making application for geographical indication

Applicants	PGI	%	PDO	%	Total	%
Chambers of commerce and industry	81	*35,4*	29	*25,7*	110	*32,2*

Souces: TPE (2018)

The most common problem expressed in implementation in GI is the inconsistency of registration properties with the Turkish Food Codex. Products with geographical indications are special products and do not comply with the legislation specified the general scope and for this reason it is necessary to make the inspections according to appropriateness to the

characteristics of the registry. The Implementing Regulation of the Industrial Property Law stipulates that the inspection shall cover all activities related to the appropriateness according to the characteristics indicated in the registry and it will be carried out by the inspection authority recorded with the registry and approved by the Turkish Patent and Trademark Office (Article 45). 49th Article of the Law No: 6769 explains the rules of inspections of the use of GI.According to the Law, the inspections specified in GI registration certificate are made by the inspection authority established by the applicant. Provisions relating to the inspection of the use of GIs and the TSG in the Law on Veterinary Services, Plant Health, Food and Feed Law No: 5996 and in other laws are also applied. GI registration procedures start with application and continue with registration and inspection. These steps;

1. Application stage

The information and documents that should be included in the application file when applying to Turkish Patent and Trademark Office are;

- Information and documents proving the conformity of the entity with the name of the desired geographical indication and the information on the product group and information and documents proving appropriateness to the definition of GI.
- Technical information and documents describing the product and its properties.
- Information and documents that clearly define the boundaries of the geographical area.
- Information and documents relating to production methods, local production techniques and procedures and customs.
- Information and documents proving the connection of the quality, the reputation or other characteristics of the product with the geographical area in question.
-.Information and documents related to the historical background of the product in geographical area in question.
- Information and documents detailing the form of the inspection.
- Information describing the use of the geographical indication and, if applicable, labeling and packaging procedures.

2. Evaluation of the application and objections

The application file is examined by the Agency and if the information and documents are incomplete, the applicant is requested to correct these deficiencies. Upon request of the applicant, additional time is given for not exceeding two times to complete the missing information and documents, If the missing information and documents cannot be remedied within the given time, or if the submitted information and documents cannot be met, the application is rejected. Application which has been examined and approved within the scope of Article 38 of the Industrial Property Law No: 6769 is published in Bulletin. If the application is rejected, it can be appealed by the applicant to the Agency in written and justified within two months from the notification of the rejection decision.

On the other hand, from the date of publication to the Bulletin for the accepted application, third parties may object to the application within three months in a reasoned and written manner. The applicant is informed by the Agency of the objection and the opinion is requested. Both of the objections mentioned above are examined by the Board and opinions can be requested from the relevant institutions or organizations for the evaluation of the alleged objections. Taking into the opinions of the institutions consideration, the applications which are deemed appropriate as a result of the examination of the objection; in the case of a change in the form or scope of the application, with the part of the application which has undergone the change, are published in the bulletin. This posting cannot be appealed. If the appeal is rejected, the Decision is published in the Bulletin.

3. Registration and Requests for Changes

Within three months from the date of publication in the Bulletin, the applications for which no objection has been made, the rejection of the objections have been finalized, or amendments

have been made upon evaluating the objections, are recorded in the registry and published in the Bulletin. In addition, if there is a change in the properties of the registered geographical indication, the request for change can be made by those who have interest.

4. Scope, use and inspection of the right

Persons entitled to use the registered geographical indication or the TSG use it on the product or its packaging together with the geographical indication or the TSG product emblem. The emblem shall be used according to the legislation. The inspection shall be carried out by the inspection authority specified in the application and approved by the Agency. The change in the inspection authority on the registry can be made with the approval of the Agency. Inspection reports are submitted to the Agency annually from the date of the publication of the registration to the Bulletin. However, in case of a complaint, the Agency may require that inspection reports be submitted before the end of the period. If the inspection reports are found to be deficient, the registrant will be notified of the registration and be asked to correct the deficiencies within six months. If it is determined that the deficiencies have not been remedied or that the inspection activity has not been carried out in accordance with the procedure, the provision of Article 43 of Law mentioned above shall apply. The registrant may claim costs related to the supervision from the audits.

Conclusions

Traditional/local/regional products in Turkey have been taken under GI protection (with PDOs and PGIs) by specific regional/local name by 2017. The regulation on "Traditional Speciality Guaranteed" was made after this date with the Industrial Property Law No: 6769. There was no regulation regarding traditional products in Turkey while products which is protected under GI with PDOs and PGSs in the EU is reflected with the GI protection as PDOs and PGSs in the Law numbered 555.For this reason, it has been an important step to have an arrangement in the Industrial Property Law No: 6769 in this regard.

CONSEQUENCE OF BREAD WHEAT COST AND MARKETING PRICES AND RELATIONSHIP WITH YIELD AND SOME QUALITY PARAMETERS

Şahinde ŞİLİ*, İrfan ÖZTÜRK, Turhan KAHRAMAN

Trakya Agricultural Research Institute, Edirne, Turkey
*Corresponding author: ozturkirfan62@yahoo.com

Abstract

Trakya region is located in the Northwestern part of Turkey and bread wheat is mainly field crops widely grown in the region. Bread wheat production area is almost 550.000 ha and yield is 5 tons per hectare depend on genotypes, environment and agronomic practices. In Trakya region in some year, adverse weather condition, disease or insects may lead to a crop loss and revenue returns that do not cover production expenses. Due to biotic and abiotic stress factors rise in farm input costs and wheat prices has had economic effects on wheat sector in Trakya region. The mean yields from 2008 to 2017 seasons used in this analysis of 4 cultivars (Pehlivan, Gelibolu, Selimiye and Aldane) growing in the region. In the study grain yield and quality parameters of four cultivars from regional bread wheat experiment used from 2008 to 2017 growing seasons. Grain yield, 1000-kernel weight, test weight, protein ratio, gluten, gluten index, hardness, sedimentation value were compared with marketing price and yield. This comparison allows for a sectorial overview of the proportion of Trakya region wheat producers covering their production costs. Across 10 years environments, average yield varied from 450.4 kg da^{-1} in 2016 and 863.6 kg da^{-1} in 2008 seasons. The year of 2008 was more profitable due to higher yield and price and followed by 2014 thanks to higher grain yield. The highest wheat yields, mean prices and mean profit were in 2008 year. Wheat marketing prices and profit continuously have fallen from 2008 to 2017, but in 2009 and 2015 years dramatically dropped. Mean marketing prices of wheat rose to record highs in 2008 thanks to highest wheat yields. In 2016 both wheat yields and mean prices including mean profit were down significantly. In Trakya region in order to get high profit the yield and some quality parameters were in the mainly factors.

Keywords: *Bread wheat, cultivars, price, inputs, costs of production*

Introduction

Bread wheat is the mainly field crops is grown in Trakya region. Due to various environment condition can cause some problem related with yield and quality in wheat production (Öztürk and Korkut, 2017). It is very important issue that for farmers to get high profit from per hectare is the mainly critical factor in wheat production. The cost of production in wheat yield increases with increase in farm size. In Trakya region farm size is not too large. So farmers are not able to sow the crop timely, spend more on fertilizer, and pesticides. Wheat yield is more responsive to this commercial input.

Almost all breeding programs in the world aim to improve varieties with stable yields (Pfeiffer and Braun, 1989). In wheat, grain yield and baking quality are dependent on the environment, genetic factors and the interaction between them (Yan and Holland, 2010). Increasing yield potential without affecting negatively the quality of the grain is difficult, mainly because increases in grain yield are generally accompanied by a decrease in the grain's protein content, which is strongly associated with bread-making quality (Pena 2002; Pena 2008). Grain protein content in the mature grain is largely determined by environmental and farm management factors, with genetics playing a minor role in being either low or high in protein content. By contrast, protein quality is determined by the genetic composition of the wheat variety and also how the environment influences genetic expression (Blakeney et al.,

2009). Although there are many other quality requirements for durum wheat in the international marketing, some physical characteristics such as 1000 kernel weights and hectolitre weights determine the marketing price (Ozberk et al., 2006).
The cost of production analysis indicates that wheat yield, cost of production and gross income per acre increases with increase in farm size. The primary reason for this is that large farmers having their own tractor plough their fields more are able to sow the crop timely, spend more on fertilizer, irrigation and weedicides. Wheat yield is more responsive to this commercial input that is why the gross income increases with farm size as above mentioned input usage increases. The increase in yield is more than the increase in cost that is why the net income per acre, cost per 40 kg and income per 40 kg reduces with farm size. So to increase the usage of these inputs, time availability of these inputs both in term of quality and quantity is ensured at the doorstep of the farmers (Hassan et al., 2005).
The rise in farm input costs and wheat prices have economic effects on wheat sector. A cumulative distribution of forecasted production costs for wheat farms shows that current high wheat marketing prices will allow a greater share of producers to cover their production costs. Because of the various environment condition yields in wheat production is not stable. Due to this fluctuation in some year farmers get lower profit. So, this study was performed with the aim of to determine profit of wheat and relation of yield and quality parameters with wheat price in Trakya region, Turkey.

Material and Methods

This research was established with 25 genotypes in randomised complete block design (RCBD) with 4 replications in Edirne location, from 2008 to 2017 growing seasons. Each plot had 6 meter long, with 6 rows, spaced 0.17 meters apart. A seed rate of 500 seeds m^2 was used. In the study four cultivars (Pehlivan, Gelibolu, Selimiye and Aldane) were selected from the regional bread wheat experiment and their yield and quality parameters from 2008 to 2017 growing seasons were used. Grain yield, 1000-kernel weight, test weight, protein ratio, wet gluten, gluten index, hardness, sedimentation value were compared with marketing price and grain yield. This comparison allows for a sectorial overview of the proportion of Trakya region wheat producers covering their production costs.
Grain yield, 1000-kernel weights and test weight, (Blakeney et al., 2009), protein ratio, grain hardness, gluten value, gluten index, and sedimentation (Köksel ve ark., 2000; Perten H. 1990; Anonymous, 2002; Anonymous, 1990) were investigated. The quality analysis of Zeleny sedimentation test and wet gluten content were determined according to ICC standard methods No. 116/1 and 106/2, respectively (Anonymous, 1972; Anonymous, 1984).
The significance of differences among means was compared by using Least Significant Difference (L.S.D. at a %5) test (Gomez and Gomez, 1984; Kalaycı, 2005).

Results and Discussion

This study's cost and returns analysis of the Trakya wheat sector provides a snapshot of the range of production expenses across the Trakya region and compares this range with the national season average price that farmers received for wheat. This comparison allows for a sectorial overview of the proportion of Trakya region wheat producers covering their production costs. This analysis uses normal yields of four cultivars and also used later in this report in comparison of actual costs and forecasted costs.
Combined analysis of variance across the 10 (from 2008 to 2017) years revealed highly significant variation among years based on grain yield, 1000-kernels weight, test weight, protein ratio, hardness, sedimentation, gluten value and gluten index, shown in Table 1.

Table 1. Mean yield and quality parameters based on years from 2008 to 2017

Years	TKW	TW	PRT	HARD	SED	GLT	IND
2008	43.9	83.2	13.2	51.3	51.3	37.5	76.2
2009	38.6	80.5	13.1	51.0	45.8	37.9	78.2
2010	39.5	80.8	11.0	46.0	50.5	28.9	91.7
2011	34.5	82.7	14.5	55.0	64.3	42.3	87.8
2012	47.0	85.3	12.5	51.5	44.5	39.1	74.9
2013	44.9	79.9	10.7	46.8	43.3	29.9	78.6
2014	48.3	80.7	9.8	46.5	41.3	25.9	93.0
2015	43.0	81.9	12.3	49.8	61.0	35.5	85.0
2016	36.1	83.7	11.2	48.0	41.0	31.7	72.0
2017	47.0	80.9	12.4	48.0	50.0	36.4	73.0
Mean	42.3	82.0	12.1	49.4	49.3	34.5	81.0

Note: Significance at **: P<0.01; *: P<0.05; TKW: 1000-kernel weight (g), TW: Test weight (kg), PRT: Protein ratio (%), HARD: Hardness (PSI), SED: Sedimentation (ml) GLT: Gluten (%), IND: Gluten index (%),

According to results there were significant differences among years based on investigated parameters, so test weight ranged from 79.9 kg in 2013 to 85.3 kg in 2012. Mean test weight was 82.0 kg. Grain 1000-kernel weight is the mass of a given number of kernels and is a useful measure of grain size (Blakeney et al., 2009). The 1000-kernel weight varied from 34.5 g in 2011 to 48.3 g in 2014 among years and mean value was 43.8 g. (Table 1). There were also significant differences among years according to protein ratio and varied from 9.8% in 2014 up to 14.5% in 2011 year and mean protein content was 12.1%. Wheat hardness is influenced especially by genetic factors, but can be influenced also by environment and its factors like moisture and protein content (Turnbull and Rahman, 2002). In the study there were significant differences among years according to grain hardness and ranged from 46.0 in 2010 up to 55.0 in 2011 year. Mean of the grain hardness was 49.4 (Table 1). Statistically significant differences for wet gluten content were found among years. The highest wet gluten content (42.3%) was measured in 2011 year, whereas the lowest with 25.9% in 2014 growing year. Mean gluten content was 33.9%. Gluten index ranged from 74.9% in 2012 up to 93.0% in 2014 year. Analysis of variance showed there was a highly significant difference among years for sedimentation value. Average sedimentation value varied from 41.0 ml (in 2016) to 64.3 ml (in 2011). Throughout all the 10 years environments, the mean grain yield was 696.4 kg da^{-1}. Due to favorable environment condition the highest average yield of four cultivars was 863.6 kg in 2008, and in 2014 with 824.4 kg/da. The lowest yield was in 2016 with 450.4 kg da^{-1} due to unfavourable environmental condition (Table 2). Wheat marketing prices and profit continuously have fallen from 2008 up to 2017, but in 2009 and 2015 dramatically dropped. Mean marketing prices of wheat rose to record highs during 2008 so the highest wheat yields, and mean profit were in 2008 year. In 2016 both wheat yields and mean marketing prices including mean profit were down significantly from their 10 year highs.

Table 2. Mean grain yield and marketing price / profit of wheat based on years

Year	Lower Prices ($/kg)	Higher Prices ($/kg)	Mean Prices ($/kg)	Mean Yield (kg ha^{-1})	Mean Profit ($/ha)	Lower Profit ($/ha)	Higher Profit ($/ha)
2008	0.32	0.55	0.42	8636	3627	2764	4750
2009	0.24	0.41	0.31	6116	1896	1468	2508
2010	0.28	0.46	0.38	6719	2553	1881	3091
2011	0.28	0.40	0.34	6660	2264	1865	2664
2012	0.28	0.42	0.34	6947	2362	1945	2918
2013	0.29	0.42	0.35	7198	2519	2087	3023
2014	0.29	0.41	0.35	8244	2885	2391	3380
2015	0.25	0.35	0.29	6885	1997	1721	2410
2016	0.27	0.32	0.30	4504	1351	1216	1441
2017	0.16	0.37	0.27	7729	2087	1237	2860
Average	0.27	0.41	0.34	6964	2354	1857	2904

Regarding the years, mean lower marketing prices ranged 0.16 $ kg, (in 2017) up to 0.32 $ kg (in 2008), and mean was 0.27 $ kg. The highest marketing prices of wheat ranged 0.32 $ kg in 2016 up to 0.55 $ kg in 2008 and mean was 0.41 $ kg (table 2). Across all the 10 years environments mean marketing prices ranged from 0.27 $ kg in 2017 to 0.42 $ kg in 2008 and mean was 0.34 $ kg.

Based on the years and profit of wheat production per hectare, lower profit ranged 1216 $ ha (in 2016) up to 2764 $ ha (in 2008), and mean was 1857 $ ha. The highest profit of wheat varied 1441 $ ha in 2016 up to 4750 $ ha in 2008 and mean was 2904 $ ha (Table 2). Across 10 years environments mean profit ranged from 1351 $ ha in 2016 to 3627 $ ha in 2008 and mean was 2354 $ ha.

Correlation coefficients among yield, quality parameters with marketing price were given in Table 3. To determining the effect of the yield and quality parameters on marketing price the correlations were determined by Pearson's correlation analysis (Table 3). It was found various relations among yield and quality parameters with marketing price and profit. Decreasing in some quality parameters was negatively affected marketing price of wheat. So, there was slightly negatively relation between low price with 1000-kernel weight (r=-0.122), protein ratio (r=-0.125), and wet gluten value (r=-0.189). Increasing in some quality parameters had a positive effect of wheat marketing price. Due to this relation there was positively slightly association between higher price with 1000-kernel weight (r=0.206), protein content (r=0.160), hardness (r=0.117), and gluten index (r=0.136).

Based on investigated quality parameters 1000-kernel weight and gluten index were the mainly factors increasing in profit. Protein ratio in wheat production had a significant effect on marketing price. Also, decreasing in yield led to various levels of reductions in profit. Increasing in gluten index was positively affected mean and high profit in wheat production so there was positive relation between gluten index with mean profit (r=0.287), and higher profit (r=0.162). The higher 1000-kerenl weight had a significant increase in mean profit (r=0458) and higher profit (r=0.482). Grain yield in wheat also positively affected mean (r=0.461) and higher marketing price (r=0.646).

Table 3. Correlation coefficients among yield, quality parameters and marketing prices

Parameters	Lower Price	Higher Price	Mean Price	Mean Yield	Mean Profit	Lower Profit	Higher Profit
Higher Price	0.544						
Mean Price	0.819	0.901

Conclusion

Bread wheat is the mainly growing field crops and due to various environment condition and misapplication agronomic practices its yield and quality could be lowered. It is very important issue that for farmers to get high profit from per hectare is the mainly critical factor in wheat production. Across 10 years grain yield varied year by year because of the various environments conditions. In Trakya region the year of 2008 was more profitable due to higher yield and marketing price and followed by 2014 thanks to higher grain yield. The highest wheat yields, mean marketing prices and mean profit were in 2008 year. Wheat marketing prices and profit continuously have fallen from 2008 up to 2017, but in 2009 and 2015 dramatically dropped. The mean marketing prices of wheat rose to record highs during 2008, due to the highest wheat yields. In 2016 both wheat yields and mean marketing prices including mean profit were down significantly from their 10 year highs. In Trakya region in order to get high profit the yield and some quality parameters were in the mainly factors. Based on investigated quality parameters 1000-kernel weight and gluten index were the mainly factors increasing in profit. Also, protein ratio in wheat production had positively effect of wheat marketing price. Also, decreasing in yield led to various levels of reductions in profit. Increasing in gluten index was positively affected mean and higher profit in wheat production. Grain yield in wheat also positively affected mean and higher marketing price.

Abstract

In this study, alternative flying fields suitable for paragliding which is one of nature sports within the boundaries of Sivas province, Turkey were automatically determined by Geographical Information Systems (GIS) analyses and the developed user interface program by taking into account the international technical conditions required for flying. The suitability of these determined fields was checked with the flight tests performed in company with the experienced paragliding pilot, and they were proposed as nature tourism areas. With this study carried out, it was ensured that the paragliding fields, which were mainly determined by observational and experimental methods, were scientifically determined in accordance with the international technical specification criteria. Furthermore, a new method has been developed in order to automatically determine alternative paragliding fields in any city with the help of the introduced GIS-based system and user interface program.

Keywords: *GIS, Ecotourism, Paragliding, Spatial analysis, Nature-based tourism.*

Introduction

There are many studies on the use of GIS in the management of recreational resources. Issues such as tourism transport capacity, sustainable tourism infrastructure planning (Boers and Cottrell, 2007), sustainable land-use planning (Bunruamkaew and Murayama, 2012), determination of areas with potential for ecotourism (Bishop and Hulse, 1994; Boyd et al., 1995; Miler et al., 1998; Tseng et al., 2013; Parladır, 2013), nature-based tourism modeling, recreational use potential modeling (Kliskey, 2000) come to the forefront in these studies. This problem is also related to geographical site selection. In the literature, different studies were performed related to site selection by GIS (Şentürk and Erener, 2017; Rutherford et al., 2015).

Paragliding which is one of the alternative nature sports appealing to adrenaline junkies carries a risk by the way it is done. It is necessary for athletes to receive a license to fly on their own. Apart from the pilot experience, the flying field should meet the technical requirements to ensure safe flying. First of all, appropriate hills are required for paragliding. The land structure of the front of the hill and the climatic conditions should be investigated very well, and their analyses in terms of suitability and risks should be performed by experienced pilots. Appropriate weather conditions (fog, wind, snow, rain, etc.) are important in areas considered for paragliding. The predominant wind direction, slope, and altitude of the take-off field are the most important features that should be primarily evaluated for the safety of the take-off field. Another feature that is essential for the safety of the take-off field is that there should be no barriers in areas within a distance that can endanger the take-off, flight and landing safety on the hills to paraglide. Landing areas should be a flat area away from anything that can cause turbulence (Topay, 2003). It is certain that these scientific determinations will provide convenience in far better elevations during flying and going away for kilometers. Although the determination of flying hills and landing areas with appropriate conditions in large geographies is difficult, the examination of all fields by pilots is also impossible. At this stage, GIS-based studies are crucial for determining potential flying fields.

In the determination of the fields for paragliding which is a risky sports branch, attention should be paid to criteria such as the take-off direction, slope and altitude of the hill to paraglide, determination of the required field widths to be able to continue flying for a long time and the fact that landing areas allow for secure landing. With this study, a new method has been developed for a short-term, low-cost and scientific determination of potential flying fields in accordance with the criteria specified in a wide area such as the provincial border. In accordance with the results obtained, an attempt to contribute to tourism in the region was made by recommending new flying fields to paragliding lovers. Furthermore, a new method has been developed to be able to automatically determine alternative paragliding fields in any city with the help of the introduced GIS-based system and user interface program.

Material and Methods

Sivas provincial border (Turkey) was selected as the study area (Fig. 1). When the tourism structure of Sivas province is examined, it is observed that thermal tourism along with cultural tourism mainly comes to the forefront. Mountaineering and trekking attract attention when the nature sports done in the region, which is not known sufficiently in terms of nature sports, are examined (Governorship of Sivas, 2011). However, the city has enough wind potential for paragliding, and it is necessary to determine suitable flying fields in the city to evaluate this feature.

Figure 1. Study Area: The border of Sivas province

The data presented below were used within the scope of this study.

- Energy transmission lines,
- Stand,
- Highways,
- Streams,
- Lakes/ponds,
- Dams,

- Corine land use,
- Protected areas,
- Military areas,
- Airports,
- Digital Elevation Model (DEM),
- Aspect and
- Wind direction.

Firstly, the grid network to be used as the basis of the study was formed in a way to cover all Sivas provincial border. The grid size was determined to be 250 m x 250 m to ensure the sufficient sensitivity in the analyses to be performed. The analysis criteria to be used in the determination of the fields were determined based on the "Flying Altitudes, Conditions and Hill Features" specified in the Turkish Aeronautical Association Flight Training Directive, supported by the International Aviation Federation (Fig. 2). Furthermore, the criteria applied with experiential knowledge for safe flight were extended with the help of experienced pilots (flight instructors with EP license). The analysis criteria created in this context are presented in Fig. 2. The analyses were performed separately for take-off and landing fields.

Different geographical analyses (Statistical analysis, spatial analysis, zonal statistics analysis, surface analysis, proximity analysis, neighborhood analysis, sieve analysis, overlay analysis, visibility analysis) were used to determine the suitable paragliding areas. These analyses, which is included in decision making and planning techniques, is based on the elimination of unfavorable locations within certain criteria starting from the most unfavorable criteria in determining location suitable for the purpose of the study. Furthermore, the criteria applied with experiential knowledge for safe flight were extended with the help of experienced pilots (flight instructors with EP license). The analyses were performed separately for take-off and landing fields.

In this study, although the criteria given in Fig. 2 were used, the relative criteria that may vary according to the flight pilot's professionalism were presented as the parameters that the user could enter in the developed user interface program depending on his/her preference. Furthermore, the user interface program was developed with the Model Builder in ArcGIS 10.1 GIS software environment (Fig. 4) so that it could be used anywhere in the world, on condition that the data listed above were provided. The variable parameters considering in this user interface program were given in Fig. 3.

Factor	*Analysis Type*	*Analysis Site*	*Suitability criteria*

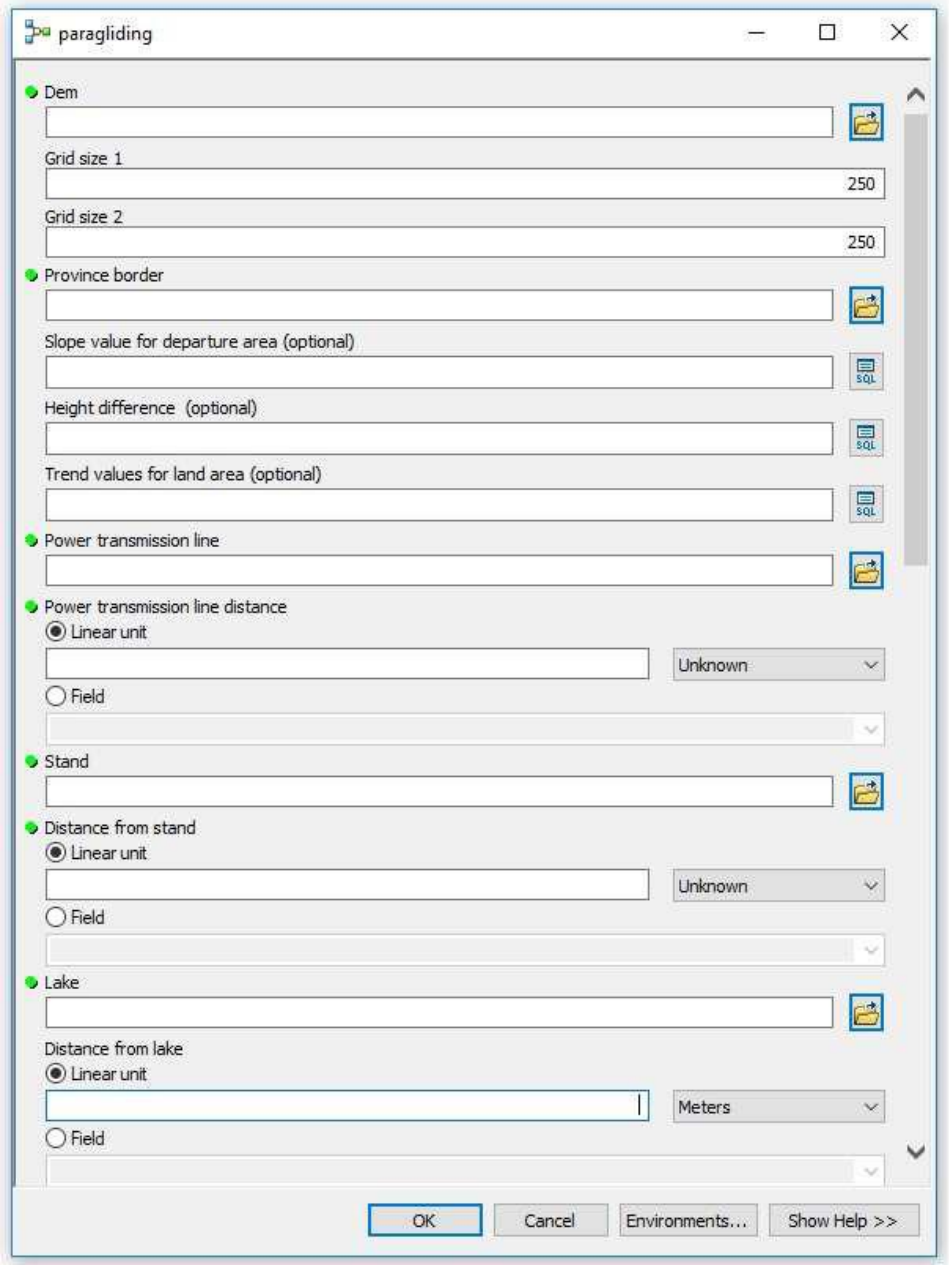

Figure 4. The user interface program developed on ArcGIS software

Results and Discussion

It was proceeded to the final stage of the study after determining automatically the fields suitable for flying in the GIS environment by the user interface program developed. 32 fields were determined as the fields suitable for paragliding (Fig. 5). 8 out of the designated target points were randomly visited (Fig. 5), and the suitability of the region for paragliding was validated. The test flight was performed in the field by the professional paragliding pilot with EP license (Fig. 7), and the acceptability of the field as a paragliding field was decided. According to the results obtained; all fields were determined as flight areas from the point of topography but one of them was not accepted due to the missing data of power transmission lines in the area.

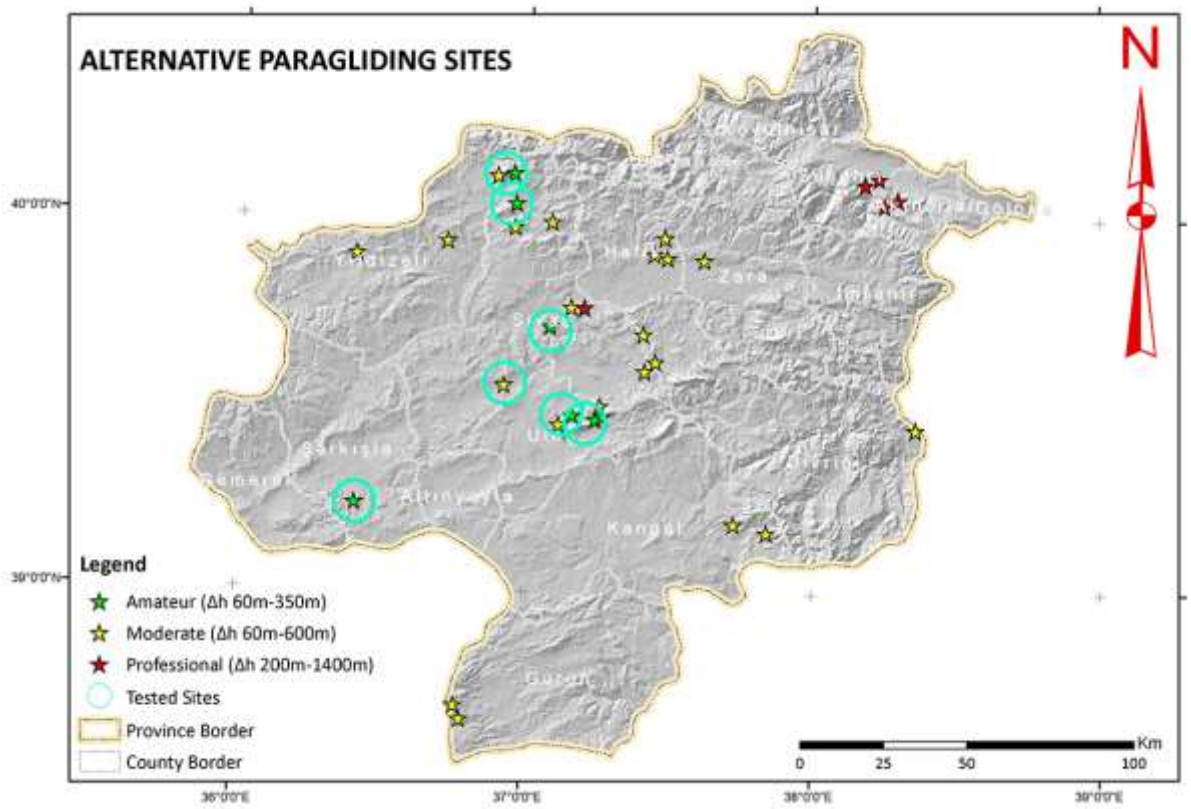

Figure 5. Suitable paragliding fields map

Conclusions

GIS is an extremely important tool in geographical analysis and provides a great deal of convenience to its users. It is seen that the large areas which cannot be analysed via observations, can be analysed objectively and scientifically by the help of GIS. However, the accurate and up-to-date data is of great importance in such GIS studies.

The outcomes of the study have indicated potential new tourism areas by bringing many fields that have not yet been discovered by paragliders to the agenda. It is thought that these fields that can be transformed into attraction centres with various promotional and demonstration flights over time will make positive contributions to the socio-economic development of the region. On the other hand, the outcomes of the study suggest new alternative flying fields that can be reached more easily and quickly by paragliding lovers. This will provide economic benefits by reducing the time and cost that athletes spend to do paragliding and also allow the sports branch to reach larger masses.

ABATEMENT OF AGRICULTURAL GREENHOUSE GAS EMISSIONS IN THE EUROPEAN UNION: A REVISED ANALYSIS OF MARGINAL ABATEMENT COST

Ancuta ISBASOIU*, Stéphane DE CARA, Pierre-Alain JAYET

Public Economics Unit, INRA-AgroParisTech, France
*Corresponding author: ancuta.isbasoiu@inra.fr

Abstract

Avoiding the adverse effects of climate change has become a key priority for the European Union. Marginal abatement cost curves of greenhouse gas emissions are essential to assess the potential for efficient reduction from a cost-effectiveness perspective. We process simulations based on an agricultural supply-side model calibrated against six economically contrasted sets of annual data (2007-2012). The paper characterises how the year-based uncertainty surrounding the MACCs influences both the initial level of emissions, as well as the carbon price elasticity of emissions. The assessment is made at the European Union level, both at regional (FADN regions) and infra-regional (farm types) levels. The paper analyses the distribution of regional and farm-types abatement rates and estimates the price elasticities of abatement rates and emissions for the different years and different carbon prices. The economic context draft by annual data accounts significantly in the variations, yearly sets of prices and tax effects playing an important role when estimating the cost of GHG emission abatement. In this regard, the elements of economic contexts condition the marginal cost curve at two levels: i) they determine the level of emissions in the absence of regulation (at zero emission prices) and ii) they determine the opportunity cost of reducing with a unit the emissions and the response that can be expected from the introduction of emission pricing.

Keywords: *Marginal abatement costs, Greenhouse gas emissions, Carbon price*

Introduction

The European Union (EU) has an ambitious agenda for addressing the effects caused by the climate change. In particular, the European Commission has introduced fixed key targets to reduce greenhouse gas (GHG) emissions. Compared to 1990, the EU should reduce GHG emissions to 40% by 2030 and to 80% by 2050. Agriculture represents a major and complex source of GHG emissions. In 2016, the EU agricultural GHG emissions accounted for approximately 10% of total EU-28 GHG emissions (European Environment Agency, 2018).

The heterogeneity that characterises agriculture, combined with many potential mitigation techniques, allow cost-effective non-CO_2 GHG abatement. In this regard, marginal abatement cost curves (MACCs) are an important and useful tool for assessing the potential for efficient reduction in the sector. A significant effort has been made to evaluate such curves in different contexts (Ragnauth et al., 2015; De Cara et al., 2005; De Cara & Jayet, 2011; Moran et al., 2010; OCDE, 2015; EPA, 2013; Eory et al., 2014, Vermont & De Cara, 2010).

To appreciate the uncertainty surrounding MACCs, several authors have proposed sensitivity analyses of the curve to several key parameters. In order to study the strength of marginal abatement cost curves, Klepper & Peterson (2003) used the computable general equilibrium model DART (Dynamic Applied Regional Trade). Vogt-Schilb et al. (2015) applied the software MACTool developed by the World Bank, in order to assess the uncertainty of MACCs. On the other hand, according to Kesicki & Strachan (2011) and Kesicki & Ekins (2012), MACCs can play an important role in the decision-making process when introducing a cap-and-trade system or a carbon price.

In order to analyse the GHG emission reduction potentials both at sectoral and regional levels, Van Vuuren et al. (2009) used six various models (three recursive-dynamic computable

general equilibrium models, two energy system models and a macro-econometric non-equilibrium hybrid simulation model). De Cara et al. (2005) showed that an emission tax of 55.8 €/tCO_2 leads to an 8%-reduction (207 MtCO_2eq) in total agricultural emissions as referred to emissions from reference-year 2001. When fixing a 10% EU abatement target, De Cara & Jayet (2011) highlighted that cap-and-trade systems could play a major role, this target being achieved at a price of 32–42 €/tCO_2.

In this paper, we are taking into consideration the direct GHG emissions sourced by agriculture, relying on the two main agricultural gases, nitrous oxide and methane respectively. By using a supply-side model, an emission tax (expressed in €/tCO_2eq) is introduced. The six years 2007-2012 on which this study is based, are characterised by very contrasted economic contexts (e.g. agricultural and fertiliser prices, changes in agricultural policy). The paper analyses the distribution of regional and farm-types abatement rates and estimates the price elasticities of abatement rates and emissions for three emission taxes, 30, 50 and 100 €, respectively.

Materials and methods

The model used in this paper is the European agro-economic model AROPAj (De Cara et al. 2005, Galko & Jayet, 2011) which simulates the agricultural supply in the European Union. AROPAj is a mathematical programming model, being built on a set of linear programming models. The Farm Accountancy Data Network (FADN) represents the main source of data for AROPAj. The model is based on *farm types* or *farm groups*, which represent a group of farms with similar features grouped by a clustering method, depending on four key variables (main types of farming, altitude, irrigation and economic size).

The paper is based on the actual V5 version of the model, calibrated against six sets of annual FADN data, more precisely 2007-2012. In order to maximise the total gross margin (π_k), in the model, the supply level and the input demand are chosen by each farm group k. The generic form of the model is:

$$max_{x_k} \quad \pi_k(x_k, \theta_k, \varphi) \qquad \text{s.t. } x_k \in A_k(\theta_k, \varphi)$$

x_k represents the vector of producing activities for farm group k, including variables such as the area of each crop or the number of animals in each category. The greenhouse gas emissions are a component of x_k, being calculated endogenously. The production constraints are indicated by A_k, the matrix of input-output coefficients. The vector θ_k relates to k-specific parameters, and the vector φ refers to common parameters. In the model, the main constraints are represented by the crop rotation constraints, the availability of utilized agricultural area, the animal feed requirements and the implementation of the Common Agricultural Policy instruments.

The paper is based on the methodology developed by De Cara & Jayet (2011). Therefore, the abatement rate is defined as:

$$abat_i(p) = 1 - \frac{E_i(p)}{E_i^0} \tag{1}$$

where E_i^0 refers to the base-year agricultural i-GHG emission in FADN region i and E_ip represents the GHG emissions for region i reported to the carbon price p introduced. The following specification for the abatement rates is used:

$$i = 1, n: \qquad abat_i(\mathrm{p}) = \alpha_i \left(1 - e^{-\left(\frac{p_i}{\tau_i}\right)^{\beta_i}}\right) \tag{2}$$

Several conditions are placed, e.g.: $0 < \alpha_i \leq 1$, $\beta_i \geq 0$ and $\tau_i > 0$. The term α_i refers to the i-asymptotic level of abatement rate ($\lim_{p\to\infty} abat_i$ (p) = α_i). In order to analyse the price response of the abatement rate, we are using two indicators, the price elasticity of the abatement rate and the price elasticity of emissions.

Results and discussion

By using the AROPAj model, our results are based on the temporal variability of the six contrasting years, bringing a quantitative clarification on MACCs. As shown in Figure 1, the lowest GHG emission abatement rate was recorded in 2012 and the highest in 2010. We can observe that a significant gap ranging from 0.25 to 0.35 being observed for a carbon price of 200 €.

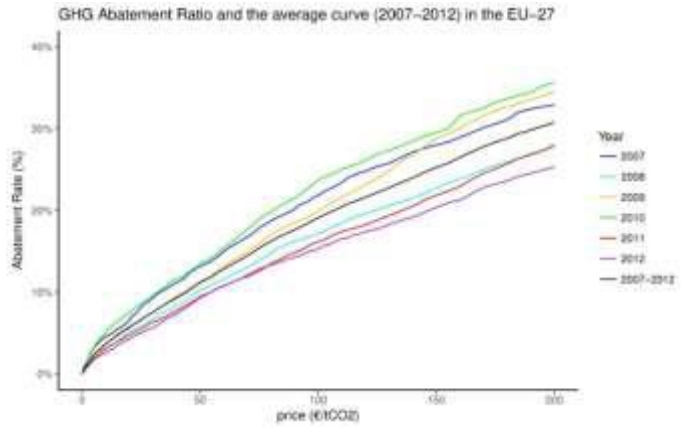

Figure 1. EU abatement ratio (2007-2012) and the average abatement rate for a carbon price up to 200 €.

Our analysis takes into consideration the fact that the initial level of GHG emissions is different for each of the six years, the highest level being in 2010 (see Figure 2).

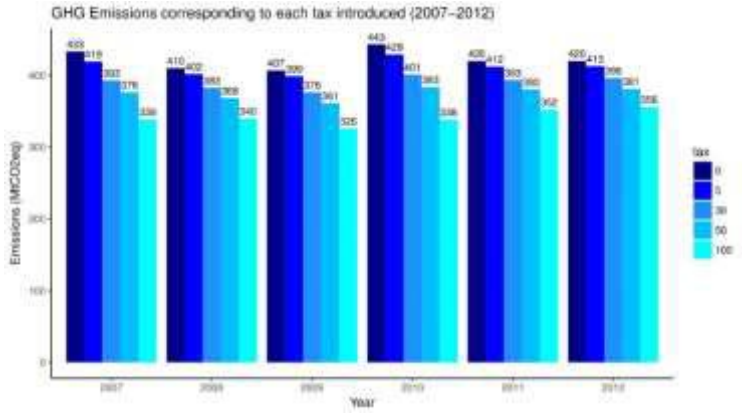

Figure 2. The EU initial emission levels (2007-2012).

If we focus on the EU aggregated results, the estimated parameters show that a 10% decrease of EU agricultural emissions implies a price elasticity of abatement rate ranging from [0.75, 0.92] and an absolute value of the price elasticity of emissions ranging from [0.08, 0.10].

In order to assess the regional distribution of abatement costs, both spatial and temporal dimensions were analyzed, allowing for a clear assessment of the significance of the year effect, as well as the tax and region effect. In doing so, Figure 3 displays the distribution of EU GHG emission abatement rates for three given carbon prices and each of the six years, as well as the average European rate of each year and the average of the six years.

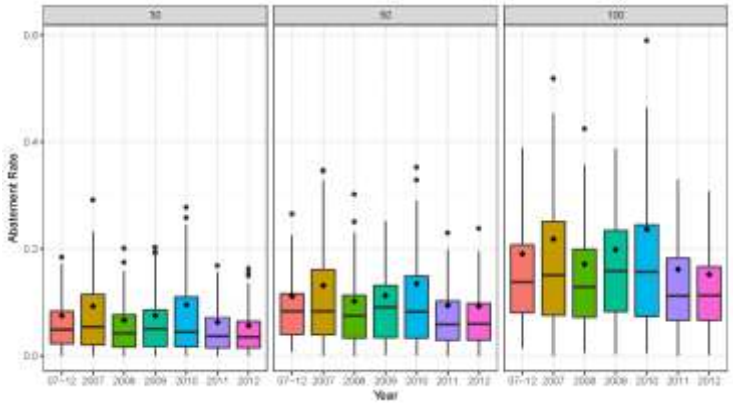

Figure 3. Distribution of GHG emission abatement rates by region, year and three tax levels.

The variability of abatement rates between regions is higher than the variability of rates between years. Depending on years, for a carbon price of 30 €, 50 € and 100 €, respectively, the median varies from 4 to 6%, from 6 to 9% and from 11 to 16%. For a tax of 100 €, by taking into account the average of the six years, 50% of regions are reducing less than 14%. Compared to the average calculated over 2007-2012, we can observe that in 2007, 2009 and 2010, the median is superior to 14%, while in 2008, 2011 and 2012, is below.

Although it can not be precisely located within which FADN region belongs, in the AROPAj model, each farm type has its place in a particular FADN region. The distribution of farm-type abatement rates plotted against the cumulative baseline emissions, for each emission tax introduced (30, 50 and 100 €/tCO2eq respectively) shows a significant variability from one tax to another for the 6 years (2007-2012) (see Figure 4). As the tax increases, the range of variability of the 6-year curves is higher both on the ordinate and on the abscissa. There is a shift of curves to the right, which suggests a shift in the concentration of abatement efforts toward farmers with the highest abatement rates.

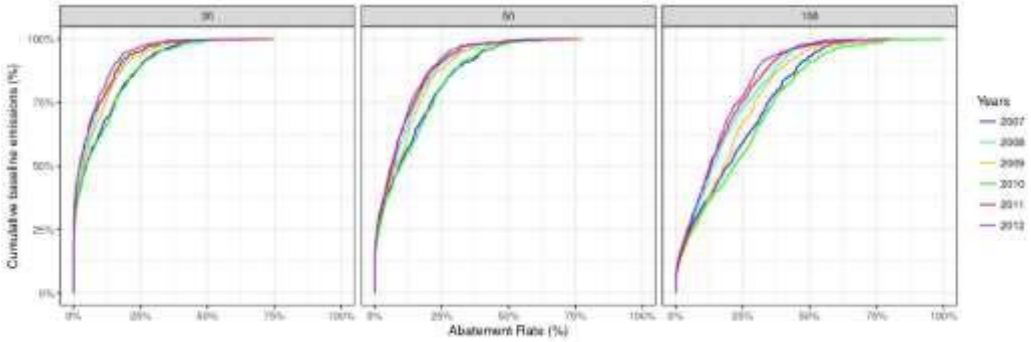

Figure 4. Distribution of farm-type abatement rates, over the period 2007-2012, in the EU-27, when emission tax is equal to: 30, 50 and 100 €/tCO_2eq respectively.

In 2010, year characterised by a low crop price, a minimum level of the fertilisers price, and, implicitly, a high fertilisers consumption, farmers who reduce their emissions by less than 15% represent approximately 76% of baseline emissions, in the case of an emission tax of 30 €/tCO2. The percentage of emissions drops to 60% for a tax of 50 €/tCO2 and to 37% in the case of a tax of 100 €/tCO2. At the extreme opposite, in 2012, year described by high crop and fertilisers prices, farmers who reduce their emissions by less than 15% represent approximately 87% of baseline emissions, in the case of an emission tax of 30 €/tCO2. For a tax of 50 €/tCO2, it drops to 76% and in the case of a tax of 100 €/tCO2, to 58%.

Due to the fact that the distribution of baseline emissions among farm-types and regions can play an important role, regional and farm-types abatement rates are plotted against the cumulative baseline emissions. Thus, the distribution can be observed for each of the FADN

regions and farm-types considered in the analysis, and this, for each of the six years and for each of the three emission taxes introduced (see Figure 5). Regions and farm-types characterised by higher abatement rates are located to the right of the graphs. Our results are robust by reference to the results obtained by De Cara et al. (2005), whose analysis was based on the year 2001.

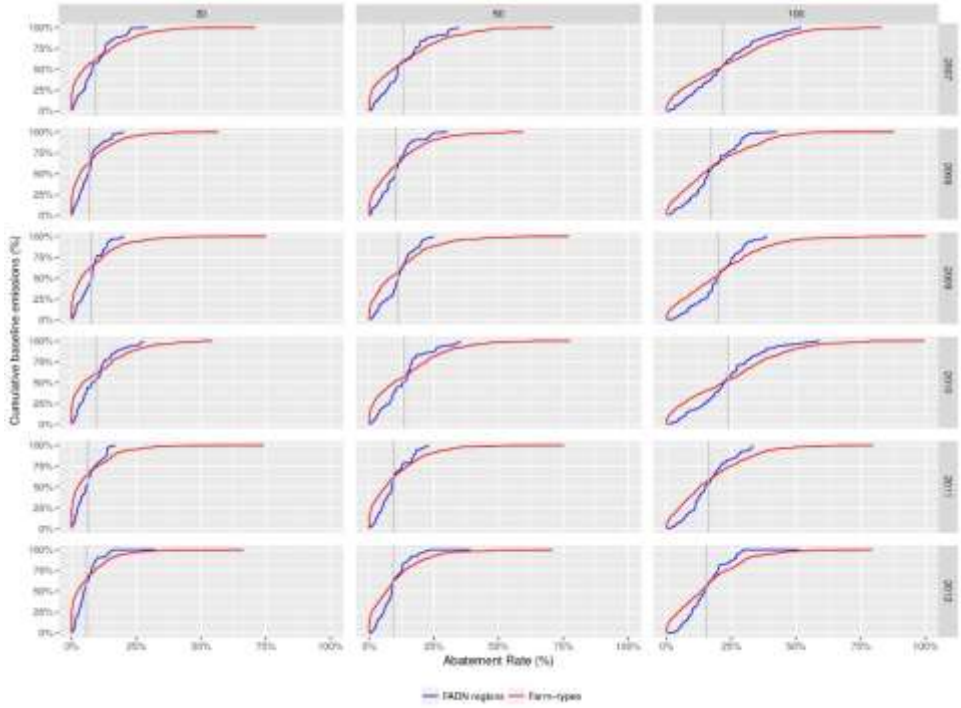

Figure 5. Distribution of regional and farm-type abatement rates, in the EU-27, for three tax levels.

The distribution of regional and farm-type abatement rates shows that the farm-type level variability is larger than regional variability. A part of the abatement cost variability remains unseen due to the regional aggregation. The farm-type curve is less concentrated around the abatement rate corresponding to the intersection between the two curves, a rate that varies depending on the level of the emission tax introduced.

Conclusion

One of the strengths of our paper consists in giving sensitivity to economic context, having the means to produce a wide estimation on important elements, such as the abatement costs, the price elasticity for the various functions of reducing emissions. This study provides an assessment of abatement costs at the European level, both at regional and infra-regional levels, showing that, when estimating the cost of emission abatement, years and tax effects have an important role, the EU being characterised by a large spectrum of individual abatement ratios against a given price. A 10% reduction of EU agricultural emissions implies a price elasticity of abatement rate of approximately [0.75, 0.92] and an absolute value of the price elasticity of emissions ranging from [0.08, 0.10]. The implied price elasticity of abatement rate for a decrease of EU base emissions by 30% ranges from 0.59 to 0.71. The distribution of regional and farm-type abatement rates shows that the farm-type level variability is larger than regional variability.

Abstract

In 1992, the Earth Summit in Rio de Janeiro considered biological diversity by introducing the term 'agricultural biodiversity' or 'agro-biodiversity', conceived as the set of varieties that each farmer recognizes and considers as part of the collective heritage of his land of origin. Italy holds a record of biodiversity for almost all the most important crops used for food, only partly due to physical and geographical factors. Apulia, in Southern Italy, is witnessed by numerous small details such as the countless units of land surface and quantity of agricultural products, the thousand dialects, habits and customs of the small towns. Apulia seems to be a happy island for biodiversity and needs to be protected with about 500 agricultural varieties between horticulture products and vegetables (Polignano carrots, onions from Acquaviva, and so on). The Southern part of Bosnia and Hercegovina, region of Herzegovina, is administratively divided to Western and Eastern Hercegovina having Neretva river as natural border between two. Due to difficult post-conflict transitional period, disputable approaches undertaken in revitalisation of the agriculture and ongoing political disagreements, the rich agro-biodiversity of the area has been partially lost. But regardless all difficulties, Herzegovina farmers, holding a strong cultural identity with food, helped saving from disappearance some of the oldest and most traditional products such as cheese in sack, kajmak (creamy cheese) in sack, roga green bean or poljak bean, all of them recognized by Slow Food movement to be 'arc of taste' products. The contribution, in addition to verifying the state of the art, intends to evaluate the different approaches regarding the subject outlined with regard to management and practices in Italy and in Bosnia and Herzegovina.

Key words: *Agriculture, Biodiversity, Development, Italy, Bosnia and Herzegovina.*

Introduction

The impact of human action on the environment has not always been negative. Since the first forms of agriculture, man has operated a 'controlled disturbance' in natural ecosystems, choosing and cultivating some plant species, rather than others. And then, selecting those that gave him more chances of survival. In this way, in harmony with the natural environment, it has created numerous varieties of fruit, olives, vines, vegetables, legumes, cereals, which have been the basis of its diet and of the food traditions of its communities, together with cause and effect of the environmental and climatic characteristics of the places inhabited by it.

The enormous wealth of local varieties, however, has been progressively reduced with the advent of intensive agriculture, according to the almost exclusive criterion of higher productivity. As a consequence, the local varieties, well adapted to their thousand cultivation environments, have been progressively and inexorably replaced by new varieties and hybrids, which allow high productions, long shelf life and greater suitability to be transported over long distances. The local food has therefore become global. The Earth Summit in Rio de Janeiro in 1992 considered biological diversity by introducing the term 'agricultural

biodiversity' or 'agro-biodiversity' understood as the set of varieties that the farmer and the inhabitant of that place recognizes and it places itself among the most cherished objects of the collective heritage of its land of origin, and the inheritance that nature leaves to itself and which contributes to making a place different from the other. The main objectives of the Conference are: conservation of biological diversity; durable use of its components; the fair and equitable distribution of benefits deriving from the use of resources genetic through, inter alia, adequate access to genetic resources and the appropriate transfer of relevant technologies, taking all rights into account on these resources and technologies, and through appropriate funding.

In the Mediterranean context, Italy holds a record of biodiversity for many of the most important crops for food use and this is only partly due to physical and geographical factors. The diversity of the climate, the orography (i.e. the reliefs), the differences between the land and the water availability of the various areas of the country can justify the cultivation of many species, but not so much the birth and spread of such a large number of cultivar locals. The richness of the varieties is, however, linked to historical and anthropic factors, invasions and dominations, productive and rural economy, religion, language, roads and transport, local customs and traditions. This in particular is analyzed for Italy in Puglia. Bosnia and Herzegovina also has a large production and local variety. The paper highlights the importance of Herzegovina with reflections on the structural difficulties of the countryside and isolation, linked to the reference context. So that talking about agriculture and biodiversity is strongly linked to the historical, political and territorial problems of a country that is being directed towards a planning and valorization of agricultural products. So that talking about agriculture and biodiversity is strongly linked to the historical, political and territorial problems of a country that is slowly taking its own path towards planning and valorization of agricultural products. The Slow Food initiative is from Italy interested in Bosnia and Herzegovina to support diversity and to make economy with agriculture by giving farmers the opportunity not to abandon the campaign. The contribution, therefore, in addition to verifying the state of the art, intends to evaluate the different approaches compared on this subject with regard to attention, management and practices. Italy calls Bosnia and Herzegovina because for some years we are working on methods, land planning and enhancement by the writers and this is a further step towards collaboration and cooperation. Finally the Introduction and the Conclusion are to be attributed to R. Grumo, Materials and methods to S. Giordano, S. Samardzic, G. Radovanovic, and Results and Discussion are to be attributed to all the authors.

Materials and methods

Biodiversity and best practices: the project BiodiverSo in Puglia Region

Starting from the definition of Biodiversity as a complex of communities of ever-changing plants, animals and micro-organisms interacting with the surrounding environment and influenced by human action, it is possible to note how those ecosystems with a wider number of species are better preserved; according to this evidence, the EU acts in order to reduce high species extinction rates by 2020 and restore natural ecosystems as much as possible.

In accordance with the International Treaty on Plant Genetic Resources for Food and Agriculture (RGV), it is fundamental to refer to two RGVs: cultivated varieties and spontaneous species. To date, a capillary and systematic survey of the present active RGV has not been carried out in Italy as well as in Puglia Region. Germplasm conservation actions are often entrusted to the initiatives of individual farmers, who hand down seeds from generation to generation, and to the ex situ conservation that is normally carried out by public entities, such as NRC (National Research Council) and Universities. The revaluation of local varieties genotypes and/or their rehabilitation is vital in order to widen the genetic base of the

horticultural sector, allowing better tolerance to stresses, to safeguard the health of consumers and the environment, as well as to enhance some typical local products. Puglia Region is particularly rich in cultivated varieties of vegetables: carrot of Polignano and Sant'Ippazio; onion of Acquaviva and Margherita; cauliflower, broccoli and black cabbage, curly kale, 'mugnoli' and 'cime di rapa'; immature melon and cucumber named 'carosello' or 'barattiere'; chicory of Molfetta and Galatina; the tomato 'Regina' and the one from Manduria. Some of these cultivated varieties were included in Annex 8 of the Puglia RDP 2007-2013, which includes 14 local varieties of vegetables at risk of genetic extinction (only six of them received applications from custodian farmers for funding measures aimed at preservation), others are included among Traditional Agri-Foodstuffs (PAT).

In Puglia Region a remarkable initiative is represented by the project 'Biodiversity of horticultural species of Puglia' (BiodiverSO), which is part of the Rural Development Program for Puglia - FEASR 2007- 2013 (EC Reg. 1698/2005) - Measure 214, Action 4 Sub-Action a) 'Integrated Biodiversity Projects'. The main purpose of the integrated BiodiverSO project is to contribute to the achievement of a significant reduction in the current rate of erosion of the biodiversity of the Apulian horticultural species, especially by intervening on all the local varieties listed in Annex 8 of the Puglia RDP 2007-2013 and other species.

A first phase consisted in an i depth research aimed at finding the horticultural genetic resources at risk of erosion, and the consequent draft of a catalogue, aimed at conserving and characterizing them. Each variety is identified by means of an identification code, combined with other information (place of collection, farmer coordinates, etc.), together with the so called 'passport data'. All these data univocally identify an accession (i.e. an entry in a database), in order to avoid cases of homonyms, overlaps and other elements of confusion. An integrated strategy was applied throughout the Project including, with mutual support, ex situ conservation, in situ and on farm ones.

Ex situ conservation is carried out in different ways: collections of plants in the field (with specific reference to catalogued fields of onion, chicory, 'carosello' and 'barattiere', 'Regina' tomato, etc.); collections of seeds kept in double, from both the IBBR-CNR and the DISSPA-UNIBA, in their seed banks; collections of propagation material kept in vitro, at DISAAT-UNIBA. The following phases are related to the organization and monitoring of in situ/on farm conservation: collection of information on existing local varieties (inventory) and collection of propagation material intended for preservation of ex situ safety and characterization activity; identification of different areas to be allocated primarily to in situ/on farm conservation (choice of those areas where priority, promotion, organization and monitoring activities should be implemented); characterization and evaluation of the differences held by local varieties; assessment of population size and genetic structure of local varieties maintained in situ/on farm; construction and management of an information system related to the in situ/on farm conservation, construction and management of communication devices, in particular the project website. The main purpose of in situ/on farm conservation is to maintain the current and potential usefulness of genetic resources, so as to meet the needs of present and future generations, intervening also in the farming activity of the so called custodian farmers, and to protect the rights of farmers themselves. The knowledge system and database is strengthened through the formation of an efficient regional biodiversity network that links above mentioned custodian farmers (holders of local varieties), farms, stakeholders (farms, agro-food industry, catering) and local authorities to the enhancement of environmental, cultural and historical and architectural resources. All this aims will at an effective development of the territory both from an environmental and economic point of view, with new micro-supply chain supporting those already existing. The integration of the different actions and methodologies developed within the mentioned Project will allow to obtain a series of tools that can be used at a macro-level in order to promote knowledge

regarding the precious heritage of horticultural agrobiodiversity in Puglia Region and to increase the awareness that the protection of genetic resources is essential.

Preservation of agrobiodiversity in BIH after the conflict, specifically in Eastern Hercegovina as case study area

Bosnia and Herzegovina, even being one of smallest countries in Europe, is one of the five European countries richest in species, what makes it an important center for biodiversity. Unfortunately, about 19% of all plant species are thought to be under significant threat, what Bosnia and Herzegovina put among countries having one of the highest proportions of threatened species of any country in Europe. Many of these species are part of traditional foods, cultivated in local way by implementing local know-how and methods of cultivation. One of major reasons for placing these species in danger to disappearance is depopulation of rural areas, to which remarkably contributed the last war in BIH. The impact which war had on agrobiodiversity state of BIH was twofold. Obviously, negative ones because large part of fertile land and cultivations were in the conflict area, thus it was not possible to be cultivated and got mined while, incredible, but there was one positive effect of the war for the preservation of the agrobiodiversity. Due to war circumstances and under sanctions, not receiving foreign seeds, inhabitants were forced to use local resources and local knowledge about plants and food in order to survive. Reproduction of local seed varieties proved to be the best practice which helped the population survival and insured the preservation of local agrobiodiversity. While in 80ies and 90ies Europe and the rest of the world started to pay attention to loss of biodiversity, take the first decisions and put in practice instruments aiming to undermine the damages, in the years after the conflict, 1996-2003, BIH found itself in a very different context in which the emergency strategy for the state agriculture recovery was production of food in whichever way it was possible. After a period of many different methods undertaken and projects launched which did not take into consideration the value of local products and biodiversity, only in 2004, thanks to specific projects of Italian cooperation agency, new approaches were made and more attention was afterwards paid to typical local products and preservation of agrobiodiversity while the first ex-situ conservation of local plant varieties was insured in 2005 by SEEDNET project and with support of the Government of the Republic of Srpska. In 2009 Institute for genetic resources of Republic of Srpska is founded which continue the work of ex and in situ conservation of seeds in RS.

Southern part of Bosnia and Herzegovina, called Herzegovina, occupies about 20% of the whole country. Herzegovina is administratively divided in two entities, Federation of BIH and Republic of Srpska. Its Western and Northern parts are characterized by upper mountains and continental climate while Southern part has all characteristics of Mediterranean region. Thanks to such a diverse relief and presence of various climates, Herzegovina is richest part of Bosnia and Herzegovina in plant species and animal breeds. But, unfortunately, Herzegovina is at the same time the region where population decline faster than in rest of B&H what put its flora and fauna in a really big danger of extension, what entails loosing local dishes and receipts and local know-how. Complicated governing administration in B&H, not yet established valid system of protection of Geographical Indications, further aggravates the situation. Due to luck of Rural development strategy at the state level, EU IPA pre-accession funds for rural development were blocked until this year when state strategy is finally adopted. Practically, in the previous ten years, the biggest contribution in making awareness for the need of safeguarding of the agrobiodiversity and local food was made by local, non-formal association 'Slow Food Convivium Trebinje, Hercegovina' which is part of the largest international and today well known network Slow Food International that operates in more than 160 countries all around the globe. Slow Food International is doing it through two main projects: Arc of Taste and Presidium project. Arc of Taste is a world catalogue of

endangered traditional foods while Presidium product and project establishes a group of producers and helps them to preserve and valorize arc of taste product. Within ESSEDRA I project 2012-2013 which Slow Food implemented in Balkan countries, are identified and catalogued local tipical products and breeds, mostly localized in Hercegovina region: Cheese in sack, 'Kajmak' from the sheepskin sack, 'Herzegovina honey', 'Livno cheese', 'Pramenka' sheep, Dry figues, Poljak bean and Popovo polje corn variety 'Stodanac'. Lately, closer cooperation is established between technical offices of Regional office of RS Ministry of Agriculture and Slow Food Trebinje, Hercegovina Convivium what brought to new applications and new breed and vegetable varieties for Slow Food Arc of taste catalogue. 'Gatacko cattle' breed, 'Roga' green bean and Trebinje tomato 'Jabucar' are the last recognized local breeds and vegetables. From Bosnia and Hercegovina 17 products are presently in Slow Food Arc of Taste catalogue among which 10 are administrated by Convivium Slow Food Trebinje, Hercegovina. The list is not finished yet. Old varieties of legumes are identified and new applications are in preparation.

Results and Discussion

In Puglia Region a remarkable initiative is represented by the project 'Biodiversity of horticultural species of Puglia' (BiodiverSO), which is part of the Rural Development Program for Puglia - FEASR 2007- 2013 (EC Reg. 1698/2005) - Measure 214, Action 4 Sub-Action a) 'Integrated Biodiversity Projects'. The main purpose of the integrated BiodiverSO project is to contribute to the achievement of a significant reduction in the current rate of erosion of the biodiversity of the Apulian horticultural species, especially by intervening on all the local varieties listed in Annex 8 of the Puglia RDP 2007-2013 (and therefore, as mentioned above, on cauliflower, broccoli, artichoke, tomato, batata, carrot, chicory, melon), as well as on 'carosello', 'barattiere', chicory, onion, carrot of S. Ippazio and other species. An important result is given by the programming that is favored in this area both nationally and regionally. In fact, the experience of the Puglia Region is one of the best practices in Italy. Therefore one can speak of a harmonization of the different levels (European, national and regional) of competence, as expressed in the contribution. Even being one of the Balkan countries with richest biodiversity, therefore being rich in food diversity, Bosnia and Herzegovina is among last European countries in sense of valorization of its food heritage. In B&H there are only five food products protected with the sign of geographical indication, of which one is Herzegovinian honey. It is due to bad political situation in B&H. Unfortunately, one of victims is agro food sector. There are two institutions who have conflict of jurisdiction who of them is in charge to do the job of protection of geographical indications. That situation discourages producers to organize themselves and do something to protect their products. From the other side process of emigration that is pronounced In Herzegovina in its worst form additionally aggravates the situation with loosing rich culinary heritage of Herzegovina. One of chances for saving our food diversity is indubitably work with Slow Food, an Italian initiative that is expanding internationally and Institute of genetic resources of RS. This model for Herzegovina proved to be the best till the moment. In addition, there are two new structures created contributing to preservation of local products and providing overall better conditions for development of agriculture in Eastern Hercegovina – Trebinje Agricultural Fund and Center for agricultural development of Mediterranean part of Eastern Hercegovina. Thanks to adoption of Rural strategy at state level, EU IPA funds for rural development are deblocked giving possibility for proper projects to be launched aiming agrobiodiversity conservation. In particular regarding the Slow Food experience permanent awareness campaigns and continuous Slow Food Trebinje, Hercegovina work on preservation of the local varieties made the best impact to those who kept the tightest cultural link with local

agricultural inheritance - local farmers, the real custodians of local varieties of Hercegovina agrobiodiversity.

Conclusion

The analysis of the theme in the two territorial realities in Italy and in Bosnia Herzegovina poses different interpretations in relation to the different agricultural systems both on the structural and the management level.

On the structural level the starting conditions that are physical-geographical and historical must be evaluated. It is well known that biodiversity and the large number of local cultivars are not only linked to the climate and the orography, the difference between land and water availability, but also to various historical and anthropogenic factors, invasions and dominations, productive economy and rural, religion, language, roads and transport, local customs and traditions. Not entering into detail it can be said that the agricultural sector has had over time both in Italy and in Bosnia and Herzegovina a different evolution even if both have experienced phases of depopulation of the countryside. Today however the attention the support and the revitalization of the sector, the return to the origins and the conservation of agrobiodiversity are decidedly common themes. On the management side, in Italy, coordinated actions have been undertaken for decades. Starting from the National Strategy on Biodiversity in Agriculture must have the following priority of intervention: to disseminate eco-compatible and sustainable agricultural practices aimed at diversifying them productions, protecting the rural landscape (reducing simplification and fragmentation of habitats), ensure the diversity of agroecosystems, the management of the territory, the environmental complexity of agricultural areas, management

soil contamination; integrate the visions, the actions and the instruments of the 'Environment' and of 'Agriculture' share criteria and methods among the local authorities called to apply the National Strategy. Furthermore, Italy is mainly assisted in the regions whose development is lagging behind with the European Union and CAP. Currently the CAP is increasingly oriented towards preventing the risks of degradation environmental. Agricultural activity is increasingly seen as an activity that it can produce 'Environment' and 'Landscape' and in this sense the farmer is increasingly framed in the role of guardian of the environmental and landscapes elements of a territory. The process of integrating environmental objectives in the CAP, started in the eighties, still continues today inside of Cap reform process that defines more broad the role of the farmer recognizing him also a producer of public goods. Bosnia and Herzegovina still lives unfortunately elements of political-administrative division and fragmentation, as witnesses refer, and yet with the presence of a huge variety of crops there is the need to support even more and raise awareness among the population and farmers in particular in this sense. In fact complicated governing administration in B&H, even is not yet established valid system of protection of Geographical Indications, further aggravates the situation. Fortunately there are experiences that are shared by the two countries and that combine to change old approaches in the name of tradition, innovation and sustainability. One of chances for saving our food diversity is indubitably work with NGO such as Slow Food. This model for Herzegovina proved to be the best till the moment. Certainly Herzegovina should keep the hope that European integrations will force institutional levels of BiH administration to trace the path to protect local products in a more adequate way. Finally it can be said that the two experiences, as case studies, have shown on the one hand that there is a greater attention on the part of the Government in Bosnia Herzegovina towards the initiatives that support agriculture according to a more sustainable model that enhances local products, This position it was unthinkable a few decades ago, considering the political events that have affected this country. On the other hand, Bosnia also looks at Italy as a partner for the possibility of transfer of know-how and importing models of

agricultural development such as the 'BiodiverSO' program to apply good practice and strengthen the links between Italy and Bosnia Herzegovina, as the Slow Food experience is showing.

Abstract

This paper analyses the issues of Geographical Indication (GI) on the internal market in the case of Côte D'Ivoire (Ivory Coast). Conjoint analysis is used to know the local population's willingness to pay (WTP). In Côte D'Ivoire, attiéké is a local food elected to GI process. Five regions (Abidjan, Dabou, Jacqueville, Grand-Lahou and Yamoussoukro) were concerned about the production and 238 consumers from these regions were investigated. As results, consumers were focused on hygienic conditions and the size of grain. The price was not so important because 41% of consumers did not look at the level of the price.

Keys words: Geographical Indication, internal market, attiéké, willingness to pay, conjoint analysis.

Introduction

Many studies have been conducted on the role played by the Geographical Indications (GI) in regional development: The link between quality and place (Brian Ilbery and al 2008), the synergy with others activities (Barjolle, Thévenod-Mottet, 2004), debate about GI issue for USA (Tina Monten, 2005). In these studies, at first glance, GI's products are important because its prices rise in international trade compared to conventional products. Several products elected in the process of certification GI saw their price increase in a short time. The famous examples of GI success stories are in France: " Puy, green lentil" price increased to 273 % between 1996 and 2002 (Agritrade, 2005). Another example about wine in the same country, between 1991 and 2013, the price of wine minus "champagne" one increased by 75% in current value, and 29% after adjusting for inflation. Between 1991 and 2013, the price of wine minus "champagne" one increased by 75% in current value, and 29% after adjusting for inflation (MAAF, 2014). The statistics also show that France is among the best consumers of their own GI's products. FranceAgriMer (2015) showed that between 2003 and 2013, the proportion of consumption of wine called "rosé" has increased to 50% and at the end of 2013, France was the first consumer of this wine in the world.

The arguments about the necessity of selling GI's products at a bargain are spread in developing countries. Africa star's one is Ziama coffee that would be estimated at more than 10,000 CFA francs instead of 6,500 CFA francs following its acceptance (OAPI, 2014). Unfortunately, African's GI products are not focusing on the internal market. Few studies were led to the acceptance of GI products in the internal market. The drawback of non-taking account of the internal market can be the fall of local population well-being and the non-sustainability of trade in the case which the international prices oscillate. In this paper, we aimed to address consumers' willingness to pay for GI's products in the internal market and the higher price that can be charged by producers without losing their internal customers. Some crucial questions are underlined: What characteristics of existing products are

appreciated or not? Is GI's label claim by local consumers? What is consumers' willingness to pay in order to make distinction between different qualities?

Barjolle and jeanneaux (2012) tried to treat localized firms and understood how they worked, how they set a price on the market. So, we aimed to go far and study the acceptance of a product in GI's certification by the local populations and the price they would be able to pay for that. The concept of Willingness To Pay (WTP) is used to this aim and defined as the maximum price that consumers gave consent to pay for a given product or service (Marine Le Gall-Ely 2009). In ordinary, we suppose that when the prices rise, sales fall. But in most cases, consumers win of the exchange in the market due to the difference between the reservation price and the market price. This win was called Consumer's surplus by Alfred Marshall (1890). Study WTP allows setting a price that maximizes the producer profit without threatening the number of its clients. In other words, the WTP allows setting a market price higher for which we have the approval of the consumer in exchange for a reduction in the uncertainty about the production's conditions, product's information and the inclusion of some consumers' aspirations.

However, the extent of the WTP requires several methods for its assessment. WTP can be calculated in different ways depending on the data source and / or expected results. When the sources are real data coming from the market, elasticity method and hedonic price can be used. If there is incitement, Vickrey auctions and BDM methods or Becker Degroot and Marschak lotteries can be used. And when prices are non-existent, we mostly resort to an investigation for fix the price. In this case, we have conjoint analysis, contingency analysis, psychological price and simulated purchases.

In the case of this study, data source are non-existent, so we face to range of choices. We chose conjoint analysis to estimate directly the maximum price that the consumer wants to pay for the acquisition of property and know at the same time the characteristics he researches. Conjoint analysis is evaluated by two main methods, namely the Conjoint analysis of the complete profile inspired from Paul green and adaptive conjoint analysis (ACA) invented by Richard Johnson through his company Sawtooth Software in 1985. Complete profile analysis is an instantaneous analysis and requires a greater intellectual sagacity to design the importance of the proposed profiles and consistently ordered while the adaptive analysis follows a dynamic evolution and a playfulness that allows interviewees to take their time in expressing their answers with automatic recording of the above. We will choose the method of conjoint analysis in the complete profile that despite its modern adaptation through nested logit method or hierarchical Bayesian analysis stays the most appropriate for our developing countries.

Materials and methods

Consumers have to make a choice between similar products which differ simply with the place, nature or date of production. Most of the time these attributes are mixed and consumers must reveal their preference by choosing appropriate products. This individual choice revealed is "path worth utilities". In conjoint analysis, a defined set of combinations of path worth utilities of each survey are ranked, organized, selected and then put on model to find the path worth utilities that can help to know the willingness to pay. As a bonus, we can know the importance of each attribute in consumers' willingness to pay. In practice, it is set in three steps:

Step 1: the preparation

We investigate about the main attributes of the products. After that, we combined a set of attributes. For instance, if we have three attributes, the number of combinations will give us eight. For K attributes we find 2K combinations. All these combinations of the attributes are present, but with their variants. Suppose that attribute one has two variants, we mark the

presence of variant one of parameter +1, and we mark the missing of variant one or the presence of variant two by parameter -1. The list of combination is called "design matrix" and the use of all combinations is called 'full factorial design". Now, we produce a matrix with the new value of each combination. We get a matrix with n line and m column. Back to our example n= 3 and m= 8. Enter this matrix there will be the number link to all variants of attributes like compose with +1 or -1.

Step two: the realisation

In this step, we go investigate the sample of surveys targeted by our study. For that, we put numbers on the set of attributes combined on the card and asked the investigated to rank order or set a logic action with these cards. And we noted the numbers on the surveys' choices.

Step 3: the utilities function and relative weight of attributes

a- utilities function

We used the model of Green P.E. and Srinavasan V. (1978)

$y_k = \mu + \sum\sum \beta_{jm}.x_{jm}$ (1)

In this model, y_k is the logic action of ranking for example, β_{jm} is the path worth utilities of attribute j with its variant or factor m, x_{jm} is a parameter of the design matrix link attribute j with its variant or factor m and μ is a constant. We remark that $\sum\sum \beta_{jm}.x_{jm}$ is the expression of the "design matrix" we talked previously and this expression (1) can be rewritten like:

$y_k = \mu + X.\beta_{jm}$ (2)

In this second model, y_k is dependant variable, X is independents variable, β_{jm} is a parameter or coefficient of the model. We are familiar with the equation (2) because it's linear and it can be solved with Ordinar Least Square (OLS) method to find the expression of β_{jm}.

b- Relative weight of attributes

To calculate the relative weight of each attribute: (i) Firstly, we used the coefficient β_{jm} of each attributes found in the equation (2); we multiplied by 2 and put in absolute value. (ii) Secondly, we summed all the values found and (iii) finally we divided each multiplied value by the total sum. Another manner to find the same result is to identify the minimum between all the values β_{jm}, we can note it ${\beta_{jm}}^{jM}$. After that, we look for relative value by making the difference between each value and the minimum of all the values computed. Let us call it ${\beta_{jm}}^{*}$with expression ${\beta_{jm}}^{*} = \beta_{jm} - {\beta_{jm}}^{jM}$. And then we calculate the weight ($\hat{\beta}_{jm}$) of each expression whit the following equation :

$$\hat{\beta}_{jm} = \frac{{\beta_{jm}}^{*}}{\sum_{j=1}^{j} max({\beta_{jm}}^{*})}$$

Data

GI is not yet realised in Côte d'Ivoire but we are trying to set the process on sixteen local's products. "Attiéké" is among these products. It's a steamed manioc very appreciate in Côte d'Ivoire and sub regions. Previously, it was done by people call lagoon's AKAN but now it is produced in and out borders by Benin, Burkina Faso, Taiwan and so far. Unfortunately, this imitation goes with a loss of quality of attiéké. Original producers- lagoon's people from Côte d'Ivoire are still doing attiéké in the traditional way. The original process of production is difficult, more costly for producers and the difference in quality proposed on the market are not distinguishable. Consumers complain many times about the non-constancy of taste. To solve this problem and avoid the relinquishment of activity by original producers, AFD and Ivorian's authorities is setting a process of GI.

In this process, lagoon's AKAN are targeted. They have been localised in four regions: Ebrié in Abidjan, Adjoukrous in Dabou, Avikam and Agni-Baoulé in Grand-Lahou and Alladjans in Jacqueville. In additional we chose Yamoussoukro which is not next to these regions and not original producers, but produce attiéké in huge quantity.

We chose two villages in each region basing on criteria:

- villages should not be distant from more than 45 km of chief of the region
- And have a legal producer group in the village.

The formula of François D. Giezendanner 2012 allows us to calculate the number of surveys. It was 238 for p= 0.9, 1-p= 0.1 with a confidence level of s= 99%. So, the tolerable error margin was e = 0.05 and t = 1.96. Surveys (25 per village) were investigated and led to take 250 persons in the sample.

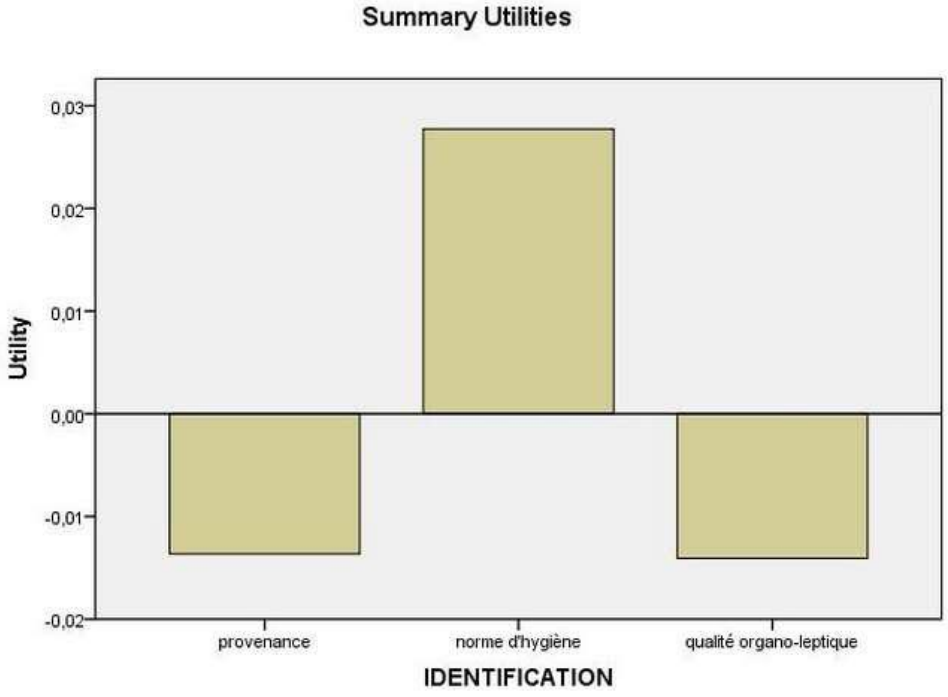
During our first investigation, people seemed to focus on some characteristics called identification (origin, organoleptic quality, level of hygiene), price (200, 250, 300), packaging (simple or sophisticated packaging), area of the distribution (open market or supermarket) and the type of attiéké (long grain, medium grain, small grain, Agbodjama, Garba or any type). We combined these attributes and proposed surveys to choose five and order them according to their preferences. Results were obtained with SPSS 17.

Results and discussion

Among 250 peoples were investigated, only 232 agreed to fill our card of conjoint analysis. It means that (250-232)/232 = 0.077 or 7%persons have not participated in our analysis. Such refusal may be interpreted as personal considerations, and psychological. However, we noticed that Non responses are not absolute non-consumers.

Some people dislike attiéké, to avoid giving false information, they didn't take part in our analysis. Some others, rich now, don't like too much attiéké because it was their main feed when they were poor and don't want to remind this period and others consider attiéké as a food for the population less fortunate. The last category of non-responses is due to the fact that some people don't want to see the price of attiéké raise because attiéké is social food, which helps many Ivorian to access food cheaply. For those who accept to take part in the survey, we have the following results.

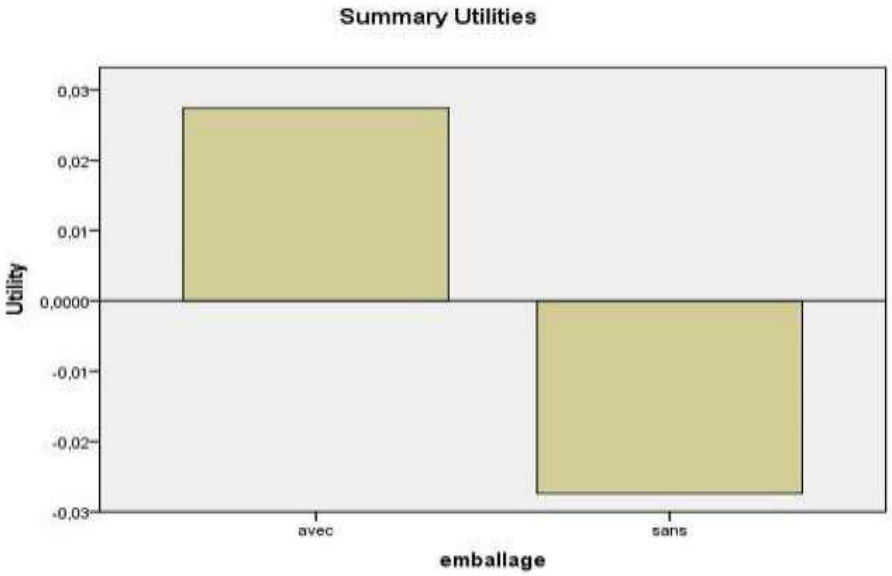
Graph 1. Identification



Source: author with SPSS 17

Identification has positive and negative scores. Hygiene has positive score (0.28) origin and organoleptic quality has same negative score (-0.014). It means that hygiene is more important for consumers than the origin and organoleptic quality. They must be sure that eating attiéké can't make them ill.

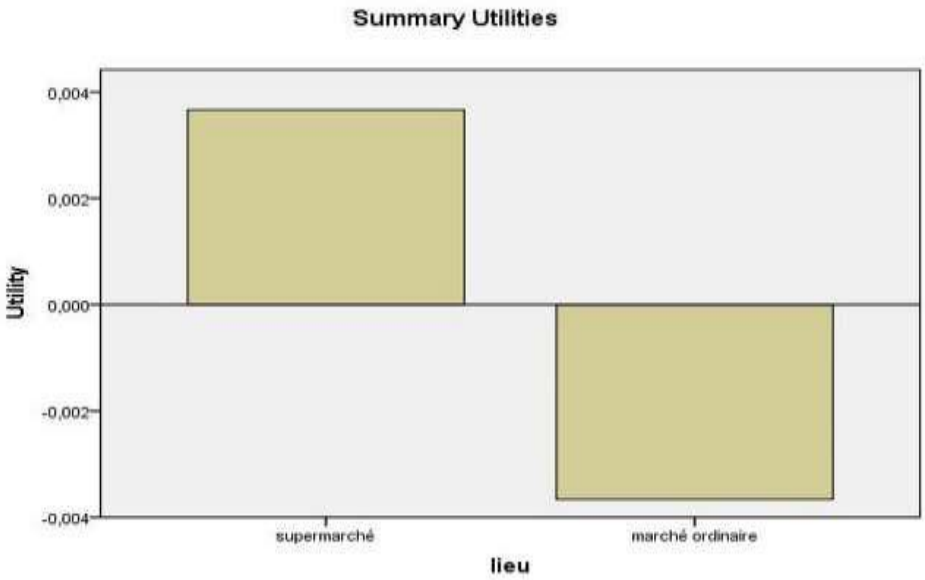
Graph 2: packaging



Source: author with SPSS 17

Packaging has also positive and negative score: positive for sophisticated packaging and negative for simple package. We also see that the absolute score is the same for both 0.027. Sophisticated packaging is the most desired because it's beautiful and seems safety.

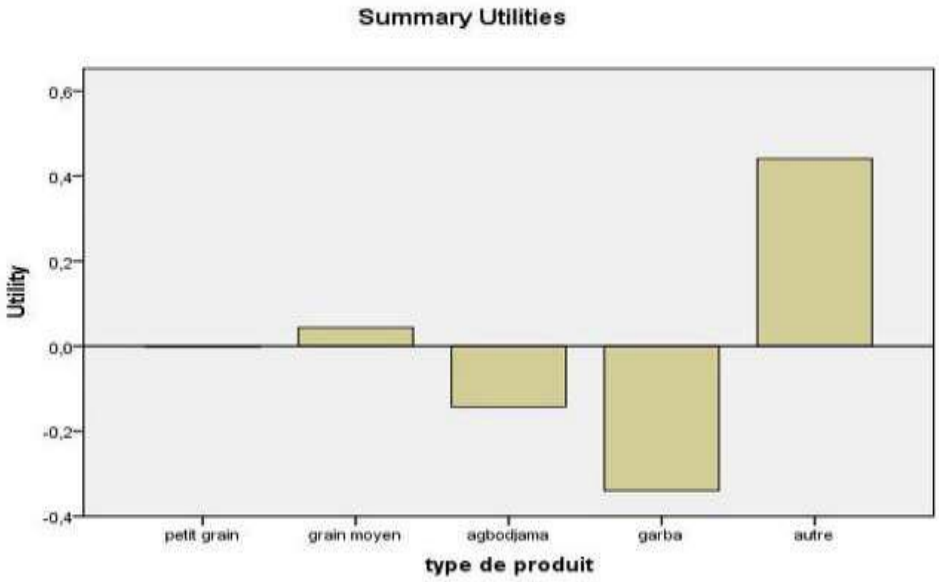
Graphic 3: Place of distribution



Source: author with SPSS 17

Concerning the **area of distribution,** the value of the score is positive for supermarket (+ 0.004) and the value of the score is negative for open market (-0.004). Like the packaging, the absolute score is the same. Consumers prefer a specific market of attiéké and think that supermarket is more hygienic than the open market.

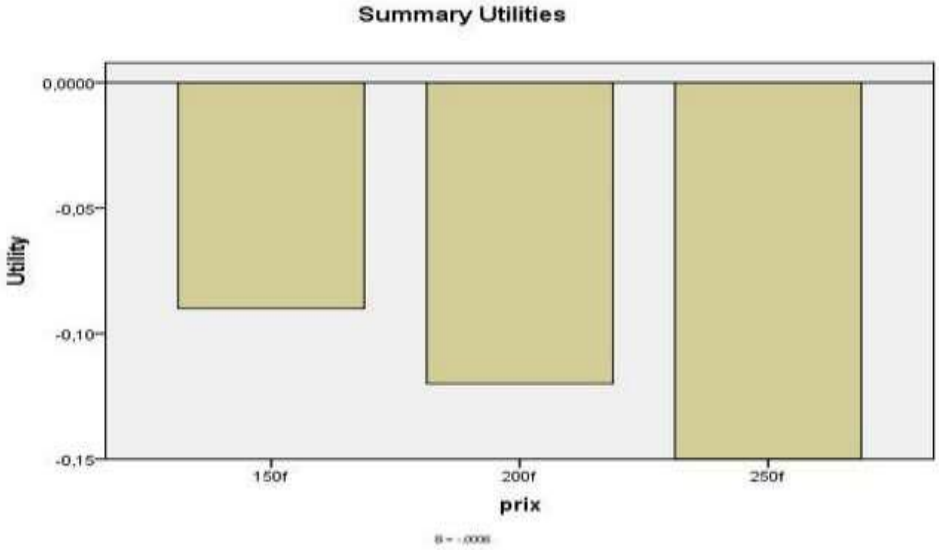
Graph 4: Type of attiéké



Source: author with SPSS 17

We have positive and negative scores. Among the positive scores, the high score is for any type of attiéké (+0.441), it is followed by medium grain (+0.043). For negative scores, we note at lower place small grain (-0.002), follow by Agbodjama (-0.143) and finally Garba (-0.339). In this case, the analysis showed that consumers preferred medium grain than any type of attiéké. If they don't find any type and medium grain, they resort firstly to small grain, secondly to Agbodjama and thirdly to Garba.

Graph 5: Price



Source: author with SPSS 17

Table 1: Reversal

Reversal Summary

N of Reversals	N of Subjects
1	96

Source : author with SPSS 17

Table2: Coefficient

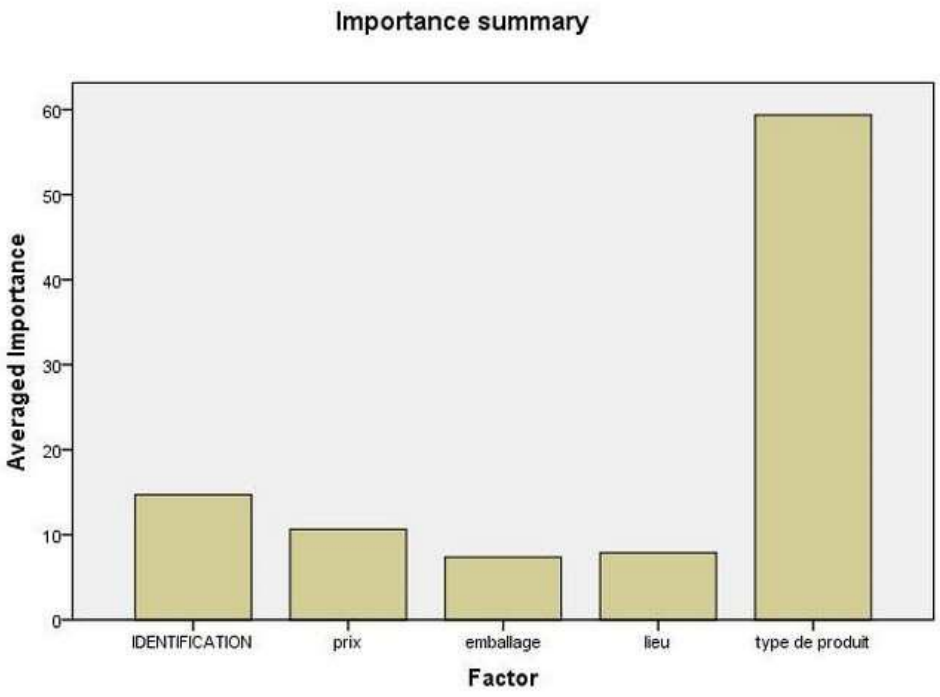
Coefficients

	Coefficient B Estimés
VENTE	-.0006

Source : author with SPSS 17

Price has only negative scores. The lowest is 150 (-0.90), follow by 250 (-0.150) and finally 200 (0.120). Price is quantitative and has a coefficient of regression is estimated to -0.0006. Consumers are not ready to pay more for attiéké in general, but if they have to pay they will pay 200f, 250 and 150 F CFA. This order means nothing, but it show just that attiéké is a normal product which price is not flexible. In another way, 41.37 % of the survey are ready to pay more than the median price.

Graph 17: Relative weight of attributes



Source: author with SPSS 17

We find that attributes have not the same weight. The most important is type of attiéké (60%), followed by the identification (15%), price (11%), instead of the distribution (8%), packaging (7%).

Model specification

Table 1: test of correlation

Correlations[a]

	Value	Sig.
Pearson's R	.978	.000
Kendall's tau	.840	.000
Kendall's tau for Holdouts	.857	.001

Source : l'author with SPSS

All the standard errors are inferior to one. This can be good for our model because it means that values find are not far from the mean/real. The coefficients R of Pearson, Kendall's tau, Kendall's tau for Holdouts are all significant at 1%, so the variables are not correlated and the model is well specified. We find that attiéké is a common food, for that, people are not ready to pay more. Unfortunately, the original producers are leaving the arduousness of job to practice other activities more easily and lucrative; we notice a decrease of the quality level of attiéké. The results show that some people dislike attiéké and some others would like to improve some attributes. The type of grain is the first criteria of choice of attiéké. The customer prefers medium grain than others. After the type, he looks at the origin of attiéké, hygiene is the most important in this case. We can note that the sum of these both attributes is 75%. In Côte d'Ivoire, each region has his type of grain and reference to grain led to one or several specific regions, but the confusion need to be overcome in order to give more precision on the region they talk about. Type of grain and origin can represent the need to have a Geographical indication of the level of 75%. After that, he looks for the price and is ready to pay until 250 but generally he dislikes pay more for attiéké cause at each time price rise only to 1% his preference fall to 0.0006. However, there is a considerable percentage (41.37 %) which wants to pay more than market price to have quality. We must identify the characteristics of this group to well-know them. With the knowledge of each score, we can compute and make a choice between a kind of products we want to sell on the market. It's a marketing tool to choose ideal product and it can help also to know what type of product is needed in a specific market or a specific group if we add more complementary studies. In this case, let take two different products which are able to be sold in our market. Let call Product 1: attiéké Agbodjama from known area, sold in supermarket at 250f with a sophisticated packaging and Product 2: attiéké with medium grain from known area, sold in supermarket at 250f with a sophisticated packaging. We can compute the part worth utilities of the both attiéké with the scores found. Let us do it

U (product 1)= u (attiéké Agbodjama) + u (origin) + (supermarket) + u(price 250f) + u (sophisticated packaging)+ constant

U(product 1)= (-0.143)+ (-0.014) + (0.004) + (-0.15) + (0.027)+ (-5.392) =(-5.668)

U (product 2) = u (attiéké medium grain) + u (origin) + u (supermarket) + u (price 250f) + u (sophisticated packaging) + constant

U (product 2) = (0.043) + (-0.014) + (0.004) + (-0.15) + (0.027) + (-5.392)= (-5.482)

We note that U (product 1)< U (product 2) because (-5,668)< (-5,482). This show clearly that product 1 is more appreciated than product 2 in the region of the survey.

Conclusion

We tried to get Scientific's basis of GI's setting. If internal market is not taken into account, opportunities given by GI can turn into disadvantages. We have to manage with the promise of international trade and deal with the local customers. Therefore the preference of local

customers can help the producers improve the product attributes and be more competitive in international trade.

Abstract

Social representations are visions of the everyday world that is historically constructed alongside the dissemination of media intensifies their audiences. In this sense, the printed media availability and water policy has not only been systematically reduced to opinions by the press, but also two logics have been grown on the credibility of the information and the verifiability of it. In this sense, this study exposes the lines of discussion for the analysis of tandem policies and agenda setting in the availability and supply of water. The results show frames from newspaper audiences are considered promoters of a relative deprivation that is the conformism of the service quality of public water supplies.

Keywords: *compliance, performance, availability, supply rate.*

Introduction

In the context of participatory democracy, the media play an important role in establishing an agenda and eventually propaganda against or in favor of a political regime centered on the security and sustainability of natural resources and public services corresponding. It is a phenomenon in which the axes and themes of discussion, although established by the traditional media such as television, radio or the press, it is citizenship that, when processing such information, generates two rationalities, one informative and other reasoned with respect to the problems inherent to natural resources and public services. In this way, civil society as a user of public services, evaluates the performance of its authorities according to the information available in the traditional media. In this sense, the study of a problem such as scarcity, shortage or unhealthiness of water resources and services can be approached as a phenomenon of establishment of agenda and propaganda of the rectory of the state, institutional protection and civil despair. The phenomenon in question lies not only in the establishment of an agenda and the diffusion of propaganda in the matter of scarcity, lack of supply and conflict over water use and consumption, but also in the attribution of responsibility to the State as the guiding principle of security and sustainability, as well as institutions for non-compliance with their ethics of care and the consequent attribution of defenselessness of civil society. However, in the face of the hypothesis of State rector and civil despair, a proposal for active, deliberative and participatory citizenship emerges which rationalizes information in order to be able to express an opinion based on the degree of credibility of the information and verifiability. There are three theoretical frameworks from which the phenomenon in question has been explored: 1) theory of agenda setting, 2) theory of media culture, and 3) theory of social representations. The agenda-setting theory points to the framing of the media as biases or systematic tendencies to disfavor or enhance the state's leadership in matters of security and sustainability. It is a process in which the television, radio or the press focus their interest in evidencing the capacity of a government based on the popularity or scientificity of its strategies and programs. A direct consequence of the establishment of the agenda is the axes and topics of discussion in public opinion, essentially in the discourse of leaders such as communicators, analysts or columnists. From this fact, the

media culture theory emphasizes the information that has been emitted by an opinion leader and its resonance in the opinion of citizens who are not experts in the axes and subjects of discussion, but who cite their leaders to construct a opinion. This phase of formation of civil opinion is known as a social representation and this consists of producing meanings around referring symbols or archetypes of information, linked to local customs and customs, values and regional norms. It is the case of security as the axis of discussion and central topic of debate in the agenda of traditional media, citizenship and rulers. It is possible to appreciate words like "sicario", "ajuste de cuentas" or "lugarteniente" in the speeches of these actors, which reflect: a) the establishment of an agenda of public insecurity, b) the cultivation of information related to delinquency organized and c) representations of the State in the exhibitions of captured criminals or representations of the defenseless citizenship before reports of political corruption linked to drug trafficking. The relationship between authorities and users of public services has been a central issue on the agenda of the media. In the case of water as a strategic resource for local development, quality of life and subjective well-being, in recent years it has been widely reported by the media (Anaya, 2014). Particularly the print media with national circulation has included reports about the imbalance posed by water scarcity and water shortages associated with the corruption of local authorities and increased rates deregulated (Gomera et al., 2013). The impact of media coverage regarding the shortage and poor health has been a central issue in the public health agenda (McCombs, 1996). It is estimated that about six million children die from diseases hidrotransmitadas in countries with high rate of water shortages, but this means not only disseminate information but also associate the performance of the authorities in terms of management. Thus, in the suburbs of large cities the problem of water supply has been addressed by a system of tandem in which increasingly restricted water consumption and substantially increase rates (Gudynas, 2010). Approximately 20% of incomes in vulnerable or water exclusion situation, is assigned to the purchase of water products, but print media rather highlight the lack of infrastructure and attention to contingencies such as drought or frost (Perez and Soler, 2013). Thus, the media have a particular view of the problem of water scarcity and shortages of attributing responsibility to the authorities and exonerating users who have regular access to drinking water or justifying the soft drink consumption or pharmaceutical industry. It is a process in which the systematic dissemination of biased information regarding the relationship between availability and management of water resources is known as agenda setting (Carreon et al., 2014). An agenda is a result of information exchange between the agents involved, but the differences between them generates information biases that are spread in the media and the information is used to justify rate increases by the authorities, waste by users, conflicts among actors or, tandem or policies restricting water (Flores, 2013). However, the agenda is also historic, as it involves the reaction of organized civil society groups regarding the performance of its authorities on quality public services (García, 2011). It is power relations that have grown and are activities to the less informative provocation, but in the case of the print media is a process more complex elaboration that this letter sets as an overview of water availability in reference to consumption human. If the media presented the conflict as central themes of water problems because the authorities responsible for the inefficiency of rates and expose closures avenues, boycotts pipe facilities or kidnappings as evidence of ungovernability that inhibit local sustainable development. Consider the following premises for addressing administrative corruption on supply and collection of public drinking water:

Premise 1. The availability of resources to be scarce generates an administration of austerity and shortages financed by a steady increase in the unit price of water in terms of political relations between local governments and civil society organizations;

Premise 2. The rates reflect political negotiations between members and militants with regard to election time and the proximity of local elections, but also in terms of management capabilities of civil society organizations;
Premise 3. Conflicts between civil society and local government in the field of municipal water services are a reflection of systematic dissemination of shortage and quality of drinking water in the media with particular emphasis on national newspapers.
Formulation: What is the proposed media for the sustainability of supply and collection system considering his framing of the facts?
Hypothesis: The journalistic framing printed media around scarcity, and water management is established from the systematic diffusion of responsibility of local officials.

Materials and methods

Design. Non-experimental, retrospective, documentary and exploratory study.
Sample. Notes the daily newspaper of national circulation during the period from 2010-2015. The sample of informative notes was made using the data mining technique of the search engine google.com, considering the keywords: "shortage", "tandem", "conflict", "leaks". The selected journals were: "El Universal", "La Jornada" and "El Reforma" (see Table 1).
Instrument. Matrix analysis of content including references consulted and processed information as shown, instruments and results.

Table 1. Index Mediatisation Leak

Newspaper	*Indicator*	*Coding*	*Weighing*	*Interpretation*
El Universal	Press releases	0 = null framing; 1 = very little frame, 2 = little frame, 3 = frame somewhat evident, 4 = very clear frame	30 to 40 points	Diffusing agenda of the direct and significant relationship between scarcity, tandem and conflict between rulers and ruled
La Jornada	Press releases	0 = null framing; 1 = very little frame, 2 = little frame, 3 = frame somewhat evident, 4 = very clear frame	30 to 40 points	Diffusing agenda of the direct and significant relationship between scarcity, tandem and conflict between rulers and ruled
El Reforma	Press releases	0 = null framing; 1 = very little frame, 2 = little frame, 3 = frame somewhat evident, 4 = very clear frame	30 to 40 points	Diffusing agenda of the direct and significant relationship between scarcity, tandem and conflict between rulers and ruled
			IML = 90 a 120	Propaganda diffusing the direct and meaningful relationship between the rectory of the state, institutional protection and civil defenselessness

N = 30 press releases. IMF = Leverage Mediation Index established by the average of the evaluations of 10 judges with respect to press releases that framed the information about the scarcity, the tandem and the conflict between authorities and users of the potable water service, focusing the problematic in municipal and residential leaks. *Source: self-made

Procedure. From the google.com data mining technology, press releases were identified regarding the scarcity, tandem and conflicts arising from municipal and residential water leaks. The Delphi technique was used to compare and integrate information concerning the framing of press releases. Ten expert judges were used in the problem: 3 officials, 3 journalists, 3 citizens and the evaluation of the researcher. Estimated impact of press releases considering its content and frequency of keywords or indicators of scarcity, shortage and cost of drinking water.

Validity. The degree of coincidence between the informed deliberation and the reasoned deliberation of the judges who were assured in writing the confidentiality and anonymity of their answers, as well as the warning that the results of the study would not affect negative or positively their economic, political and social status.

Coding. Each one of the headings of the press releases was evaluated by the judges, considering a scale that goes from 0 = null framing to 4 = very evident framing. For example, consider: "In Iztapalapa there is water for the next 50 years" was considered by the 10 judges as a biased or biased header since, if it is related to the discovery of a well, its degree of contamination and water inaccessibility limit the supply even of the colony in which the well is located. Therefore, it was evaluated with 4 points.

Weighing. The Leverage Mediation Index was established based on the average of 10 judges 'evaluations of the headings of the press releases, following the criterion of validity regarding differences and similarities between the judges' responses. Such a weighting strategy allows us to move towards multivariate estimates that require averages, standard deviations and variances to establish differences between groups, but whose purpose has not been that of the present work, which only presents a first approximation to the explanation of the phenomenon. **Interpretation.** Since the options "frame something evident" and "very clear frame" reflect a position in favor of considering the establishment of an agenda in each newspaper and the emergence of a propaganda by the three newspapers, the sum of these options formed a range ranging from 30 to 40 (90 to 120 for the case of summation of options 3 and 4 with respect to the total of 30 notes). It was considered that the summations inferior to the rank would reflect a null establishment of the agenda for each newspaper and consequently, a null propaganda campaign for the case of the three newspapers.

Results and discussion

Table 2 shows a synthesis of the findings related to the establishment of an agenda and propaganda regarding scarcity, tandem and conflicts over municipal and residential leaks.

Table 2. Index Mediatisation Leaks

Newspaper	*Indicators*	*Coding*	*Weighing*	*Interpretation*
El Universal	10 news headlines identified in the google.com data mining system	0 = null framing; 1 = very little frame, 2 = little frame, 3 = frame somewhat evident, 4 = very clear frame	27 points from 30 minimum and up to 40 possible to assume the frame, bias or information trend	Null agenda of diffusion of the significant relation between scarcity, tandem and conflict between the authorities and the users of the public service
La Jornada	10 news headlines identified in the google.com data mining system	0 = null framing; 1 = very little frame, 2 = little frame, 3 = frame somewhat evident, 4 = very clear frame	31 points from 30 minimum and up to 40 possible to assume the frame, bias or information trend	Diffusing agenda of the direct and significant relationship between scarcity, tandem and conflict between rulers and ruled
El Reforma	10 news headlines identified in the google.com data mining system	0 = null framing; 1 = very little frame, 2 = little frame, 3 = frame somewhat evident, 4 = very clear frame	23 points from 30 minimum and up to 40 possible to assume the frame, bias or information trend	Null agenda of diffusion of the significant relation between scarcity, tandem and conflict between the authorities and the users of the public service
			IML = 81 points from 90 minimums and up to 120 possible	Null advertisement of diffusion of the Governing State and the institutional protection in the matter of supply

Source: self-made

It is possible to appreciate the null establishment of an agenda by El Universal and El Reforma, but in the case of La Jornada there is a bias that implies the social representation of the source of information and the problem, would consist in associating the prestige of the newspaper with the context of scarcity, tandem and conflict between authorities and users.
However, if the index is analyzed in its entirety the bias of the press does not reach a minimum level of frame that allows observing a propaganda of the State, institutional protection and the civil despair.
The weights of notes and images as well as their mutual correspondence concerning the coverage of water leaks Iztapalapa. The indices show that the items appear to be biased as they reached a total value of 4 points of 40 possible. Only in notes III (Alistan constitution water Iztapalapa) and V (is lost in leaks 35% water) reporters tried to externalize their opinion on the issue. The note V journalist quotes two officers: David Robles and Hector Reyes to support the header of your report regarding the volume is wasted by visible and invisible leaks without establishing a percentage distinction between the two issues and link it with 35% announcing at the top of the note. Regarding framed pictures, media coverage seems to be high since it reached a total of 36 points of 44 possible. A quarter of the selected notes reached the maximum weighting relative to framing. IX and X notes included images out of context without any connection with the note. Such notes did not try to influence or confuse readers. However, the notes I, II, III, IV, V, VI, VII, VIII and XI included images that seems evident extreme shortages; public service users storing water in drums, jars and buckets. Or, images where principal photography leaks seem to be uncontrollable.
In the case of the relationship between discourses and images, the index was 22 Framed Hybrid which was considered moderate as only the notes III, VI, IX and X included images that did not correspond to the briefing notes.
However, if the note III who headed: "ready incorporation of water in Iztapalapa" included images of water users away. That is, "El Universal" describes a leak to argue the need for a legal agreement and illustrates his message with images relating to a possible consequence: the improvised water storage. The results showed a moderate mediation except Framed Images Index (IEI), which was close to a very high degree of media coverage. Such findings are consistent with those found by Garcia (2011) who found moderate levels of media coverage regarding the participation of users in situations of scarcity and shortage. Finally, the index Mediatisation Leak scored a total of 81 of 120 possible to settle at a moderate level. That is, the press coverage about the shortage prompted by leaks seem to have an unusual bias in relation to the description and illustration of the water situation is diffused.
The contribution of the present study to the theoretical frameworks of the establishment of the agenda and propaganda of the rectory of the State and civil defenselessness lies in the proposal of measurement of the level of framing of the print media regarding the problem of scarcity, shortages and activated conflict for municipal leaks.
However, the type of sample selection through google.com data mining and the Dephi technique limit the results to a specific study context since it is necessary to extend the information search to the subsidy, remission or tariffs of the public service, as well as to carry out a representative study with citizens of at least two demarcations, one with high and another with low availability of water in order to be able to compare the findings in different contexts and samples. With respect to the theoretical and conceptual frameworks related to the establishment of the agenda, media culture and social representation, the present work has shown that this process is partial since the IML reached a moderate level, but above all, the phenomenon that is going of diffusion of scarcity, tandem and conflict seems to show only part of a more global and extensive problem, namely: the anthropocentrism that consists in the management, distribution and consumption of water in a region or locality considering it as

the exclusive patrimony of its inhabitants and rulers without considering the needs and capacities of future generations of animal and plant species.

It is necessary to include categories of anthropocentrism, biosferism or ecofemminism in order to be able to establish the agenda and the propaganda of the State, but not only with respect to security but with respect to sustainability. This will allow us to anticipate scenarios of authoritarianism or informational totalitarianism, where the central agency version prevails, unilateral communication, impersonal defenselessness and unidirectional demotivation, the main indicators of a context of null civil participation.

Conclusion

The phenomenon of diffusion relative to the rectory of the State in the matter of the management of water resources and services before the scarcity, tandem and conflict exposed in the press and established as axes of discussion in a local agenda as in a campaign of conjunctural propaganda supposes: 1) the analysis of the impression or bias of the print media in a given electoral period, 2) the observation of the impact of the framing on the civil opinion, its preferences and voting intentions 3) the discussion concerning the level of framing of the press and its effects on the speeches of public and private actors and sectors before, during and after the local or federal elections. This exercise will allow us to infer the degree of deliberation, participation and responsibility of the civil actors regarding the information on the performance of their authorities and the reflection of their anthropocentric or biospheric logic and ethics in the supply and collection of drinking water service.

MECHANISMS AND ECONOMIC CONSEQUENCES OF PUBLIC INTERVENTION IN AGRICULTURAL HOLDINGS IN POLAND DURING THE PERIOD OF EU MEMBERSHIP

Marek WIGIER, Adam WASILEWSKI

Institute of Agricultural and Food Economics – National Research Institute, Warsaw, Poland
*Corresponding author: wigier@ierigz.waw.pl

Abstract

The concept of public intervention in agriculture can be understood very broadly, as any act or omission of the operation of public state institutions. The article discusses the economic reasons for the public intervention, then presents the types and effects of intervention implemented by the CAP as well as the impact of intervention policy on economic decisions of agricultural producers. In the further part of the article, based on the statistic data from 2004-2016, were presented the changes in agriculture sector. A characteristic feature of this process is the deagrarisation the national economy and the development of rural areas. Throughout this process, it is extremely important for the ongoing structural changes to result in the improvement of the competitive position of farms and long-term and sustainable rural development. Poland's accession to the EU has generated new economic and organisational conditions to support structural changes in the broadly defined food economy and rural areas. Policy instruments implemented within the CAP create chances for the stabilisation of structural policy conditions over the period of several production cycles, thus stimulating the desired changes in the area structure of farms, the improvements in the competitiveness of production, environmental protection and multi-functional development of rural areas. Thus they are a fundamental instrument supporting the process of modernisation of Polish rural areas and agriculture. The article conclusions refer to structural changes and to competitiveness of agri-food sector.

Keywords: *public support policy, competitiveness, intervention in agriculture.*

Introduction

The active role of government and justification for state intervention in economic process results from the conviction about market failure (Bator, 1958). This concept suggests that in the realities of the market economy the processes of allocation of goods and services show a number of frictions. As a result, the state of actual equilibrium achieved by the market is not compliant with Pareto optimum. In broader terms, the concept of market failure identifies the scope and circumstances of observed defects of market mechanisms that lead to the perpetuation of market imbalances (Baumol, 1952). In this context, it emphasizes the positive aspects of market intervention by public authorities (Stiglitz, 1989). Economic theory distinguishes a number of reasons for market failure. The mechanism and the logic of intervention in modern agriculture is shown in figure 1.

Arrow (1983) was one of the first to point out that, in fact, one can distinguish two different states of efficiency in the allocation of goods depending on the degree of fulfilment of the Pareto demands. The first approach suggests that each allocation of goods in equilibrium meets only the demand of the so-called "poor efficiency" in the sense of Pareto.

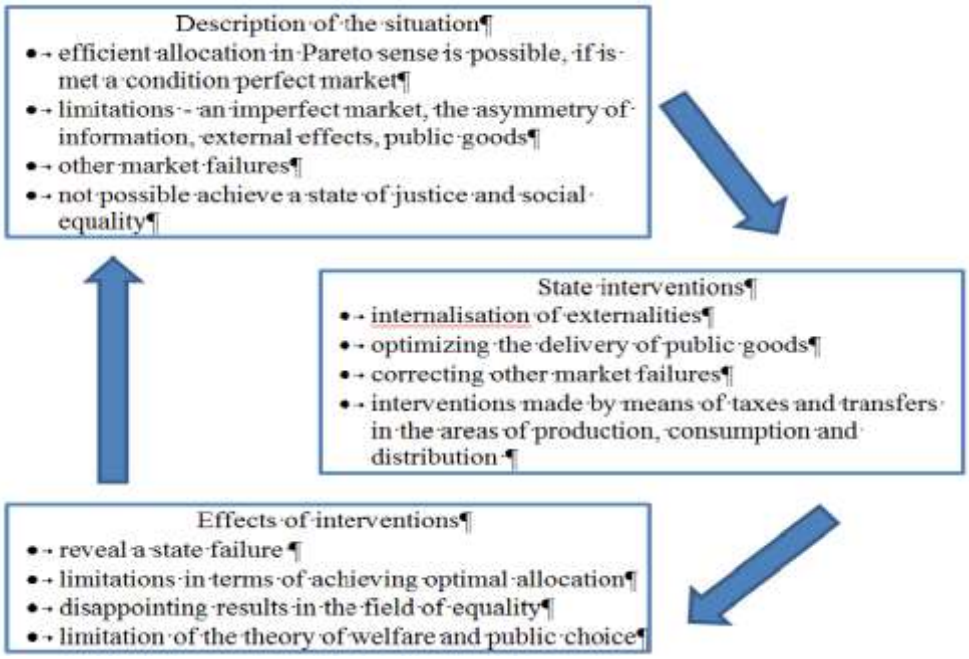

Figure 1 The mechanism of the modern intervention in agriculture

Source: Own study based on a literature review of studies of welfare economics and public choice economics

The global experiences prove that the market and the state have to co-exist and the state intervention should be always limited to support market mechanism and not replacement thereof. The state should interfere only when it has a clear advantage over the market mechanism; hence only when the market fails to protect the general interests of the society (Woś, 2004). The contemporary global economy often rejects the thesis on the perfect market (Czyżewski, 2007) thereby justifying the role of state intervention. When explaining the main reasons for intervention in the modern global agriculture point to the high level of risk linked to agricultural activity and lack of effectiveness in prevention of this risk. The risk results from e.g. changing climate conditions, lack of sufficient information and underdevelopment of agribusiness structures, including also consultancy. The need for interventions in the agribusiness sector is justified also by: the phenomena of external costs and effects, low price elasticity of supply, lower level of labour productivity than in other sectors of the national economy, low mobility of the workforce employed in agriculture, the need to provide public goods, implementation of the sustainable development concept. Implementing the objectives of CAP support has important impacts on food economy. The current objective set of the CAP, according to the "EU 2020" strategy, is that agriculture should contribute to smart, sustainable and inclusive growth. Government policy measures have static effects, risk-related effects and dynamic effects on production, and different transfer efficiency on farm income depending on policy tools applied. The impact of agricultural subsidies on income distributional effects depends on their type, the structure of the markets and the existence of market imperfections. Most of the studies investigate the direct impacts of subsidies on prices, output, income, the environment, etc. by assuming that subsidies do not alter the structure of agricultural markets and do not interact with market institutions. In reality, government policies may have various unintended effects (they can change the structure of market organization or crowed out some market institutions) (Forgasi et al., 2014). The objective of this study is presentation of the mechanisms and economic consequences of public intervention in agriculture in Poland during the period of EU membership which seems to be very important for rural economy as well as whole economy of Poland.

Material and Methods

The basis for the research was studied literature, especially in the field of main stream economics, welfare economy and public choice theory, referring to the question and to the consequence of public support in agriculture. Documentation studies were carried out also in the field of literature consolidating issues related to public support and process of structural changes, innovation transfer, the development strategy of determining the directions of the policy and the main acts forming the regulatory environment. Assessment of the importance of structural changes in agriculture was carried out using methods of descriptive and comparative analysis. The empirical material was the statistical data of the Central Statistical Office (CSO) for the years 2004-2016 and Agency for Restructuring and Modernisation of Agriculture (ARMA).

Results and Discussion

The specific nature of the agricultural sector and its entities boils down primarily to the limited mobility of production factors involved in this sector. This particularly regards land, family labour resources, and, to a significant extent, the capital adjusted to agricultural activity. Agriculture and its entities are deprived of the benefits from transferring resources to more effective sectors, which determines the nature of competitiveness. Following the accession to the EU, there have been major changes in the agrarian structure, which continued long-term trends. In the period preceding accession to the EU (1996-2002), large agricultural holdings (20-50 ha of utilised agricultural area - UAA), which took over arable land from small and medium agricultural holdings, but also from holdings of over 50 ha, developed dynamically. The growth in numbers was accompanied with the decrease of surface. The arable land of holdings below 1 ha grew, but their number dwindled. Following the accession to the EU, the number of holdings decreased by 28%, and their surface – by 3%. The development of large holdings lost dynamics, but still arable land was taken over by holdings of the surface of 20 to 50 ha, for both smaller holdings, of which the number and area decreased, and bigger, the number of which, despite the decrease of the area, grew. The number of holdings taking over land slightly increased. The number of holdings smaller than 1 ha decreased by 27%. To a slightly lesser extent the number of small and medium holdings decreased (from 25% to 16%). Their area also shrunk, including, to a largest extent, in the group of 10 to 20 ha (by 8%). These changes indicate that the Polish agriculture, despite major changes, is still to a large extent dispersed. Figure 2 shows the use of land in different groups of farms in 2016.

The basic source of reduction in production cost is the change to the relation between production factors – particularly the relation between capital on one hand, and land and labour on the other. In Poland, the equipment of labour with land and capital is much lower than in most EU countries, which determines relatively low labour and land productivity (Figure 3). Low cost of labour in Poland is the primary factor that contributes to the advantage of Polish agriculture over agricultural products of the majority of EU countries with regard to cost and prices. Low remuneration for labour, however, cannot be the basis for maintaining competitiveness of agri-food sector product on the European and global market. Improvement in efficiency of use of land and labour means also the improvement in the quality of production conditioned by technical and technological progress, and the level of producers' knowledge. At the same time, the land cultivation system, which is less intensive in Poland than in most EU countries, is a kind of competitive advantage because Polish agriculture can become "sustainable" agriculture faster that agriculture of other EU countries, which is the EU objective in the 2050 perspective.

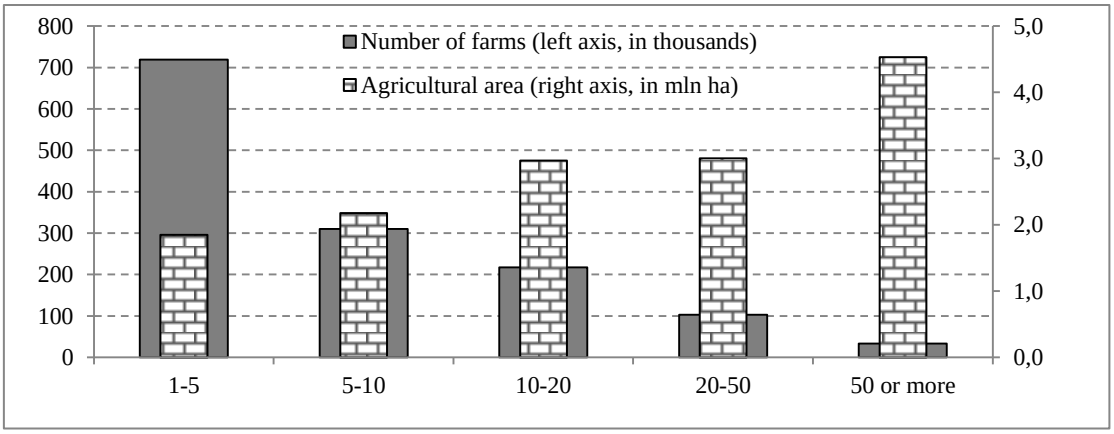

Figure 2. Land use by groups of farms in 2016.

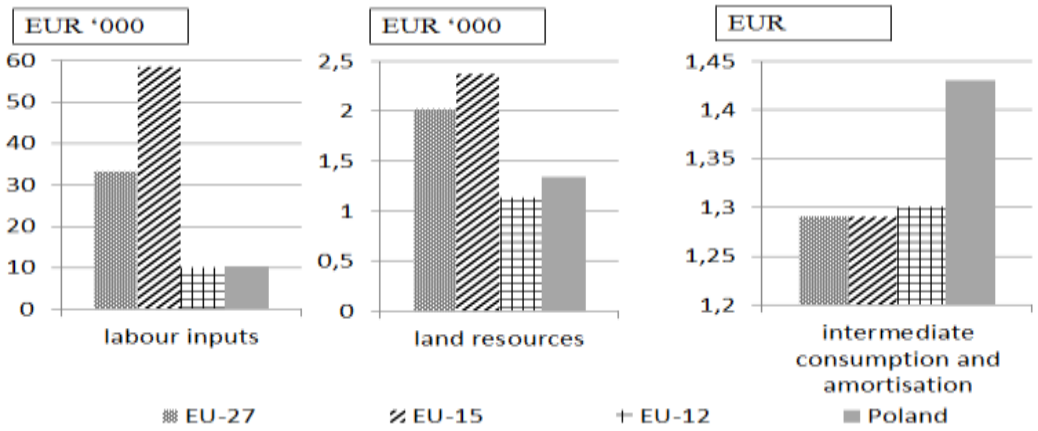

Figure 3. Productivity in Poland against average values for groups of EU Member States in 2016.

Source: Eurostat 2017.

The EU funds had a significant share in the financing of transformations in agriculture until Poland's accession to the EU. The direct payments are the most common type of support, each year about 1.4 million of farmers use this form of support. The value of payments in the 2004-2016 period increased and fluctued betwen ca. Euro 1.5 billion to Euro 3.5 billion per year. When calculated per one farm it reaches an average of ca. Euro 2.3 thousand, and this form of support is used by 87% of farms having an area of more than 1 ha. An equally important source of income (regardless of production, and only based on the farm's location) are payments for less-favoured areas (LFA). Each year these payments are granted to ca. 700 thousand farmers, i.e. half of those receiving direct payments. The land surface covered with LFA payments amounts to ca. 6.9 million ha. The manner of spending of the resources is not subject to settlement. Smaller farms usually allocate the granted payments to current needs and means of production (fuel, fertilisers), while the bigger ones also make investments.
The resources earmarked for investments are also an important source of aid for farms. So far, the financial resources for investments in farms, available under SAPARD, SOP "Agriculture", RDP 2004-2006, RDP 2007-2013 and RDP 2014-2020 were used in their entirety. The SAPARD programme was aimed at preparing the Polish agri-food sector to the accession, in particular in the adjustments to the sanitary, hygienic and environmental protection requirements of the EU. After 2004, the strategic objectives of agricultural policy implemented via SOP Programme "Agriculture" and RDP 2004-2006 covered: improving the

competitiveness of the agri-food sector, sustainable development of rural areas, improvement of the condition of the natural environment, improvement of the quality of life and diversification of economy in rural areas. In the next programming period, the RDP 2007-2013 has become the programme to support the implementation of the concept of multifunctionality of agriculture and rural development. It assumed economic strengthening of farms and an increase in the competitiveness of the agri-food sector, while assuring instruments for diversification of economic activities towards the acquisition and the creation of alternative sources of income for the rural population. RDP 2014-2020 for Poland focuses on three main objectives, i.e. supporting competitiveness and productivity in the agri-food sector, ensuring sustainable management of natural resources and climate action, as well as achieving sustainable territorial development of rural economies through the development of local infrastructure, investments in the field of education, culture and public services, creation of new and maintenance of existing jobs.

In the 2004-2016 period, the cumulative value of support for the agri-food sectors from three main sources of support: the payments from the EU budget, a grant from the national budget to KRUS and grant from the national budget, exceeded in total PLN 581 billion (EUR 145 billion) (Figure 4).

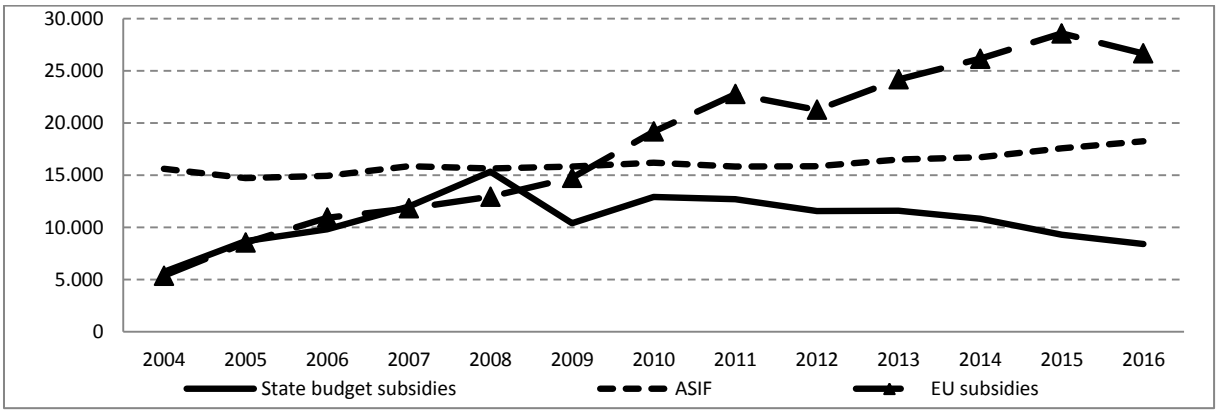

Figure 4 Budget spending on the agricultural sector in 2004-2016 (PLN '000 000).
Source: Authors' own calculation according to Budget Act (different years).

Rural development programmes, and indirectly also direct payments, are the primary source of support for investments in the Polish agriculture[22]. The role of the latter is particularly significant in farms with a large area. The area-related nature of direct and supplementary payments and LFAs[23] means that each year, farms receive cash they can spend on any purpose they want. The importance of these payments in the support for income, indirectly also for investment, is evidenced by the fact that they are received commonly. In order to obtain the payments, a farmer is only required to properly fill in an application and keep land in a good agricultural condition.

Conclusions

In the last decade the structural changes taking place in the Polish agriculture became more dynamic. The most important among them cover: a drop in the number of farms with

[22] Direct payments in agriculture fulfil a number of functions, i.e. the income function (they compensate the farmers' increased production costs), the stimulating function (they can define the direction of agricultural production), the modernisation function (they can be used for co-financing of investment), the information function (they indicate the areas of production).

[23] About half of the land used for agricultural purposes in Poland is located within LFAs. These include e.g. the areas where there are difficult climatic conditions, rainfall is too big or too small, there is a disadvantageous topography (e.g. mountains), or the quality of soil is low.

simultaneous growth in the share of the largest farms, which directly influences the increase in the average area of farms, drop in employment in agriculture and progressing production concentration and specialisation. The structural changes are, however, slow and cannot be efficiently accelerated due to non-agricultural circumstances. The Polish agriculture is still characterised by a strong polarization of the agrarian structure.

Policy instruments implemented within the CAP created chances for the stabilisation of structural policy conditions over the period of several production cycles, thus stimulating the desired changes in the area structure of farms, the improvements in the competitiveness of production and multi-functional development of rural areas. Thus they are a fundamental instrument supporting the process of modernisation of Polish rural areas and agriculture (Wigier, 2014a). Today, we already know that CAP has actually caused an increase in support for agriculture, while structural funds have triggered considerable cash flows intended for modernisation of food economy and rural areas development. However, not all investments proved to be effective, which undoubtedly prompts us to reflect on the scale and the value of investments in agriculture.

REACHING TERRITORIAL COHESION? PRINCIPLES AND PRACTICES OF THE NEW REGIONAL POLICY: THE CASE OF INTEGRATED TERRITORIAL INVESTMENTS AND COMMUNITY LED LOCAL DEVELOPMENT IN POLAND

Michał DUDEK*

Institute of Agricultural and Food Economics-National Research Institute, city, Poland
*Corresponding author: dudek@ierigz.waw.pl

Abstract

The emerging concepts and regional policy instruments are focused on balancing socio-economic development in the spatial aspect. They differ from each other not only in the approach to scale and scope of support of individual territorial units, but also in the way and conditions of assistance. New regional policy tools can be considered through the prism of links with the rural development process and policy, and in particular the potential effects that they may have on these areas. The paper analyses new instruments of the EU Cohesion Policy and Common Agricultural Policy (CAP) in a form of Integrated Territorial Investment (ITI) and Community-led Local Development (CLLD). The aim of the research was to determine potential impact of these initiatives on the socio-economic situation of the countryside in Poland. The study showed that both the ITI and CLLD could play a positive role in creating conditions conducive to improving the situation of rural population in Poland. However, their implementation involves a number of barriers and risks. The progress in implementing projects under analysed instruments is limited and does not allow for their comprehensive assessment. The conducted research has been based on literature review, available quantitative data and qualitative information published by the public bodies implementing the ITI and CLLD in Poland.

Keywords: *Regional Policy, Rural Areas, EU, Integrated Territorial Investment, Community-led Local Development*.

Introduction

Phasing out the approach to territories through the prism of borders for the benefit of their functions, specialisations, links, potentials and development barriers is increasingly reflected in the economic and regional policy (Shucksmith and Brown, 2016). This trend also applies to the EU policies, in particular the Cohesion Policy and the CAP (McCann, 2015). Given the challenges and problems in the situation of many rural territories, as an appropriate approach of government intervention, the neoendogenous paradigm is often recommended (Tödtling, 2011). According to this concept, the development programmes and projects should be created at the local level and based on support, knowledge, advice and strategies generated at the regional and central level (Copus *et al.*, 2011). What is widely discussed currently, is the postulate of the rural development policy, which takes into account the properly targeted top-down programmes with bottom-up projects. In the context of designing the Cohesion Policy and CAP and their implementation systems, it is suggested to reduce the support treated as compensation for poor territories and allocation resulting from the "objective" demand, in favour of strengthening the capacity of all local and regional units. In such approach, local stakeholders could shape their own situation independently basing on their own material, intellectual, environmental and social resources as well as on links with external actors (Copus *et al*., 2011). This argument is linked to a belief in the effectiveness of public intervention which is financially consolidated and based on simple principles and objectives. It is argued that new possibilities for intensifying connections between rural and urban areas, defined more by their functional connections rather than administrative classifications, are

provided within the current EU development (the financial framework 2014-2020) (Nurzyńska, 2014). The chances of strengthening contacts motivated by obtaining mutual benefits are to be expressed, *inter alia*, by a relatively deeper decentralisation of financial support from the structural funds, promoting cooperation between self-governments and thematic concentration of interventions. The EU policy mechanism under which these postulates are implemented is the integrated territorial approach, in particular the instruments called ITI and CLLD (Kozak, 2016). The purpose of the paper was to analyse and assess this instruments as the new tools of regional policy aiming at reaching territorial cohesion for the different types of rural terrains, namely: suburbs, intermediate and peripheral areas. This mechanisms were characterised in the context of selected regional and social development theories. Using the data on the implementation of ITI and CLLD in Poland the potential effects for the development of rural areas were considered.

Material and methods

The paper is based on literature review. The presented conclusions were also drawn from the analysis of the strategies and legal documents relating to the implementation of the EU Cohesion Policy and the CAP in 2014-2020 in Poland. In the analyses the information and data published by public bodies involved in implementing the ITI and CLLD in the EU and Poland were taken into consideration as well.

Results and Discussion

A new subject in the EU regional policy is the integrated territorial approach concept. This idea, understood in a narrow sense, applies to the specific tools of the EU Cohesion Policy and CAP. The EU law identifies three integrated territorial approach instruments: ITI, other integrated operations and CLLD. These tools have been regulated at the EU and country level. These instruments differ in terms of the main area of implementation, method of management, functioning and supervision, as well as the size and type of the source of financing.

Within the framework of ITI, there are instruments supporting the sustainable urban development and instruments supporting various areas. The former is described by Article 7 of the Regulation on the European Regional Development Fund (ERDF). The overall objective of the mechanism is the sustainable urban development, which is implemented by investments, separate priority axes or operational programme (*top-down approach*). The allocation under Article 7 of ERDF mainly covers the thematic objective of the Cohesion Policy related to promoting the transition to the low-carbon economy of all sectors, conservation and protection of the environment and resource efficiency, as well as the objective referring to social inclusion and the fight against poverty. ITI supporting various areas, including urban areas is under Article 36 of the general regulation (van der Zwet *et al*., 2014; Łukaszewska-Krawiec, 2015).

In turn the CLLD is implemented using development strategies which are multi-sectoral, integrated and customised to the specific sub-regional area. Its use is a rule for the CAP (at least 5% of the European Agricultural Fund for Rural Development allocation, EAFRD) and is voluntary in the case of the Cohesion Policy (European Social Fund, ESF and ERDF) and maritime and fisheries policy (European Maritime and Fisheries Fund). CLLD is to encourage local communities to take action for the benefit of their area, civic activity and involvement in implementing the development policy objectives (*bottom-up* instrument). The beneficiaries of this instrument are Local Action Groups (LAG), which function based on Local Development Strategies (LDS). The LDS selection criteria are defined by the Member States.

It is estimated that in 2014-2020 the EU Cohesion Policy allocated EUR 15 billion for the integrated territorial approach mechanism, i.e. about 5% of the total budget of this policy (Committee on Regional Development, 2016). The majority of funds for this initiative are

spent from the ERDF (82%) and the remainder is from the ESF (14%) and the Cohesion Fund (CF) (4%) (Łukaszewska-Krawiec, 2015). ITI is implemented by 20 EU Member States, particularly for the projects designed for urban areas. On the other hand, CLLD is based mainly on the LEADER programme implemented within the second pillar of the CAP and financed by the EAFRD (use of this instrument is obligatory for this fund). CLLD as a Cohesion Policy tool is implemented in case of 17 Member States[24] (Committee on Regional Development, 2016).

The regional policy of the EU and Poland is focused on deepening and streamlining urban-rural relations. It is expected that *the effects of ITI and CLLD interventions will not be the same in different rural regions* (Table 1). The ITI will relatively apply most to the *suburban rural areas* as these locations are situated within the strong impact of sprawling cities and most often constitute a part of their functional area. In suburban villages the economic problems resulting from the insufficient level of diversification of local economy are often not so urgent. In turn, they are characterised by single family development, various forms of land use, intensive commuting flows, high landscape values, gentrification and advanced multifunctionality (Bański, 2017). In the case of villages located in the neighbourhood of big agglomerations, the ITI could broaden and increase the intensity of existing urban-rural relations, notably in the aspect of integration of labour markets, education and other public and private services (e.g. by development and modernisation of transport infrastructure). This should result in strengthening the urbanisation process, as well as improving the position of the commuters, in the inward direction i.e. from the places of residence to the location where work and services are concentrated (Śleszynski, 2013; Hadyński, 2015). For some localities, the ITI should also contribute to the intensification of pressure towards the growth of the administrative boundaries of cities, which sometimes may result in local conflicts (Table 1).

Table 1. Integrated Territorial Investments and Community Led Local Development: selected opportunities, barriers and risks for rural areas in Poland

OPPORTUNITIES	BARRIERS AND RISKS
Strengthening urban-rural socio-economic relations and creating the synergy effect	Reduction of importance of rural areas in favour of cities, development centres and their functional areas
Increasing the living standard of the commuters	Local conflicts
Increasing the impact of rural population and local authorities on implementing the cohesion policy	Uneven participation in the decision-making process and distribution of financial resources
Development of cooperation between self-governments and local communities	Orientation towards spending resources and implementation of simple short-term projects
Solution of rural areas' urgent problems	Low scale of activity of the local community
Creation of new markets and development of existing supply and consumption markets	Problems in cooperation between self-governments and local communities
	Development of administrative structures and low inputs for supporting projects

Source: Own elaboration.

The ITI increase the scope and capacity of collaboration between self-government bodies. A formal or informal field of cooperation between communes, which is created and developed within this instrument, will include units of different size and economic and personal potential. This may be accompanied by an uneven impact on the decision-making process, rewarding the urban units and not bringing any benefits to rural communes (Table 1). The observed process of capturing EU support by institutions with the high potential often results in reducing opportunities for obtaining mutual benefits, which, in the case of ITI, means

[24] In most cases it is financed from the ERDF and ESF budgets (11 countries), less often only from the ESF (4 countries). In the case of Lithuania, CLLD is financed only from the ESF and, in the case of Sweden, a separate operational programme has been created (Łukaszewska-Krawiec, 2015).

limited possibility for achieving integrated effects. At the same time, the budgetary constraints and other resources provided for the implementation of collective projects makes the urban influence on their selection and implementation higher. On the other hand, an insufficient level of financial support may result in the selection of operations which are simple, not challenging, problem-solving and oriented exclusively towards spending resources (e.g. investment in unnecessary infrastructure) (Table 1). However, the final shape and effects of undertaken urban-rural cooperations will depend, to a large extent, on the developed ways of collaboration, acquired experience, level of involvement of participants and amount of available financial resources.

For *intermediate rural areas* the ITI instrument will be of relatively lower importance. These areas, though located often far from big cities, are characterised by various economic and social connections with other towns and villages. In this case the impact of urban centres does not eliminate a number of elements typical for rural areas, as well as economic problems stemming from the insufficient effect of agglomeration. Intermediate rural locations are often characterised by the lack of identification of major socio-economic function. For some villages located in these areas, especially those linked with the urban functional areas and oriented towards spatial integration, the ITI should be one of useful development policy tools. In these locations, integrated projects may foster the greater networking of rural economic entities (including farms) by creating or strengthening links with urban markets[25] (Table 1). However, for the majority of villages from intermediate area relatively more adequate seems to be the *CLLD* mechanism. The opportunities and effects created by both analysed instruments will depend on the conditions of financial support adopted at national, regional and local levels, as well as on the level of participation and engagement of given communities and authorities.

A significant distance from urban centres along with a predominance of traditional industries, which are based on the use or management of natural resources (i.e. agriculture, forestry, hunting, tourism and recreation, health services) is characteristic of *peripheral rural areas*. Villages located in these terrains often face poor level of technical and social infrastructure, shallow markets and social problems. At the same time, peripheral locations are highly valued due to their amenities, especially environmental resources, which are appreciated by both locals and tourists. It should be assumed that in case of these villages the impact of the ITI will be limited. Among the analysed instruments the CLLD could play a significant role in supporting development processes in peripheries. However, it is stressed that the problems of rural areas should not be tackled using regional policy tools, which are not adjusted to the challenges faced by poor villages. In this context, it is postulated to maintain mechanisms providing services to the countryside and supporting its development by agricultural and rural development policies (Röhl and Schröder, 2017). Nevertheless, nowadays the idea of integration is nowadays often discussed (Ministry of Regional Development, 2010).

The projects within the ITI formula are implemented in Poland in 24 functional areas. In 17 cases, their implementation is carried out within regional capitals and their functional areas (most important agglomerations), and in 7 cases in sub-regional cities and their functional areas. Delimitation of functional areas was prepared by the Polish Ministry of Development. There are two legal forms of ITI implementation in Poland: ITI associations (10 cases) and ITI Partnerships (14 cases). The partnerships of cities and related functional areas have a form of agreements (14 cases) or associations (10 cases) known as unions. In the formulas of cooperation agreements of communes, the leading role is played by a leader i.e. mayor of the city. A prerequisite for implementing ITI is the development of a cross-sectoral strategy that

[25] For example, benefits of joint initiatives may be profitable for farms oriented towards direct sales in cities and towns, as well as for urban dwellers preferring organic food or agri-tourism as a form of spending free time (Peters and Gregory, 2015).

addresses the needs of the area concerned. In Poland more than 550 local government units are involved in implementing ITI by the end of the 2016 (Żygadło, 2017). The most important source of financing the projects within the ITI instrument is the ERDF and ESF provided for the implementation of regional operational programmes (ROP) – approx. 3.8 bln EUR. In total an allocation for implementation of ITI in Poland amounted to more than EUR 6 bln[26] (Żygadło, 2017).

The CLLD as a new instrument of integrated territorial approach policy principle is aimed at encouraging local communities and various entities in the development process of the given area by creating and implementing the LDS. In Poland this tool is implemented under the CAP, Common Fisheries Policy and Cohesion Policy. This instrument has been indicated as appropriate for implementing the measures in areas of strategic intervention regarding cities and districts requiring revitalisation and rural areas with the lowest level of access to goods and services determining development opportunities. As for the Cohesion Policy, the use of CLLD instrument under the ROP in particular region were determined by the decision of self-government authorities. For the time being, CLLD is implemented only in two Polish regions: Kujawsko-Pomorskie and Podlaskie Voivodeship. The vast majority of LAG in Poland have used so far financial support available under the EAFRD. It is estimated that for the CLLD instrument in Poland in 2014-2020 about 900 million EUR was allocated, of which the vast majority came from the EAFRD (82%) (Gierulska, 2016).

Conclusion

The main instruments of implementing the integrated territorial approach concept in the EU Cohesion Policy are ITI and CLLD. The former is dedicated primarily to cities and its functional areas. Its objective is to support joint projects undertaken by self-governments and local communities. The latter mechanism is addressed for the rural residents in order to assist in taking development projects based on endogenous resources. Both policy tools are different not only in terms of the area concerned, way of management, implementation and supervision but also have various size and main source of financing.

Analyses showed that ITI and CLLD instruments are an important component of the current EU Cohesion Policy. They could bring new opportunities for the rural development, particularly in creating and broadening the multidimensional rural-urban relationships. These build-up connections could be strengthened by projects integrating labour markets, investments in education system and healthcare services, as well as by increase of local social capital. It is expected that the implementation of ITI will be especially favourable for the villages located in suburban areas. Though, the ITI projects will include significant improvements in the condition of technical infrastructure and investments conducing environment protection and public health. In the case of intermediate and peripheral rural areas, the impact of the ITI will be rather limited. However, significant opportunities to start or intensify the bottom-up development processes in these territories should be offered by the CLLD mechanism.

In Polish regional policy in 2014-2020, the integrated territorial approach principle concerned the eastern part of the country, cities with functional areas, rural areas and border areas. New instruments related to this policy concept, namely ITI and CLLD are used in Poland as well. The process of implementing of these tools has been launched. It runs relatively slow. So far, the formal, legal and organisational foundations for using granted financial resources from the EU funds have been created and the implementation of various projects has been started. For

[26] Additional support for the urban transport development and energy efficiency use is provided within the Infrastructure and Environment Operational Programme (IE OP) and Eastern Poland Operational Programme (EP OP) – approx. 2.4 bln EUR. The ITI unions are financed from the Technical Assistance Operational Programme (OP TA) (20 mln EUR).

the time being institutions involved in ITI mechanism face many problems and constraints (weak status, focus on building an institutional capacity rather than implementation of integrated projects, lack of territorial dimension of the projects, allocation is treated as granted). Available data showed that ITI strategies were implemented by different partnerships in the country, covering more than 550 self-government units in 24 urban functional areas. In turn, the LDS were implemented by more than 320 LAG. Institutional delays and the initial phase of introduction of many projects do not allow to formulate assessments concerning the effects of analysed interventions, particularly in solving local problems.

RISK MANAGEMENT IN OCCUPATIONAL EXPOSURE TO PESTICIDES: THE ROMANIAN PERSPECTIVE

Mihaela STOIA*

Faculty of Medicine, "Lucian Blaga" University of Sibiu, Romania
*Corresponding author: medmuncii@dspsibiu.ro

Abstract

This study aimed to establish the importance of controlling exposure and health effects of toxic chemicals used in agriculture, and to raise awareness in rural communities. Data regarding main categories of pesticides, number of exposed workers, number of occupational diseases caused by these chemicals, and the value of biomarkers in certain exposures were collected from plant protection offices and from official public health reports. Specific health effects in agricultural workers were analyzed following a 14-year retrospective study between 1993 and 2006. On the basis of national data and scientific literature review, educational materials were written, respectively a dedicated chapter in the work health promotion guide and a dedicated module for the training course for practitioners of occupational medicine in the agriculture sector. Currently, there are about 9300 Romanian workers applying pesticides in agriculture, while 3523 are involved in mixing, loading, and storage. Occupational intoxications have decreased significantly until 2006 and occur only accidentally nowadays. Activity of serum cholinesterase - significantly decreased at $p < 0.01$ - is a reliable biomarker to be used in occupational exposure to organophosphates and carbamates. In 2017 the training course was accredited as Continuous Medical Education course at European level and is expected to engage more than 10000 participants. Research and official statistics subjected an informational system created to support agricultural communities to better manage the risk posed by plant protection products.

Keywords: *Pesticide, Agriculture, Intoxication, Risk management.*

Introduction

Agriculture is one of the most hazardous occupations based on occupational fatality rates, nonfatal occupational injury rates, and occupational illness rates (Donham and Thelin, 2006). The main chemical risk is posed by a wide range of substances used to combat and control pests, generally called pesticides or plant protection products. Classification of toxic materials under the Globally Harmonized System includes acute toxicity - i.e., lethal dose for 50 percent LD50, skin irritation / skin corrosion, serious eye damage / eye irritation, respiratory or skin sensitization, mutagens, carcinogens, reproductive toxicity, specific target organ toxicity, aspiration hazard, and chemical mixtures. Usually, the Hazard Communication Standard translated into the Safety Data Sheets must be consistent with the Globally Harmonized System of Classification. For many chemicals there will be a dose called threshold dose bellow which no effect or response is observed in individuals. The regulations on plant protection products focus on the active substance and do not apply to the potential combined effect resulting from the concomitant use of several formulations (i.e., mixture) as applied in practice, therefore it must take into account the cumulative exposure to more than one active substance (Kienzler *et al.*, 2016; US EPA, 2015). However, the best approach is to always keep exposures or the risk of a hazard as low as possible.

The threat for farmers and operators is posed especially by organophosphates, carbamates and pyrethroids. The main target-organs are skin, lungs and central nervous system, and chronic effects are mainly respiratory (bronchial asthma) and neurological diseases (deficits in neurobehavioral performance, abnormalities in nerve function, and Parkinson's disease),

diseases of the reproductive system, as well as different types of cancer (California Department of Public Health, 2015).
Scientific evidence suggests aluminium (heavy metal) is involved in Alzheimer's disease (Dyck, 1994; Yokel, 2000), while pyrethroids are known to cause respiratory and skin problems – asthma and allergies. Organophosphates are by far the most toxic pesticides responsible for neurotoxicity (acute and chronic) *via* inactivating acetylcholine esterase (Frumkin, 2010). In humans, important families of enzymes are involved in xenobiotic metabolism. For example, unusual variants of paraoxonase (PON) have recently been associated with genetic risk to organophosphate exposure, while the variant PON1 may detoxify the pesticide poisoning more efficiently (Kaur *et al.*, 2017).
Carbamates and aluminium phosphide are also associated with acute toxicity. Organochlorine pesticides may have developmental, endocrine and reproductive effects (Frumkin, 2010). Naphthalene, the first registered pesticide in the USA in 1948, is now classified by the International Agency for Research on Cancer as a possible human carcinogen. Used as a household insecticide against moths, it was replaced with 1-naphthyl-*N*-methylcarbamate.
The objective of the present paper is to provide Romanian evidence on occupational pesticide exposure, and to encourage the use and/or development of new instruments to raise awareness in relevant communities involved in risk management and rural economy.

Material and Methods

A retrospective study was conducted on agricultural workers chronically exposed to pesticides between 1993 and 2006 following the eligible criteria of occupational poisoning.
In order to evaluate the current situation in terms of exposure and health effects, quantitative and comparative analysis was done on the basis of the following data sources:
1. Occupational Morbidity in Romania, managed by the Operative registry book of occupational diseases, monthly updated (National Institute of Public Health, 2017);
2. Health and Environment Report (National Institute of Public Health, 2014): number of workers handling pesticides, occupations, geographical distribution, reported symptoms, and reliable biomarkers - activity of serum cholinesterase (CHE). Normal blood values of CHE vary widely between individuals therefore it is best to have individual baseline test results: 20% depression from baseline suggests a possible poisoning; 40% depression of serum CHE suggests a diagnosis of acute poisoning and removal from work exposure (Donham and Thelin, 2016). The Romanian study considered normal limits for serum CHE concentration (U/L) within 4620 – 11500 in males; and 3930 – 10800 in females.
3. *Phytosanitary Authority of Sibiu*: evidence of commercial pesticides approved in 2017, according to European Regulations.
The threshold limit value – time-weighted average (TLV-TWA) is the concentration for a normal 8-hour workday, repeatedly day after day without adverse effect. For example, TLV-TWA = 0.5 mg/mc air for pirimiphos (organophosphate) and zineb (carbamate); and TLV-TWA = 1 mg/mc air for pyrethrum (Romanian Government Decision, 2006).
The preparatory stage for training course included an up-to-date literature review, reports, statistics and publications on good practices on prevention on occupational diseases in agriculture. The original search was conducted in 2015 (Stoia, 2015), and updated in 2017 as part of the AGROSH+ Project (Stoia, 2017).

Results and discussion

The number of occupational poisonings due to pesticides has decreased within the period 1993-2006 (Figure 1); the number of exposed workers was, on average, 7628 ± 1237; and 7% of those workers were exposed to concentrations above TLV-TWA.

Since 2007 no incidence of pesticide poisonings was reported in workers. The reasonable explanation was law enforcement due to harmonization with European Union Regulations, putting in place regulations regarding the distribution, selling and use of pesticides, a proper recording, certifying and labeling of the products, regulations regarding the tolerable amounts in foodstuffs, and proper occupational risk management (Romanian Parliament Act, 2006).

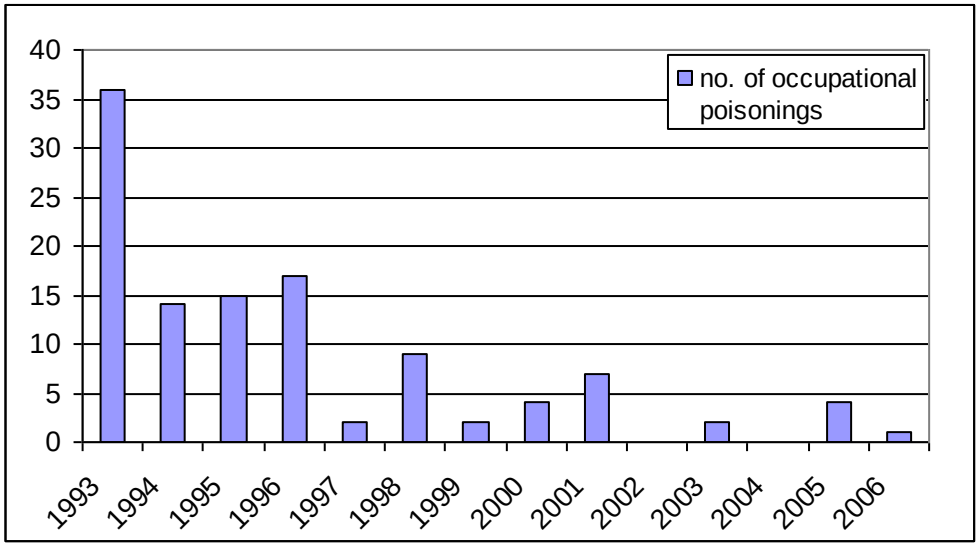

Figure 1. Incidence of occupational poisonings due to pesticides between 1993 and 2006

Since 2005, the most common occupational diseases in Romanian agriculture were respiratory diseases (chronic bronchitis, bronchial asthma, and hypersensitivity pneumonitis caused by organic dust allergens) and musculoskeletal disorders (National Institute of Public Health, 2017). This issue may point out the fact that pesticide poisonings commuted into occupational diseases by target organ systems (respiratory diseases) and the comparative exercise is nevertheless still useful to derive the important trends of the future.

Data reported by the National Institute of Public Health in 2014 show a number of 12823 Romanian exposed workers including 9300 pesticide-users, 1572 warehouse-operators, and 1951 others. Typically, pesticide use is associated with mixing and loading the product, application of the spray solution, and clean-up of the spraying equipment (Damalas and Koutroubas, 2016). The greatest part of users is distributed in the South, i.e. 2182 self-employed cultivators in the Olt County. Skin and eye irritation are the most frequent symptoms workers complain about when handling pesticides.Organophosphates affect the nervous system by altering the efficacy of the enzyme CHE, and enzyme levels may be used as a molecular biomarker in risk assessment (Robson and Toscano, 2007). CHE was shown to be specific for the exposure to organophosphates and carbamates in the Romanian study, exhibiting low concentrations compared with controls but within the acceptable limits, as summarized in Table 1. Sometimes, elevated transaminases occur in liver injury produced by certain pesticides, as well as elevated glycaemia and risk for diabetes (Ki-Hyun *et al.*, 2017).

Table 1. Comparison between the average concentrations of CHE in pesticide-exposed workers and controls.

Group (N = 100)	**CHE (U/L)**	**Standard deviation**	**Student test t**	**p**
Exposed	6773.3	±1596.2	3.09	**< 0.01**
Controls	7714.7	±1355.2

In Romania, control and approval of pesticide products is performed by the Ministry of Agriculture and Rural Development *via* local phytosanitary offices. Commercial plant protection products in use on January 2018 are listed in Table 2.

The term "pesticide" may communicate an unintended negative perception based on fear, therefore terms such as insecticide or herbicide, or even the class of chemical, are more appropriate. Agriculturalists often utilize the term "plant protection products" to help avoid the general negativity associated with "pesticides" (Donham and Thelin, 2016). Reducing pesticide use was demonstrated to rarely decrease productivity and profitability in arable farms (Lechenet *et al.*, 2017). Complementary to risk management in Romanian agriculture, the educational activity was provided by Romtens Foundation of Bucharest in collaboration with experts and consisted in two main results, namely: (1) editing and distribution of a guidance book to 200 occupational health and safety specialists, in 2015; (2) training and providing additional qualifications for about 30 practitioners of occupational medicine in the agriculture sector, in November of 2017, as part of the project "OSH+ for the European Agriculture sector - Stimulating growth in rural areas through capacity building for providers (and beneficiaries) of occupational medicine and OSH services" (AGROSH+)[27]. The training material was peer reviewed and accredited as Continuous Medical Education course at European level. This project aims to have more than 10000 participants who will be getting in contact with the project activities or results. Increasing the role of occupational health services and physicians, including important issues such as training, and legal protection to allow them to do their jobs without fear of sanctions by employers is of great importance in preventing occupational diseases (European Commission, 2013). In the future, it would be very useful to raise the awareness of the national health care system with respect to a comprehensive prevention plan.

Conclusions

The commercial plant protection products used in Romania are harmful, mostly of them, and the health professionals should find out what pesticides are used in their community. In the past, the incidence of occupational poisonings due to pesticides was about 8 new cases per year. Since 2007, specific morbidity in agriculture belongs to respiratory diseases. In particular, pyrethroids are recognized as causal factors for bronchial asthma. At this time, there are a few instruments to measure a specific effect in the human body, and the most reliable biomarker is CHE activity depressed by organophosphates and carbamates. In 100 Romanian agriculturists the enzyme was found within normal range, significantly different in the exposed group of subjects compared to controls. Because pesticides can cause syndromes that are difficult to differentiate from other types of common diseases, the occupational history is essential, as well as identifying the toxic product that the worker has been exposed to. The relative acute human toxicity of insecticides classes from most to least toxic is organophosphates > carbamates > organochlorines > pyrethroids > neonicotinoids. Generally, uncertainty is present in all risk assessments and it occurs because of a lack of knowledge, therefore it is important to detect new adverse occupational health consequences. In the future, it would be very useful to develop new instruments of information and hazard communication in rural communities with respect to their health needs and local economy.

THE IMPORTANCE OF TV SHOWS FOR FARMERS AND THEIR PRESENCE IN THE MEDIA SPACE OF SERBIA AND REGION

Aleksandra ŠARKOVIĆ*

Radio Television Serbia, Serbia
*Corresponding author: aleksandrasarkovic@yahoo.com

Abstract

Starting from the importance of television, due to its close relationship with viewers, as a convenient means of informing and education, its offer of special contents that can have an impact on the acquisition of specific knowledge and motivation of agricultural producers in Serbia has been analyzed. The research for this paper was to determine the importance of special programs intended for countryside and agriculture to inform producers as well as to establish the confidence of agricultural producers regarding information provided by such content. A sample that covered 314 inhabitants of rural areas in Serbia was created. A questionnaire was used as a test instrument, which consisted of a group of questions relating to the respondents' views of special programs intended for agricultural producers, as well as assessing the usefulness of the information received and trust in the subjects in the programs. The programs that were analyzed were broadcast on four television channels that have a national frequency, two of which are public and two are commercial. Compared with other ways of informing about news in agricultural production, among agricultural producers, TV shows about agriculture are in second place immediately behind Agricultural Advisory Services. Almost half the respondents (47.8%) singled out interviews with government officials and attachments that recommend different products as the least useful information. When it comes to trust in the subjects that speak in programs about agriculture, the surveyed viewers give priority to experts (almost every second viewer), while in second place are agricultural producers.

Keywords: *television, information, knowledge, agricultural producers*.

Introduction

Television is the most influential medium and the most numerous auditorium (McQueen, 2000), which provides it with deep penetration into all spheres of society. Media theorists speak about the diverse functions that the media perform (fun, escapism, distracting, socializing and ideological), and as the primary ones, the informative and educational functions of television have been identified (Lorimer, 1998; McKuley 1976; McKinn, 2000). The transfer of information using television technology, which includes sound and image, contributes to the formation of a knowledge system in people (Marković, 2010). Information and knowledge are two important factors for rural development. The knowledge of the locality further assists the farmers. Dissemination of information along with new concepts and farming techniques can bring new opportunities for farmers (Mohammad et al., 2010). FAO (2001) reported that television is the most important medium for communicating information among rural people in developing countries. In rural areas, people are facing many problems and obstacles to get information about agriculture. Farmers have little accessibility and access to information in rural areas. In remote rural areas, where direct contact between advisers and farmers is difficult due to underdeveloped infrastructure and inaccessibility, mass media (radio and television) are useful tools for improving the knowledge of farmers (Nazari et al., 2011). The notion of television content intended for the rural population besides being informational and educational must also have a motivational character to encourage the viewers to personal action and the acceptance of contemporary methods of production

(Šarković, 2016). The largest number of studies on the impact of media acquisition and dissemination of specific knowledge in agriculture has been achieved in developing countries where television is still, regardless of the increasing presence of the Internet and its influence, the most important mass media in informing and educating inhabitants of rural areas. Among the areas studied is India, where agriculture accounts for about half the population, that most frequently lives in poor rural areas where radio and television are the most important sources of information and education (Kappor, 2011). Kappor (2011) stated that research evaluating the efficiency of programs for the rural population in the Hisar district showed the following:
1 - emissions for the rural population were not as attractive as most programs because they were based on monologues with low visual content;
2 - many more recommendations by TV specialists were intended for large producers than small farmers who make up the majority of the rural population.
Research which analyzed the environmental awareness of residents in two rural provinces in Turkey (Akca, 2007) showed that television and print are the main sources of information about the environment among the rural population. Television as a medium has the potential to improve the information and knowledge of farmers. There is a need to produce more agriculture-related programs on television and to adapt the broadcasting time to agricultural producers so that they can make better use of television content (Chhachhar et al., 2012). Producers that are more intensive than others follow specialized broadcasts for farmers and show a higher degree of concern for the environment. The level of information also shows a high correlation with the adoption of ecological practices, such as soil analysis and harvesting of harvest residues (Šarković, 2016). Most of the television stations that were part of Yugoslav Radio Television (JRT) used to broadcast on their national channels programs dedicated to agriculture and the village. This can be considered somewhat of a tradition as these are, most often, the longest-running broadcasts in the program scheme.
On the former Television Belgrade and Zagreb, specialized shows for rural communities and agriculture have been broadcast since the year of their establishment (1958). Today, RTS1 broadcasts *Knowing-Having*, and the Croatian National Television HRT1broadcasts "Fruits of the Land". At RT Republic of Srpska (RTRS), one of the oldest programs on agriculture called *Bundle* has been broadcast since 1993. Federal Television (FTV) Bosnia and Herzegovina broadcasts a program called *Green Panorama* on Sundays. Television Slovenia broadcasts the show *People and the Earth*. All programs dedicated to rural communities and agriculture are broadcast on Sundays on Channel 1 of these television stations.
Television has a strong role in informing and educating agricultural producers, having special programs on rural communities and agriculture in public media service programs in Europe. The British public service BBC, on its first channel, has broadcast a show once a week since 1988 called *Countrylife* for 60 minutes. The Austrian Public Service (ORF) broadcasts the *Land and Leute* Program for 26 minutes every day at 16.30 on the ORF2 channel. The Italian National Television RAI (RAI) on its first channel on Sundays at 12:20 pm broadcasts a special program dedicated to agriculture and the development of villages with special themes for each show. The series is called the *Green Line* (Linea Verde), and each show lasts about 56 min. The Hungarian MTVA's public broadcasting service on its first M1 channel once a week broadcasts a program entitled *Magary Boss* for 20 min. All these broadcasts confirm that television in many parts of the world accepts that in addition to its informative function, it has the function to educate viewers.
With this background of widespread agricultural programs targeting rural communities and farmers, the objectives of this research were to determine the importance for rural inhabitants of Serbia of special programs intended for countryside and agriculture to inform producers as well as to establish the confidence of agricultural producers regarding information provided by such content.

Material and Methods

In the theoretical part of the research, scientific papers and professional journals were analyzed. The presence and content of specialized programs for farmers in the media channels in Serbia and the region were also monitored. In the empirical part of the research, a sample of 314 inhabitants of rural areas in Serbia was made for collecting reliable and relevant indicators using a questionnaire. Serbia has four national television channels, two of which are public and two are commercial. The sample included a monthly one-time broadcast throughout 2012. These were "Knowing-Having" - RTS, Broadcasts - RTV, "Good Land" TV show-TV B92 and "Host" show - TV Prva.

Results and Discussion

In the period January-December 2012, the broadcasts/programs for agriculture and the village, which were broadcast on four television channels with national frequencies had ratings of between 2.4 and 1.2 (Table 1). The most-watched broadcast was "Knowing-Having" (ZnanjeImanje) whose rating (2.4) was twice that of Host (Domaćin) (1.2) on TV Prva (Josifović and Senić, 2012). The explanation for these results should be sought in the long-standing tradition of monitoring the Public Service programs of Serbia that has existed since 1958, as this media institution, in its various program contents, is engaged in the field of countryside and agriculture. Of these four programs, the program "Knowing-Having" (ZnanjeImanje) has the longest tradition, having been broadcast since 1972, and has also broadcast "Furrows" (Brazde) since 1975. The other two programs have a significantly shorter tradition of broadcasting (TV B92 - 2002; TV Prva - 2007).

Table 1. Annual rating of analyzed emissions

Broadcast title	Rating	
	Average number of viewers per minute	%
Host	81000	1.2
Good Land	112000	1.6
Furrows	123000	1.8
Knowing Having	166000	2.4

Source: Šarković (2016).

In this survey, informing the population in rural areas was observed through information on new and modern methods of agricultural production that would ensure yields and product quality. The results of the survey, which included 314 inhabitants of rural areas in Serbia, showed that the highest percentage of respondents (22%) were informed about the novelties in agricultural production through the Agricultural Advisory Services (AAS), while a slightly lower percentage of respondents (19.1%) selected TV shows on agriculture.

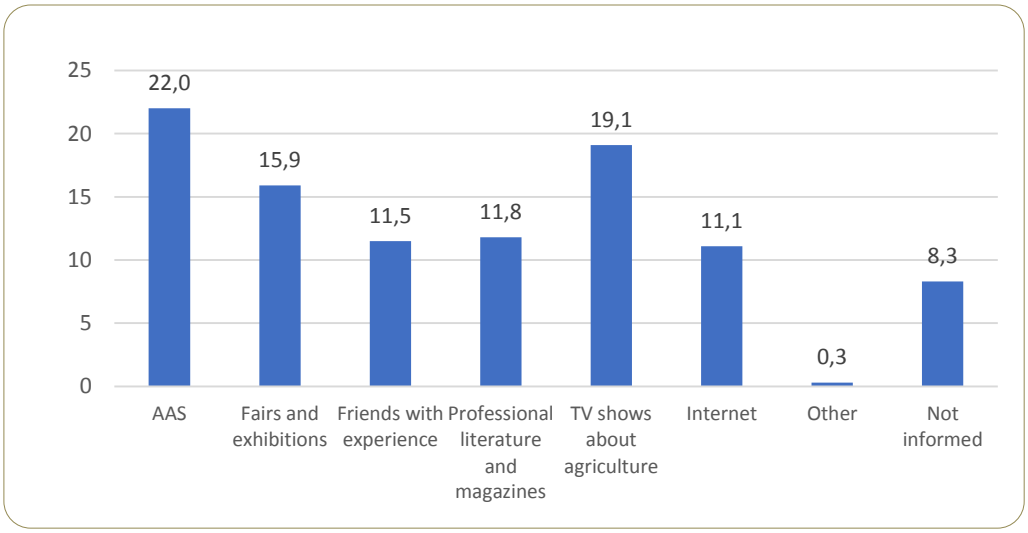

Figure 1. The most important sources of information on news in agricultural production.
Legend: AAS - Agricultural Advisory Service.

The highest percentage of regular viewers (41.1%) was for the program "Good Land" (Dobra Zemlja), and the smallest (23.9%) for the program "Host" (Domaćin), while "Znanje-Imanje" (Knowing–Having) and "Furrows" (Brazde) changed regularly, with the same percentage of respondents (34.4%) being regularly monitored. Further analyzes showed that the total viewers (regular and occasional viewers) for each of the above mentioned shows was more than 70% of the analyzed sample (Figure 2).

	Knowing - Having	Furrows	Good Land	Host
Regularly*	34,4	34,4	41,1	23,9
Occasionally**	53,2	43,7	50,3	46,8
Never	12,4	22	8,6	29,3

Figure 2. Frequency of watching programs on agriculture.
*Regularly - once to four times a month
**Occasionally - once in three months and rarely
Source: Šarković (2016).

Regarding the usefulness of different sources of information for respondents watching the programs (Table 2), almost half of the respondents considered that the least useful interviews were with state officials and contributions suggesting different products (47.8%), and slightly more than a third of viewers (35.6%) thought that all contributions were useful. A very small percentage of viewers (6.1%) identified reports on farmers and their experiences as the least

useful information. When it comes to trust in subjects that talk about topics from different fields of agriculture in agricultural programs, viewers generally gave their preference to experts in these areas (almost every second viewer). The experiences of other farmers were most believed by every fourth respondent, and experts from the Agricultural Advisory Services (AAS) were trusted by around 15% of viewers. Significantly smaller percentages were found for other sources of information. Thus, science, experience and profession give the highest confidence to agricultural producers who viewed these four programs.

Table 2. Trust in the sources of information given in the four agriculture programs

Source of information	%
Experts	46.8
Authorities / government officials	1.3
AAS - Agricultural Advisory Services	15.0
Representatives of the company recommending the product	0.0
Agricultural producers	22.6
Journalists	0.3
To all	1.3
Nobody	3.5
Don't watch agricultural shows	9.2
Total	100

Conclusion

Television as a medium has exceptional potential for transmitting information, advice and opinions from the domain of modern agriculture. At the same time, through image and sound, television directly influences the acceptance of different norms and rules to change behavior and to accept good agricultural practice. Compared with other ways of informing about news in agricultural production, among agricultural producers, TV programs about agriculture come in second place immediately behind the Agricultural Advisory Services (AAS). Almost half the respondents (47.8%) singled out interviews with government officials and attachments that recommend different products as the least useful information. When talking about trust in subjects in agricultural programs, the surveyed viewers gave preference to experts (almost one in two) while agricultural producers were in second place. Television as a medium did not fully use its potentials for transferring knowledge and information to farmers in Serbia. Experts who appear in shows with clear and simple messages will contribute to overcoming the gap between scientists, researchers and agricultural producers as the end users of information. Journalists and editors of specialized programs intended for farmers, creating visually attractive content at the same time, would educate and motivate farmers to adopt good agricultural and environmental practices.

Abstract

Agriculture production nowadays is considered as a commercial activity. Consequently, it must be treated through the market tools of analysis. One among many strategic activities in development of agricultural production is land consolidation. Relations between land consolidation and profitability of agricultural production are complex and not clearly visible. Method for research on those relations could be based on researching relations structure between land consolidation and profitability of agricultural production. The connection between those two phenomena in economics is analysed through the profitability ratios. Profitability ratios in final form are simple equations between two measurable values and they are obtained *a posteriori* after realization of agricultural products on the market. When planning land consolidation numerous unknown parameters exists and it is almost impossible to predict all of them and consequently the prediction of profitability is very uncertain. Bearing in mind the importance of agricultural production and accepting the assumption that in next decades the demands for food will increase or, at least will keep the actual level, it is possible to develop models for prediction of profitability in agricultural industry depending on land consolidation. The analysis is based on micro economic level which encompasses the structure of costs and gains in agricultural production as well as certain intervals in which the parameters of profitability could belong in the future period of time. According to those intervals, the different scenarios were investigated. The profitability ratios were analysed depending on fixed and variable costs where fixed and variable costs were decomposed on the part which depended on land consolidation and part which was independent of land consolidations. The research and results are predominantly in the theoretical context including efforts to be done on the base of available data from practice in Republic of Serbia.

Key words: *Land consolidation, Profitability ratios, Parcel size, Economics.*

Introduction

Land consolidation is a process which is expected to improve agricultural production on the area where it is provided. Measuring effects of land consolidation is very complex and process tied with lots of uncertainties depending on parameters which are intended for measurements. This is a consequence of market nature of contemporary agriculture. On the one hand, the land as a base of agricultural production should be managed very carefully in order to keep and improve its arable characteristics and, on the other side, the market results are also expected in order to provide economically sustainable agriculture. It is obvious that those two principles are opposite and conflicted.

Land consolidation evaluated from the beginning of its appearance in the fourteenth century (Van Dijk, 2003; Uimonen, 2004) with the emergence of legislation in the middle of the eighteenth century. Beginning with the aim to group fragmented land ownership it evolved to one of the most powerful tools for agricultural land management which should provide improvement of agricultural productivity. The following definition include elements which explains land consolidation as a complex process with final aim of increasing agricultural

productivity: "Land consolidation is a land management activity that involves all the procedures for exchanging, rearranging and expanding farmland parcels with the goal of increasing farm productivity" (Asiama et al., 2017). The main aim of this paper is in the concordance with this definition of land consolidation and the research will be provided according to it. The second group of aims is connected with profitability in agriculture. In the contemporary circumstances the agricultural products are realized on the market. If the agricultural production is profitable it could be capable for investments and, consequently, for development. Bearing in mind that profitability depends not only on productivity but as well on the market conditions (which are mostly unpredictable and predominantly tied by prices of agricultural products) it is necessary to analyse the structure of different influences on agricultural productivity and its potential contribution to profitability in agricultural production. The profitability ratios in economy are well known and explicated in simple formulae, but analysing their structure they could provide a lots of information about certain economic activity in agricultural production. Bearing in mind that lot of information are not available in analysing profitability ratios some assumptions are introduced in proposed methodology.

This paper aims to analyse the effects of land consolidation, as a tool for land management which shall meet the both requirements: improvement of economic results in agriculture and savings and improvement of arable land characteristics.

Material and Methods

The paper is based on a model which has been developed to research different scenarios for profitability ratios in agricultural production in case of different levels of land consolidation influences.

The common and well known profitability ratios are:

- Profit Margin on Sales;
- Basic Earning Power;
- Return on Total Assets;
- Return on Equity;
- Return on Investment and
- Earnings per Share.

Bearing in mind that land consolidation predominantly affects the productivity and real assets (land) of agricultural production in this paper the following ratios were investigated: Profit Margin on sales, Return on Total Assets and Return on Investments. Basic Earning Power, Return on Equity and Earnings per Share are dependent on the factors which are not directly influenced by land consolidation and consequently were not included in this research. The basic assumptions in this research are that assets and prices are constant after land consolidation. It is possible to introduce changes in asset and prices of agricultural products and but it require broader approach and it is not main focus of this research.

Profitability ratios are given by following formulae:

$$\boldsymbol{PMS = \frac{NI}{S}} \qquad (\mathbf{1})$$

where:

- $\boldsymbol{PMS}$ - Profit Margin on Sales ratio;
- $\boldsymbol{NI}$ – Net Income and
- $\boldsymbol{S}$ - Sales

$$\boldsymbol{ROA = \frac{NI}{A}} \qquad (\mathbf{2})$$

where:

- $\boldsymbol{ROA}$ – Return on Total Assets ratio;
- $\boldsymbol{NI}$ – Net Income and
- $\boldsymbol{A}$ – Total Assets

$$\boldsymbol{ROI = \frac{IR - IC}{IC}} \quad (\mathbf{3})$$

where:

- $\boldsymbol{ROI}$– Return on Investment ratio;
- $\boldsymbol{IR}$ – Investment Revenue and
- $\boldsymbol{IC}$– Investment Cost.

Analysing the structure of given formulae (1), (2) and (3) immediately follows that land consolidation should increase the net income, Sales and investment costs. Also it is assumed that investment revenues will increase after land consolidation and that assets will remain the same before land consolidation.

Net income, sales, investment revenue and investment costs could be calculated by following formulae:

$$\boldsymbol{NI = n * (p_u - c_u)} \quad (\mathbf{4})$$

$$\boldsymbol{S = n * p_u} \quad (\mathbf{5})$$

$$\boldsymbol{IR = (n + \Delta n) * p_u} \quad (\mathbf{6})$$

$$\boldsymbol{IC = \alpha_{LC} * c_\alpha} \quad (\mathbf{7})$$

where:

- $\boldsymbol{n}$ – number of agricultural production units;
- $\boldsymbol{p_u}$ – price per agricultural product unit sold;
- $\boldsymbol{c_u}$ – cost per agricultural product unit sold;
- $\Delta\boldsymbol{n}$ – increased product units as a result of land consolidation;
- $\boldsymbol{\alpha_{LC}}$ – the land consolidated area and
- $\boldsymbol{c_\alpha}$ – the cost of land consolidation per unit of land consolidated area.

Rearranging formulae (1), (2) and (3) we obtain as follows:

$$\boldsymbol{PMS = \frac{n * (p_u - c_u)}{n * p_u} = 1 - \frac{c_u}{p_u}} \quad (\mathbf{8})$$

$$\boldsymbol{ROA = \frac{n * (p_u - c_u)}{A}} \quad (\mathbf{9})$$

$$\boldsymbol{ROI = \frac{(n + \Delta n) * p_u - \alpha_{LC} * c_\alpha}{\alpha_{LC} * c_\alpha} = \frac{(n + \Delta n) * p_u}{\alpha_{LC} * c_\alpha} - 1} \quad (\mathbf{10})$$

Analysis of profitability ratios shall be also provided before and after land consolidation. This is illustrated by figure 1 and explication of model is given by formulae as follows:

$$\Delta PMS = PMS_a - PMS_b = 1 - \frac{c_u^a}{p_u} - 1 + \frac{c_u^b}{p_u} = \frac{c_u^b - c_u^a}{p_u} = -\frac{c_u^b - \Delta c - c_u^b}{p_u} = \frac{\Delta c}{p_u} \quad (11)$$

$$\Delta ROA = ROA_a - ROA_b = \frac{n_a * (p_u - c_u^a)}{A} - \frac{n_b * (p_u - c_u^b)}{A} \quad (12)$$

$$\Delta ROA = ROA_a - ROA_b = \frac{(n_b + \Delta n) * (p_u - c_u^b + \Delta c)}{A} - \frac{n_b * (p_u - c_u^b)}{A} \quad (12a)$$

$$\Delta ROA = \frac{n_b * (p_u - c_u^b)}{A} + \frac{\Delta n * (p_u - c_u^b + \Delta c)}{A} - \frac{n_b * (p_u - c_u^b)}{A} \quad (12b)$$

$$\Delta ROA = \frac{\Delta n * (p_u - c_u^b + \Delta c)}{A} \quad (12c)$$

$$\Delta ROI = \frac{(n_b + \Delta n) * p_u}{\alpha_{LC} * c_\alpha} - 1 \quad (13)$$

where indexed or exponential letters a and b means the value after and before land consolidation and:

- ΔPMS – difference of Profit Margin of Sales after and before land consolidation;
- ΔROA - difference of Return on Total Assets ratio after and before land consolidation;
- ΔROI - difference of Return on Investment ratio after and before land consolidation;
- Δn – increment in agricultural production units after land consolidation and
- Δc – increment of costs per agricultural unit produced after land consolidation (should be negative value related to costs before land consolidation i.e. the costs should be reduced related to the value c_u^b).

The values of prices (p_u) and assets (A) are adopted as a constant because the prices of agricultural products are not affected by land consolidation and the value of land after land consolidation shall be the same as before it.

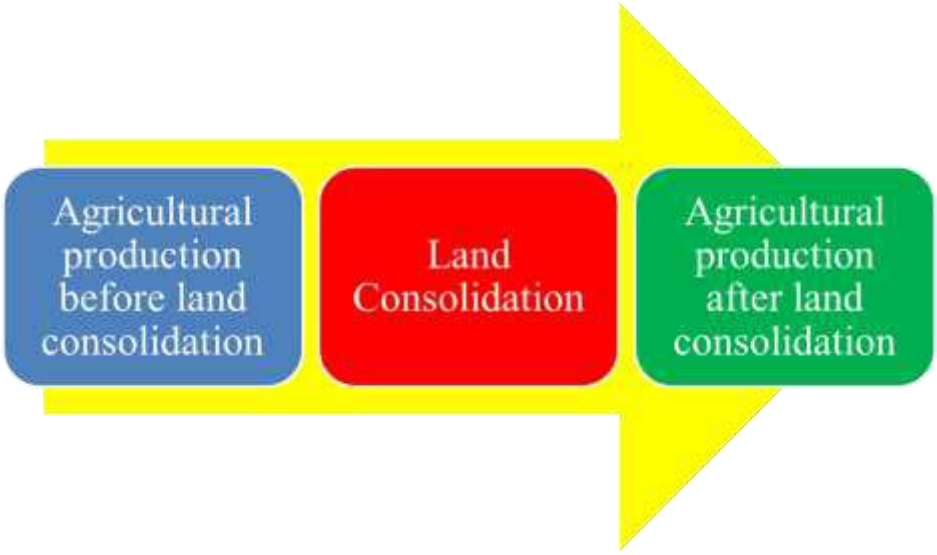

Figure 1. Timeline of land consolidation influence on profitability ratios analysis

Finally, proposed models for research on the influence of land consolidation on profitability ratios are as follows:

$$\Delta PMS = \frac{\Delta c}{p_u} \tag{14}$$

$$\boldsymbol{\Delta ROA = \frac{\Delta n * (p_u - c_u^b + \Delta c)}{A}} \tag{15}$$

$$\boldsymbol{\Delta ROI = \frac{(n_b + \Delta n) * p_u}{\alpha_{LC} * c_\alpha} - 1} \tag{16}$$

Results and Discussion

According to formula (14) it is obvious that the contribution of land consolidation to the Profit Margin of Sales is proportional to and linear dependent on costs reduction per agricultural unit produced. If the cost reduction was explicated as a percentage of the constant price per agricultural production unit, the formula (14) reads:

$$\Delta PMS = \frac{\Delta c}{p_u} = k\frac{p_u}{p_u} = k \tag{17}$$

The graphical interpretation of land consolidation contribution to the Profit Margin of Sales is shown on figure 1.

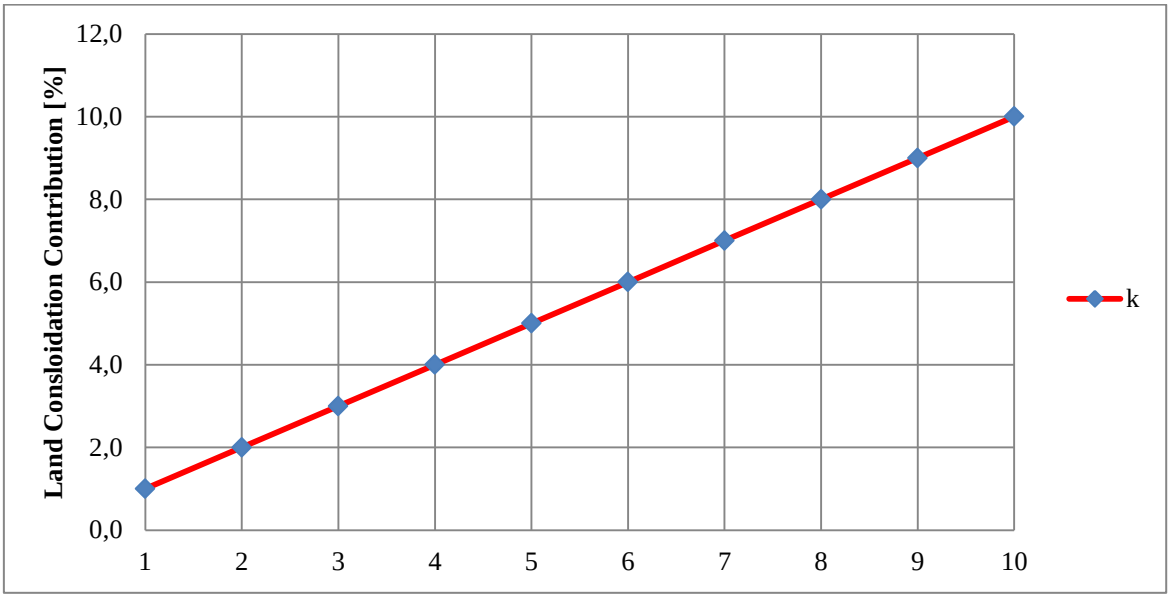

Figure 1. Land consolidation contribution to the Profit Margin of Sales ratio.

Analysis of contribution of land consolidation to return on total assets ratio (15) leads to conclusion that it is dependent on increment of agricultural production and cost reduction. The total assets A shall be constant before and after land consolidation and consequently it should not affect the return on asset ratio from the aspect of land consolidation.

For the accepted values p_u=0.15$ per agricultural unit produced, costs before land consolidation per agricultural unit produced c_u^b=0.10$ and if increment of production belongs to the interval [100,1000] with cost reduction which belongs to the interval [-0.05, -.01] $ per agricultural unit after land consolidation the obtained results for land consolidation contribution belongs to the interval $[\frac{6}{A}, \frac{100}{A}]$. The graphical interpretation of result is shown on figure 2.

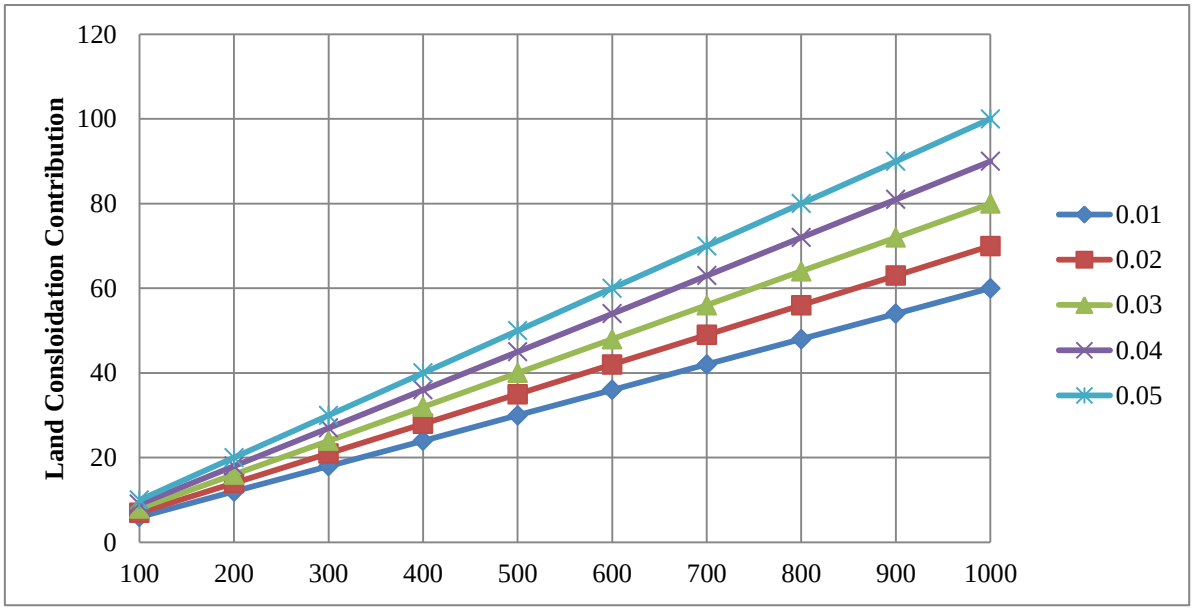

Figure 2. Land consolidation contribution to the Return on Assets Ratio.

Return on investment depends on the land consolidation contribution to the agricultural production explicated by increment Δn and of the land consolidation cost per area unit. The return on investments could be determined per area unit and consequently formula (16) reads:

$$\Delta \boldsymbol{ROI} = \frac{(\boldsymbol{n_b} + \Delta \boldsymbol{n}) * \boldsymbol{p_u}}{\boldsymbol{c_\alpha}} - \mathbf{1} \qquad (\mathbf{18})$$

In that case the Δn and c_α are related per unit of area i.e. per hectare. In the case of accepted values p_u=0.15\$ per agricultural unit produced, $n_b = 5000$ agricultural units produced per hectare before land consolidation, if increment Δn belongs to the interval [100, 1000] and the cost of land consolidation belongs to the interval [200, 600] \$ per hectare the Land consolidation contribution to the Return on Investment ratio will belong to the interval [0.3,3.5]. The results are shown on the figure 3.

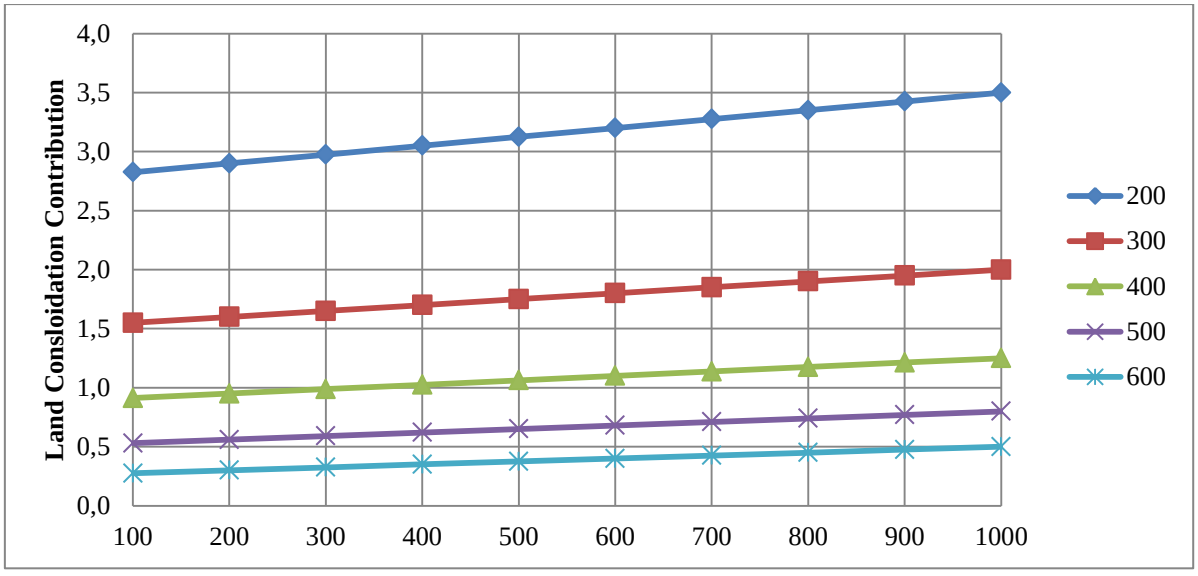

Figure 3. Land consolidation contribution to the Return on Investment Ratio.

Conclusions

The analysis of land consolidation contribution to the profitability ratios resulted by following conclusions:

- Contribution to the Profit Margin of Sales ratio is linear and proportional to the cost reduction per agricultural produced unit caused by land consolidation;
- Contribution to the Return on Assets Ratio is dependent on the increment of agricultural production and the cost reduction caused by land consolidation and
- Contribution to Return on Investment Ratio depends on the increment of agricultural production caused by land consolidation and the cost of land consolidation.

Those conclusions were obtained under the fixed prices because prices of agricultural products are independent of land consolidation and are formed on the market. Further investigation could include research about mutual influences of agricultural prices changes and land consolidation contribution to the profitability ratios.

Abstract

The paper captures trends regarding the production and marketing of sorghum in Romania during 2007-2016. For this purpose, a series of specific indicators were analyzed, among which: the area cultivated with sorghum for consumption and sorghum for brooms, in Romania, on Macroregions and Development Regions; the production of sorghum for consumption and sorghum for brooms, in Romania, on Macroregions and Development Regions and the commercial balance of sorghum for consumption. Worldwide, in 2016, the area cultivated with sorghum was 43,186.79 thousand ha, and the production of 70,212.22 thousand tons. For the year 2025 it is foreseen an increase of the cultivated areas to 44,113.98 thousand ha and the production to 79,123.45 thousand tons. The surface cultivated with sorghum for consumption in the year 2016 in the EU was 123.18 thousand ha and the production of 676.4 thousand tons. The main sorghum cultivars for consumption in the EU in 2016 were: France (47.92 thousand hectares), Italy (43.84 thousand hectares) and Romania (9.16 thousand ha), and in the top producing countries for the year 2016 were: Italy (313.79 thousand tons), France (244.89 thousand tons), Spain (36.36 thousand tons) and Romania (24.41 thousand tons). The data used in this paper was taken up primarily from the National Institute of Statistics of Romania (INS), but also from other international specialized websites. It is necessary to specify that the results of the research are presented in tables and are graphically illustrated.

Keywords: *area cultivated, production, Romania, sorghum.*

Introduction

Sorghum is the world's fifth largest grain crop. The first places in this ranking are occupied by the following grains: wheat; rice; corn and barley. Sorghum along with Amaranth was the basis of the Romanians' diet in the 1970s. This cereal is beneficial for the population because it contains: 43% of the daily protein requirement; 47% of the iron requirement and 55% of the recommended phosphorus value. The sorghum is on the one hand an important source of Mg, Cu, Ca, Zn, K, niacin, thiamine and antioxidants and, on the other hand, is a source of natural fibers (48% of the daily dose). According to the research, the components of sorghum contribute directly to: slowing the aging process; reduce the risk of cardiovascular disease, diabetes, cancer; reduce cholesterol and maintain the digestive tract healthy. (The main benefits of sorghum consumption, https://viataverdeviu.ro/beneficii-consum-sorg-cereala)

Sorghum is a plant with very good tolerance to drought and moderate climate and soil requirements. This is why it can be cultivated in lowland areas affected by drought, with soil poor in nutrients where corn cannot grow. Sorghum is sown 2-3 weeks later than the maize, when the soil temperature at 10 cm is 10-12℃. The sorghum culture needs water until the appearance of the panicle, after that it supports drought. (GRIGORIEV A., Sorghum - culture guide). Currently, it has been found that the use of sorghum culture before the sunflower culture presents a number of positive aspects among which the most representative are: a high degree of nutrient conservation in the soil in order to assimilate them during the spring period and a better structure for the soil. (www.agrointel.ro)

Sorghum bicolor is the most common and most widely grown species of this genus. This species also has several natural varieties and several modern varieties obtained by hybridization: Sorghum for grains (*Sorghum bicolor var. sorghum*); Sorghum for brooms (*Sorghum vulgare var. technicum*); Sweet sorghum (*Sorghum bicolor var. saccharatum* or simplified *Sorghum saccharatum*); Forage sorghum, also known as the Sudan grass (*Sorghum sudanense*). In Romania there are cultivated several types of autochthonous hybrids, but also imported varieties. At the National Institute of Agricultural Research and Development from Fundulea, several hybrid varieties were registered: Hybridized sorghum with Sudan grass – *Tutova, Tereza, Tinca* (changed in *Catinca* by an order of the Ministry of Agriculture in 2007); Sugar sorghum hybrids – *Roza, Doina, Prut, varieties: Fundulea and Carmen;* Broom sorghum hybrids – *Siret, Denisa* and *Donari* (https://ierburiuitate.wordpress.com/tag/matura/)
Worldwide, lately, sorghum is used: for feeding cattle and poultry (because it has nutritional value close to maize); in order to obtain alcohol, starch, sugar, vinegar, beer and biofuel; for traditional braids. The sorghum can be a good substitute for wheat flour, so it can be used by those who do not tolerate gluten. Due to the nutritional properties of sorghum, top restaurants in California and New York have introduced sorghum preparations in their meals. At present, Sorghum is considered versatile and has replaced some rice and quinoa preparations. Another advantage is that it is cheap. It's called the 'wonder grain', as says Chef Michelle Bernstein of Cena by Michy and Seagrape Restaurants in Miami (www.theguardian.com).
An important aspect is that many smaller, higher-yielding sorghum hybrids have been created, which have higher productivity, 20-30% higher than old varieties.
At the EU level, a new orientation has emerged, namely the use of biofuels that are important substitutes for diesel and gasoline. In this case, there is an orientation of the enterprises from agriculture towards the cultivation of energy plants. Currently, sweet sorghum culture is the best bioethanol production culture. (Popescu and Condei, 2014)
Researchers from EUBIA (European Biomass Industry Association) have proposed two optimal options of sorghum cultivation:
- Plantation of at least 1,000 hectares with a production of 6,000 cubic meters of bioethanol per year;
- Plantation ranging from 10,000-50,000 ha, with a production of bioethanol of 60,000-300,000 cubic meters/year.
The proposed options could, at present, provide a lower production cost for bioethanol than in 2005, when the production cost was 600 Euro/tons in the European Union. (Grassi, 2007)
Due to the vast uses of sorghum in the European Union it is noted that it imports annually an average of 160,000 tons. In perspective, in Europe, the development of sorghum culture is expected to reduce the annual import level and even to export significant quantities to the international market. (www.sorghum-id.com/ro/piete-sorgul-o-solutie-sigura/)
Currently, due to climate change, specialists in the field are looking for new solutions for profitable farming activities. The sorghum could be one of these. In Romania it is cultivated for about 50 years, but on small surfaces. It is cultivated especially for brooms, but also as feed. In Romania, there is the tradition to sweep the house with sorghum brooms. Even if the population has modern vacuum cleaners, there is still a sorghum straw broom in people's homes. From the published data, it can easily be noticed that these sorghum strawers brooms have raised the interest of exporters. For example, a company in Bihor has exported this product to Austria and Germany. Salonta is the town with the oldest tradition in Romania, in terms of cultivation and processing of sorghum used for broom breeding. The tradition of producing brooms in Salonta began in 1903, when the Soront Farmers' Salt Producers and Manufacturing Processors of Sorghum was established, which also had a broom brewing workshop with 70 workers. Nowadays, Salonta sorghum broom cleans houses and courtyards from Germany, Austria and Italy. (Tudor, 2017)

Results and Discussions

According to the statistical data published in relation to the situation of the sorghum surfaces grown at the level of the European Union, it can be noticed that these surfaces are smaller compared to the surfaces cultivated with maize. It has been forced to say this because sorghum culture is currently considered by the specialists in the field as an alternative to corn crop, especially for animal feed. In Table 1 is showed the evolution of the areas cultivated with sorghum in the main cultivating countries at the level of the European Union in the period 2010-2017. During the analyzed period, in the European Union it is observed that the surfaces with sorghum have recorded oscillations from one year to another. The largest area cultivated with sorghum in the European Union was registered in 2014 (158.09 thousand ha), and the smallest in 2010 (114.19 thousand ha). According to the data presented in Table 1, the main European Union sorghum cultivator is France. In this country, the areas occupied with sorghum have changed from time to time. The lowest area with sorghum was 42.19 thousand ha (2012), and the largest area was 62.97 thousand ha (2014). In 2017, in France it can be seen that the surfaces with sorghum increased by 18.02% compared to 2010.

The next position in the top of the sorghum cultivation countries is occupied by Italy. In Italy, in 2017, 46.21 thousand ha of sorghum have been grown. In this country in 2017, the surfaces cultivated with sorghum registered an increase of 13.45% compared to 2010. On the third place, Romania was with 15.75 thousand ha cultivated with sorghum in 2017. Romania in 2017 cultivated 28.00 % of the surface cultivated with sorghum from France and only 11.17% of the total area cultivated with sorghum in the European Union. In 2017, the areas cultivated with sorghum increased compared to 2010, in most of the presented countries except for Bulgaria and Spain. In table 2 is showed the evolution of sorghum production in the main cultivating countries within the European Union during 2010-2017. After analyzing data on the production of sorghum produced in the European Union, it is found that this varied every year. The largest production made with sorghum in the European Union was 940.51 thousand tons (2014), and the lowest in 2012 (493.90 thousand tons). The significant production of sorghum produced in 2014 at the European Union level is closely related to the area cultivated with sorghum during the same period. In 2017, sorghum production in the European Union increased by 17.81% compared to 2010.

Concerning the production of sorghum in the main producing countries, the situation remained unchanged, as in the case of the main sorghum cultivation countries. The top three positions in the top of the sorghum producing countries in the European Union are occupied by: France; Italy and Romania. In 2017, France recorded a production of 326.68 thousand tons, 24.39% higher than in 2010. This year, Italy also made 243.60 thousand tons of sorghum and Romania had a production of 63.97 thousand tons. In 2017, Romania achieved only 8.91% of the EU production and 19.58% of the production made by the leader of the sorghum-producing countries. Bulgaria and Greece obtained the smallest production of sorghum in 2017, below 10.00 thousand tons.

Table 3. Evolution of sale prices for Sorghum in some producing countries in the European Union, 2010-2016

- Euro/100 kg Sorghum-

Table 3 presents the evolution of sales prices for sorghum in some producing countries in the European Union in the period 2010-2016. From the analysis of the data presented, it can be seen that the sales prices for sorghum in the studied countries recorded changes from year to year. In 2016, in France the price for sorghum was 21.00 Euro /100 kg, registering an increase of 44.62% compared to 2010. The highest price recorded in France was 30.39 Euro/100 kg, while the smallest was 14.52 Euro /100 kg (2010). In the rest of the studied countries, sales prices for sorghum have decreased in 2016 compared to 2010, as follows: Bulgaria (-20.97%); Spain (-14.95%) and Hungary (-5.68%).

In order to present the main tendencies related to the production and marketing of sorghum in Romania, statistical indicators have been presented in the paper at both national and macroregional level. It is necessary to specify that in Romania it is made up of four macroregions and eight development regions.

(https://www.upet.ro/annals/economics/pdf/2010/20100224.pdf)

Table 4 presents the dynamics of the areas cultivated with sorghum in Romania and at the level of the macroregions of development, during 2010-2016. From the data presented and analyzed it may be obvious that the areas cultivated in Romania in 2010 almost doubled compared to 1990. At national level, during the analyzed period we witness a significant change of the surfaces cultivated with sorghum. The largest area cultivated with sorghum in Romania was in 2013 (21,668 ha). On the opposite side, the smallest area cultivated with sorghum was recorded in 2016 (9,160 ha). In 2016, at national level there is a decrease, with 10.92% of the surface cultivated with sorghum compared to 2010. At the macroregional level, the oscillation of the surfaces cultivated with sorghum in the analyzed period can easily be noticed. Macroregion 4 is highlighted by the largest areas cultivated with sorghum. In 2016, over 50.00% of the area cultivated with sorghum at national level was cultivated in this macro-region. At the opposite end, in Macroregion 1, has the smallest areas cultivated with sorghum.For example, only 902 ha were cultivated in 2016, which represents only 9.84% of the area cultivated at national level and 19.61% of the area cultivated in Macroregion 4. In 2016, the surface cultivated with sorghum in Macroregion 2 was of 2,422 ha and 1,216 ha in Macroregion 3. According to data provided by the National Institute of Statistics, in 1990, Romania cultivated 5,195 ha of sorghum. In 2000, the area cultivated with sorghum fell significantly to 1,602 ha. In 2007, which represents the year of Romania's accession to the European Union, only 20.36% of the area which was cultivated in 1990 with sorghum can be found, respectively 1.058 ha. Gradually, after 2007, the farmers in Romania began to turn to the sorghum culture, because this has several advantages.

Table 4. Dynamics of the surfaces cultivated with sorghum in Romania and in the macroregions of development, during 2010-2016

Source: INS, 10.11.2017; own calculations

Between 1990 and 2007, according to data provided by the National Institute of Statistics, in Romania the production of sorghum had the following evolution: 3,522 tons (1990); 1,479 tones (2000), and in 2007, the year of joining the European Union, 1,193 tones.

In Table 5 it is presented the evolution of the sorghum production in Romania and in the macroregions of development, during 2010-2016. From the analysis of the data on the production of sorghum in Romania, it can be seen that it recorded oscillations from one year to the next. The most significant national sorghum production was 51,543 tones (2014) and the smallest of 18,677 tons in 2010. At the national level, in 2016, sorghum production increased by 69.87% compared to 2010.

Regarding the production of sorghum made within the macroregions, it can easily be noticed that there have been changes in production from year to year. Macroregion 4, during the analyzed period, recorded the largest outputs. In 2014, a production peak of 24,948 tones was registered, and in 2010 there was a minimum production (9,944 tones). In Macroregion 1, the smallest production of sorghum is recorded at national level. In this macroregion the production of sorghum varied between 809 tons and 5,043 tons during the analyzed period.

Table 5. The evolution of sorghum production in Romania and by macroregions of development, 2010-2016

-Tons-

Specification	2010	2011	2012	2013	2014	2015	2016	2016/2010 (%)
Romania	18,677	39,696	37,481	49,829	51,543	31,728	24,413	169.87

*Source: INS, 10.11.2017; own calculations

In 2016, this macro-region recorded the highest percentage increase of sorghum production, by 242.02% compared to 2010. Macroregion 1, in 2016, made only 10.40% of the national sorghum production. Regarding the production of sorghum made in Macroregion 2, it can be observed that this has recorded changes every year. A maximum production point was recorded in 2013 (15,795 tones), and a minimum point was in 2015 (4,847 tones). In Macroregion 3, in 2016, sorghum production registered a 39.13% increase compared to 2010.
According to the statistical data on average yield per hectare of sorghum produced in Romania in the period 1990-2007, it was found that it evolved as follows: 674 kg / ha of sorghum (1990); 923 kg / ha (2000) and 1,128 kg / ha in 2007, the year of accession to the European Union.

Table 6. Evolution of the average yield of sorghum per hectare in Romania and in the macroregions of development, during 2010-2016

-Kg/ha-

Specification	2010	2011	2012	2013	2014	2015	2016	2016/2010 (%)

Macroregion4	1,852	3,018	2,233	2,438	2,783	2,568	2,652	143.19

*Source: INS, 10.11.2017; own calculations

In Table 6 it is presented the evolution of the average production of sorghum per hectare in Romania and in the macroregions of development, during 2010-2016. In Romania, in 2016, an average yield of sorghum per hectare was 2,665 kg / ha. At the macroregional level in 2016, the following situation was recorded: Macroregion 3 (3,065 kg / ha); Macroregion 1 (2,815 kg / ha), Macroregion 4 (2,652 kg / ha) and Macroregion 2 (2,433 kg / ha).
In 2016, there was a percentage increase in the average yield of sorghum per hectare compared to 2010, both at national level and at macroregional level. At the national level, in the year 2016, there was an increase of 46.75% compared to 2010. At the macroregional level in 2016, compared to 2010, the following increases were registered: Macroregion 1 (+20.40%); Macroregion 2 (+63.06%); Macroregion 3 (+23.04%) and Macroregion 4 (+43.19%). The production of brooms was a traditional seasonal activity (autumn-winter). In each village there were some craftsmen known as Sweepers who, after clearing the dry inflorescences of sorghum (panicles with branches of 100cm long) and sorting them by thickness, tightened them in small bundles which were bounded with wire and after that sew them (http://www.patrimoniuimaterial.md/ro).

During 1990-2007, in Romania, the areas cultivated with broom sorghum developed as follows: 7,162 ha (1990); 5,213 ha (2000) and 4,508 ha (2007) in the year of accession to the European Union. (INS)
Table 7 shows the evolution of the surfaces cultivated with sorghum in Romania and in the macroregions of development, between 2010 and 2016. During the analyzed period, the areas cultivated with sorghum for brooms at the national level and in the development regions recorded changes from year to year. At national level, the largest area cultivated with broom sorghum was registered in 2012 (3,597 ha), and the smallest area was 2,611 ha (2016). Since 2013, the areas cultivated with broom sorghum have been on a declining trend. In 2016, the areas cultivated with sorghum in Romania dropped by 17.19% compared to 2010.

Table 7. Evolution of the areas cultivated with broom sorghum in Romania and by macroregions of development, between 2010-2016

*Source: INS, 10.11.2017; own calculations

In Macroregion 4, it is observed that the largest surfaces with sorghum for brooms were cultivated, except for the year 2016, when a surface of only 867 ha was recorded. In this Macroregion, in 2016, the area cultivated with broom sorghum decreased by 41.86% compared to 2010. In 2016, Macroregion 1 cultivated 36.49% of the surface cultivated with sorghum at national level, in Macroregion 2, a percent of 13.63% of the total cultivated area was registered, in Macroregion 3, 16.67% of the total cultivated area was found and in Macroregion 4, 33.20% of the cultivated area was grown.
According to the data presented in Figure 1, Romania's sorghum exports have changed over the period 2012-2017. For sorghum, the highest value exports were recorded in 2014 (4,200,000 Euros) and the lowest exports were 1,358,000 Euros (2013). In 2017, the value of sorghum exports fell by 34.63% compared to 2012.

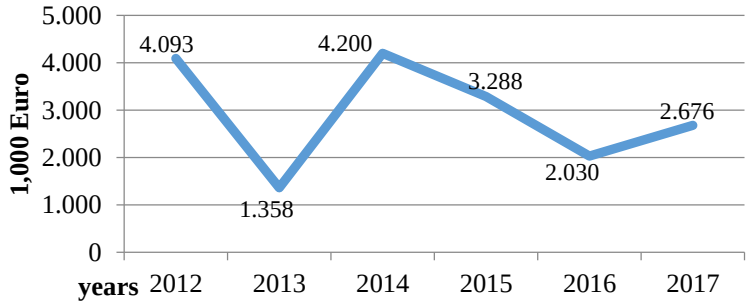

Figure 1. Value of grain sorghum exported from Romania between 2012 and 2017
Source: www.statista.com/statistics/762900/grain-sorghum-export-value-romania, 2018

Between 2013 and 2017, sorghum imports were outpaced by sorghum exports. The largest imports of sorghum were 1,610 thousand Euro (2013) and the smallest were 798 thousand Euro (2017) (see fig. 2).

Currently, in Romania, according to the official data on the production and marketing of sorghum, there is a growing interest in this culture.

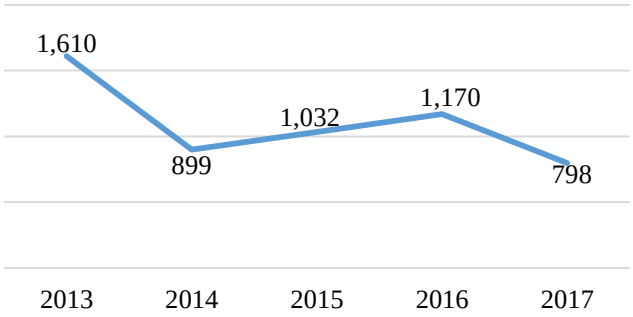

Figure 2- Value of grain sorghum imported from Romania between 2013 and 2017 (Thousand Euro)

*Source: Trade Map, 2018

After analysing data on imports and exports for the Sorghum category, it was noticed that in 2013 there was a trade balance deficit of 252 thousand Euros, but since 2014, a positive balance has been recorded.

Conclusions

Following the analysis of the main indicators referring to the sorghum production and marketing sector in Romania, the following aspects were identified:

- At national level, there is a 10.92% decrease in the surface cultivated with sorghum in 2016 compared to 2010;
- In Macroregion 4 the most significant surfaces with sorghum are cultivated. In this macroregion, in 2016, more than half of the nationwide surface cultivated with sorghum was grown;
- Year 2014, was noted by the highest production of sorghum at national level of 51,543 tons;
- in 2010, the smallest production of sorghum from the analyzed period was achieved, of 18,677 tons;
- In 2014, in Macroregion 4, a production of 24,948 tons of sorghum was obtained, being the highest production from the analyzed period;
- In 2016, the average yield per hectare for sorghum culture increased by 46.75% compared to 2010;
- Macroregion 3 was highlighted in 2016 by the highest average yield per hectare for sorghum crop of 3,065 kg / ha;
- In Romania, both sorghum used for animal feed and for the production of brooms used in the household sector is cultivated;
- In 2012, the most significant surface with broom sorghum was cultivated, of 3,597 ha. On the opposite side, the smallest surface cultivated with broom sorghum was cultivated in 2016 (2,611 ha);
- In Macroregion 4, the most significant areas with broom sorghum have been cultivated within the macroregions of development, with only one exception, in 2016, when only 867 ha were cultivated;
- During 2012-2017, the value of sorghum exports recorded fluctuations from year to year;

- In 2014, the highest export value for sorghum was recorded, 4,200,000 Euro; the smallest value of imports for sorghum was 798,000 Euro (2017);
- In 2013, there was a commercial deficit for the "Sorghum" category, of 252,000 Euros. Also in this year, an import coverage by exports of 84.34% was registered;
- In the period 2014-2017, there was a positive trade balance for the "Sorghum" category;

In perspective, an increase in the areas cultivated with sorghum in Romania is expected because, on the one hand, this culture is suitable for all soil types and resists the drought, and on the other hand the demand for sorghum on the international market will increase.

FORESTRY AND AGRO-FORESTRY

STUDY OF THE VISUAL QUALITY PARAMETERS OF THE CORK OF SOME CORKFORESTS IN THE EXTREME NORTH-WEST ALGERIA

Ahmed CHORANA, Belkheir DEHANE

Faculty of Sciences of Nature and Life and Sciences of the Earth and the Universe, Laboratory Conservatory Management of Water, Soil and Forests (LGCESF)
Department of Forest Resources, University of Abu Bekr Belkaid, Tlemcen, Algeria

Abstract

The cork forests in northwestern Algeria are confronted with a series of environmental constraints that accentuate their degradation, especially fires, drought, conifer afforestation and the health of trees. Initial cork quality analysis (with Coveless device CQ05 n°0017) revealed that the cork is well distributed between the southern and northern zones of the geographical area of production.Cork for producing natural and colmated stoppers (Q-A and Q-B) growmainly in Hafir (69.33%) and M'Sila (49.33%). On the other hand, the cork bark with low thickness (Q-C) and corkwood refuse (Q-D) are individualized respectively on the samples of Nesmoth (40%) and Beni Ouarssous (30.67%). The superimposition of its cork quality values to environmental factors by means of MCA has shown that the effect of biotic and abiotic factors is decisive. In the mountains of Hafir, there are healthy trees (trunk and crown), in full production (circumference and height), which grow on stony ground that give the best quality of cork (Q-A) between the four provenances. On the other hand, in the Beni Ouarssous coastline, trees are declining (trunk and top), invaded by the conifer afforestation and the aftereffects of fires that produce poor quality of corkwood refuse (Q-D). Between its two boundaries, the M'Sila (littoral) and Nesmoth (mountain) stands are well adapted to their natural environment by simultaneously providing Q-B and Q-C cork.

Keywords: *Oak cork, cork, quality, environmental factors, MCA.*

Introduction

The cork is a non-wood forest product, natural and renewable. It is very adapted to its growing area in the seven subericulture countries forming the western part of the Mediterranean and the Atlantic coast (Spain, Italy, France, Algeria, Morocco, Tunisia and Portugal). This area of 2.7 million hectares produces an annual tonnage of 300 million kg / year (Santos Pereira et al., 2008, Aronson et al., 2009). The cork is a highly prized product, once classified as a strategic product of the world economy (Marc, 1930). Indeed, the assets and the outlets of the cork are countless, they concern great panoply of use, from the simple object of leather goods to the complex product used in the cosmetic industry. Its price is very variable between 0.08 and 3.54 € / kg for raw cork. In the case of prepared and treated cork; it ranges from 0.21 to 6.61 € / kg, and in the case of cork products it ranges between 1.80 and 2.40 € / kg (Santiago Beltrán and Elena Rosselló, 2015). But the first use of cork remains indisputably its transformation into a natural cork stopper. A medium-sized cork oak produces about 3.9 kg of cork per year; 74 natural corks of average quality. In terms of the economy, one kilogram of natural corks oscillates between an average price of almost 46 €, and some batches can reach up to 240 €. As a subericulture management, this is consistent with the sustained production of 2500 natural corks of 33 cork oaks forming one hectare of well-managed and valued cork oak. It also implies that the abandonment of this form of management inevitably leads to dieback of the oak groves and the loss of rare biodiversity as a result of scrubbing and fires (Santiago Beltrán and Elena Rosselló, 2009; Varela, 2008). These good practices also nourish an important industrial fabric. The demand from these industries is increasingly focused on corks that can provide high quality corks. The majority

of these transactions take place annually in the forest, several months before harvesting the cork, between industrialists and private or public landowners. They frequently result in very complicated payment methods because of the complexity and heterogeneity of the species itself (Natividade, 1956, Courtois and Masson, 1999). A harvest of cork stored in piles and presented for sale is very rarely free of waste or bad quality boards. The purchaser and the manager can both consolidate losses as profits; it is a product that is valued according to its quantity (the caliber) and its appearance (the visual quality). Experience has shown that these two attributes are very difficult to define and very often lead to very controversial assumptions and conclusions. For a large number of cork professionals, the caliber and visual quality of cork are related to tree characteristics and applied sylvo-pastoral management, especially: trunk diameter, tree height, canopy diameter, height debarking, tree density and stripping number. For others, the geographical situation, the climate, the topography, the altitude, the nature of the source rock are of a very important influence (Bossuet, 1988; Gonzalez-Adrados, 1989; Pereira 2007). Other external factors are already known to influence the growth of cork: age of cork at the time of cork stripping, quality of exploitation, phytosanitary status of trees and fire passage (Montoya 1988, Dehane et al., 2015). According to the same authors, in trees that are too old, the accumulation of wounds and scars and the reduction in the growth of wood and cork with age, lead to a marked decrease in the increases in the cork obtained.

The purpose of this study is to confirm or refute these environmental factors through a tedious investigation carried out on the majority of oak groves in the extreme north-west of Algeria. The work presented in this article is part of other previously undertaken studies, including the evaluation of cork growth and health status of trees, the analysis of cork quality and the physical-chemical parameters of the cork, study of the growth of Algerian cork according to the origin and the mineralogical analysis of the cork (Dehane et al., 2013; Dehane et al., 2014, Dehane and Gheffar, 2017; Chourana and Dehane, 2018).

Material and Methods

Site

In the northwestern part of Algeria, four representative sites of cork oak production areas are selected: the Hafirforets (HA) (Tlemcen, Sabra locality), the Nesmoth forest (NE) (Mascara, locality of Tighenif), the forest of M'Sila (MS) (Oran, locality of Boutelis), the cork forest of Beni Ouarssous (BO) (Tlemcen, locality of Borj Arima). These cork forests come from two types of facies and are characterized by a Mediterranean climate: In mountain, we distinguish a subhumid and fresh bioclimate for HA (650mm / year), semi-arid and hot for NE (400mm / year). In the littoral, the two forests MS, BO are temperate semi-arid (450mm / year, 430mm / year). The analysis of the pH level of the cork oak soils indicates acid soils and it is between 5 and 6.5. The electrical conductivity of soils is low (<120 µs / cm), characteristic of unsalted soils. The nature of the bedrock is siliceous (sandstone in the mountain and schistous in the littoral). With the exception of the MS site which is of the "dehesa" type, all the others are of the "maquis" type with a low density of trees per hectare and with dense and high undergrowth.

Sampling methods

The recent use of the techniques of the estimation of the quality of the cork on tree before the stripping offers a big advantage to sub-growers and to administrators. Indeed, the coveless proposes a multitude of information on the maturity of the cork (thickness and aspect), its quality and its price without passing by the extraction of the samples which are very often harmful for the health of the tree and very prohibited by the forest departments.

Due to the low density of producing trees (reproduction cork) (<20 trees / ha) and dense undergrowth, sampling by itinerary was used. In this type of sampling, the area is scanned

and, generally, at predefined intervals, the sample trees are probed as much as necessary, up to a total of 75 trees. (Gonzalez Montero, 2004; Santiago Beltran et al., 2015). In the case of the present study and to cover a wide variation of trees, topography and reliefs, we approached the itinerary according to three altitude levels in each oak groves (Crest, slope and shallows). In each level, and on zigzagged passages at intervals of 200m in length, the first spotted tree from the front is probed at 1.30m then materialized at the GPS as a starting point until reaching the last subject thus indicating the 75 samples.
Depending on the offered exposure, the sounding by the instrument is performed on an applicable surface of 20cm x 20 cm, similar to traditional cala. With each measurement memorized and validated by the device, various quantitative and qualitative characteristics of the trees are mentioned jointly: diameter and height of the tree, height of stripping, debarking coefficient, trace of fire, conifer afforestation and undergrowth. Other environmental factors are also noted such as altitude, soil texture, surface deposition, pH and electrical conductivity of the soil, silviculture work.
Other visual measurements are noted to assess the overall health status of the trees. This is the foliar deficit in the crowns (slight defoliation: loss of foliage less than 20%, significant defoliation: 20 to 75% of leaves lost, very serious defoliation: more than 75% of leaves lost). The examination of the trunk concerns the wounds caused by the stripping and the ensuing damages such as the holes of insects, the cavities, the dryness of the mother of the cork, the carbonaceous canker. Three health conditions are distinguished: a healthy state (no defoliation, no damage on the trunk), a weakened state (weak defoliation, no cavities or injuries on the trunk), a state of decline (severe defoliation and injury with damage marked).

Quality analysis methods

The device relies on the electrical conductivity of the mother to determine the thickness of the cork and its appearance. The data provided by the instrument is divided into nine quality classes by merging the thickness and aspect orders (IPROCOR, 2006) (Tab.1).

Table1. Commercial Quality Classes (Iprocor, 2006)

	1	2	3	4	5	6	7	8	9
Qualityclass	19ª more. 6ª more.	15-19 5ª more.	15-19 6ª	13-15 5ª more.	13-15 6ª	11-13 5ª more.	11-13 6ª	11less. 4ª more.	Refuse

Each quality class has a value based on the selling price of cork (Tab.). A quality index is calculated for each tree from the percentages of all cork choices and their value (weighted average) (Iprocor, 1994):

$$\mathbf{IQ= (5/100) \times \Sigma_{i=1\text{-}9} (A_i \times Q_i)}$$

Where:

- IQ = corkquality index
- A_i = average value savings / kg of cork categories 1-9 boiled and baled.
- Qi = proportion of the material volume of the given category in relation to the total production volume (%).

Statistical analysis methods

Variance analysis and the chi-square test are used to explain the possible relationships between the different quantified variables. To better understand and explain the impact of the Environmental factors of the four sites on the quality of the cork produced, a Multiple

Correspondence Analysis (MCA) was carried out by the XlStat software. The MCA was based on an observation / variable table of various modalities measured on trees, cork and route. We used 15 variables and 300- observations.

Results and Discussion

Dendrometric characteristics of trees

The table 2 below presents per site the average dendrometric characteristics of the sampled trees.

Table 2. Measurements of sample trees

	(HA) Forest1	(NE) Forest2	(MS) Forest3	(BO) Forest4	Statistical test *
Circumference of the tree (cm)	181,53	102,29	131,82	91,36	F=63,32 ; p<0,000
Height of the tree	15	12	16	18	F=74,66 ; p<0,000
Debarking height (m)	1,70	2,37	1,92	1,70	F=44,57 ; p<0,000
Thickness of cork (mm)	29,60	24,55	32,55	24,37	F=27,99 ; p<0,000

*: Anova test, significant difference (p <0.000)

The table 2 gives the averages of the 300 trees in each forest. In the BO forest, the tree heights are relatively high (18m), conversely the circumferences are reduced (91.36 cm). In this forest, trees are highly competitive with high and dense undergrowth, thus producing a very thin cork (24.37mm). The HA and MS forests consist of trees of average circumference respectively (181.53 cm and 131.82 cm) and heights of reasoned bark (1.70 m and 1.92 m), the thickness of the cork is better on these topics. The NE forest has the lowest tree heights between the four forests (12 m), high bark heights giving a low cork (24.55 mm).

Appearance of cork

According to the IPROCOR standards, the 300 sample trees sampled with the Coveless CQ05 contain the following classes of enlarged and summarized quality (Fig.1 and Fig.2). Both figures show a strong presence of the cork bark with low thickness and cork stoppers respectively proportions of the order of 28.33% and 26.33%. The first proportion is very frequent in the Nesmoth and Beni Ouarssous samples, namely 40% and 35% respectively. The second proportion is more marked on Hafir trees with a rate of around 51% and M'Sila (23%). Thick cork constitutes only 4% of the total and very particularly present in the forest of M'Sila and Hafir (7% and 7%). Raw corkwaste (refuse) absorbs 24% of the samples, very marked at Beni Ouarssous cork (31%) and relatively homogeneous on the other provenances, HA (20%), MS (23%), NE (23%).

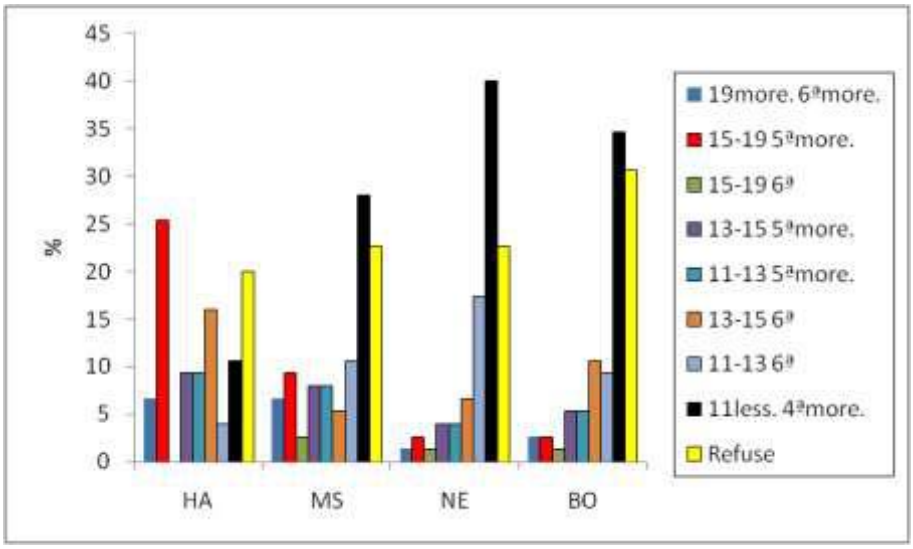

Figure1: Extended quality class of cork

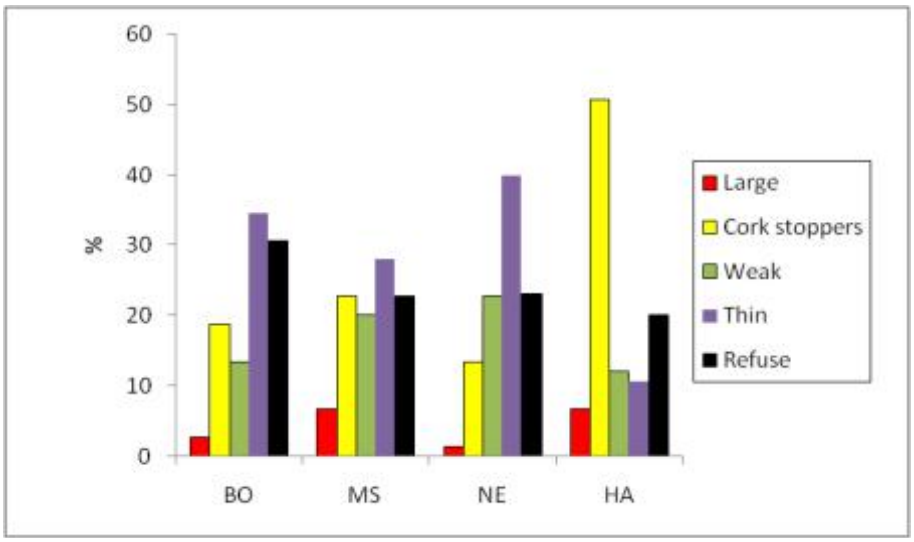

Figure 2: Summary class quality of cork

Industrial grade class

Industrially speaking, the nine extended quality classes and the five summarized quality classes can be merged into two levels of industrial grade classes 1 and 2:

-Industrial grade class 1: These are the primary outlets for cork samples before they are punched in the factory (cork stoppers, refuse, and cork bark with low thickness).

Indeed, the cork stoppers of this level of quality is attributed to classes of cork able to be perforated for diameters of 24 and 21 mm with all classes of minor and ordinary defects they contain. On the other hand, the raw cork waste by excess of major anomalies cannot be perforated. Finally, thin cork despite these minor defects, its small thickness does not allow it to be punched in stoppers.

-Industrial grade class 2: This is the final outlet for cork samples after casing, manual or automatic sorting in the plant (natural corkwood stoppers, colmated natural stoppers, refuse, grinding). Indeed, the cork stoppers of this level of quality are divided into two subclasses. The first subclass, natural stoppers are assigned to classes of cork able to be perforated for diameters of 24 and 21 mm and only for the classes of minor defects not requiring a colmation.

-The second class, colmated natural stoppers is assigned to classes of cork able to be perforated for diameters of 24 and 21 mm and only for the classes of ordinary defects requiring obligatorily work of colmation. On the other hand, refuse cork under defects of major anomalies and intended for grinding. Finally, thin cork despite these minor defects, its small thickness allows it to be cased into discs or washers.
The results obtained from the merger of the extended and summarized quality classes are shown in the table 3.

Table 3. Industrial grade class grades 1 and 2 of corks of sample trees

Provenance	N	V1		N	V2	
BO	26(34,67%)	Cork stopper	A	16(21,33%)	Natural cork stopper	A
	26(34,67%)	Thin	B	10(13,33%)	Colmated stopper	B
	23(30,67%)	Refuse	C	16(34,67%)	Washer	C
				23(30,67%)	Grinding	D
HA	52(69,33%)	Cork stopper	A	43(57,33%)	Natural cork stopper	A
	8(10,67%)	Thin	B	9(12%)	Colmated stopper	B
	15(20%)	Refuse	C	8(10,67%)	Washer	C
				15(20%)	Grinding	D
MS	37(49,33%)	Cork stopper	A	22(29,33%)	Natural cork stopper	A
	21(34,67%)	Thin	B	15(20%)	Colmated stopper	B
	17(22,67%)	Refuse	C	21(28%)	Washer	C
				17(22,67%)	Grinding	D
NE	28(37,33%)	Cork stopper	B	11(14,67%)	Natural cork stopper	A
	30(40%)	Thin	C	17(22,67%)	Colmated stopper	B
	17(22,66%)	Refuse	A	30(40%)	Washer	C
				17(22,67%)	Grinding	D
	118(52,44%)	Cork stopper	B	92(30,66%)	Natural cork stopper	A
	50(22,22%)	Thin	C	51(17,00%)	Colmated stopper	B
	57(25,33%)	Refuse	A	85(28,33%)	Washer	C
				72(24,00%)	Grinding	D
Total	300(100%)			300(100%)		

Legend: N: Number of sample; V1: Industrial Grade Class 1; V2: Industrial Grade Class 2; %: Percentage

Industrial Class 1 encompassing three classes simultaneously: the cork stoppers; the thin cork and the refuse cork are individualized respectively on the samples of Hafir (69.33%), Nesmoth (40%) and Beni Ouarssous (30.67%). The Chi-square test indicates a highly significant difference at the 5% threshold between the four sources (X 2 = 26,69; p=0,0001).

The table also shows that industrial grade classes 2 are heterogeneously distributed within and between the four provenances. Indeed, the cork natural cork (with limited minor defects) and well present in Hafir (57.33%) than the other oak groves. In contrast, cork stopper is very common in M'Sila (20%) and Beni Ouarssous (22.67%). For its part, thin cork for washers is dependent on Hafir (40%) and Beni Ouarssous (53.67%). Lastly, cork with no value and destined for grinding is the majority in Beni Ouarssous (30.67%) than the other origins. The chi-square test at the 5% threshold records a very highly significant difference between the four provenances (χ^2 = 44,26; ddl= p< 0,0001).

Study of the quality parameters of the plain and mountain cork (Beni-Ouarssous-M'Sila VS Hafir-Nesmoth)

The cork processing industry would like to better control their supply and therefore know the factors that favor the production of quality cork, tree and stand parameters, environmental factors, management parameters and better yet, to find objective criteria for measurement of quality easily quantifiable. In the real state of the constraints of the environment in which these trees grow, these findings are very difficult to detect because of the high variability between subjects and provenances. In fact, the cork quality analysis of any cork forest cannot be limited to the identification of quality classes and quality indices.

In fact, these two variables are the consequences of tree growth conditions, that is to say the environmental factors that surround them and also certain parameters used in cork-oak growing. To do this, a multivariate analysis (MCA) was used by taking into account several quantitative and qualitative variables specific to the four oak groves (Tab.4).

Table 4. The modalities adopted for the MCA

Variables	Codes	Description and modalities
Situation of the production area	G	1: North, 2: South
Cork oak area	A	1:Littoral1(MS) ;2:Littoral2(BO) ;3:Montain1(NE) ; 4: Montain2 (HA)
Climate	Cli	1: Semi arid; 2: Sub-humid; 3: Humid
Topography	Tp	1: Ridge, 2: Slope, 3: Bottom
The nature of the bedrock	R	1: Sandstone; 2: Shale
Circumferences (cm)	Cr	1:70-107 ; 2 :107-1140 ; 3:140-170; 4: 170-200 ; 5:>200
Height of trees (m)	H	1:7-12m ; 2:12-14m; 3:14-16m; 4:>16m
Debarking height (m)	H.e	1:<1,5; 2: 1,5-2,5 ; 3:2,5-3,5 ; 4:>3,5
Cork thickness (mm)	Cal	1: Large (>42,75mm), 2: Standard (24,75-42,75mm); 3: Thin (<24,75mm)
Soil	Sol	11: deep, 2: stony
Texture	Tx	11: (sandy), 2: (sandy-silt), 3 :(sandy-clay),4: clay-sandly
Health status	St	1: Healthy; 2: weakened; 3: decaying
Fire Pass	Inc	Inc 1: None; 2: 1 passage; 3 (recurrence)
Conifer afforestation	Er	1: No, 2: weak, 3: medium; 4: Strong
Quality type	Q	1:Q-A; 2:Q-B; 3:Q-C; 4:Q-D

The multivariate analysis represented in the table 4 and the figure 3, tries to explain the impact of certain environmental parameters on the qualitative and quantitative variables of the quality namely the commercial and industrial quality (Tab.5).

Table 5. Eigen values and percentages of inertia (environmental parameters / quality)

	F1	F2
Own value	0,465	0,332
Variability(%)	20,834	14,416
% cumulated	20,834	35,250

Through the table 5, we observe that the first axis represents 20.83% of the inertia, while the second axis shows 14.41%. These two axes together account for 35.25% of the majority of the variation of the point cloud of the sample trees and the modalities taken into consideration (300 subjects and 14 variables) (Fig.3).

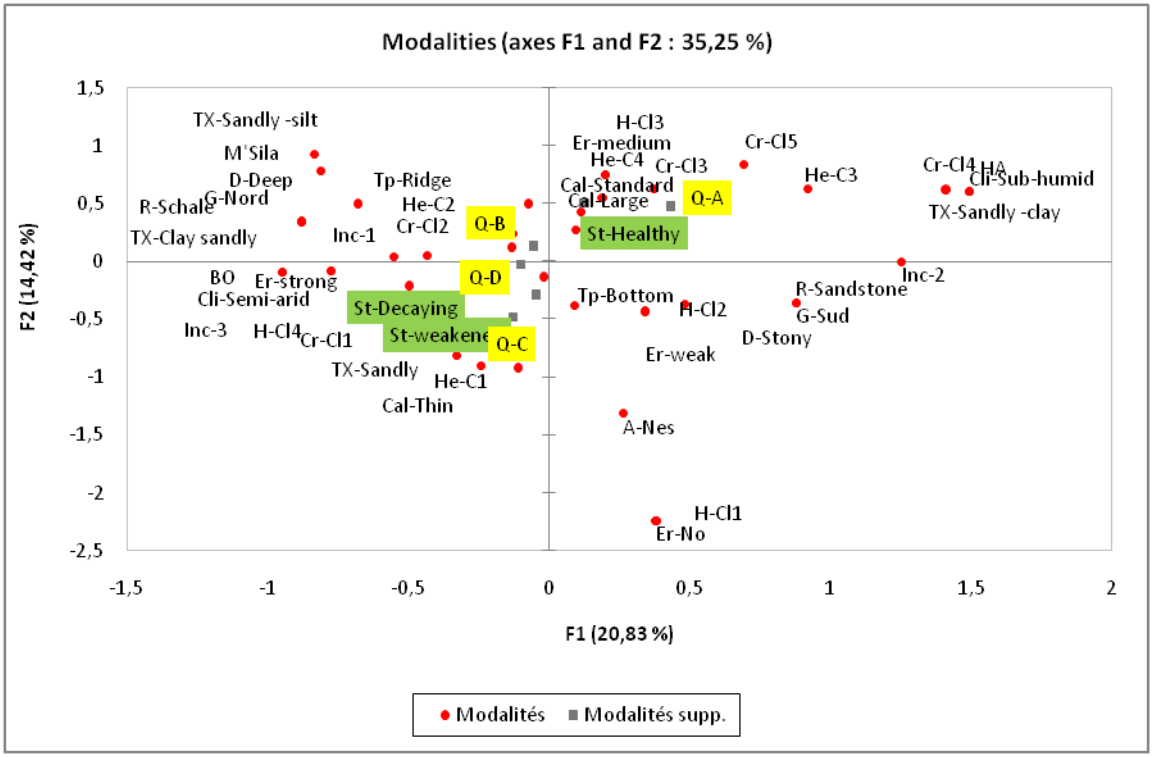

Figure 3. Representation in the factorial plane F1 x F2 of the environmental parameters / quality.

Interpretation of axes

In the first axis (F1), quality cork Q-A is opposed to Q-B, Q-C and Q-D cork. In fact, the type QA favored by the cork processing industry, with the quantitative and qualitative characteristics mentioned (Standard caliber, appearance 5amore, cork stopper with minor waste, natural cork stoppers) seems to depend on the natural area of Montain whether it is in Hafir or Nesmoth. This type of product is significantly related to the health status of healthy sample trees (crown and trunk). On the other hand, the other three types (Q-B, Q-C, Q-D) form a single block and they are more related to the natural coastal area (M'Sila and Beni Ouarssous). These three types are not related to the overall health status of the sample trees. In the second axis 2 (F2), the quality cork Q-A and Q-B are distinguished from Q-C and Q-D. These two products are the most popular on the market both in mountain (HA) and coastal (MS). The significant values at the alpha threshold = 0.05 are mentioned in the table 6.

Table 6. Variables tests of environmental parameters / quality

Variables	F1	F2
G-North	**-15,167**	**6,067**

According to Courtois and Masson (1999), the results are very succinct in terms of the relationships between the quality of the cork and the factors of the physical environment such as the geographical situation, the climate, the topography, the altitude, the nature of the cork, the bedrock because of the complexity of the growth factors of the species in itself. In the factorial plane (F1), the type Q-A cork (natural stoppers and with minor waste) is Mountain (Hafir and Nesmoth), it is the domain of the southern geographical region of the production zone, particularly in the ridges. It is common in stony, low-fertility sites, on a Sandstone hardens of sub-humid and semi-arid where it usually freezes in autumn and winters.

With reference to Lombardero and Montero (1980), these areas refer to poor and degraded soils but producing a good quality cork with very slow increases with exploitation rotations exceeding the usual 10 years or even 12 to 15 years and which are at the best prices. According to Dehane (2012), mountain cork is dominated by reduced cells. The Q-A cork is very present on tall trees in search of light and photosynthesis (12-14m) and adults of class 3 (140-170cm),4 (170-20cm) and also on large trees of the class 5 (>200cm). The caliber produced belongs to the ordinary and thick commercial class (24.75-42.75mm; 42.75mm). This class of quality is also related to the debarking heights of class 3 and 4. These subjects are moderately invaded by *Pinus halepensis* and *Juniperus oxycedrus*.

As reported by to the literature, the commercial and industrial classification of cork quality according to tree parameters (circumference, height, debarking height) is not fully scientifically identified. in agreement with Montero and Cañellas (2003), the best quality of cork accompanies the subjects in full production that is to say the subjects in the sizes are between the classes of circumference (107-140cm) and (170-200cm) especially the class (140-170cm) at 1.30m from the ground than young (<107cm) and old and very large (>200cm) subjects. The same authors argue that cork extracted from high parts of the tree, despite its good quality is classified as refuse cork (Q-D) or thin cork (Q-C) with all the price losses it generates. The better quality cork (QA) seems to be influenced by the overall health

of the trees (healthy), ie with a leafy crown with more than 75% foliage and a trunk free from wounds and fungi. (parched mother, chancre, cavity, insect holes). For cork type QB, QC, QD (cork stopper, thin (washer) and refuse (grinding) are at least within the range of the northern geographic area of the production area, growing on schistose ground semi arid with high maritime humidity (>60%). In this area, the trees of the Beni Ouarssous oak forest are distinguished by their high sensitivity to the recurrence of fires than those of M'Sila. In Beni Ouarssous, because of a strong greening of the Aleppo Pine, the trees are declining and the production of cork is weak and gives only a thin product type Q-C (washers).

In M'Sila, Q-B type cork is common in shallows on deep sandy loam soil. Conversely in the factorial plane (F2), whether in the mountains or on the coast, the suberaies of M'Sila and Hafir are the two major production areas in Oran. Q-A type cork with natural corks of choice is obviously Hafir while Q-B plugs are from M'Sila. Indeed, in northern Algeria, the quality of the cork takes a descending character from the Hafir-Zarieffet forest to all the other oak groves in Algeria (Lamey, 1893 and GGA, 1927). On the other hand, the type Q-D (refuse-grinding) does not seem to be related to any entity, it manifests itself in the four oak groves and it is more frequent in littoral. Thin Q-C type cork (washers) is not as specific for a single area, with a slight exception in Beni Ouarssous and Nesmoth.

Conclusion

Globally, we can say that the study of the impact of environmental parameters on the quality of cork remains a very complicated and controversial theme. The species is characterized by strong allogamy acting on forms of inter-specific and intra-specific hybridization where a large number of subjects per hectare do not have the same genetic characteristics resulting in a varied quality of cork., and a different form of adaptation. Indeed, in Algeria, *Quercus suber* covers 400000 ha and grows from a few meters of the coast to more than 1500 m in the mountains. This geographical distribution is characterized by very marked climatic, edaphic and silviculture contrasts. The obtained results, do not generally come out of those proposed by some cork authors and professionals (Lamey, 1893, Saccardy, 1937; Natividade, 1956; Montoya, 1988; Bossuet, 1988; Seigue, 1989 and Pereira, 2007). All these authors agree that the best quality improves with the increase in the operating cycle of cork (12 to 15 years instead of 9 to 10 years) where equilibrium cells formed in the spring and in autumn. This configuration is found more in the mountains, on the stony soils of the ridges and on the mature trees in full production, strewn with a vigorous sanitary state (crown and trunk). The cork forests management parameters are often quoted and on which the authors group together can improve the production mode of the stands. These are the silviculture operations (combating brushing, the space between trees, the quality of the exploitation and the respect of the rotations) and the plant health control against the defoliating and xylophagous insects and the pathogenic fungi, and also the fight against fires.

CORK OAK RESISTANCE TO FOREST FIRES IN THE REGION OF TLEMCEN (NORTHWESTERN ALGERIA)

Yacine BENHALIMA, Belkheir DEHANE*

Faculty of Sciences of Nature and Life and Sciences of the Earth and the Universe, Laboratory Conservatory Management of Water, Soil and Forests (LGCESF), Department of Forest Resources, University of Abu Bekr Belkaid, Tlemcen, Algeria

Abstract

The fire resistance of cork oak has long been known. Through to the protection provided by its suberous bark and the many dormant buds located under it, can keep its trunk and restore a forest atmosphere in a few years. To confirm or deny this hypothesis, four stands of cork oak trees surviving two different fires were studied in 2018. In Hafir, two stands (H1 and H2) survived the 2005 fire and Zarieffet two others (Z1 and Z2) survived the 2007 fire. The measurements performed on the sample trees concerned dendrometric parameters and health status. On cork, we conducted an analysis of its growth and quality. The results revealed a major change in the structure of the four stands due to the dominance of the small wood species (Hafir: 14%, Zarieffet: 53%) and woodland (Hafir: 90.9%, Zarieffet: 42%). These traumatized subjects support verdant crowns with a sanitary state leading to a start of attrition (1.60 <IS <2.0). The percentage of "mother of cork" low damaged and very damaged is high in Hafir than Zarieffet, 57% against 40% of the total. The visual quality of cork produced by these trees carries the clues of a healthy cork since only the bark is soaring. Due to a high presence of waste cork, the quality indices is better in Hafir stands (H1: 10.20; H2: 6.69) than in Zarieffet (Z1: 5.92; Z2: 6.92). 66% of cork trees can produce stoppers cork in Hafir versus only 48% in Zarieffet.

Keywords: *Cork forest, fire, caliber, growth, quality.*

Introduction

The forest fire is an element of nature; it is an exteriorization of energy. This destructive element is, in forests of many parts of the world, a recurring phenomenon that recurs year after year with an apparently increasing intensity (Benyacoub, 1993). This disturbance is considered a natural ecological force against which certain plants have acquired adaptation mechanisms to survive and regenerate, mainly in the Mediterranean region (Pausas et al., 2004; Pausas and Verdu, 2005). Indeed, Mediterranean landscapes have been shaped from eternity by the action of recurrent fires, i. e. 2 million hectares were burned between 2006-2010 (FAO, 2013). According to Valette (1990), in this region, the absence of precipitation during the summer period, the air temperature, above 35°C under cover and 45°C in open ground level, and the atmospheric humidity, below 30%, modify not only the water status of dead plants and their debris (leaves or needles, twigs, pieces of bark), but also that of living plants. Among the typical Mediterranean species, *Quercus suber* L. is the best adapted to the structural phenomenon represented by the summer fire since its suberous protection allows it to resist the passage of fire.

In Algeria, forest fires are currently the most destructive factor of degradation. Algerian forest fire statistics are among the best archived in the world, covering a continuous period of 137 years (1876-2013) (Sari, 1976; Grim 1989). The colonial period was fatal for this heritage, from 1876 to 1962, the records of the French administration record a cumulative surface of about 3506 942 ha or an average of 40 778 ha/year. The catastrophic fires, of more than 100 000 ha/year very frequent during this period, mark several years sadly famous in the Algerian

statistics on this subject (Meddour et al., 2008). After independence, the Algerian forest experienced a relative calm, since the areas burned decreased compared to the colonial period, when the annual average was about 34254 ha (16% less). As an indication, this heritage lost 1162484 ha between 1979 and 2009, with a total number of fires declared of 41 644, (Bekdouche, 2010). The year 2012 remains the most catastrophic with a total of 90 061 ha (DGF, 2013). Currently, forest fires threaten 40% of the Algerian population, or 13 million inhabitants living in or around forest massifs (Bachouche, 2013). The Algerian oak cork stands did not escape this phenomenon, the fires started during the period 1993-2012 had unfortunate consequences on the area where 117317 ha were lost (Abbas, 2013). Cork production is currently at its lowest level at 8000 t/year. The resistance of cork oak to fire has been known for a long time, the bibliography joins all on the same observation: "Where other oaks, pines, arbutus, and all the different woody species of the Mediterranean maquis are forced to reject stump or rely on natural regeneration, cork oak, thanks to the protection provided by its suberose bark and the many dormant buds located under it, can keep its tree habit and restore a forest atmosphere in a few years (Elena Rossello, 2004, Piazzetta,2004). Our work was carried out in the southern part of the Tlemcen mountains, in two cork production areas, namely "Zarieffet" and "Hafir" with a sub-humid climate. Indeed, during the last twenty years, the forest massif Zarieffet-Hafir has been transformed from a dense forest to an open area overwhelmed by the massive degradation of its trees and the structural transformation of its stands; these two areas are very well known by the recurrence of fires. In this massif, nearly 228 ha of cork oak went up in smoke between 2005 and 2011 (C. F. W. T. ,2012). The objective of this work is to explain the behaviour of cork oak after a fire by a series of measurements in the field and laboratory. The vulnerability and post-fire resistance of the species were studied following the various modifications recorded on the structure of the stands, their sanitary state and their productive and qualitative potential.

Material and Methods

Four cork oak stands surviving two different fires were studied. In Hafir, two stands (H1 and H2) survived the 2005 fire and in Zarieffet two others (Z1 and Z2) survived the 2007 fire. The sample trees taken into consideration are living subjects of cork oak, particularly inscribed in the archives of the same fire and holding a flaming reproductive cork. The number of trees meeting these criteria totals 45 individuals in Zarieffet and 38 in Hafir. The measurements made on these trees concerned the following parameters: external circumference (SW: small wood, MW: medium wood and LW: large wood), debarking height, cork thickness and measurement of annual increases. The assessment of the health status of the surviving subjects is based on leaf deficiency. It is noted after examination of the tree branches according to its sanitary class (Bouhraoua & Villemant, 2002). 1: healthy (defoliation < 25%); 2: weakened (defoliation between 25-60%); 3: decaying (defoliation > 60%). This index allows expressing directly the general state of the population from a set of trees taken individually. It is calculated as follows: $$Is = \frac{\sum_{i=1}^{5} n_i P_i}{N}$$

where

ni: Number of trees of defoliation type i
Pi: Weight of type i (1 if i=1; 2 if i=2, etc.)
N: Observed total number of observed trees

The growth and quality of the cork were analysed by the assessment of the "mother" state of the cork and by the first use of Coveless CQ05. The quality class is established according to the IPROCOR method (1994). Thick : 19 plus 6ª plus; stopper cork bark (15-19 5ª more 13-15

5ª more, 11-13 5ª more); Thin (15-19 6ª; 13-15 6ª; 11-13 6ª); Low (4ªmore 8-11minus) and Refuse. The calculation of the quality index of each stand is obtained according to the formula proposed by IPROCOR (1994):

$$Q = (5/100) \times \Sigma i = 1\text{-}9\ (Ai \times Qi)$$

where:

Ai = number of trees of defoliation type I; Qi = weight of type i (1 if i = 1; 2 if = 2, etc.);

The chi-square test was used to compare certain parameters taken into consideration.

Results and discussion

All the indicators taken into account on the four stands are mentioned in Table 1.

Number of sample trees	24	21	22	16

The table shows that the trees that survived the 2005 and 2007 fires are generally natural, of varying ages, resting on sandy silty soil. Zarieffet and Hafir plots 1 appeared to be the least dense with 55 and 60 subjects/ha while Zarieffet and Hafir plots are the least dense with 55

and 60 subjects/ha. The altitude of 1313m is maximum at H2 (Hafir) while it is minimal at Z1 (Zarieffet) around 1041m.

Stand structure

One of the first negative consequences of forest fires is a marked reduction in overall stand density. The size distribution of the subjects is shown in Figure1.

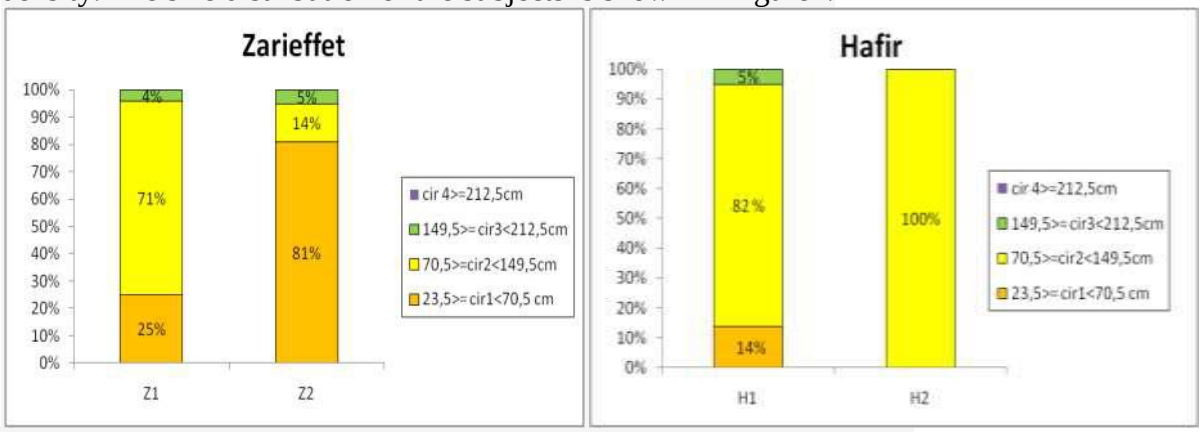

Figure1. Distribution of resistant trees according to their circumference

The fires of 2005 and 2007 directly affected the structure of the two forests. Only three categories of wood exist in the four stands (small, medium and large). The presence of small wood records a rate of around 14% (H1) and 25 to 80.9% (Z1,Z2). The average wood occupies simultaneously 81 to 100% (H1,H2) and 70.8 to 14. 29% (Z1,Z2). Finally, large wood has a low resistance with a percentage of 5% (H1) and 4. 76 to 4% (Z1,Z2).

According to Amandier (2004) and Bernal Chacón and Cardillo Amo (2005), it is in particular the old trees (very large wood) and the small poles (very small wood) that give way first to the flames. In the case of cork oak, this situation is dependent on the thickness of the cork on these subjects at the time of the fire. In this context, measurements made on cork increases revealed that the average age of the latter is around 9 years in Hafir and 11 years in Zarieffet. This is made by the suberous layer detached from the neo-formed layer after healing (Fig. 2).

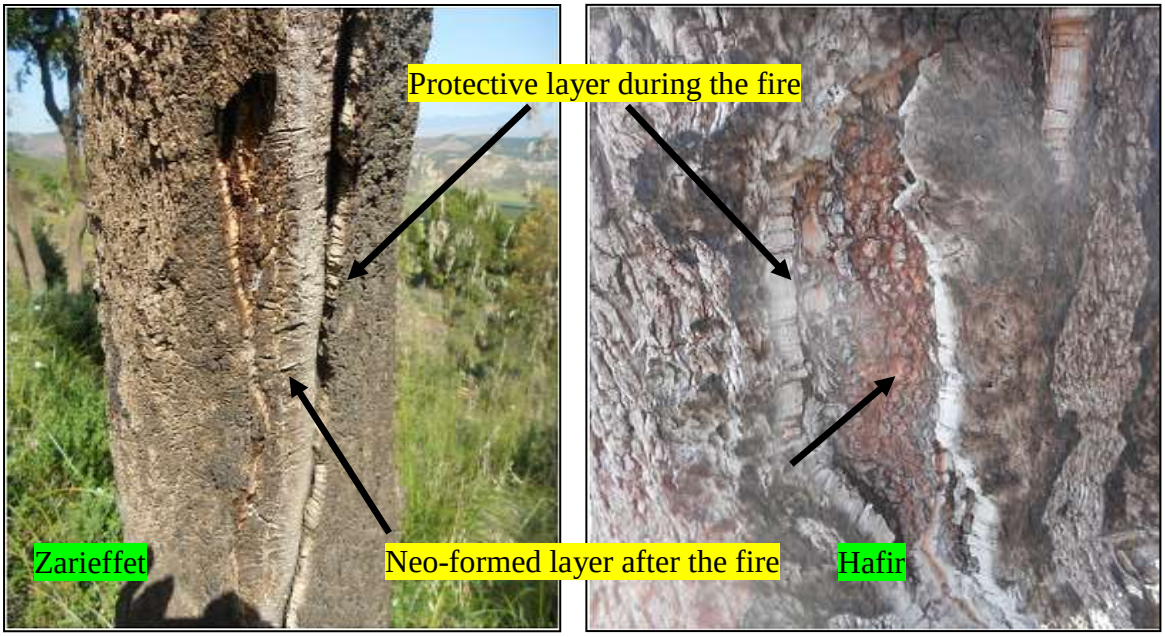

Figure 2: Bark resistance due to visible cork growth before and after the fire

State of the peaks

The foliar deficit (of the tops) recorded on the sample trees is illustrated in Figure 3.

According to the figure, we could note that the tops of the sample trees are generally green, i. e. a rate of 47.36% of healthy subjects in Hafir against 48.88% in Zarieffet. The Hafir plot1 has 59% vigorous individuals while they are 61.47% in Zarieffet (Pl2).

The average number of weakened cases is 39.47% in Hafir and 35.35% in Zarieffet. The Hafir H1 plot is individualized with 40.90% of cases against 54.16% in Z1 (Zarieffet). For decaying subjects exceeding 60% leaf deficit, this rate varies from 13.15% (Hafir) to 15.55% (Zarieffet). H2 trees total 31.5% while they are only 23.8% at Z2. The Chi-square test records a non-significant difference (χ^2 = 0.17; 2ddl).

Furthermore, the health indices seem balanced between the two entities: Hafir (IS = 1. 67) and Zarieffet (IS = 1. 62) and converge the four stands towards the beginning of decline (1. 60 < IS < 2.0) (Fig.3).

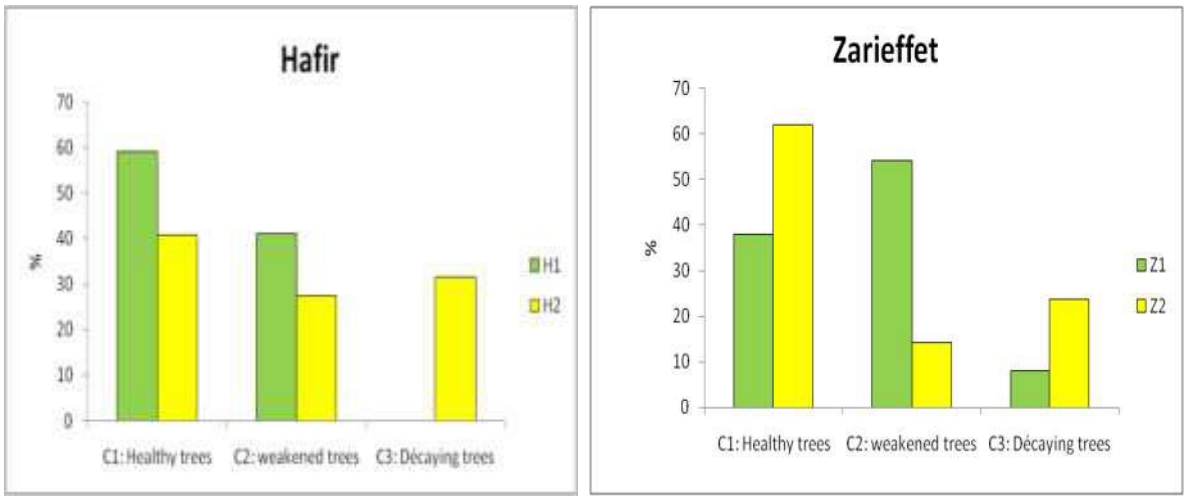

Figure3. Post-fire crown appearance on sample trees

Indeed, forest fires are among the factors that often trigger the description of the health deterioration of cork oak and correspond quite clearly to regions where low annual rainfall, high summer temperatures and a low useful soil water reserve are combined. The intensity of the fire firstly burns the soil and favours its exposure to sunlight and leads to its degradation; subsequently accelerates the phenomenon of erosion and consequently the disappearance of fertility which is essentially linked to organic matter and the biological activity of the soil (Dehane, 2012). This pattern creates a dry atmosphere unfavourable to cork oak. Trees directly affected by fire irreversibly lose their foliage and then die, the survivors regenerate it (dormant buds) with symptoms of twig alteration and a modified crown architecture, by the fall of the leaf mass (Nageleisen, 1999).

It has been found in several studies that repeated fires over a period of time and in the same area, without the possibility of sufficient healing, accelerate completion factors that are generally related to the presence of xylophagous and xylomycetophagous insects and pathogenic fungi of weakness and injury (Griffin et al. , 1992; Cherubini et al. , 2002). Some of these symptoms were encountered in Zarieffet plot 1 with respect to the mother's charcoal (Fig. 4).

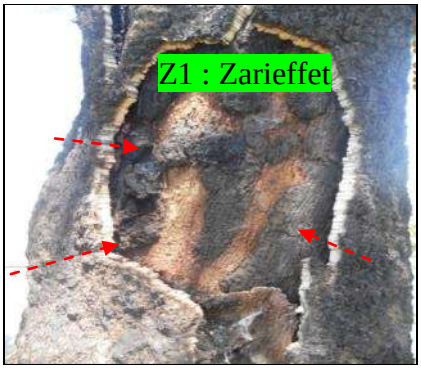

Figure 4.Mother of cork damaged by the fire and infested by mother's coal *Hypoxylon mediterraneum* (De Not) Mill.

State of mother of cork

The distribution of the appearance of "mother" on the sample trees is illustrated in Figure 5.

Legend: SW(small wood) ; MW(medium wood); LW(large wood)

Figure 5. Proportion of the state of "mother" of cork on the sample trees

Through the figure 5, we notice that in the plots of Hafir the aspect of the mother of the cork seems very damaged on the large circumferences is a rate of 100%. However, in Zarieffet, this rate does not exceed 4% respectively for small and medium wood (Z1) and 9% for PB (Z2). As regards the damaged states, they always remain within the individuals of Hafir (particularly MB) with a rate of about 42% against 22% in Zarieffet (PB+MB). The Chi-square test calculated between the two forests makes a significant difference (χ^2 = 8.36; 2ddl).

During the fire, the mother of cork (subero-phellodermic Assisi and libero-ligneous Assisi) very sensitive to flames can be destroyed by the heat which will completely consume it. This heat depends on the intensity of the fire and the adequate protection of the cork. The destruction of a localized cork mother surface involves the eradication of wood growths in this area so that they cannot create new conductive vessels and consequently the meristematic activity of bast. Indeed, when the sap rise is highest during spring and summer, this area (on trees surviving after the fire) appears dry and bare. The death of cork mother also means the end of its suberous production and the appearance of zones vulnerable to the penetration of fungi and xylophagous insects (Fig.6). If the destruction occurs over the entire circumference, the entire life of the tree will be compromised.

Bernal Chacón and Cardillo Amo (2005), state that the protective power of cork is proportional to its thickness. A cork thickness of 20 mm implies sufficient protection for the mother whatever the type of fire. In the case of low intensity lights, 10 mm seems sufficient to protect the mother. Indeed, on our sample trees, the rates of "mothers" damaged and very damaged (according to our observations) are more related to the quality of exploitation before the fire in both entities. Whether they act on young or old trees, the accumulation of injuries, the slow growth of wood and cork with age increase the deteriorated surfaces of the bunk during fire. This situation is more present in Hafir. According to Piazzetta (2011), the injuries caused as successive debarks are as many entry doors ("decay") for the fire inside the tree (Fig.6).

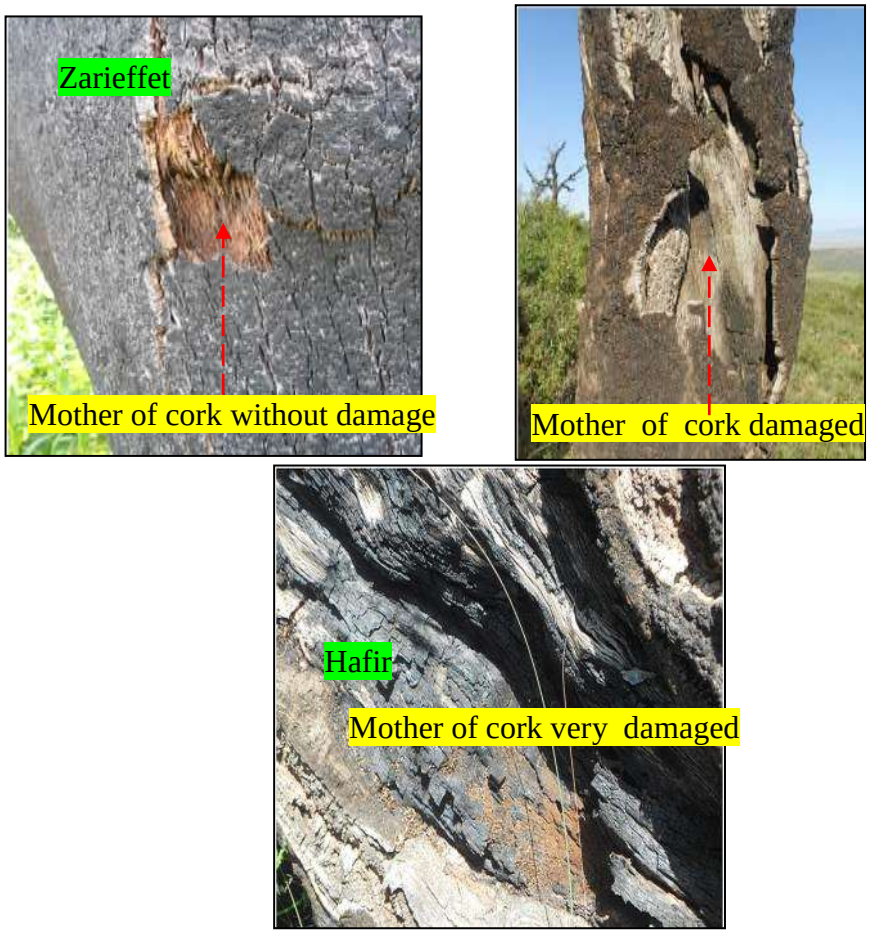

Figure 6. Observation made on the appearance of cork mother

Study the quality of cork

The results of cork quality sampling on the surviving fire trees are shown in Figures 7 and 8 according to the commercial and industrial classification:

-Extended classification: The extended classification merges the calibers and visual appearance to produce the quality class according to the IPROCOR method (1994) (Fig. 7).

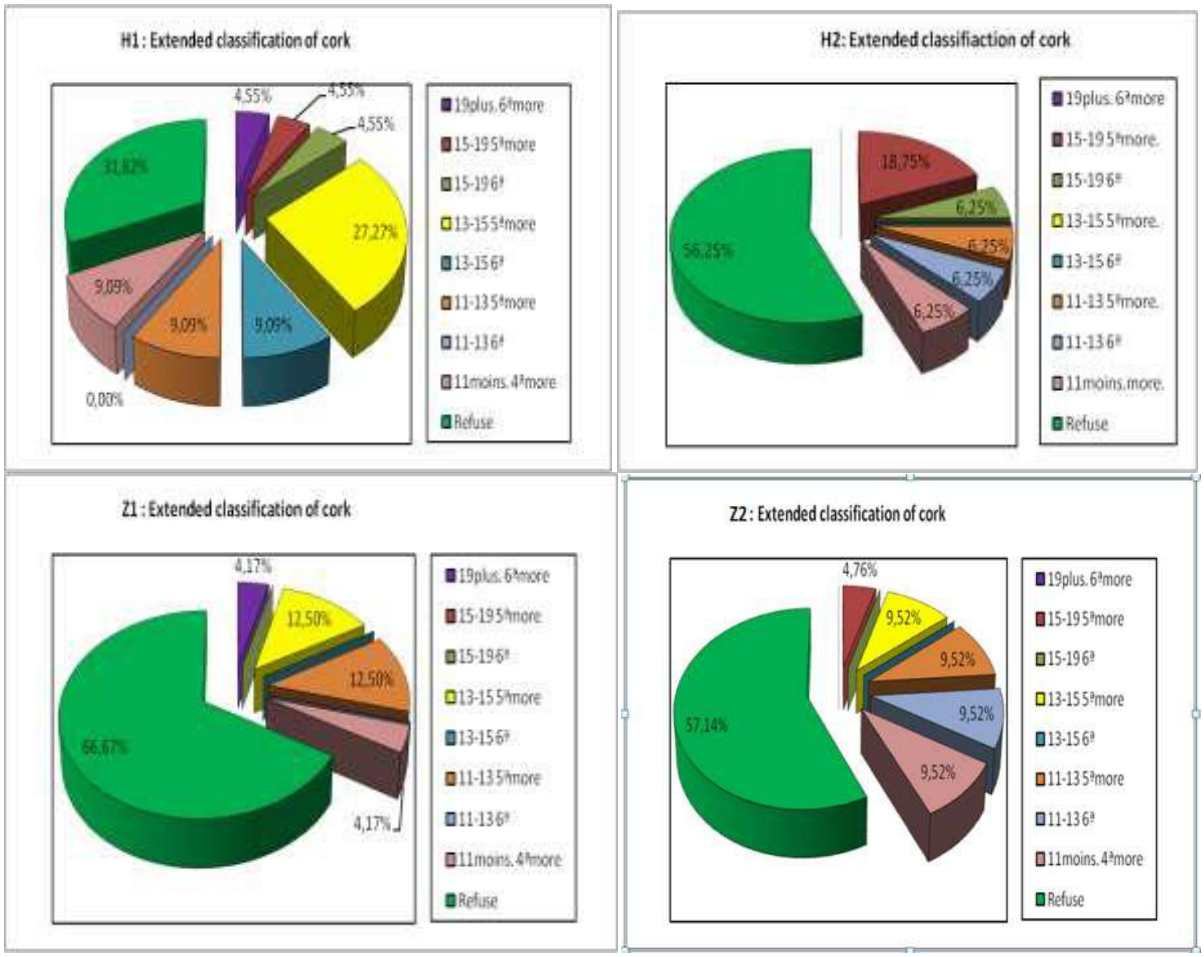

Figure 7.Commercial cork quality classification on the subjects of both forests

In Hafir, only H1 sample trees generate 4.55% thick cork (quality 19 plus. 6ªplus). The cork of the class 2 (15-19 5ª more) is imputed to H2 of the order of 18.75 % against 4.5 % with Pl1. At the same time, very poor quality waste cork (Refuse) is more present in H2 with a rate of 56.25% and in H1 with 31. 82%. Very thin cork of 4th choice and higher (11minus.4ª more) ranges from 9.09% (H1) to 6.25% (H2).

In Zarieffet, the proportion of thick cork in class 1 (19 plus. 6ªplus) is identified only in 4. 17% of the Z1 population. In plot Z2, class 8 (11 minus. 4aplus), synonymous with very thin cork, seems to be the most important, i. e. a rate of 9.52%. Refuse cork is generally higher in both plots, 66.67% (Z1) and 57.14% (Z2).

Summary classification

The summary classification gives us an idea of the industrial outlets of the product surveyed on the sample trees. Figure 8 summarizes the results of the extended classification.

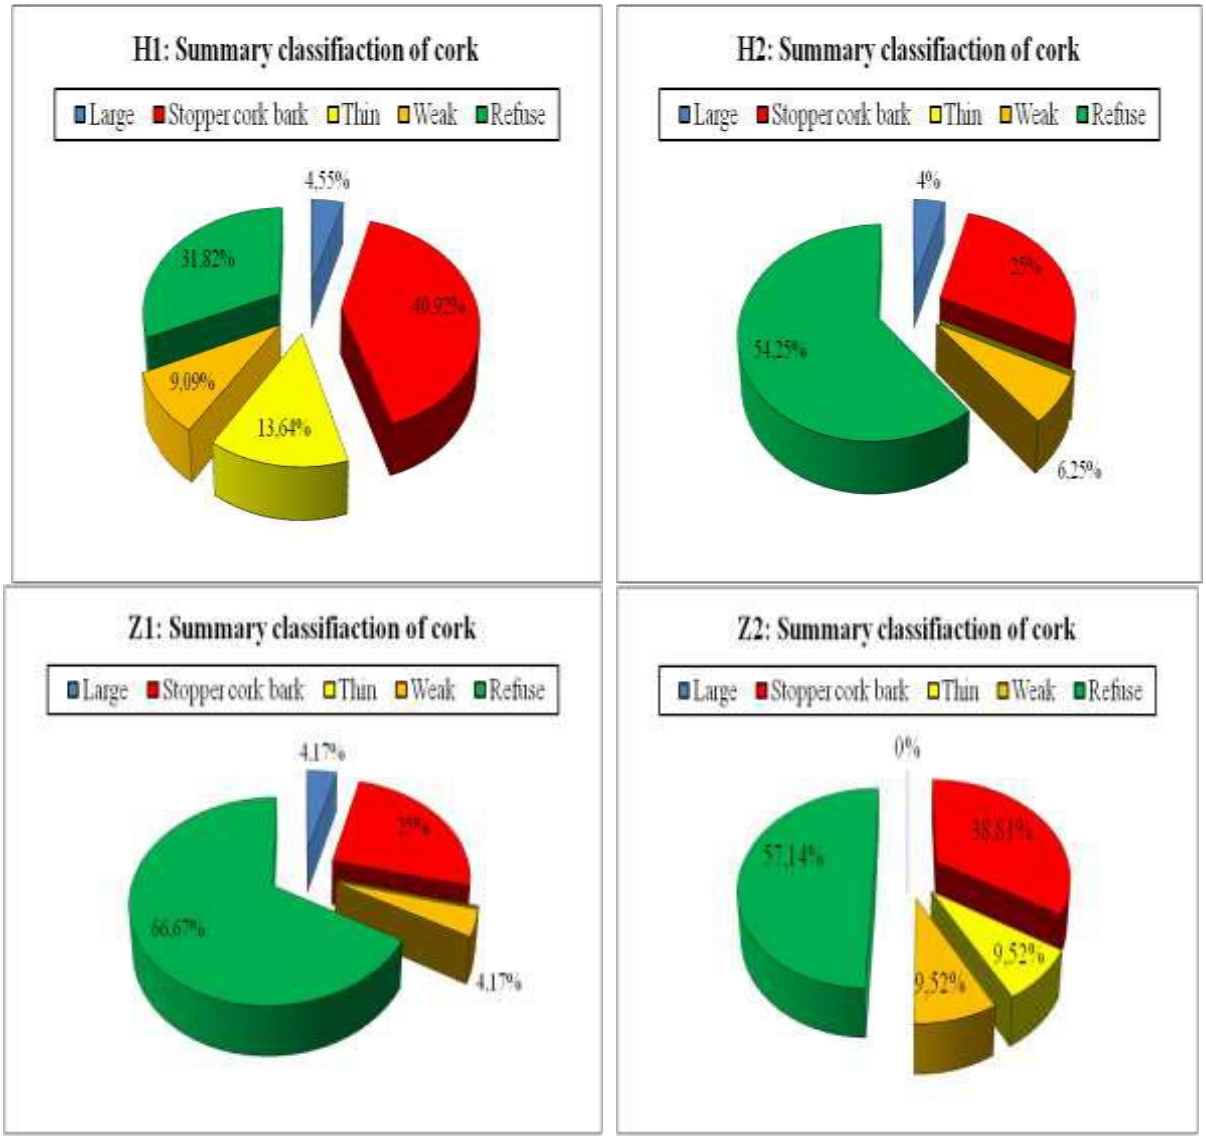

Figure 8.Industrial classification of cork quality on the subjects of the two forests

The summarized classification indicates that the stopper cork bark (Φ: 24mm) of Hafir groups together 3 classes (15-19 5ª more, 13-15 5a more, 11-13 5a more) of 49,91 % on H1 and 25% on H2. Thin cork concerns only 13.64% (H1) and 12.50% (H2) of cases. The weak cork for the confection of the discs is identified in the 6th choice (of the classes 15-19,13-15,11-13) with a percentage of 9,09%(H1) and 6,25%(H2). Refuse cork for crushing and other uses holds 31.82% and 52.25% respectively.

The Zarieffet workforce produces less cork (Φ : 24mm) than in Hafir, i. e. 25% (Z1) and 23. 81% (Z2) (Fig.9). Thin cork for 21 mm diameter corks is only present at Z1(9.52%). The weak cork for the washers varies from 4.17% (Z1) to 9.52% (Z2). Refuse cork is important, exceeding 55% in both plots.

Several authors agree that the decline in cork quality on trees is linked to excessive competition within the cork forests, which would lead to strong competition between trees, a weak vegetative state with a slight increase in wood and cork (Bossuet 1988 ; Montoya,1988). The passage of fire depreciates the quality of the cork only through the thickness of the flare recorded on the gauge of the boards (Fig. 9). The buyers decline this type of cork because of the flambéed bark and the additional work during the boiling and scraping of the crust. Dubois (1990) estimates the additional cost of exploiting burnt cork at 20%, and that of

transport at 12 to 15%. According to Bernal Chacón and Cardillo Amo (2005), whatever the intensity of the fire, the black band that appears on the transverse layer of the board rarely exceeds 2.5 mm for a thickness of 10 mm and 10 to 12 mm for an over-thick cork of 50 mm (Fig.9).

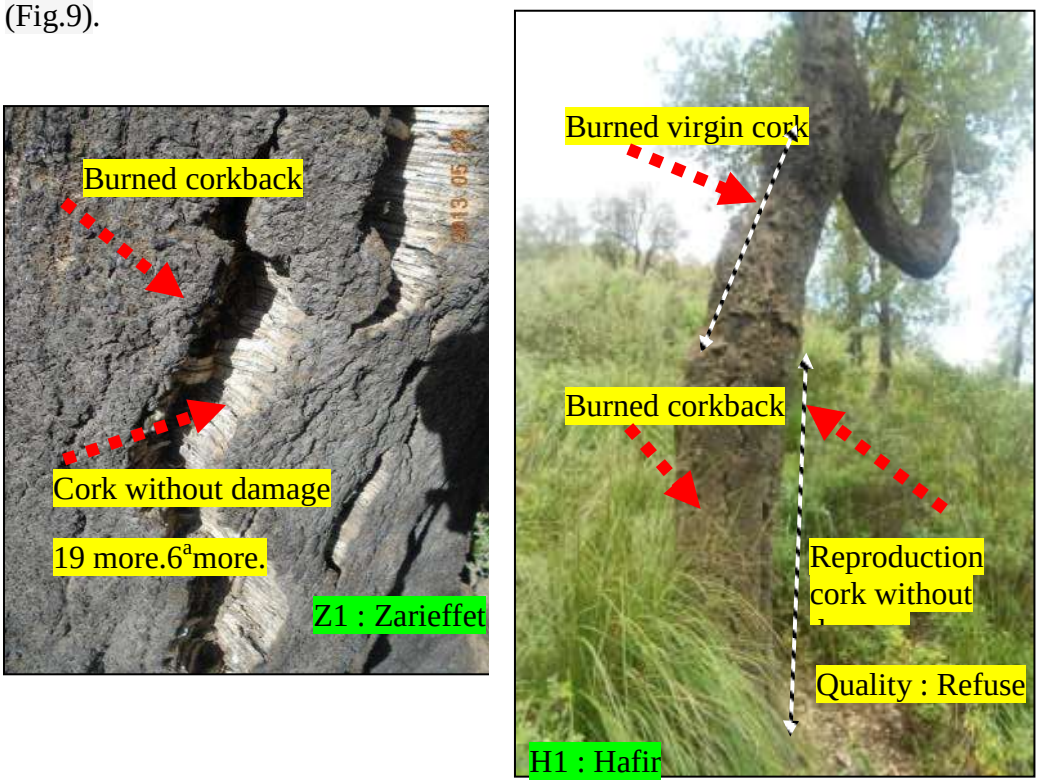

Figure 9.Quality of cork produced by burned trees

In this work, in spite of the healthy visual aspect of the cork which is characterized by a localized superficial flare at the level of the crust, the coveless probing showed that the quality of the cork is rather attenuated. This consequence is due in large part, to the strong presence of defects especially folded corkwood, vertical and horizontal lignification. Indeed, the quality indices were different from one plot to another. Only H1 subjects seem to stand out with a QI = 10.20 (Fig. 10).

Figure 10.Quality indices recorded in the plots of the two forests

Conclusion

The forest massif Zarieffet-Hafir represents the large area of the oak cork stands of north-west Algeria. These stands with regard to the entire subericolous Mediterranean are characterized by their resilience and their more or less marked resistance to fires. Through this work, it is found that fire influences certain aspects related to stand structure, the state of health of trees

and their productive potential in general. Repeated fires lead to clear cork oak stands that favour the development of the maquis, thus increasing the risk of future fire. The good management of these two entities must be based essentially on the notion of the omnipresent occurrence and intensity of fires according to a fire hazard map. Indeed, both forests have been subject to more than 4 fires in 50 years. Fuel in both forests must be located and mechanically controlled according to its structure and type (plant species, height, cover, dense scrub, clear scrub).

In Zarieffet, the landscape is dotted with gaps between the surviving trees and very colonized by a very flammable thorny bush.

In Hafir, the existence of a dense and high maquis based on rock rose and tree heather favours the vertical connection between the trees, thus allowing fire to spread to the top.

In our opinion, in both cases, the exaggerated presence of this forest fuel does not in any way help any attempt at natural or assisted regeneration. Even more, it acts negatively on the physiology and nutrition of trees and consequently on their radial and suberous growth.

ESTIMATION OF BIOMASS AND CARBON STOCKS: ADAPTIVE MEASURES TOWARDS CLIMATE CHANGE AND FOREST MANAGEMENT IN RUSSIA

Tatiana DEMKINA[1*]

[1]Department of Sustainable Agricultural Systems, University of Natural Resources and Life Sciences in Vienna, Austria
Department of Management and Economics, University of Agriculture in Nitra, Slovak Republic.

Abstract

Current land use in Russia has an impact on the pools of carbon and biodiversity conservation in forest areas. Total forest area in Russia has exceeded 885 million hectares, that is around almost a half of the total area of the country. These areas play a major role in climate change, due to the carbon concentration. However, it is problematic to measure of total carbon stocks and biomass. The carbon storage estimation can be represented by three methods: an individual-based gap model of forest dynamics (FAREAST), mapping of distribution of living forest biomass (MODIS) and individual tree-based forest gap model University of Virginia Forest Model Enhanced (UVAFME). Due to the results of the Model estimations multiply scenarios could be implemented; for example, improvement of the stakeholder's network and land use control on the governmental level. At the same time, a complex of factors has an influence on future scenarios. For instance, permafrost affected soil and led to the stronger dependence on climatic conditions over the last 15 years in Russia, as well as on fire disturbance. To follow changes in soil and air temperature, in this paper was analyzed collected data from weather stations in Russia. Climate change influenced on agricultural land use. Traditional Siberian crops would be changed to new crop varieties with an extra irrigation. These adaptation measures would promote sustainability and food security in Siberia within the context of global warming. Meanwhile the new land use legislation does not rely on natural ecosystems and biodiversity conservation. Alternative policies will be reflected on through the framework of *Green economy*.

Key words: *Biomass, Biodiversity, Carbon stocks, Policy implementation.*

Introduction

The discourse about sustainable development began in the 1980s. During the last year policy has been improved in a response of forest goods, ecosystems and woodland landscape (e.g., Kennedy *et al.,* 2001; Campbell and Sayer, 2003; Innes and Hoen, 2005; Sastamoinen, 2005). To support *Green economy* policy implementation (Zaharova, 2015), several approaches such as "Priorities of the national environmental policy of Russia: from the federal center to the regions", the "Environmental and Climate Doctrine of the Russian Federation", "The Comprehensive Plan for the Implementation of the Climate Doctrine of the Russian Federation for the Period to 2020" will be introduced and discussed during the International conference "Basics of federal policy in field of ecological development of Russia till 2030". However, polices will be beneficial in case of appropriate observation and research methods. Hence analyzing the results of empirical studies and evaluation of climate change as well as their influence on sinks of carbon, biomass and biodiversity, are researched using the following three methods: an individual-based gap model of forest dynamics (FAREAST), mapping of distribution of living forest biomass (MODIS), and the individual tree-based forest gap model University of Virginia Forest Model Enhanced (UVAFME). The paper is aimed to address three specific questions. First, which strength and weaknesses have reviewed methods? Second, how disturbances and climate change influence on carbon stocks? Third, if

the forest management can be one of the adaptive practices to the climate change? The research aim of this paper is built around these questions. Thus, the author aims to identify the current state of research to depict how the scientists respond to problems regarding carbon stocks in Russia and adoptive measures towards the climate change. Thereby 2 main objectives are specified. The first objective is to summarize the evidence and provide a quantitative assessment concerning the recent research statement on carbon stocks in Russia. The second objective is to find out the adaptive management actions, for instance, possible initiative collaboration between neighboring countries.

In the Siberia changes in carbon stock was caused by burned part of the southern dark taiga aimed to convert those lands to the arable one (Baranchikov and Kondakov, 2002). An intensive land use for the agricultural purposes contributes to the biodiversity and biomass losses in Russia. It is important to promote future scenarios for the ecological, economic and sociocultural development by estimation of carbon and biomass content in different regions of Russia, to promote improvement of the regulation norms and the structural management in agricultural land and forests use.

Material and Methods

These paper is based on the literature review of secondary data published in research articles on the topic "Carbon stocks and biomass estimation methods in Russia" and aimed to compare the efficiency and output of the used methods. Selection of the articles have been done by the key words: "Land use policy in Russia", "Forestry in Russia", "Carbon stocks in Russia", "Climate change in Russia", "Green economy in Russia" in Google Scholar database and IOP Science online service.

Represented articles observe qualitative and quantitative methods. For the MODIS from polygons ranged in size from 0.7 to 1503 ha in 12 Russian geographical units (Krasnoyarsk Yart, Northern Khabarovsk, Karelia, Krasnoyarsk Usol, Kamchatka, Southern Khabarovsk, Magadan, Murmansk, Udmurtia, Novosibirsk, St. Petersburg, Kursk), with an average of 18 ha/polygon (Houghton *et al.*, 2007). Estimation air and soil temperature changes are represented by collected data from regular weather stations of permanent frost regions and samples from the locations over 100m x 100m (1 ha) and forest management enterprises (Leskhozes) or special stations for soil temperature estimation in framework of the Roshydromet network in Russia (Sherstiukov *et al.*, 2012). Russian territory based on all of the available daily soil temperature data was originally developed in the late 2000s (Sherstyukov, 2008). Linear regression allows to compare simulated and inventory measured biomass by the FAREAST model at around 2000 sites in Russia.

Sustainable Forest Management implementation provided by the survey (2010) on multi-stakeholder model forests (MFs) initiatives opinions in selected Russian regions (Komi MF and Pskov MF) and Sweden one (Vilhelmina MF and the Foundation Säfsen Forests in the Bergslagen region) (Elbakidze *et al.*, 2010). Research and clear vision on the present problematic zones in Russia can develop proper management and policy, which will correspond current climate changes.

Results and Discussion

Soil as natural resource and soil sciences play a major role towards achieving sustainable development goals (Keesstra *et al.*, 2016). Three soil functions are acting as carbon pool, biomass production, and biodiversity, have been assumed applying three methods mentioned above (MODIS, FAREAST and UVAFME). Data on change in forests dynamics (burned, deforestation, recovered) and volume of biomass are used for the carbon stocks measurements.

Each of the overviewed articles has an inaccuracy in the final estimation results. In the article of Houghton et al (2007) proposed MODIS database use was only partially successful. The analysis was performed with the random Forest package (Liaw and Wiener, 2002) and the calculation of weighted mean biomass was an aggregation process that often follows to assign a particular forest type to a MODIS cell. According to the analysis, ∼60% of the forest area in Russia had biomass values greater than 64 Mg ha^{-1}. However, there was a number of estimation limitations: the first was - in regression model, which did not include calculation option of the biomass in closed-canopy forests (the age was more than 20 years), as a result the error in final volume of biomass was around 39%. A second limitation to the prediction of above-ground biomass with MODIS data has been the extent to which the forest polygon data (difference in size of observed land by individual polygons) matched the spatial size criteria of MODIS cells. Disturbance effects of fire, insect damage and logging, are not explicitly included in these simulations using the FAREAST model. Therefore, the model can provide higher biomass estimation compare to the inventory-based estimation. FAREAST model can be improved by Dynamic global vegetation models (DGVMs), which focuses on type of vegetation and can cover large scales for stimulations (future scenarios) for carbon accounting (Shuman *et al.,* 2013). The simulation of all individual trees and their dynamics for around 30.000 plots can provide a complete carbon accounting in dynamics influenced by changes in the system. In the last years Eurasian forests were disturbed in the western part of Russia; however it was affected by intensification of land use and climate change that influenced on the pattern of carbon sources and sinks (Krankina *et al.,* 2002). The capacity for aboveground biomass growth is limited, as well as maintenance of the extensive landscape mature stage forest for the purpose of accumulating and accounting of low carbon stocks capacity across Russia during disturbances. Decreasing the rotation age for an even-aged distribution from 210 to 150 years does result in decreased biomass in all regions, but this decrease is only statistically significant in the east region. Where the simulated average total standing biomass (tC ha1) is 69.21 for the 150-year rotation which is significantly lower than the current simulated biomass of 83.42, whereas the 210-year rotation has a simulated biomass of 79.42 (Shuman *et al.,* 2013). This method does not consider the sink coming from build-up of downed and dead trees that one might expect in a mature forest mosaic landscape, weather it is an important component of the carbon content. Within the FAREAST model, individual trees competition in nutrient uptakes determines biomass accumulation, annual leaf and fine root renewal (Shuman *et al.,* 2013). The model allows to determinate in the Eurasian forests, as 87.4% of the forested areas in Russia are covered by *Pinus spp, Picea spp, Abies spp, Larix spp, Betula spp, and Populus ssp* (Shvidenko and Nilsson, 2003).

The alternative individual-based gap model has been proposed by University of Virginia Forest Model Enhanced (UVAFME). It is based on the systematical approach of the FAREAST (Yan and Shugart, 2005) and contributes to the Regionally-Adjusted MODIS Burned Area (RAMBA) method of mapping burned area (Loboda *et al.,* 2011). The model also allows to estimating future scenarios, formed by fire and climate disturbance (Shuman *et al.*, 2017). Fires effect on carbon and biomass, as well as biodiversity, seedbank, seeds can be destroyed or removed by other species seedlings. The results of the studies in the increase of aboveground carbon storage are familiar with previous boreal forest modeling work of Kasischke *et al.* (1995), which demonstrated the positive effect of biomass storage with warming and growth of fire frequency. In case reduced fire frequencies carbon will increase from 82.06 tC ha^{-1} to 86.11 tC ha^{-1} and within climate change and fire from 112 tC ha^{-1} to 119.17 tC ha^{-1}(Shuman *et al*., 2017). It is predicted that low to mid-severity fires will lead to a thin organic layer and changes in temperature of soil. The UVAFME model does not review results of relationship between vegetation and fire. However, predicted future scenarios

present changes in carbon and biomass dynamics and help to form relevant management according to the use of available natural resources.
The increase of soil temperature (around 0.4 °C/decade) in the Central Siberian Plateau (although observations are sparse) and in the southern mountainous regions (Altay, Sayan Mountains, Stanovoy Range) during the last 50 years resulted in thickening of the active layer and possibility to develop the residual thaw layer above the permafrost over the last decade (Streletskiy *et al.,* 2015). Changes in the ground thermal regime will afford the food security of indigenous communities, development of infrastructure and agricultural land use in geographical areas of the Russian Arctic (Streletskiy *et al.*, 2014). Scientists already predict about 50 to 85% of central Siberia areas to be climatically suitable for agriculture by the end of the century, however, soil fertility (carbon contain) can be a boarder for a crop cultivation (Tchebakova *et al.*, 2011). The previous experience without proper estimation of fertility limitations and establishment of regulations of intensive land use in the 1991 in the southern central Siberia, leads to the degradation of 1.5 million ha of an arable land. In Khakassia, in particular, 81% of the arable land was subject to Aeolian erosion (Lysanova, 2001).
Biomass estimations are diverse; therefore carbon stores and fluxes from Russian forest ecosystems are also vary. Those findings contribute mainly to the uncertainty of world estimates. Improved commitment of biomass and the results of management policy implementation is a base of future management formation in concordance with the Kyoto Protocol[28], signed by Russia in 2004. This document is just one of the 100 international agreements of Russia. Nowadays Russia started to follow in *Green economy* concept in order to minimize ecological risks and to achieve the basic sustainable goals. The main aims are sustainable consumption and production (food security), protect and restore sustainable use of terrestrial ecosystems, and sustainable manage of forests (Zaharova, 2015). Survey from the 2010 year analyzes the four selected Model Forest initiatives (Komi MF and Pskov MF in Russia and Vilhelmina MF and the Foundation Säfsen Forests in the Bergslagen region in Sweden) and the influence on decision-making and sustainable forest management (SFM) policies formation processes, as well as the motivations for their establishment (Elbakidze *et al.*, 2010). Fragile governance system at the national level in the Russian Federation does not have any NGO's influence, lack in the property rights, corruption and demonstrated low level of the social capital (Olsson *et al.*, 2006). However, in Sweden exists a rigid governance regulations at the national level. As an adaptive measure to the forest management and climate change – collaboration between neighboring countries, which aims to obtain the experience and exchange knowledge (Elbakidze *et al.*, 2010). Furthermore, initiative elaboration of approaches will lead to sustainable development by creation of projects between Sweden and Russian researchers. Those projects are often supported by international companies, organizations and NGO's, for instance, the World Wildlife Fund (WWF) submitted project to prevent exploitation of the large intact forest landscapes (Yaroshenko *et al.*, 2001). Collaboration initiatives can be implemented easily on the local, regional, national and international levels; however, modern Nordic approaches are often conflicting with the present Russian system of forestry norms and regulations (Elbakidze *et al.*, 2010). International collaborations will be successful when primary data from the local institutes will be analyzed in sufficient scientific way. Moreover, agricultural lands' biodiversity directly depends on the land use peculiarities. Soil fertility and land value elements comprise of current and former biodiversity (more than 6 000 species of plants, around 100 species of mammals, 180 species of birds and thousands of species of insects and other invertebrates),

[28] The Kyoto Protocol is an international treaty which extends the 1992 United Nations Framework Convention on Climate Change (UNFCCC) that commits State Parties to reduce greenhouse gas emissions, based on the scientific consensus that (a) global warming is occurring and (b) it is extremely likely that human-made CO2 emissions have predominantly caused it.

which also influence on carbon pools and biomass. This fact is forgotten by society and is not taken into account either by political and administrative decisions in regards to the Russian agricultural lands or while current use practices (Smelansky *et al.,* 2003).

Conclusions

The measuring of carbon and biomass is important in sense of eco-system dynamics and proper management implementations. Several models can provide such data and predict future scenarios. MODIS data showed a difference in biomass across the mixed types of forests in Russia (non-forests, open forests, young forests, and old forests). The maps of forest biomass described by this method will help to construct estimation of carbon emissions connected to changes in the land use, fire disturbances and changes in permanent frost period. However, better understanding of influence of disturbances on biomass and carbon can be assumed by UVAFME model, which tracks individual trees. This model is based on the FAREAST, which gives an opportunity to predict and analyze management influence on the aboveground carbon storage.

Sources and sinks of carbon are the outcome of movements in biomass volume (carbon stocks), which can be better measured by changes in carbon stocks directly, than by observing transitions across an arbitrary threshold of forest–non-forest. With the same trends towards climate change conditions, being the same one can say with a rather high degree of certainty that this accumulation is practically irreversible and unlimited in time. The adaptation measures to the climate change and loses in carbon stock are creation of proper managed forest condition even when if these forests is highly unlikely given the economic importance of wood harvest. The State have to allocate funds on the bases of *Green economy* policy implementation for that purpose. In fact, the regulation norms in land use and management proposed by government is weak, despite the formal compliance with extraordinary strict lands accounting and extremely complicated permission granting procedure required for introducing changes in the way of land use. It is important to underline that Russia has a rich biodiversity and natural resources, but still formal institutions are week because of gaps in knowledge. Hence, the third adaptation measure is collaboration initiatives on the regional, national and International levels by civil, private and public sectors. Further development of international Educational and Cooperative Programmes with neighboring countries on issues of land use, tools of carbon, and biodiversity conservation remain an important measure.

Abstract

Indian strawberry (*Duchesnea indica* (Jacks.) Focke) comes from subcontinent of India and south China. It is unknown when exactly this species has arrived on our soil. The analyzed population of Indian strawberry from a forest garden in Banja Luka is relatively old. It was brought from Syria in the middle of the last century. Despite the fact that this species is considered invasive, its micro-population in this forest garden has not expands.

Indian strawberry is classified into strawberries, although in terms of the systematic it does not belong to the genus *Fragaria*, but to the genera *Duchesnea* or *Potentilla*. From the common forest strawberry (*Fragaria vesca L.*) it is distinguished by yellow flowers, top-fruits, which are almost tasteless and odourless, while the flowers of the forest strawberry are white, the fruits slightly hanging, sweet and fragrant.

Regarding the chemical composition, the content of dry matter (14.35 g/100g), total content of sugar (4.26 g/100g), vitamin C (5.96 mg/100g), total acidity (expressed as the content of citric acid) (0.25 g/100g) have been analyzed. Also, the content of some mineral elements in Indian strawberry have been determined, with following results: sodium (5.3 mg/100g), potassium (152.4 mg/100g), magnesium (17.7 mg/100g), calcium (26.6 mg/100g), iron (0.72 mg/100g), phosphorus (27.6 mg/100g), zinc (0.22 mg/100g), manganese (0.32 mg/100g), copper (0.06 mg/100g), selenium (0.16 μg/100g) and chrome (2.1 μg/100g). Content of total phenolic (4.985±0.204 mg GEA/g_{FW}), flavonoids (2.124±0.183 mg Qc/g_{FW}), flavonols (0.518±0.03 mg Qc/g_{FW}), total anthocyanins (1.274±0.001 mg/g_{FW}) and monomeric anthocyanins (1.05±0.08 mg/g_{FW}) have been determined as well. The results obtained for Indian strawberry are compared with the content of these components in other strawberries.

Key words: *Indian strawberry, chemical composition, mineral composition, antioxidant activity*

Introduction

A number of scientific names have been attributed to the Indian strawberry plant species. The first name of *Fragaria indica* was given by Andrews in 1807. In 1811, Smith extracted a new genus of *Duchesnea* from the *Fragaria* genus. This motivated Teschmscher to give the species the name *Duchesnea fragiformis*. This name was not widely accepted in the scientific community. Focke in 1888 introduced new name, *Duchesnea indica*. In 1904, Wolf included this species to the genus *Potentilla* and named it *Potentilla indica* (Ertter et al., 2015).

Duchesnea indica is a native species in southern China and the Indian subcontinent. All parts of this plant have been found in Chinese medicine for anti-cancer drug production. It is used to reduce swelling, also for skin treatment such as abscesses, eczema and ringworm, infections such as laryngitis and tonsillitis, as well as snake and insect bites, under Chinese species and drug name "*she mei*" (Umesh & Thoppil, 2014). The exact time when the species is brought to Europe and our regions is not known. In the flora of the former Yugoslavia, the

species was the first time mentioned by Trinajstic (1973), who found it in the village of Turcin in the vicinity of the city Varazdin (today in Croatia).
Although named strawberry, it does not belong to the genus *Fragaria*, but is classified in the genera *Duchesnea* or *Potentilla*. It is distinguished from the common wild strawberry by yellow flowers, topped fruits (Fig. 1 & 2), which are almost without flavour and odour, while the flowers of the wild (forest) strawberry (*Fragaria vesca* L.) are white, the fruits are slightly hanging, sweet and fragrant. The observed population of Indian strawberry in the city of Banja Luka is relatively old. It was brought from Syria in the middle of the last century. Even though this species is considered as a rather invasive, the footprint of its mico-population remained unchanged from the moment of introduction until today.

Figures 1 & 2: Flower and fruit of Indian strawberry (Photo: S. Ljubojevic)

Material and Methods

Fresh fruits of the Indian strawberry were collected in the summer of 2017. To determine the chemical composition of the components, the fruits are washed, cut into chops, chopped and homogenized in an stainless steel rotating knife homogenizer according to Vasilisin et al. (2015, 2016, 2017). Certain components of the chemical composition were determined by standard AOAC methods (AOAC, 2000). For each component of the chemical composition three parallel analyzes were performed, and the results are expressed as mean values. For the purposes of determining total and monomeric anthocyanins, 20g of the sample was extracted with 20 mL of anthocyanin extraction solution (85 mL of 95% ethanol solution and 15 mL of 1.5 mol/l HCl solution) at 24°C for 24 hours (Kukric et al. 2018), after standing, the resulting mixture was filtered through a paper filter and the filtrate was used for further analysis. The content of total phenols was determined by the modified Folin-Ciocalte method (Wolfe et al., 2003). As a standard compound, gallic acid was used and the results were expressed as equivalents of equivalent galenic acid (GAE), i.e. mg GAE/g_{FW}. Total flavonoids were determined by Kumaran method (Kumaran & Karunakaran, 2007), and the total flavonols by Ordonez method (Ordonez et al., 2006). Quercetin was used as the standard compound, and the results were expressed as mg quercetin (Qc)/g_{FW}. Antioxidant activity against the DPPH radical was determined by the Liyana-Pathiranana and Shahidi method (Liyana-Pathiranana & Shahidi, 2005), and for the ABTS radical the modified method of Re and associates was used (Re et al., 1999). As a standard compound, Trolox was used. The results were presented with the TEAC value (Trolox equivalent antioxidant activity), i.e. as μg Trolox-a/g_{FW}. Total and monomeric anthocyanins were determined by spectrophotometrically modified "*single*" pH and pH differential method (Sun et al., 2002). Experiments were made in three parallel repetitions, and the results are expressed as the mean ± standard deviation.

Plant material samples were manually cut and homogenized for digestion. After preparation samples are burned in a mixture of concentrated acids (nitrogen and perchloric acid) in the digestion thermoblock according to the prescribed temperature regime. After digestion, the solutes were filtered in 50 mL dilution flask, diluted with deionized water, with conductivity of 0.056 μS/cm and stored for analysis of mineral substances. Each sample was prepared in duplicate.

The obtained solutions were used to determine the concentration of the analyzed elements (Na, K, Ca, Mg, P, Fe, Mn, Cu, Zn, Se, Mo, Ni, Cd, Pb). Containers and equipment, used during ICP OES analysis, are made of plastic or stainless steel. Before contact with plant samples, dishes and equipment were washed with distilled water, then with 2% nitrogen solution and finally deionized water (0.056μS/cm). Nitrogen and argon used during analysis had a purity of 5.0 (99.999%).

Optical Emission Spectrophotometer (ICP OES) was used to determine the mineral content of samples of Indian strawberry *Duchesnea indica*. The sample solutions were pumped by a peristaltic pump from tubes arranged on a Perkin Elmer auto-sampler model 510. Certificate reference standard solution, instrument calibration standard , with concentration of elements 100 mg/L was used for calibration of spectrophotometer. The concentrations of the elements for the calibration direction were different, determined according to preliminary measurements for the specified metals (Vucic et al., 2018).

Linearity was performed by analysis of standard solutions. 20 standard solutions of five concentration levels depending on the analyse were determined. Limit of determination and quantification was performed by analysis of blanks. At least 21 blank samples after correction for typical sample weight were determined. Different concentration of CRM solution was analyzed as check on the accuracy of the analyzers. The LOD values (limit of detection) and LOQ values (limit of quantification) was calculated as 3 times and 10 times of STD (standard deviation) of the ten measured blank signals. The achieved results were compared with the values for the wild (forest) strawberry (*Fragaria vesca*) and for the cultivated (commercial) strawberries, which are cultivars (cultivated varieties) of *Fragaria* × *ananassa* Duch (Savic et al., 2007; Hossain et al., 2016; USDA, 2018).

Results and Discussion

The content of individual components of the chemical composition in fresh fruits of Indian strawberriy *Duchesnea indica* and their comparison with the literature data is presented in Table 1.

Table 1. Chemical composition of *Duchesnea indica*

	Duchesnea indica	*Fragaria ananassa*[*]	*Fragaria vesca*[**]	Strawberry raw in USA[***]
Dry matter (%)	14.35	7.81	19.98	9.15
Total sugars (%)	4.26	4.45	6.26	4.89
Total organic acids (like citric acid. %)	0.25	-	1.64	-
Vitamin C mg/100g	5.96	26.46	75.80	58.80

[*](Hossain et al., 2016); [**](Savic et al., 2007); [***](USDA,2018)

The content of dry matter in the Indian strawberries *Duchesnea indica* is higher than in cultivated strawberries, other strawberries, but lower in comparison with wild strawberry *Fragaria vesca*. The content of total sugars in Indian strawberry is approximately the same as for other strawberry species, while the content of vitamin C is considerably lower.

The total acidity expressed as citric acid in the Indian strawberry is almost seven times lower than in wild strawberries. Table 2 shows the results of measurements of secondary metabolic content and antioxidant activity of *Duchesnea indica*.

Table 2. Content of secondary metabolites and antioxidant activity of *Duchesnea indica*

Analyzed parameters	*Duchesnea indica*
Total phenolics mgGEA/g_{FW}	4.985±0.204
Flavonoids mgQc/g_{FW}	2.124±0.183
Flavonols mgQc/g_{FW}	0.518±0.003
Total antocyanins mg/g_{FW}	1.274±0.001
Monomeric antocyanins mg/g_{FW}	1.05±0.008
DPPH (IC_{50})* µg Trolox/mg_{FW}	2.32±0.027
ABTS (IC_{50})* µg Trolox/mg_{FW}	0.506±0.007

*IC_{50}-concentracion for 50% inhibition of DPPH radicals

The content of total phenolic in the Indian strawberry was significantly higher than the literature data for different strawberry varieties, ranging from 96-236 mg GEA/ 100g_{FW} (Toronnen & Maatta, 2002; Voca et al., 2008). The flavonoid and flavonol content according to literature data for different strawberry varieties ranges from 176-335 µgQc/g_{FW} (Kukric et al., 2016). Accordingly it can be stated that the amount of flavone and flavonoids in Indian strawberry is higher than other strawberry varieties. The content of total and monomeric anthocyanins is also several times higher compared to the literature data (Kukric et al., 2016). Results in Table 2 presents that the antioxidant activity of Indian strawberry is considerably higher in compared to literature sources. According to literature data, the antioxidant activity against the DPPH radical for different strain varieties was 6.11 mmolTrolox/kg_{FW} (Jakobek, 2007), 9.7 mmolTrolox/kg_{FW} (Hartman et al., 2008) and 8.29-11.15 mmolTrolox / kg_{FW} (Dragovic-Uzelac et al., 2007). Literature values for antioxidant activity against a stable ABTS radical were 9.70 mmolTrolox/kg_{FW} (Jakobek et al., 2007), 12.08 mmolTrolox/kg_{FW} (Hartman et al., 2008) and 26.92-30.06 mmolTrolox/kg_{FW} (Dragovic-Uzelac et al., 2007). Disclosed in Table 2, antioxidant activity values for a stable ABTS radical in Indian strawberry are higher than those of literature.

The mineral composition of Indian strawberry is presented in Table 3. In addition to certain macro and microelements, toxic metal concentrations (Pb, Cd, As) were also measured. Estimated toxic elements were below the detection level (LOD) and were labelled with ND (not detected). From the tables above, it is evident that the results, for virtually all metals, with the exception of Fe (0.72 mg/100g), are significantly different from the literary allegations. According to research by Ozean & Haciseferogullari (2007), the content of Fe in the strawberry varieties surveyed was around 1.22 mg/100g, while Serce et al. (2016) reported the Fe content of 0.264 mg/100g. The content of Ca (26.6 mg/100) is considerably lower than the literary allegations of some authors. Ozean & Haciseferogullari (2007) and Serce et al. (2016) were determinate values for calcium in strawberries of 459.2 to 4202 mg/100g respectively.

Table 3. Mineral content of *Duchesnea indica* in comparison with some other strawberry varieties (literary citations)

Mineral content			**Literature sources**					
Minerals	Content (mg/100g)	Mineral content in *Duchesnea indica*	Content (mg/100g)	Ozean& Haciseferogullari (2007)	Content (mg/100g)	Serce et al. (2016)	Content (mg/100g)	Vanessa Rios de Souza et al.(2014)
Al	-		2.011		-		-	
As	ND		1.06		-		-	
Ca	26.6		459.2		420.2		2.20

P	27.6		366.9		646		6.59	
Pb	ND		0.051		-		-	
Zn	0.22		0.82		0.153		0.13	
Se (µg/100g)	0.16		-		-		-	

Conclusions

The content of individual components of the chemical composition of Indian strawberry *Duchesnea indica* is approximately the same as in other strawberries species. The exception is the content of vitamin C, which is considerably lower than. Antioxidant activity in Indian strawberries is considerably higher than in other species. These facts clarify the usage of *Duchesnea indica* in Chinese traditional medicine for cancer treatment. Toxic elements have not been detected in the analyzed samples. The content of certain macroelements is significantly lower compared with literature data.

Abstract

In Serbia, there are 10 native species of oaks, of which three species in the sessile oak aggregate hold a significant position: Central European sessile oak (*Quercus petraea* /Matt./Libl.), Balkan sessile oak (*Quercus dalechampii* Ten.) and cluster-fruited oak (*Quercus polycarpa* Schur.) Sessile oak in Serbia makes 13 different associations and numerous sub-associations on different bedrocks which is manifested by the great phyto-coeno-diversity of this species. This paper deals with sessile oak variability and breeding in Serbia. Thanks to a great heterogeneity of site conditions of this polymorphic oak species, there is a significant intra- and inter-provenance variation of morphological and physiological properties. The research of sessile oak genetic variation by molecular markers, cp DNA, mt DNA and micro-satellite methods, point to the need for further analyses of sessile oak genetics diversity. These results will be practically applicable in the identification and selection of seed stands with the best-quality autochthonous populations, with the suitable desirable quantitative and qualitative characteristics. Further efforts on breeding of this polymorphic and polyvalent species, require the application of the methods of mass and individual selection, by which the already registered seed forests will be revised, the new ones will be selected and test trees will be selected in all regions of sessile oak native range. In this way, a wide sessile oak genetic potential will be archived in the established seed orchards and progeny tests.

Key words: *sessile oak, conservation, management, Serbia*

Introduction

In the last 13 thousand years, *Quercus* L. species have been undergoing constant dynamic shifts caused by dramatic climate change, *i.e.* migrations of its populations in the south of Europe towards central, western, and Eastern Europe. Previous studies of the dynamics and directions of these migrations were based on the analysis of fossil pollen. Recent research studies have been using methods of molecular genetics with chloroplast (cp) DNA, mitochondrial (mt) DNA and microsatellites to confirm and complete data on the postglacial migration of oaks and the specificities of their populations. The research of Petit *et al*., 1993, Petit *et al*., 2002 confirmed earlier assumptions on the differentiation of the haplotype variability of oaks caused by the shifts in the range of distribution of species belonging to *Quercus* L. towards central and northern Europe following the last Ice Age.

Of numerous botanical synonyms for sessile oak, the best-known ones are *Quercus sessilis* Ehrh.1789 and *Quercus sessiliflora* Salisb. 1796. This species includes a large number of subspecies since natural habitats of sessile oak are quite heterogeneous in terms of climatic and edaphic conditions while the established populations have different gene pools. Comparative morphological and physiological analyses of the sessile oak variability, as well as the statistical analysis of the habitats of autochthonous sessile oak and related oaks, have shown that *Quercus petraea* Liebl is an aggregate of several species. The differences between the species of *Quercus petraea* agg, namely between the sessile oak /*Quercus petraea*/, Transylvanian sessile oak /*Quercus polycarpa* Schur/ and Balkan sessile oak /*Q.dalchampii* Ten/ have been determined for the habitus, bark, leaves – hairy underside and fruit – the shape

and the color of stipules on the cupules. The genetic bases of the differences between the species that form the aggregate have not been sufficiently studied and defined. These studies have been greatly hampered by a large number of spontaneously formed hybrids, as well as their backcross with each other and with parental species. Further application of molecular studies with cpDNA, mtDNA, microsatellitec, *etc*., will help define species, intraspecific differences and hybrid characteristics more precisely.

In order to achieve closer determination and targeted use of intra- and inter-population variability of sessile oak, provenance tests have been established and analyzed in several European countries. These tests are experimental polygons in which the methods of tree improvement are used to study the effects of the interaction between the ecological and the genetic components on the extent of variation of phenotypic properties of vegetative and generative organs of the sessile oak. However, morphological traits are highly susceptible to the influence of changing environmental conditions, thereby reducing the expression of the genotype itself. More accurate studies of the genetic variability of sessile oak of different provenances involve molecular genetics methods with the use of molecular (genetic) markers, which considerably reduce the effects of environmental factors, and thus the variability that is primarily and directly under genetic control can be observed. It has been determined the shape and the straightness of the stem are the properties strongly controlled by genetics, which can be significantly improved by applying special tree improvement programes. The study of the morphological variability included several quantitative parameters, while the molecular variability included chloroplast DNA and microsatellites, Jan Svejgaard Jensen (2000), Bruschi, P. *et al*., 2003, Graham M *et al*., 2004. The results of the conducted analyses point to significant genetic variability between the studied populations. However, the scope of the variation of morphological properties was not completely confirmed at the level of microsatellite differentiation. The relatively high genetic diversity in the studied populations of sessile oak suggests that their evolutionary potential can be preserved if the size of the population is maintained or increased with time. The results of the conducted analyses have shown that these populations have very pronounced genetic variability which is similar to that found in most European countries despite the facts that sessile oak forests occur only in refugia and that they suffered severe destruction in the past. In addition, the present genetic structure of sessile oak forests does not show any undesirable founder effects.

A programe for the protection and targeted use of sessile oak in Serbia

The results of the analyses carried out in the provenance and progeny tests indicate that sessile oak is an extremely variable species. The differences were observed in the tree growth stem formation and in the attacks of mildew and insects. Furthermore, biochemical studies of the fruit of different provenances revealed significant differences in the content of agglutinin, which could contribute to an easier identification of oak provenances, Jovanović and Tucović, 1973, 1975. Apart from the inter-provenance differences, there are significant differences within provenances, *i.e.* within individual stands in terms of the height increment, onset of certain phenophases, crown shape, branching, trunk characteristics, morphometric properties of the acorn, *etc*. (Figure 1). Within a natural sessile oak stand, trees clearly differentiate into the following phenotypes: monopodial, forked and broomed.

Figure 1. Acorn from different trees from seed stand 02.02.02.07 in MU «Cer-Vidojevica», 186b

The progeny tests revealed that the phenotypic characteristics of the trees and the acorn were under significant genetic control. The literature on dendrology contains extensive data on the distribution of spontaneous hybrids of: *Quercus petraea* and *Quercus robur*; *Quercus petraea* and *Q. dalechampii*; *Quercus petraea* and *Q.polycarpa*, described under different names. The hybrid progeny of these parental species is characterized by extreme variability of quantitative and qualitative characters. The great variability of morphological and physiological characters of spontaneous hybrids causes great difficulties in the taxonomic, sociological and ecological research of species belonging to the genus of *Quercus*, as well as in the organization and realization of the production of raw materials for the needs of forest seed and seedling production.

New program for the establishment of sessile oak provenance tests in Serbia include: (a) the selection of provenances to be tested, (b) the locations where the tests will be set up, and (c) the selection of control provenance(s). The implementation of this program is based on the past and future activities, such as:

- study of climatic and edaphic similarities and differences between the areas belonging to the belt of sessile oak forests in the selected regions of Serbia;
- carrying out biological and economic analyses of sessile oak forest communities, especially those where it is the dominant species, regardless of the status and degree of the site and (or) stand degradation;
- application of the methods of classical and molecular genetics to determine and measure genetic variability within and/or between sessile oak provenances, populations and genotypes;
- application of mass and individual selection to quantitative and qualitative characters within natural sessile oak populations;
- permanent monitoring of the sessile oak reproduction cycle at population and individual levels in order to gain a deeper insight into gene-environment interactions that affect the frequency, abundance and quality of seed production;
- securing abundant seed crop and production of seedlings of half and full-sib lines, scions, cuttings and rooted cuttings with the aim of increasing the number of experimental and productive seed orchards of sessile oak.

Further long-term research within the framework of sessile oak provenance tests will provide a higher degree of genetic determination of the production potential of certain provenances, *i.e.* accurate information on the characteristics and variability of sessile oak within and between the selected provenances in the network of experimental objects in Serbia. By gaining an insight into the genetic potential and degree of determination of the adaptability, productivity and quality of different sessile oak populations, we will obtain the basis for the zonation of seed stands on the basis of gene-environment characteristics. Investigations conducted within the network of provenance tests play an important role in the forest

profession because they facilitate the selection of provenances or groups of provenances suitable for specific sites. The selection and cultivation of the reproductive material of sessile oak from the provenances in which the range of variation in the adaptability and production capacity is determined will help accomplish the established objectives by carrying out the planned works in the areas with defined general ecological and production characteristics Isajev et all. (2005, 2006).

Further improvement of the sessile oak in Serbia is based on individual level by selection of test trees in seed stands of this species. There are nine seed stands of sessile oak in Serbia, Table 1, and ninety test trees have been selected – ten in every seed stand.

The variability of the continuous and discontinuous traits of test («plus») - seed trees is analyzed based on the variability of several characters

- leaf phenophase;
- good growth;
- good trunk and crown shape;
- absence of spiral grain;
- straight and monopodial trunk;
- slight tendency towards the formation of water sprouts;
- frost resistance;
- resistance to diseases and pests;

The results of the analysis will direct further work towards the selection of the best sessile oak genotypes so that a certain genetic improvement can be expected in the next generation. If the parent population has a poor phenotype, *i.e.* if there is a high percentage of minus trees and a small or insufficient percentage of above-average or plus trees, this tree improvement method cannot yield positive results. If the work is directed towards the production of new species and hybrids of sessile oak, the improvement will last longer, but it will produce a higher genetic gain.

The Program for the establishment of sessile oak seed orchards in Serbia

In addition to preserving, testing and directed use of the genetic potential of sessile oak in natural populations in different sites, the establishment of purposeful orchards - seed orchards of this species, will create conditions for:

- the improved production of selected seed;
- checking the combining ability and the heritability of the selected test trees;
- determining the value of the potential variability of sessile oak within the same and different provenance regions;
- biodiversity testing and preservation;
- production of prospective hybrids.
-

Seed orchards and pilot objects, as specialized cultures, not only contribute to the translation of the potential genetic variability into the free variability, which is the basis for the targeted use of the sessile oak gene pool, but also create polygons for testing and preservationing its biodiversity. Starting from the floristic, genetic and production potential of sessile oak, it is not possible to establish seed orchards of this species using the same model.

Different models of clonal and generative seed sessile oak orchards will ensure a more reliable determination and targeted use of heritability and combining ability of the selected genotypes of sessile oak. The quality and regularity of the seed crop in clonal seed orchards are primarily determined by the genetic potential of vegetative copies - ramets – of selected genotypes and ecological characteristics of the sites where they are established. The selection of genotypes to be incorporated into seed orchards should be preceded by long-term analyses of the degree of genetic control of their reproductive functionality and the variation of properties, Isajev *et al*., 2012. The application of controlled hybridization and the testing of the obtained hybrids through progeny tests will determine the heritability of characters from parents to hybrids. This procedure will determine potentially valuable genotypes which should be cloned to be incorporated into the seed orchard.

The selection of parents, *i.e.* their combinations, with good general and specific combining ability and heritability, is the starting point for the establishment of clonal seed orchards for the production of intraspecific hybrids of sessile oak. Which of the genetic compositions of the hybrids obtained will be the focus of further interest will primarily depend on the biotechnical conditions for which the reproductive material is produced and on the market demands. These factors must be taken into account in the future mass production of seed, which means that the type of genotype we want to create should be clearly determined in the initial stages of work. Multiline sessile oak varieties to be obtained as a result of controlled hybridization and the composition of the seed orchard should provide higher yield stability and adaptability.

Further work on the conservation and targeted use of sessile oak in Serbia

In Serbia, forest phytocoenoses of sessile oak belong to *Quercion petraeae-cerris* Lakš- et Jov. 1980. association, in which there are pure and mixed communities Table 2.

Table 2. Main sessile oak communities in Serbia, according to Tomić Z 2004

Sessile oak and Turkey oak forests	-	***Quercetum patreaeae-ceris* Jov. 1979**.
Hop-hornbeam and sessile oak forests	-	***Helleboro – Ostryo-Quercetum* Tom.1980.**
Pure sessile oak forests	-	***Qurecetum montanum* Čer.et Jov. 1953.s.l.**

Forests of sessile oak with Oriental hornbeam	-	***Carpino orientalis – Qurcetum montanum* Jov. 1979.**
Forests of sessile oak with flowering ash	-	***Orno-Quercetum petraeae* Miš. 1972.**
Forests of Transylvanian sessile oak	-	***Poa nemoralis – Qurcetum polycarpae* Jov. 1979.**

General environmental characteristics of the areas in Serbia where pure and (or) mixed populations of sessile oak spontaneously occur in interaction with their gene pool have caused expressed variability in a large number of its morphological and genetic-physiological traits. Considering the fact that *Quercus petraea* is characterized by great individual and group variability and includes plethora of intraspecific taxa - varieties, biotypes and ecotypes, this calls for a multidisciplinary and complex approach to its further improvement. Protection and targeted use of the most valuable genetic resources of sessile oak will be mostly realized: ***in situ*** – by selecting the best natural sessile oak populations and revising the existing ones as well as establishing new seed stands, groups and individual trees, and ***ex situ*** – by establishing provenance tests, live archives, clonal and generative seed orchards.

According to the needs of the forestry profession and the state of its forests, further work on the improvement of sessile oak trees in Serbia should be carried out in two directions. It is necessary to continue and modernise activities aimed at improving the stability, productivity and genetic richness of natural sessile oak populations, and then to intensify improvement methods in order to obtain new selected genotypes and hybrids that will be better according to the values of target characteristics. In the first stage of work which is based on the application of the mass selection method, it is necessary to revise the selected seed populations of sessile oak and, if necessary, to determine the new ones in order to cover its vertical and horizontal distribution in Serbia. Using the method of individual selection, a large number of test trees should be continually specified in the selected populations. Subpopulations, or provenances from Serbia, should be tested in a network of provenance field experiments. Selection of genotypes - test trees - should be done in all the regions of sessile oak provenances in order to get a deeper insight into its ecological, sociological and genetic diversity. Further research work in specialized plantations and seed orchards of second and subsequent generations should create conditions for long-term production of sessile oak variety seed.

Conclusions

Thanks to a great heterogeneity of site conditions in sessile oak natural forests in Serbia there is a significant intra- and inter-provenance variation of morphological and physiological properties within populations of this species. The comparative analyses of provenance tests performed in several West European countries point to a rich gene pool of sessile oak, resulting from the action of complex genetic factors, ecological factors and different management procedures in sessile oak natural forests. The research of sessile oak genetic variation by molecular markers, cp DNA, mt DNA and micro-satellite methods, point to the need of future analyses of sessile oak genetic diversity. These results will be practically

applicable in the identification and selection of seed stands with the best-quality autochthonous populations, with the suitable, desirable quantitative and qualitative characteristics. Further efforts on breeding of this polymorphic and polyvalent species, taking into account the current states of its forests and the need for increasing the areas under this species, require the application of the methods of mass and individual selection, by which the already registered seed forests will be revised, the new ones will be selected and test trees will be selected in all regions of sessile oak native range, In this way, a wide sessile oak genetic potential will be archived in the established seed orchards and progeny tests.

Abstract

The aim of this study was to determine the chemical composition, nutritional value and antioxidant properties of three crabapples: *Malus* `Pink Perfection` *Malus* `Royalti` and *Malus* x *zumi* `Golden Hornet`, with distinctive appearance characteristics. Subjects of the analysis were fresh fruits and juice obtained from the last one by steam extractor. Crabapples were taken from an urban garden. Chemical analysis includes the following parameters: macro- and microelements (As, Ca, Cu, Fe, K, Mg, Mn, N, Na, P, Se, Zn), water, dry matter, ash, proteins, sugars, total acidity, pectin, minerals, pH, vitamin C, anthocyanins, phenolic compounds, nonflavonoids, flavonols and free radical scavenging capacity (applying DPPH and ABTS tests). Basic phenotypic and morphometric characteristics of the fruits were observed as well. Results obtained from the research have shown that *M.* 'Pink Prefection' and *M.* x *zumi* 'Golden Hornet' have a fairly similar chemical composition. *M.* `Royalti contains significantly more vitamin C and a little more sugar, but is also poorer in pectin and has much greater acidity. Compared to commercial apples, crabapples do not lag behind in sugar content, but they have significantly higher acidity and half the amount of vitamins C. The elemental composition of crabapples is also fairly uniform. When it comes to phytochemicals, *M.* 'Royalti is particularly prominent by the high content of anthocyanins, flavonols and phenols. The ABTS test showed that *M.* x *zumi* 'Golden Hornet' has the strongest antioxidant capacity. We have reached the same result by applying the DPPH method.

Key words: *crabapples, chemical composition, nutritional value, antioxidant properties*

Introduction

Crabapple is rather loosely defined term in a different connotation. Its origin was believed to come from Scandinavia at the beginning of the 18th century, with meaning - "fruit of the wild apple tree" (Anon., 2017). Jefferson (1970) indicates that any tree or shrub of genus *Malus* whose fruit diameter does not exceed 5.2 cm (2 inches), whether it is ornamental or economical plant implies under crabapple. From our point of view this term implies decorative (horticultural) apples, which are introduced into urban and peri-urban gardens and other horticultural facilities primarily due to their aesthetic values: the color of leaves, flowers and fruits, the abundance and duration of flowering, the abundance of fruiting and prolonged fruits retention. These characteristics do not exclude or neglect their other useful properties, such as: pollinizers in apple orchards, raw materials for the production of vinegar, jams, juices, then rootstocks in the production of grafted seedlings, bonsai cultures, etc., not to forget their role as a habitat and a shelter for wildlife, especially birds.

About the names of crabapples there are certain dilemmas and doubts, most often when it comes to the categories hybrid and cultivar. The assignment of names within the first category is governed by the International Code of Nomenclature for algae fungi and plants (earlier International Code of Botanical Nomenclature) and within the second category through the

International Code of Nomenclature for Cultivated Plants. According to Jefferson (1970), referring to Wyman (1955), cit.: "Crab apples hybridize very freely, and because of this, much controversy has resulted in their proper identification. Seed has been gathered in large collections, grown and seedlings were named after the trees from which the seed was collected. Frequently, such seed has produced plants with totally different characteristics from the parent plant, and once this has become evident, it has caused much confusion." The native (indigenous) apple in Europe is considered a wild (forest) apple *Malus sylvestris* (L.) Mill., although many orchard apples actually derived from Asian apple *M. pumila* (Mabberley *et al*., 2001). This paper analyzes the chemical composition, the nutritional value and the antioxidant properties of three taxa of crabapples, one hybrid and two cultivars. The obtained results were compared with the values of the most common sort of apple (*Malus domestica* Borkh.) in South East Serbia: `Fuji` (hybrid), `Golden Delicious` (cultivar), `Granny Smith` (cultivar), `Idared` (cultivar) and `Mutsu` (cultivar), presented by Stojanović (2014); it is undivided opinion that apples are delicious and nutritous fruits, which, in addition, possess a high antioxidative capacity (Lotito *et* Frei, 2004). Morphometric parameters of the fruit, such as diameter and weight (*id est* mass), are also measured.

Material and method

Material

The subject of our research are three taxa of crabapples that grow in an urban garden in the city of Banja Luka in Bosnia and Herzegovina. These are two cultivated varieties: *Malus* `Pink Perfection` and *Malus* `Royalty`, and hybrid cultivar *Malus* x *zumi* `Golden Hornet`. The trees were purchased from garden center "Flora" in Busovača (B & H), previously imported from Italy. At the time of planting, in the spring of 2013, each tree was five years old. Material for analysis was collected during year 2017.

Malus 'Pink Perfection' was selected by W. Flemer, III, 1960, at Princeton Nurseries, USA. Seed was taken from *Malus* 'Katherine' and the male parent was *Malus* 'Almey' (Hebb, 1970). The main characteristic of this crabapple is blossom. It is made of clusters of lightly fragrant, double, light pink and white flowers (Fig. 1). Fruits from this apple also have a beautiful appearance and may be used in nutrition (Fig. 2). Research by Matsumoto *et al*. (2015) have shown that *Malus* 'Pink Perfection' is among the most superior pollinators and can be a useful pollinator for all domestic cultivars.

Malus 'Royalty' was selected by W. L. Kerr in 1958 in Canada (Saskatchewan), using a large number of open pollinated rosy bloom seedlings he found growing there. As a rootstock he used wild apples of small fruits - *M. baccata* (L.) Borkh. Crabapple *M*. 'Royalty' is recognizable by the purple-red pigmentation of foliage, flowers and fruits (Fig. 3 & 4), and was the first crabapple with this feature, which was until then unique to plums. Purple pigmentation comes from the presence of anthocyanins. These compounds are powerful antioxidants in vitro, and are

Figures 1 & 2: *M.* 'Pink Perfection' in blossom and fruits (photo: S. Ljubojević)

widely believed to contribute to human health (Van Nocker *et al*., 2012). However, due to very low mass and hardness, the fruits are not yet used in the nutrition.
Malus x *zumi* 'Golden Hornet' originates from the United Kingdom, created in the first half of the 20th century. It is thought to be a natural cross hybrid between two other crabapple species, *Malus sieboldii calocarpa* and *Malus prunifolia coccinea*. Its main characteristic is lush pink-white flowers, also from which numerous butter yellow fruits occur, which remain on the tree for long (Fig. 5). The leaves also turn yellow and become attractive in autumn. Unlike the previous taxon, the fruits are used in culinary art, preparation of jams and jellies, juices and vinegar.

Figures 3 & 4: Flowers and fruits of *M.* 'Royalty' (photo: S. LJubojević)

Figure 5: Fruits of x *zumi* 'Golden Hornet' (photo: S. LJubojević)

Thus, all three observed trees are of the same age and grow under the same agro-environmental regime. This prevents bias in terms of fruit acidity and some other features, considering that many agronomic studies have shown the impact of cultural practices on these characteristics (Etienne *et al*., 2013).

Method

Fresh samples of crabapples were collected at the moment of optimal ripeness. This stage was visually evaluated on the basis of daily monitoring. The harvest was carried out at the time when participation of the immature or overripe fruits compared to mature ones, was minimal. Namely, it has been known for a long time that the total acid content of apples is directly related to the ripening processes (Nybom, 1959). In addition to fresh fruits, a sample of *Malus* x *zum* 'Golden Hornet' juice was taken, using a steam extractor, simple household utensil, without any additives (sugar, preservatives, etc.).

Before harvesting and homogenization on the mill "Triple Spindle Mixer, Hamilton Beach", according to Vasilišin *et al*. (2017), the seeds were extracted from the fruits. It is known that seeds of crabapples contain trace amounts of amygdalin, which is under stomach acid transformed into toxic compound. At the same time, it is known that apple seed is a rich source of selenium, which is an antioxidant and important element for enzymatic activity of liver (Stojanović, 2014). From the homogenised material, 5 g of fruits of each taxon was extracted with 80% ethanol, twice at 25 ml. The solutions were refilled with 80 % ethanol up to 50 mL. Thus, 100 mg/mL concentrations were obtained and further used to determine total phenols, flavonoids, flavonols, neutralization of 2.2-diphenyl-1-picrylhydrazyl radical (DPPH) and 2,2'-azinobis (3-ethylbenzothiazoline-6-sulfonic acid) (ABTS +) radicals. To determine a total and monomeric anthocyanins, 20 g of samples was extracted with a 20 mL solution (85 ml of 95 % ethanol solution in 15 ml of 1.5 mol/L HCl solution) at 0^o C for 24 hours. After being left to stand, resulting mixture was filtered through a filter paper, and the filtrates were used for further analysis. The content of dry matter, ash, total acidity and vitamin C were determined by standard AOAC methods (Anon., 2000). Total phenol content was determined by the modified Folin-Ciocalteu method (Wolfe, 2003). Gallic acid was used as the standard compound and the results were expressed as phenol equivalent to gallic acid (GAE), i.e. μg GAE/g_{FW}. The total flavonoids are determined by the method of Kumaran and Karunakaran (Kumaran, 2007), and the total flavonols according to the method of Ordoñez *et al*. (2006). Quercetin was used as the standard compound, and the results were expressed as μg Quercetine (Qc) /g_{FW}. The antioxidant activity in relation to the DPPH radical was determined by the method of Liyana-Pathirana and Shahidi (Liyana-Pathirana, 2005). The modified method of Re *et al*. (1999) was used fot the ABTS radical. The results were presented with the TEAC value (Trolox equivalent of antioxidant activity), i.e. as μg Trolox/g_{FW}. Total and monomeric anthocyanins were determined by the spectrophotometrically modified "single" pH and by the pH differential method. The overall experiments were performed in three parallel repetitions.

Five hundred healthy, undamaged fruits were collected from each taxon. In a random manner 120 fruits were further taken from each set. They are given an average diameter in millimeters, as the mean of two cross-measurements. Also, their weight (mass) was measured with accuracy of 0.01 g. In this way, a better insight into the morphometric characteristics of the observed fruits was obtained.

Results and discussion

The chemical composition of *Malus* 'Pink Prefection' and *M*. x *zumi* 'Golden Hornet' is quite similar (Tab. 1). *M*. 'Royalti' contains considerably more vitamin C and a little more sugars, but is also poorer in pectin and has much higher acidity. The relationship between increased vitamin C concentration and total acidity, among the first was observed by Nybom (1959), in soft apples. However, the same author finds that sometimes sweet fruits have a rather high vitamin C content.

Table 1: Chemical composition of fresh fruit and juice of crabapples

Components	Unit	*M.* 'Pink Prefection'	*M.* 'Royalti '	*M.* x *zumi* 'Golden Hornet'	Crabapple juice
		Mean value			
Invert sugars	%	9.99	11.19	9.17	3.71
Pectin	%	0.48	0.35	0.56	0.43
Proteins	%	0.37	0.37	0.39	-
Total acidity (as malic acid)	%	1.11	2.75	1.12	0.56
Total ash	%	0.48	0.78	0.35	-
Vitamin C (Tillmans)	mg/100 g	2.45	5.94	1.19	2.07
pH		3.28	3.02	3.17	-
Sugar-acid ratio	Invert sugars / Total acidity	9.0	4.33	8.19	6.62

Compared to commercial apples (Campeanu *et al*., 2009; Stojanović, 2014), crabapples do not lag behind sugar content, but they have significantly higher acidity and double less vitamin C (Tab. 2). Difference in malic acid concentration between cultivated and wild apple fruits was also noted by Ma *et al*. (2015). The same source emphasizes that the major components of soluble sugars (fructose, glucose and sucrose) are different between cultivated and wild fruits.

Table 2: Comparative overview of fresh fruits of crabapples and commercial apples

Components	Unit	Crabapples	Comercial apples (Stojanović, 2014)	Statistical differences
		Mean value & range		
Sugars content	%	10.12 (9.17 – 11.19)	10.62 (9.53 – 12.34)	statistically random
Water content	%	78.27 (70.97 – 82.269	83.75 (76.69- 88.37)	statistically random
Vitamin C	mg/100 g	3.19 (2.45 – 5.94)	7.51 (7.19 – 7.89)	statistically significant
Ash content	%	1.61 (0.35 – 0.78)	2.18 (1.63 – 2.77)	statistically significant
Total acidity	%	1.66 (1.11 – 2.75)	0.20 (0.127- 0.345)	statistically highly significant

By variance analysis, a statistically significant difference was found between Ca, P, Mn and Se content in crabapples fruits and juice (Tab. 3). Crabapples on average have significantly lower Na and Fe content compared to the average for five varieties of commercial apples from Southeast Serbia - 11.31 mg / 100 g and 0.41 mg / 100 g, respectively, and slightly lower content of Ca - 87.62 mg / 100 g (Stojanovic, 2014). However, crabapples have significantly higher content of K and Mn compared to orchard apples from Southeast Serbia, where K takes values from 57.25 to 98.23 mg / 100 g, Mn - 0.05 mg / 100 g, then Mg - 6.44 mg / 100,

Cu - 0.09 mg / 100 g and Zn - 0.04 mg / 100 g (Stojanović, 2014). The average selenium content in apple peel is also lower in relation to fresh fruits of crabapples - 0.62 μg / 100g (Stojanović, 2014), taking note that peel is considered as a better source of minerals in comparison to apple flesh.

Table 3: Macro- and microelements in fresh fruits and juice of crabapples

Elements	Unit	*M.* 'Pink Prefection'	*M.* 'Royalti '	*M.* x *zumi* 'Golden Hornet'	Crabapple juice
		Mean value			
Na	mg/100 g	1.15	1.11	1.07	1.07
K	mg/100 g	161.92	161	160.45	160.45
Ca	mg/100 g	8.28	8.27	8.35	10.03
Mg	mg/100 g	10.05	9.99	9.58	9.83
P	mg/100 g	17.02	17.42	17.67	13.42
Fe	mg/100 g	0.21	0.20	0.20	0.19
Cu	mg/100 g	0.11	0.11	0.12	0.09
Mn	mg/100 g	0.39	0.38	0.34	0.46
Zn	mg/100 g	0.13	0.12	0.12	0.10
Se	μg/100g	0.73	0.68	0.62	0.82

When it comes to phytochemicals, *M.* 'Royalti is particularly prominent in the high content of anthocyanins, flavonols and phenols, compared to the other two taxa. The ABTS test showed that the strongest antioxidant capacity has *M.* x *zum*i 'Golden Hornet'. We obtained the same results using the DPPH method (Tab. 4).

Table 4: Phytochemicals and antioxidant activity of fresh fruits and juice of crabapples

Component	Unit	*M.* 'Pink Prefection'	*M.* 'Royalti '	*M.* x *zumi* 'Golden Hornet'	Crabapple juice
		Mean value			
Anthocyanins	mg/L	0.09	2.77	0.04	0.02
Monomeric anthocyanins	mg/L	0.02	2.01	-	-
Flavonols	mgQcE/g	0.65	1.21	0.62	0.24
Phenols	mg GAE /g	7.99	42.46	5.86	4.21
Flavonoids	mgQcE/g	7.39	42.12	5.36	3.74
Nonflavonoids	mgQcE/g	0.60	0.34	0.50	0.47
ABTS	mg Trolox /mL	0.08	0.04	0.13	0.39
DPPH	mg Trolox /mL	0.46	0.18	0.70	1.21

Among the observed crabapples *Malus* x *zumi* 'Golden Hornet' has the largest and heaviest fruits (Tab. 5). An ocular estimation suggests that this apple yields the highest fruit yield per tree, under the same other conditions.

All observed species possess high aesthetic properties (Fig. 1-5) throughout the vegetation period and even afterwards in the first winter months. In this context, the crabapple *M.* x *zumi* 'Golden Hornet' is particularly remarkable, which keeps the fruits many months during the winter and can serve as Christmas or New Year decoration.

Table 5. Morphometric features of crabapple fruit

Crabapple	Diameter (mm)			Weight (g)			$r_{d.w}$
	M	S_x	Range	M	S_x	Range	
*M*alus 'Pink Prefection'	22.87	± 2.23	14 - 33	7.03	± 1.23	4.8 – 9.5	0.54
Malus 'Royalti'	17.19	± 1.58	14 - 20	2.97	± 0.67	1.7 – 4.5	0.82
Malus x *zumi* 'Golden Hornet'	24.92	± 3.17	15 - 30	9.06	± 2.00	3.4 – 13.8	0.52

Conclusions

The analyzed crabapples have a fairly similar chemical composition, with *M.* 'Royalti' predominating in the vitamin C content and hold a slightly higher sugar content but are also poorer in pectin content and contain much greater acidity.

Compared to commercial apples, crabapples do not lag behind in sugar content but are inferior to vitamin C and have significantly higher acidity.

The elemental composition of crabapples is also fairly uniform. Compared to commercial apples, they have lower sodium and iron content and a partially lower amount of calcium. On the other hand, they have significantly higher quantity of potassium and manganese, and some higher content of magnesium, copper, zinc and selenium.

Crabapple *Malu*s 'Royalti' predominates in the amount of anthocyanins, flavonols and phenols versus *M.* 'Pink Prefection' and *M.* x *zumi* 'Golden Hornet', while the ABTS test showed that the strongest antioxidant capacity has *M.* x *zum*i 'Golden Hornet'. We came to the same conclusion by applying the DPPH method.

Crabapple *Malus* x *zumi* 'Golden Hornet' has the largest and the heaviest fruits and gives the highest fruit yield per tree, under the same other conditions.

All observed species have high aesthetic properties throughout the vegetation period and even during the winter .

Abstract

Greece has various climatic and biological conditions which favors the development and spread of forests with rich biodiversity (flora and fauna species). The present study was conducted at the Special Protected Area of Mount Taygetos, Southern Greece (*Site of Community Importance: GR2550006*), during 2016 and 2017. This study presents the species richness, relative abundance (%) and alpha diversity of flora and vegetative species in burned and unburned areas in forest ecosystems of *Fraxinus ornus* L. The sampling of flora was carried out in randomly selected plots of 0.25 m^2 and vegetation was recorded in randomly selected sampling plots of 100 m^2. The highest relative abundances of flora and vegetative species were *Bromus rubens* L. (21%) and *Fraxinus ornus* L. (27%), respectively, in forest burned areas. Also, *Prunella vulgaris* L. (32%) and *Fraxinus ornus* L. (61%) have the highest relative abundances in unburned areas. It is noteworthy that two important endemic species (*Abies cephalonica* Loudon and *Origanum scabrum* Boiss. & Heldr.) were recorded in the study area. These species have high ecological value and may attract researchers and nature enthusiasts. Moreover, the data revealed significantly higher vegetation diversity in the forest burned areas whereas the forest unburned areas had the lowest vegetation diversity. It is important that the study areas are appearing to have evidence supporting the fact that Mount Taygetos is a self-healing ecosystem with very high rates of regeneration. This contribution will be utilized as a valuable tool to the scientific community and providing baseline information for further research.

Keywords: *Native flora, regeneration, monitoring, utilization, Natura 2000.*

Introduction

Greece with lengthiness 132.000 km^2 is located in the southeast region of Balkan Peninsula and it belongs in Mediterranean zone of paleoarctical biogeographic region. More specifically, it is located in the limits of three continents (European, Asian and African), consisted by huge topographical variety (big number of islands, rivers, valleys, gorges, etc.). Also, it demonstrates large varieties of geomorphological formations (caves and other underground formations), and stones (pro-alpine, alpine and after alpine).

Greece is characterized by high values of flora and fauna, with big numbers of macro-fungi, a variety of ecosystems and landscapes, as well as big numbers of endemism in plant and animal kingdom. The flora of Greece is consisted approximately of 5.652 species and 1.893 subspecies of angiosperm plants, which represent approximately 6.600 taxa which are belonging to 1.072 genus and 185 families. As far as it concerns fauna, by this day, are recorded about 23.130 species of animals, inland and fresh waters, noting that the 3.956 are endemic as other 3.500 sea species (Strid and Tan, 1997; 2002; Ministry of Environment, Energy and Climatic Change, 2014).

The vegetation of an area is the result of interactions of a number of factors such as climate, geomorphology, human impact, etc. Regarding the vegetation zones identified in Taygetos, decisive shapes of plant communities' physique are the geographical position, altitude, soil and bioclimatic characteristics (Legakis and Maragou, 2009). According to the distribution of vegetation zones of Dafis (1973), which is based mainly in the Braun-Blanquet system, in the region of Taygetos divided into three different zones vegetation: the eu-mediterranean, the para-mediterranean and Alpine- subalpine zones (Biosfaira, 2011). Hence, the main purpose of the present study is to research the flora and vegetation between burned and unburned areas in forest ecosystems mainly inhabited by ash trees (*Fraxinus ornus* L.), in the Special Protected Area, with rare species of plants, landscapes and ecosystems of Mount Taygetos (Site of Community Importance: GR2550006).

Material and methods

Study area

The present study is conducted at the Special Protected Area of Mount Taygetos, Southern Greece (*Site of Community Importance: GR2550006*) ($37^0$13′19,898′′N, $22^0$12′21,663′′E), during 2016 and 2017 (Figures 1, 2, 3). Mount Taygetos (2.407 m.) is the highest mountain range in the Peloponnese peninsula in Southern Greece.

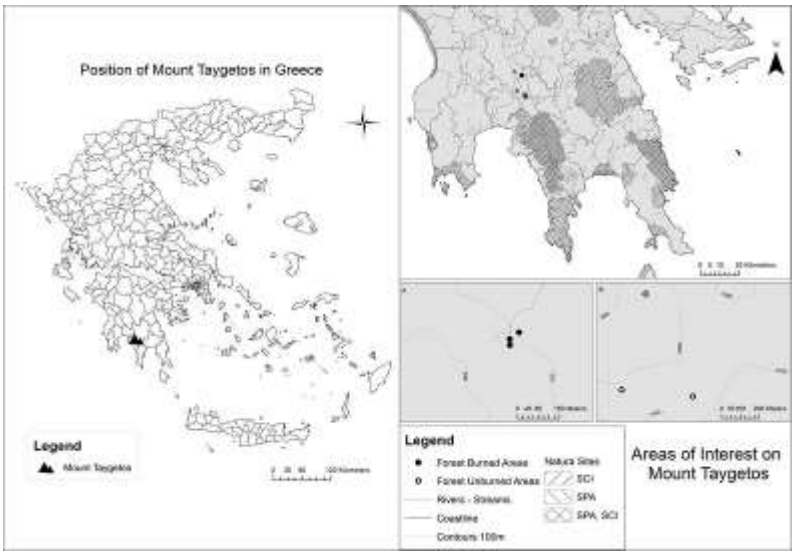

Figure 1. Study area.

Figure 2. Mount Taygetos.

Figure 3. Forest view (*Fraxinus ornus* L.).

Geologically, it is a continuation of the Gavrovo-Tripoli zone composed of phyllites, plated limestones and flysch. Its length is about 40 km and its southern limits touch Mt. Sangias

while the northern one is the Langada gorge. The forest ecosystems of the mountain are dominated by the Greek endemic, Greek Fir (*Abies cephalonica* Loud.) and excellent clusters of Black Pine (*Pinus nigra* Arnold). Also, Mount Taygetos constituted by *Fraxinus ornus* L. which is a small-medium deciduous tree which occurs typically in Mediterranean temperate colline-mountain forests. The mean annual precipitation needed is between 500 and 650 mm, although it has a good drought resistance, storing water in densely branched roots, and reducing transpiration. The root system is widely developed, requiring gravelly, well-aerated and drained soils. Moreover, this is an important site for breeding raptors and species associated with open montane habitats. Breeding birds include some of the species in Europe that are restricted (when breeding) to the Mediterranean biome. Species of concern include *Aquila chrysaetos*, *Hieraaetus fasciatus*, *Falco naumanni*, *Sylvia rueppelli* and *Pyrrhocorax pyrrhocorax*. Also, the low altitude gorges at the peripheral of the mountain are of great importance for birds of prey. Unfortunately, wildfires in 2005 and 2007 spent much of the forests on the central west slopes. In accordance with the Forest Service, the overall burned area of Taygetos is calculated almost 113,000 acres (Biosfaira, 2011). In total, within the protected area were burned 86, 542 hectares, i.e. 16.3% of the total forest areas (WWF, 2007).

Flora and vegetation survey

The sampling of flora was carried out in spring of 2016 and 2017 in randomly selected plots of 0.25 m^2. Species richness and relative abundance were estimated (Theodorakis, 1995). Vegetation was recorded in randomly selected sampling plots of 100 m^2. Species richness and relative abundance were measured (Koutsidou, 1995).

Statistical analysis

Flora and vegetation were evaluated for normality and homogeneity with the Kolmogorov–Smirnov and Shapiro–Wilk tests. This data was transformed using log (x+1) when necessary to meet normality assumptions. General Linear Model (GLM, Type III Sum of Squares) (One-way ANOVA) was used for the analysis of the above data. All statistical analyses for the flora and vegetation data were performed using the software package IBM SPSS Statistics ver. 23.0 for Windows (IBM, 2015).

Results and discussion

Flora and vegetation species richness and relative abundance

In total, in the forest ecosystems, 18 species of flora (burned areas: 9, unburned areas: 9) and 14 vegetative species (burned areas: 8, unburned areas: 6) were detected in the study area. The highest relative abundances of flora and vegetative species were *Bromus rubens* L. (21%) (Status: Native, Chorology: Mediterranean-SW Asian, Life-form: Therophyte, Habitat: Coastal habitats) and *Fraxinus ornus* L. (27%) (Status: Native, Chorology: Mediterranean-European, Life-form: Phanerophyte, Habitat: Woodlands and scrubs), respectively, in forest burned areas. Moreover, *Prunella vulgaris* L. (32%) (Status: Native, Chorology: European-SW Asian, Life-form: Hemicryptophyte, Habitat: Temperate and submediterranean grasslands, agricultural and ruderal habitats, woodlands and scrubs) (Dimopoulos et al., 2013) and *Fraxinus ornus* L. (61%) (Status, etc. see above) have the highest relative abundances in forest unburned areas (Figure 4, 5, 6).

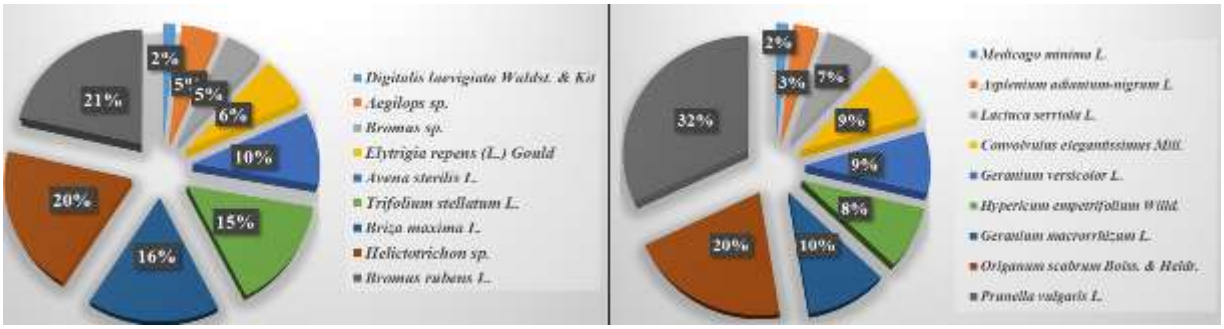

Figure 4. Relative abundance (%) of flora species in burned and unburned areas.

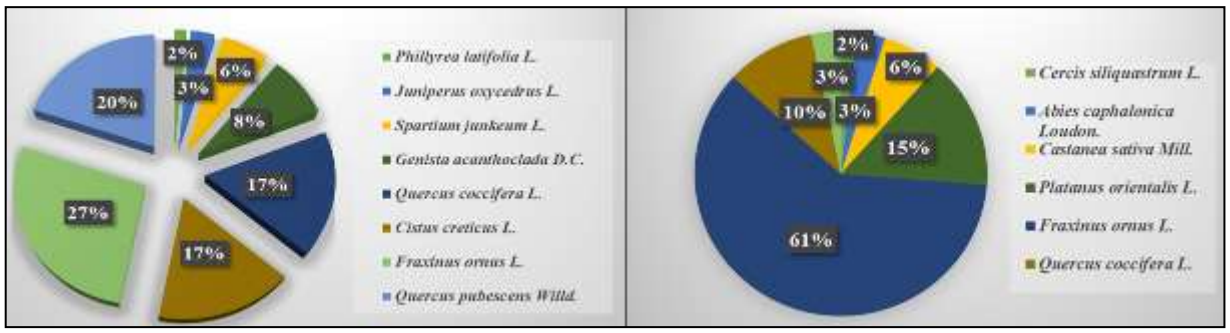

Figure 5. Relative abundance (%) of vegetative species in burned and unburned areas.

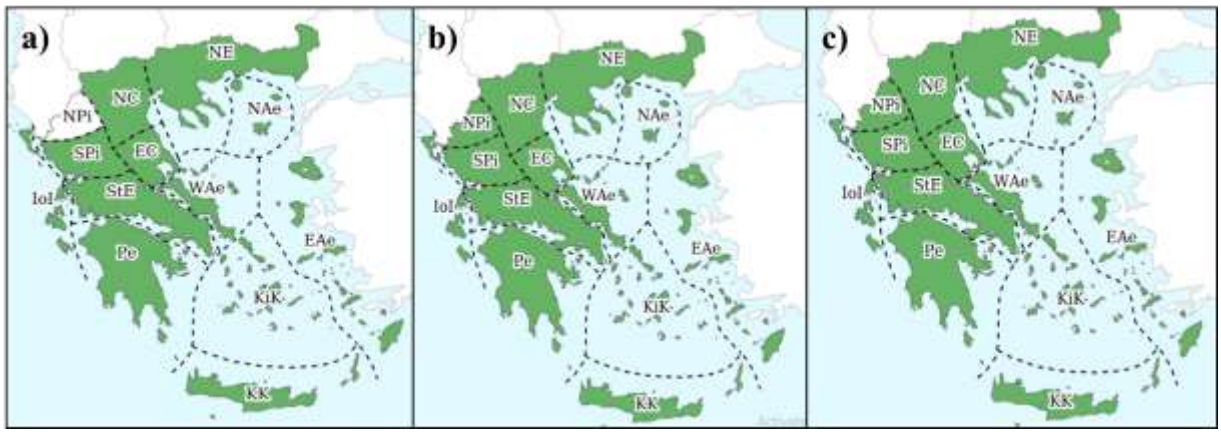

Figure 6. Distribution of highest relative abundance plant species in Greece: a) *Bromus rubens* L., b) *Fraxinus ornus* L., c) *Prunella vulgaris* L. (IoI: Ionian islands, NPi: North Pindos, SPi: South Pindos, Pe: Peloponnisos, StE: Sterea Ellas, EC: East Central Greece, NC: North Central Greece, NE: North-East Greece, NAe: North Aegean islands, WAe: West Aegean islands, Kik: Kiklades, KK: Kriti and Karpathos, EAe: East Aegean islands) (Dimopoulos et al., 2013).

Alpha diversity in burned and unburned areas

According to Table 1, the results didn't show higher alpha flora diversity between forests burned areas and unburned areas. Also, the forest burned areas exhibited the highest values of alpha vegetation diversity, whereas the forest unburned areas had the lowest values (Table 2). Disturbances such as fire play a role in the maintenance of species diversity that has become well recognized in ecological theory (Mackey and Currie, 2000). Even if a fire had occurred, the flora diversity between burned and unburned forest areas is at a relative balance. The most feasible explanation for this result is that the fire was not absolute and most of the trees have survived. These referred burned areas of this study happen to be in the exact limits which the

fire had stopped. For example, in this mountain, a previous research about burned and unburned forest areas showed that higher alpha flora diversity in Forests-Unburned areas, Natural Ecosystems-Unburned areas, and Forests-Burned areas than in Natural Ecosystems-Burned areas have occurred (Solomou and Tsipas, 2017).

According to literature, fire frequency determines the floristic composition of an area by selecting species, which will continue to occupy a site. A plant species may eclipse depending on the time that a fire occurs, e.g. late, early or after the plant's life cycle (Chandler et al., 1983). However, species have many reactions to fire in order to survive. There are sprouts which can endure repeated fires while those that produce seed are favored by infrequent fire (Keeley, 1981).

Table 1. Alpha diversity indexes of flora in forests (burned and unburned areas).

Alpha diversity indices	**Forests-Burned areas**	**Forests-Unburned areas**

Simpson	5.65a	2.52b
Fisher's alpha	2.03a	1.87b
Eveness	0.67a	0.47b

*Different letters show statistical significances.

Conclusions

Mount Taygetos is the highest and most impressive mountain not only of Messenia but of all Peloponnese. This ecosystem is a real botanical paradise, preserving an ecological balance as well as providing different biotic components. On the basis of the above, it is important to estimate and monitor the populations' size of flora and fauna dynamics, all seasons of the year in order to be effectively protected and utilized from the scientific community and wider audiences. It is known that the forest-based sector plays a significant role in Bioeconomy. Forests supply and contribute to bioenergy with wood and non-wood materials forming the basis for many management, regulating and ecosystem services. Hence, management of forest biomass in Mount Taygetos can be succeeded within the Bioeconomy concepts, while this high-value diversity can be protected and utilized through these concepts, projects and monitoring.

POTENTIAL ENERGY WOOD RESOURCES IN UNDERSTOREY OF *MYRTILLOSA MEL.* FOREST SITE TYPE STANDS IN LATVIA

Aigars INDRIKSONS*, Martins GRAUDUMS

Department of Silviculture, Latvia University of Life Sciences and Technologies, Latvia
*Corresponding author:aigars.indriksons@llu.lv

Abstract

Forest resources are the most significant natural resources of the state of Latvia. According to the second stage data of Forest Resource Monitoring, in 2014, Latvia has 3575 thousand hectares of forest land, which accounts for approximately 55.3 percent of the total territory of Latvia, while the total wood stock is estimated at 668 million cubic meters. A considerable part of it can be used for energy production, thus practically providing most of the necessary heat energy, a large part of the amount of electricity, as well as the amount of energy needed to provide transport movement. In recent years, the consumption of certain woody biomass products, such as chips and pellets, has a tendency to grow, due to a number of factors: the opportunity to use its own resources, export them, the increase in international financing for renewable energy projects etc. The fossil fuel price increases and the development of strategic and regulatory decisions contribute to this.The forest undergrowth and understorey which according to the Rules for cutting trees in forest lands are suggested partially to be preserved, contain a considerable amount of potential energy wood.In the forthcoming study on the assessment of energy wood resources, a sufficient number of plots to be established in drained forests are foreseen, in order to ascertain the exact potential of their energy extraction in the drained forest site types in the country, as they reach or are close to the cutting age.The results obtained in Myrtillosa mel. forest site type suggest that the biomass of naturally humid wood of shrubs of understorey comprises of 22 665 kg per hectare but calculated the dry mass - 12 590 kg per hectare. The results suggest that this biomass is considerable and it is reasonable to use it for energy wood extraction simultaneously with final felling.

Keywords: *energy wood, understorey, Myrtillosa mel. forest site type*

Introduction

Forest resources are the most significant natural wealth of the state of Latvia. According to the data of the 2nd stage of the forest resource monitoring for 2014, Latvia has 3575 thousand hectares of forest land comprising 55.3 percent of the total territory of Latvia, while the total timber stock was estimated at 668 million cubic meters (Bumanis *et al*., 2014). With economically justified solutions of forestry issues, a significant part of it can be used for energy production, thus practically providing most of the required amount of heat energy, a large part of electric power, as well as of the required energy for transport access. In recent years, the consumption of definite wood biomass products, like wood chips and pellets, tends to increase due to several factors, and it is clear that the possibility to use own resources and to export them, the increase of international financial support for projects anticipating usage of renewable energy, the price increase of fossil fuel and the development of strategic and regulatory decisions are promoting it. In the last decade, with the financial support of EU Funds, a substantial amount of cogeneration plants and boiler houses have started their work, replacing imported fossil fuel with fuelwood. During the EU fund programming period 2007-2013, over 84 million Euros worth co-financing was invested in increased energy efficiency of the centralized heat supply. While carrying out131 projects, an appreciable increase of power capacity due to the renewable energy resources was achieved. Although in recent years the consumption growth of wood biomass has halted, starting the implementation of the new

projects of the EU fund programming period of 2014-2020, there will be a need for additional supply of wood biomass. In March 2017 the Cabinet of Ministers of the Republic of Latvia approved a new program supporting the improvement of the energy efficiency of the centralized heat supply systems and the usage of local renewable energy resources. Within the framework of the first project call, the support of these activities reached 35 million Euros. For these reasons, the usage of wood chips, pellets and briquettes fruitfully increases in recent years, especially in comparative perspective, contrary to the use of firewood (Table 1).

Table 1. Wood biomass products consumed in Latvia in the period from 2005 to 2013 (thous. m^3thous. t^{-1}) (Bumanis *et al*., 2014).

Year	Firewood thous. m^3	Woodchips thous. m^3, loose volume	Sliver thous. m^3, loose volume	Pellets, briquettes thous. t

However, from the available forest resources data it is only theoretically and hypothetically possible to define what proportion of these resources would be useful and economically justified for energy supply. Each stand has a certain amount of undergrowth resources, which need not necessarily be left for further provision of its vitality, and there are felling residues in any final cutting where the economic justification of usage would undoubtedly be that of the source of energy (Ohman *et al*., 1976). The most precise determination of the amount of wood energy in Latvian forests, the creation of mathematical models for its determination, as well as economic substantiation of the usage of forest resources for energy production, as opposed to importing energy resources, would be of great benefit to Latvian economy.

The object of the study is the timber resources in drained forest conditions available in the country and potentially to be used for energy production in the near future. Forests on drained peat soils occupy 14%, and forests on drained mineral soils occupy 19% of the total forest area (Libiete, 2008).

The subject of the study is the stands of felling age in drained forest conditions, in addition, starting the research with the class of the seasoning stand and estimating the potential 20-year period of wood resources available for energy production. The research reveals the volume of wood energy resources in undergrowth and its potentially available volume from the felling residues. Research hypothesis – the use of undergrowth and felling residues in the production of wood energy is profitable, and therefore, is also economically viable, and also corresponding to silvicultural and ecological substantiations.

The study aims to clarify precisely as possible the mass and volume of energy-producing mechanical pulp in the stands of felling age (and also seasoning stands) in drained forest conditions in Latvia.

The research objectives are to develop the methodology of the assessment of wood energy resources (development of mathematical models), as well as to provide a silvicultural and economical estimation of the usage of wood energy resources grown in drained forest conditions for energy production.

Material and Methods

The research data were collected in forests of Jelgava Forest District of Agency "Forest Research Station". The territory is located in the Cenu Parish of Ozolnieki District, in the northern part of Zemgale Plain.

The research was carried out in two forest subquarters of forest site type *Myrtillosa mel.* The *Myrtillosa mel*. forest site type belongs to the edaphic row of drained hydromorphic mineral soils. The site conditions here are excellent to grow up a high yield tree stands, as well having a dense floor of undergrowth and understorey. Taking in to account the potential richness of woody plants biomass eight circle shaped sample plots with radius of 2.82 m were established. The area of each single plot is 25 m^2.

The data were collected in area of 1st and 4th Subquarters of the 37th Forest Quarter. The area of 1^{st}subquarter comprises 0.6 hectares, the stand composition is 10Pine66 years old, stand density 0.7. The average tree height of dominant stand in this subquarter is 27 m and average diameter 25 cm. The stand volume is 365 m^3 ha^{-1} and site index Ia. The area of 4^{th}subquarter reaches 0.9 hectares, the stand composition is 9Pine1Birch88 years old, stand density 0.7. The average height of trees is 26 m, the average diameter – 29 cm. It is aIst site index stand with volume of 352 m^3 ha^{-1}.

The sample plot method is the method used for obtaining the figures of wood resources, which means that there is a characteristic sample plots created in forest subquarter (four sample plots per hectare) and the results obtained there are applied to the entire stand (Kangas and Maltamo, 2006). The chosen forest parcel has its randomly defined centre. At its ninety-degree angle diagonals are drawn in different directions and circular plots are established on each side of the diagonal, equidistant from the centre and the border of the sample plot.

In the sample plots, the understorey and undergrowth trees were surveyed. The treeswere cut into the root neck. Using the measuring tape there was the height of trees measured and the diameter in height of 1.3 m. For trees which had not reached the height of 1.3 m, the diameter was determined at the root neck. The mass was determined with or without leafs. Leafs were also weighted separately.

From each tree harvested, there was also a sample prepared which was then sent for drying. The mass, length, and diameter were determined for this sample. The length was determined in three places, in the lower half, in the middle and in the upper half.

The wood samples for moisture determination were transferred to Ltd. "Forest and wood products research and development institute", where the total moisture content of the wood sample is determined according to the standards of LVS EN ISO 18134-2: 2016. The Laboratory uses the simple method ISO 18134 - 2: 2015 (LVS EN ISO 18134-2: 2016, 2016).

The wood samples for drying are initially weighed using Li - 86 Weights. After weighing, the samples are placed in a Drying Oven Li-77, where they are dried at 105 ± 2ºC. After 60 minutes of drying, an intermediate check is carried out, during which time the mass change percentage is determined. Drying is completely completed after 48 hours when mass changes are no longer observed. After drying the trees, they are weighed again and the moisture content of the sample is determined as a percentage. The standard deviation of the moisture value and the coefficient of variation are also calculated in the Laboratory.

Dry mass rate is calculated using the results obtained from the drying of wood samples. To calculate the dry matter content of 100, the percentage moisture content of the wood sample is subtracted. For example, if the wood moisture after drying is 36%, then the dry matter content is 64%.The obtained mass of energy producing wood is attributed to the whole plot and hectare of forest.

In the research there is a wood mass of undergrowth and understorey separated. The undergrowth is formed by tree species which are able to reach the dimensions of dominant stand by suitable circumstances, e.g., improvement of lighting or by cutting of mother stand

trees. Such species in Latvian conditions are, e.g., Norway spruce (*Picea abies* (L.) Karsten), Scots pine *(Pinus sylvestris* L.), English oak (*Quercus robur* L.) and common ash (*Fraxinus excelsior* L.). The understorey consists of trees and shrubs which are not able to reach the size of dominant stand. There belongs such species as rowan (*Sorbus aucuparia* L.), alder buckthorn (*Frangula alnus* Mill.), bird cherry (*Padus avium* Mill.), common hazel (*Corylus avellana* L.), plum (*Prunus domestica*L.) and other species.

Several species like silver birch (*Betula pendula* Roth), pubescent birch (*Betula pubescens* Ehrh.), Norway maple (*Acer platanoides* L.), small-leaved lime (*Tilia cordata* Mill.), common aspen (*Populus tremula* L.) and gray alder (*Alnus incana* (L.) Moench) act uncertain: theoretically they can reach the dominant stand tree dimensions but as they are light demanding, they do not survive long time under the canopies of mother stand. Growing long time in suppressed conditions they form a weak crown, the stems are sinuous or inclined – not being able to take a vertical position any more. Taking in to account mentioned arguments, these tree species are considered as understorey.

Results and Discussion

Together, 10 different species of woody plants – birch (both species - silver and pubescent birch counted together), English oak, Norway maple, rowan, common aspen, gray alder, alder buckthorn, bird cherry, common hazel and plum - were measured in undergrowth and understorey of both forest subquarters.

In the first sample plot of the forest subquarter with tree stand composition 10Pine 66 years old, the mass of separate woody plants in naturally conditions varies between 5 and 4235 grams. The average mass before drying is 982.18 g. The largest mass before drying is for buckthorn, but with the lowest weight are both the rowan and the oak. Absolutely dry mass of wood varies from 3.59 to 2275.31 g, the average mass is 605.94 g. The average mass difference between the raw and absolutely dry biomass in this plot is 376.24 g. The wood moisture here varies from 56.33 to 65.42%. The highest moisture content of wood was for plum tree - 65.42%.

In the 2nd plot, the mass of the trees before drying varies from 50 – 26080 g, the average mass is 3601.58 g. Absolutely dry mass of wood varies from 29.92 to 14403.09 g, the average absolutely dry mass is 1967.65 g. The biggest loss in weight is for buckthorn with an initial mass of 2300 g, but after drying its weight decreased by 1765.52 g.The highest moisture content in the 2nd plot is for birch - 57.00%. The lowest moisture content is for the buckthorn - 41.97%. The average moisture content in plot 2 is 51.80%.

In the 3rd plot, the average weight of the trees before drying is 3643 g, but the average dry weight of the wood is 2066.85 g. The largest mass before drying was for oak - 14220 g, but after drying oak wood mass decreased by 7006.74 g. The moisture content of the wood here varies from 53.86 to 75.99%. The highest moisture content of wood is for hazel 75.99%, but the lowest moisture content is for oak - 53.86%.

Of the trees in the 4th plot considerably superior is rowan which mass before drying is 21170 g and dry mass is 11125.83 g. The average mass of woody plants in naturally moist conditions is 1215.51 g, after drying – 653.15 g. The average moisture content in plot 4 varies from 53.24 to 62.44%. The average moisture content is 56.66%. The highest moisture content of wood is for oak, the smallest – for rowan.

In the first sample plot of the forest subquarter with tree stand composition 9Pine1Birch 88 years old, the woody plants mass before drying varies from 5 to 2660 g, the average mass is 290.32 g. The absolute dry mass of wood varies from 3.85 to 1648.2 g, the average mass is 179.16 g.In the first plot of the given subquarter, the lowest moisture content of the wood is for buckthorn - 61.66%, the largest - 62.52% for rowan. However, the difference between the moisture content of both species here is small - 0.86%.

In the 2nd plot of subquarter, the wood mass varied from 2 to 2858 grams before drying. The absolute dry mass of wood varied from 1.43 to 1609.3 g. The largest changes in mass are observed for rowan with an initial weight of 34 g, but after drying it has a mass of 18.37 g. The highest moisture content here is for rowan - 67.25%, the lowest is 56.47% for the buckthorn. The difference between the highest moisture content and the smallest is 10.78%.
In the 3rd plot, the average weight of wood before drying is 635.90 g. Absolutely dry wood has an average mass of 338.88 g. Consequently, the difference between the weight before drying and after the average is 297.02 g. The largest mass of wood before drying is for maple - 7730 g. The highest moisture content of wood is oak - 56.53%. The lowest moisture content of the wood is for the buckthorn - 4.41%. The difference between these two indicators is high - 52.12%.
In the 4th plot, the wood mass varies from 40 to 49140 g before drying, with an average weight of 6538.64 g. Absolutely dry mass of wood varies from 21.23 to 23559.2 g. The largest and smallest mass before drying is for the rowan. The largest loss of weight is for buckthorn with an initial mass of 260 g. After drying, its weight has decreased by 163.86 g. The highest moisture content of wood here is for gray alder - 63.01% and the smallest for oak - 40.74%. The average moisture content of wood in plot is 49.60%.
The average biomass of undergrowth and understorey in Subquarters 1 and 4 of Quarter 37 is shown in the Table 2.

Table 2. Amount of biomass in inventoried sample plots.

Research object	Biomass per sample plot, t	Biomass, t ha^{-1}
1^{st}subquarter 1^{st} plot	0.027	10.68
1^{st}subquarter 2^{nd} plot	0.031	12.4
1^{st}subquarter 3^{rd} plot	0.047	18.84
1^{st}subquarter 4^{th} plot	0.019	7.56
Average in 1^{st}subquarter	0.03	12.37
4^{th}subquarter 1^{st} plot	0.005	2
4^{th}subquarter 2^{nd} plot	0.011	4.28
4^{th}subquarter 3^{rd} plot	0.014	5.68
4^{th}subquarter 4^{th} plot	0.073	29
Average in 4^{th}subquarter	0.03	10.24

According to previous researches, in Sweden obtains 7-20 t ha^{-1} of dry mass, in Poland -7 to 12 t ha^{-1}, in Germany, from 6 to 14 t ha^{-1} and in Latvia 8 to 12 t ha^{-1} (Lazdina *et al*., 2010).There are also several researches that describe biomass from young hardwood stands on abandoned agricultural lands in Canada: the values varies between 0.6 t ha^{-1} and 82.6 t ha^{-1} (Lupi *et al*., 2017). Consequently, a sufficient amount of biomass is obtained in forest subquarters investigated in our research, which fits with the results of other studies carried out.

Conclusions

The diameter of the woody plants in undergrowth and understorey of the inventoried *Myrtillosa mel*. site type forest stands varied between 0.2 and 8 cm, the height – between 0.2 and 9.5 m, the average naturally moist wood mass is 813.68 g. The dimensions of trees are big enough to get the sufficient amount of biomass.
In the forest subquarter with stand composition of 10Pine 66 years old the sum of total biomass of undergrowth and understorey comprises 177.91 kg per sample plot. In the forest

subquarter with the stand composition of 9Pine1Birch 88 years old there is the sum of understorey tree mass 180.9 kg but of undergrowth – 16.17 kg per plot. It means that in understorey is the more biomass as in undergrowth in the site investigated.

In conditions of tree stand 10Pine 66 years old the amount of dry matter to be extracted in average from all sample plots is 12.37 t ha^{-1}. In the forest subquarter with stand composition of 9Pine1Birch 88 years old the amount of dry mass in average is 10.24 t ha^{-1}. In Latvia there the average amount of dry biomass obtained in other investigations is between 8 and 12 t ha^{-1}. This allows to conclude that *Myrtillosa mel*. forest site type is appropriate for the use of undergrowth and understorey biomass for production of energy wood.

The amount of the energy producing wood growing in drained forest conditions, adding also the felling residues and the potential energy producing wood of the undergrowth and understorey, comprises almost half of the wood potentially and justifiably used for energy production in Latvia.

SOIL/PLANT RELATIONSHIPS IN ARCTIC AND ALPINE AREAS A LITERATURE SURVEY.

Oddvar SKRE*

Skre Nature and Environment (NMV), N-5243 Fana, Norway
* Corresponding author: oddvar@nmvskre.no

Abstract

A literature survey on the issue of soil/plant relationships at low temperatures showed that plant growth at low temperatures are controlled by incomplete seed maturation because of too low summer temperatures (1), winter damage on needles and bark tissue above snow cover, as a result of freezing and drying stress, due to temporarily frozen soil in spring, leading to photochemical damage on chloroplasts (2), and growth limitation at low soil temperatures because of slow uptake rates of nutrients and decomposition rates of organic nitrogen (3). This last process is particularly important because it is directly linked to growth and uptake of nutrients through the dark respiration process. In most plants the uptake of nitrate and phosphate from soil takes place against a concentration gradient and is dependent on energy from respiration, and the growth limitation is probably through the active uptake of nutrients (mostly nitrogen) in roots. The process is further dependent on nutrient content in soil and decomposition rates of organic matter. In accordance with this, a strong response in root nitrogen uptake rates have been found in birch seedlings on soil nitrogen level and temperature, and the effect of soil temperature is further amplified by its effect on microbial activity and decomposition rates. The mycorrhiza in soil is in this respect functioning as an extended root system, supplying the plants with nitrogen, in exchange with carbohydrates.

Keywords: *nutrient uptake, temperature, respiration, soil, decomposition, mycorrhiza.*

Introduction

The treeline ecotone in alpine and arctic areas is an important climatic indicator. The growth and survival of trees in these areas is mainly controlled by temperature (e.g. Kupfer & Cairns 1996) through various mechanisms like winter desiccation and freezing stress (Tranquillini 1979, Taulavuori et al. (2004)), incomplete seed maturation and regeneration (Juntunen & Neuvonen 2006) and limitation of nutrient uptake (e.g. Karlsson & Nordell 1987), where the last mentioned process seems to be the most important. A close relationship has been found between soil temperature, nitrogen accumulation and winter survival in birch seedlings (Weih & Karlsson 1999). In addition, Körner & Paulsen (2004) found support for a general world-wide tree-line related mean ground temperature limit of 6.7^{o}C, regardless of winter conditions.

The basic process behind this temperature-limited nutrient uptake at low temperatures, is probably the active uptake of nitrogen and phosphorus through the root membranes, against a concentration gradient (Chapin 1979, Karlsson & Nordell 1996). This process is mediated through the dark respiration, which is strongly temperature-dependent with exponential increase (e.g. Skre & Laine 2007).

Materials and methods

The energy kcal/g (R) from dark respiration is released in small steps through energy-rich nucleotides, and in addition to the active uptake of nutrients, it is used for growth, maintenance and transport of photosynthates, in accordance with the following relationship (Lambers 1998, Skre & Laine 2007), where carbon exchange units are given relative to leaf area:

$R = r_m + c_g \times RGR + c_t \times TR$ where

r_m = maintenance respiration $gCm^{-2}yr^{-1}$
RGR = relative growth rate mg g^{-1} yr^{-1}
TR = transport across membranes (including active uptake in roots and photosynthates) $gCm^{-2}yr^{-1}$
c_g - kcal g^{-1} /mg g^{-1} yr^{-1} = kcal/mg yr^{-1}
c_t - kcal $g^{-1}/gCm^{-2}yr^{-1}$

According to Lambers (1998) the balance between growth and maintenance respiration is dependent on the availability of nutrients and the genetic background of the plants. Plants with free nutrient availability have a tendency of using the available energy for biomass growth in order to increase their root uptake capacity, while plants with limited nutrient supply tend to put their energy into root respiration and active uptake of nutrients, which would increase the photosynthetic capacity in leaves (Thornley 1972). This is a useful adaptation, formulated as the "balanced growth" model. Seedling growth rates in birch has been found to be controlled by nitrogen concentration, which is dependent on N uptake rate (summer + winter) and N loss in the autumn. Simulation experiments showed that increased net uptake of nitrogen during autumn increased growth the following season by the same magnitude as a 1-2^oC increase in soil temperatures (Weih 2000a).

Results and discussion

Nutrient uptake and balanced growth. In accordance with Hagedorn et al (2010) the soil respiration and decomposition rates are much more temperature dependent than the uptake rates through root respiration. However, Kabeya (2010) found that the growth limitation was a two-step process, i.e. the relative growth rates were limited by (1) nitrogen uptake rates in roots and (2) by availability of non-structural carbohydrates from photosynthesis. In arctic soils the uptake and decomposition rates of nitrogen and phosphorus are low because of the low soil temperatures and have been shown to be limiting factors by Chapin (1979, 1980) and by Karlsson & Nordell (1996) and Weih & Karlsson (1999) in experiments on *Betula pubescens* seedlings. Further evidence was found by Aphalo et al. (2010) on *Betula pendula*, where relative growth rates (RGR) and stomatal conductance were almost completely inhibited by low soil temperature through limitation of nitrogen uptake in roots. However, these relationships were not found in slow-growing conifers with evergreen leaves. According to e.g. Goh et al (2012) photo-inhibition of photosynthesis may occur as a result of formation of harmful by-products from the light reaction or other stress factors, e.g. freezing and drying stress. Plants have developed mechanisms e.g. CO_2 acclimation or alternative respiration to avoid photo-inhibition (cf. Skre 2001).

Table 1
Root nitrogen uptake rates (mmol N $g^{-1}week^{-1}$) as a function of soil temperature (^oC) and nutrient level for mountain birch seedlings grown under experimental conditions for one season in Abisko, northern Sweden. Data is taken from Karlsson & Nordell (1996), see also Skre & Laine (2007).

Soil temperature (^oC)	**Nitrogen uptake rates (mmol N $g^{-1}week^{-1}$)**		
	Low fertilization level	**High fertilization level**	**Organic soil (humus)**
5	0.00	0.04	0.27
10	0.02	0.20	0.75
15	0.03	0.45	1.47

Repo et al (2004) found that low soil temperatures would lead to more starch accumulaton in spruce needles and delayed loss of starch in fall, because of higher C/N ratio, due to reduced N uptake in roots. In accordance with this, Karlsson & Nordell (1996) found a strong response in nitrogen uptake rates in fast-growing birch seedlings to soil nitrogen level and temperature, and the effect of soil temperature was further amplified by its effect on microbial activity and decomposition rates (Table 1). The much higher nutrient uptake rates from organic soil than from artificial soil with fertilization indicates this strong effect of soil temperature on decomposition rates, making nutrients more available for root and mycorrhiza uptake. In accordance, Sveinbjørnsson et al. (1992) found a strong increase in shoot elongation rates in mountain birch (*Betula pubescens*) grown at treeline in Abisko, northern Sweden, in response to N and P, but the response to P was particularly strong at treeline altitudes. P has been shown to be limiting factor for growth in arbuscular mycorrhiza (Valentine & Kleinert 2007) and it has been shown that mycorrhizal symbiosis increases P uptake at low and medium soil temperatures (Kytöviita & Ruotsalainen 2007). Plants growing close to their distribution limits often show strong responses to N and P, mostly because of low soil temperatures and low concentrations of available nitrogen and (partly) phosphorus in soil. Hence mycorrhizal is functioning as an extended root system in nutrient uptake.
The nitrogen/carbon balance in plants is affecting shoot and root growth in the following manner, according to the balanced growth model (Thornley 1972) where > means "leading to":

N > Leaf protein > Photosynthesis > C > Root growth > N uptake

The significance of this relationship is that at high temperatures and low light intensity, excess nitrogen is transported from roots to shoots for leaf protein production, increasing photosynthetic efficiency. On the opposite, high light intensity and low temperatures would lead to formation of excess carbohydrates, that is transported from leaves to roots in order to increase root growth and the uptake capacity of nitrogen at low soil temperatures (cf. Skre & Laine 2007, Lambers 1998). In this connection, arbuscular mycorrhiza (Valentine & Kleinert 2007) is functioning as an extended root system.

Adaptation to temperature changes. Arctic and alpine plants that are adapted to a nutrient-poor environment without competition and where low temperatures are limiting factor, tend to avoid growth rather than producing nutrient-deficient tissue (Chapin 1979). Instead they are using excess carbohydrates to put out more root growth in order to increase their nitrogen uptake capacity. In addition, northern plants have been found to have slightly higher photosynthetic efficiency than southern relatives (Weih & Karlsson 1999). This is called "metabolic compensation", because it partly compensates for the shorter growing season in northern areas (Billings et al. 1971). Stronger root growth and related increased nutrient uptake is a precondition for this process. In experiments with birch seedlings, Weih (2000b) found that reduced soil temperatures and/or nutrient supply caused delayed growth response, e.g. the plants maintained a high root/growth ratio (RGR) during the next season, at the

expense of plant nitrogen concentration (PNC). This situation is relevant because great year-to-year climatic variations are common in the Arctic (e.g. Skre et al 2002).

The raised temperature impact on sensitive stages like seed reproduction, winter dormancy, migration rates and soil conditions (Callaghan 1993, Heide 1993, Huntley 1997) is expected to affect subarctic plant species. Increased CO_2 level will normally cause increased growth rates due to a combination of increased photosynthetic rates and increased water use efficiency (Hall et al. 1993). In most deciduous trees, e.g. birch, shoot growth will take place over the whole season ("free growth") and there will be no sink limitation on photosynthesis. According to the "balanced growth model" (Thornley 1972), the expected CO_2 increase would lead to higher C/N ratio, that would have to be balanced by increased root growth. The most pronounced effect of increased CO_2 content is therefore increase in root biomass (Mousseau 1993). In Norway spruce (*Picea abies*) Lahti et al. (2005) found that there was a certain depression of root growth during the period of strongest shoot growth. In another study on *Betula pubescens,* Weih & Karlsson (2002) found that root damages due to freezing soil temperatures would be compensated by new root formation the following season, but at the expense of shoot growth. The results agree well with previous studies (e.g. Murray et al. 1989), indicating that ecotypes and species that are competetive and adapted to a high-growth strategy may take advantage of the expected climate change, because they would tend to put more of their carbon and nutrients into new growth, while the northern populations tend to use their resources for storage and defence against climatic and herbivore stress (e.g. Skre & Naess 1999), which seems to be more important as selective factors in northern areas than competition (Chapin 1980, Ågren 1985).

Conclusion

The active uptake of nitrogen and phosphorus in roots has been found to be the probably most important limiting factor for growth and survival in arctic and alpine plants at low temperatures. This process is mediated through the respiration and is strongly temperature-dependent. In accordance with this, a strong response in root nitrogen uptake rates has been found in birch seedlings on soil nitrogen level and temperature, and the effect of soil temperature is further amplified by its effect on microbial activity and decomposition rates. The mycorrhiza in soil is in this respect functioning as an extended root system, supplying the plants with nitrogen, in exchange with carbohydrates. In agreement with these relationships, plants from northern and alpine populations have been found to have higher photosynthesis rates than southern and lowland relatives, this so-called «metabolic compensation» is looked at as a compensation for the short growing season in cold areas.

Abstract

The poplar is widely used in protective and recreational plantings due to the ease of reproduction, the rate of increase and decorativeness. Often poplar trees become the object of unauthorized destruction, due to its negative qualities: brittle wood, insect and fungus infestation, annual and abundant fuzz. The destruction investigator must determine the damage cost based on the tree species and trunk diameter. On the locale, the trunk diameter will be determined by the stump diameter. This calculation is made by using a specific table. Nevertheless, there are not poplar species in that table, except the aspen. The article presents the results of a study on the poplar trunk diameter dependence on the stembase diameter. The research was done in a specially protected natural area called the «Chernyayevsky forest» in Perm. The purpose of the study was to improve the methodology for determining damage caused by illegal logging of trees (poplar) in forest and urban areas. The study on the poplar stembase formation was carried out in September 2017 in artificial plantations of the «Chernyayevsky forest». The plantation age was 60 years. The forest type of the research plantation was a pine pleurocarpous moss forest. The forest site was fresh subor (B_2) according to the Pogrebniak classification. The research data showed the trunk diameter calculation error attained one calliper scale.

Key words*: Berlin poplar, aspen, breast height diameter, stump diameter, correlation, illegal logging.*

Introduction

Poplar is a genus of deciduous fast-growing trees in the family *Salicaceae* (Willow), widely used in protective, landscaping and recreational plantings, due to the ease of reproduction, high performance and decorative qualities. A significant disadvantage of poplars are: brittle wood, short-lived, damage by pests and diseases, annual and abundant fuzz (Redko, 1975; Tsarev, 1985; Plotnikova, 1994; Isebrands et al., 2014). Therefore, poplar is often the subject of unauthorized destruction of city residents. Calculation of damage in the case of unauthorized felling of wood in the city of Perm is carried out in accordance with the document on approval of "procedure for calculating the replacement value of green spaces demolished in the city of Perm" (About the statement…, 2015), where the cost of restoration of planting increases depending on the type of wood and its diameter at breast height. In forestry of the Perm Krai in the investigation of cases of illegal logging of aspen (*Populus tremula* L.) using a translation table developed by A. M. Mezhibovski (Zagreev et al., 1992). For other types of poplar, there are no table data. At the same time, analyzing the "Sorting and commodity tables" (Verkhunov et al., 2002), it is possible to observe differences in the stock of the same thickness of the tree between aspen and poplar (aspen). Thus indicating differences in the formation of the trunks of different species of poplar.

The aim of the study was to improve the methodology of determining the damage caused by illegal tree logging (poplar) in forest and urban areas. Objectives: 1) to determine the dependence of the trunk diameter based on the stump diameter, for the subsequent

determination of the stock; 2) to create a translation table from the diameter of the stump to the diameter of the trunk for use in practice.

Material and Methods

In September 2017, on the territory of the protected area called the "Chernyaevsky forest", studies were conducted out on the formation of the butt part of poplars growing in artificial plantations of the 6th class of age. The investigated stratums belongs to the type of forest – pine pleurocarpous moss forest. The survey of plantings was conducted by the method of sub-tree inventory (Regulations on works…, 2007); the species belonging of poplar was determined by a number of sources (Redko, 1975; Tsvelev, 2000; Ovesnov et al., 2007 Molganova et al., 2016), the height of each tree was measured. As every tree was measured, the diameters of the trunk at a height of 10 cm (d10), 20 cm (d20) and 1.3 m (d1,3) from the surface of the earth or the presence of roots from the root collar, up to 0.5 cm (in this case also determined the height of the root collar above the ground). Trees with a diameter of more than 64 cm were measured along the circumference using tape measure. Trunk volume in the bark was determined on the basis of state-approved structures of assortment and commodity tables (Verkhunov et al., 2002). A total of 446 trees of Berlin poplar were examined.

Results and Discussion

Due to the fact that in the literature devoted to the study of compliance of stump diameter to diameter at a height of 1.3 m from the root collar, often missing the height of the diameter measurement of the stump, were analyzed two ratios: measuring at a height of 10 cm and 20 cm. Plots of the diameters of the stump and the diameter of the trunk is shown in Figure 1. As control was used the dependence developed by A. M. Mezhibovski (for aspen).

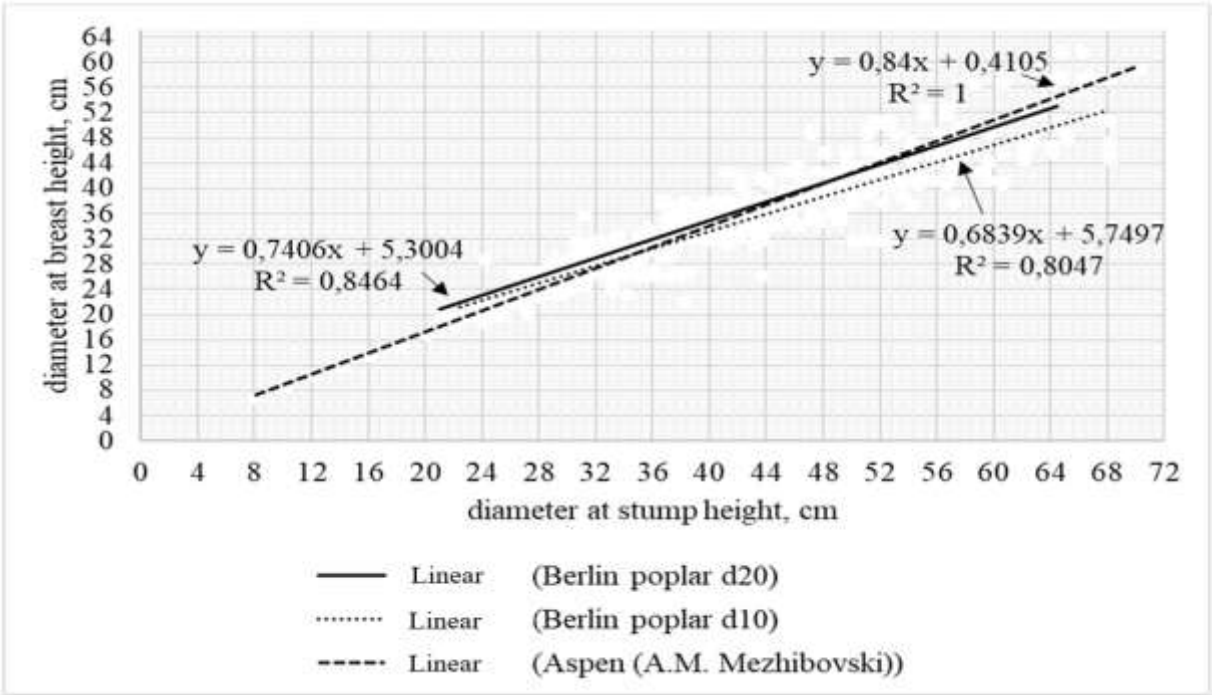

Figure 1. Graphs and linear equations based on diameter at breast height from stump diameter at different heights

Graphics matching the diameter of the stump at different heights to a diameter at 1.3 m to the Berlin poplar indicate that the thinner trunks are in the form of a butt close to the cylindrical. With the increase in the thickness of the trunk, the butt become more fleeting. The dependence of the diameter of the trunk from stump diameter at a height of 20 cm from the

ground to the tree somewhat reminiscent of a similar relationship with aspen but doesn't allow to fully use the data of A. M. Mezhibovski in relation to the poplar. The table shows the error values when using different diameter conversion techniques

Table 1. Comparison of the established D1,3 dependencies on stump with the data of A. M. Mezhibovski

64	54.2	2.91	49.5	+4.7	+9.5	2.47	52.5	+1.7	+3.2	2.91

In the study of dependencies (see table 1) d1,3 of diameter stump of Berlin poplar with the data of A. M. Mezhibovski shows that, with d10 values ranging from of -2. 1 (-10%) to +4.7 in (9,5%), while d20 from -3,1 (-14,1%) +1,7 (3,2%). Translation table for aspen can be used in the calculation of damage from the illegal logging of poplar, with the following amendment: at the diameter of the stump 32 to 44 cm, measure the diameter of the stump at a height of 10 cm from ground level (root collar); when the stump diameter from 42 to 58 cm, measure the diameter at a height of 20 cm, considering the use of the calliper scale of 4 cm.

Conclusions

1) Comparison of the graphs of dependence of the barrel diameter on the diameter of the stump Berlin poplar and aspen showed differences for both thin and thick trunks.

2) Recommended to use the translation table (Mezhibovski) can be used to calculate the damage from the illegal logging of poplars as amended: when the thickness of the stump 32 to 44 cm, measure the diameter of the stump at a height of 10 cm from ground level, with a thickness of

42 to 58 cm, measure the diameter at a height of 20 cm, considering the use of the calliper scale 4 cm. However, for a more accurate calculation of appropriate tabulations for each poplar separately.

Abstract

Forest management in a protected area, such as the Special Nature Reserve "Kovilj-Petrovaradin marshes" is determined by the rules and regulations that require nature protection, as well as forestry. All actions to be taken must strive to achieve the objectives of both professions. But, most importantly, it is necessary to manage the forest, this complex and very valuable natural resource, in the way that is most appropriate to the natural conditions on the ground. This paper presents an analysis of the natural conditions, bioecological characteristics of the forest habitats in the first protection regime. Pedological analyses are given, data about the plant cover on the studied area are given and finally, the characteristics of the forests are shown. Forest stands are also analysed from the aspect of classification into high conservation value forests, together with the classification and management process of these forest types, all in terms of the protection provided in this regime.

The aim of this paper is to examine and analyse the natural characteristics of forests and forest habitats in the first protection regime, as well as the management of this natural resource in the past. Eventually, the most important goal is to provide potential improvement options based on the greatest challenges during the past period.

Keywords: *Special nature reserve, Forest management, I protection regime, HCV forests*

Introduction

Forest management presents a set of harmonised technical, technical-technological, economic, organisational and social activities taken to protect, maintain, improve and use the forests (Forest Law, OG of RS 30/10, 93/12 and 89/15). On the other hand, nature protection presents a multidisciplinary approach of managing natural resources, created in order to solve different questions of nature management in a sustainable manner (Panjković *et al.*, 2016). Forest management in Serbia is defined by the Forest Law. The nature protection is defined by the Law on Nature Protection, which is determined as "lex specialis", considering specific function of forests and forest sites having the conservation function prioritized (Tarjan Tobolka, Stevanov, 2016). Common forest management measures cannot be applied in protected areas, they should rather be harmonised with protection goals. Forest management in the Special Nature Reserve "Kovilj-Petrovaradin Marshes" should be in accordance with the nature protection plans, which leaves very little space for forest management goals, in the first protection regime almost none. In the first protection regime there is neither forest management, nor nature resource management, in classical terms. In fact, only survey and research of spontaneous processes are allowed (Law on Nature Protection, OG of RS, 14/16). The aim of this paper is to provide analyses of the nature resource conditions in the first protection regime of the selected area by crossing the relevant data from forest management and nature protection. The final goal is to contribute to better understanding of the specialities and possible improvement of forest management in protected areas.

Materials and methods

The present work is done by document analysis, an iterative process of skimming, reading and interpretation of relevant data. According to Bowen (2009), combination of content and thematic analysis leads to new discoveries about the central questions of the research.

Materials for the analyses were the Study for the Protection, Forest Management Plans, revision documents, publications about the protected area and about other protected areas or nature protection both in Vojvodina province and Serbia. The legal framework of nature protection in Serbia has been included in the examinations. The analysis has been done in combination with the authors' personal studies and experience altogether with numerous contacts and interviews with relevant professionals. The analytic processing of relevant data has made it possible to provide a general overview of the environmental conditions and forest management in the first protection regime of the Special Nature Reserve Kovilj-Petrovaradin Marshes and to formulate possible suggestions for the future protection and forest management.

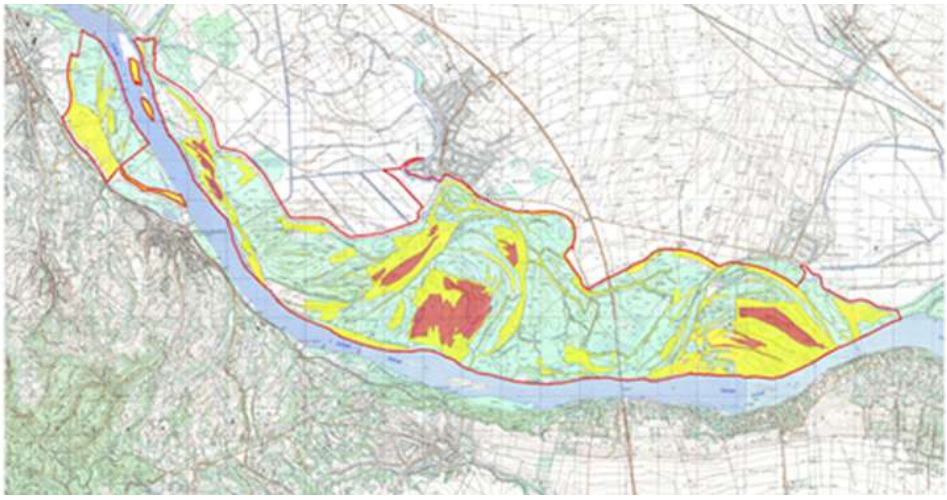
First protection regime

The first regime of protection (strict protection) is established on 373 ha (6%) of the total of 5.895 ha. It includes parts of the protected area with original or slightly modified ecosystems of exceptional scientific and practical significance (Law on Nature Protection, OG of RS", 14/16). In the first protection regime focus is put on the preservation of habitats and on enabling the processes of natural succession, being defined in the Law. The first protection regime is prescribed for the localities where natural or slightly modified forests of white willow (*Salix alba*), black and white poplars (*Populus nigra and P. alba*), pedunculate oak (*Quercus robur*), narrow-leafed ash (*Fraxinus angustifolia*), smoothleaf elm (*Ulmus carpinifolia*), and European white elm (*Ulmus effusa*) can be found, and also for the larger complexes of swamps and damp meadows that are isolated and difficult to access (Kurjacka greda: Ada Jamina I, Ada Jamina II; Kozjak: Veliki pesak, Kotao, Kozarnica; Carski Prud, swamps: Agla, Tonja, Zatonja, Barka, Provalija). From the aspect of forestry, the most important are the white and black poplar stands and the natural willow stands.

Characteristics of the vegetation

The whole area of the Kovilj-Petrovaradin Marshes lies by the river Danube and is in direct influence of the river's water regime. The vegetation is also hydrologically conditioned. The water regime of the habitats (high groundwater level and surface waters that regularly float them) has been the main ecological factor in the formation of the vegetation. Stevanović (1995) classes this area into the Pannonian-Danubian subregion of the Pontic-South Siberian floristic region.

The potential natural vegetation would be the community of lowland autochthonous forests of willows and poplars (*Ass. Salici-Populetum sensu lato*) and community of pedunculate oak (*Ass. Genisto-Quercetum roboris* Horv. 1938) (Parabućski *et* Janković, 1978). The associations of poplars and willows are formed on recent soils with longer remaining of floods, with groundwater on around 150 cm, the only few fragments of pedunculate oak communities are formed on older, stabilized or genetically developed alluvial soils (Panjković *et al.*, 2010).



Picture 1 SNR Kovilj-Petrovaradin Marshes - protection regimes
(I-red, II-yellow, III-light blue colors)[29]

Forest vegetation

The actual forest management plan (2012) classifies the forests of the first protection regime into two major groups: the forests formed in inundation, under influence of the water regime of the Danube river, and the forests formed by intensive human influence (plantations of poplar and willow clones) under influence of water management facilities such as embankments, canals, conduits, etc.

The forest management plan recognises seven groups of forests in the first protection regime:

1. High willow stands on wet recent alluvial deposits and gleyed soils;
2. Devastated willow stands on wet recent alluvial deposits and gleyed soils;
3. High stands of other poplars on mosaic of different alluvial soils;
4. High devastated poplar stands on mosaic of different alluvial soils;
5. High stands of green ash on mosaic of different alluvial soils;
6. Willow plantations on wet recent alluvial deposits and gleyed soils;
7. Plantations of euroamerican poplar clones on mosaic of different alluvial soils.

Natural stands of white and black poplars (on 30.60 ha) are classified into the third group, other poplars, with the aim to divide them of the economically managed plantations. Even in the first protection regime we can find clonal plantations, euroamerican poplars on 1.55 and willow on 18.19 ha. The green ash (4.33 ha) presents an introduced, invasive species, its presence testify about the forest management in the past period. However, one of the main goals is to replace it with native species, but only after the period of renewal (80 years for green ash).

Regarding the soil types, the management plans mention just two groups of soils, the wet recent alluvial deposits and gleyed soils and the mosaic of different alluvial soils. The Study of protection states that soils are formed on alluvial deposits, and that they are in permanent influence of the floods and groundwater. The soils are generally undeveloped, because of the oscillations of the groundwater, which transports elements with water, and because of the floods which removes the few formed soil parts. The mechanical composition of soils alters by moving from the river banks: sand dominates near the riverbed, and in farther parts dominate the sludge, with different combinations of deposited layers between them. The chemical characteristics are favourable for forest vegetation, they are rich in carbonates, neutral to slightly alkali reaction. Humification and mineralisation is well, except on swamped

[29] Source: Panjković *et al*., 2010.

soils. Beginning of real pedogenetical processes can be found only on higher positions with minimal deposition and removing of substrates (Panjković *et al.*, 2010).
The available reference data about the soils suggests, that further research, particularly for smaller sites, would describe better the site characteristics, which could lead to better understanding of the natural conditions and processes, convenient for each tree species, and finally help in deciding for future planning in forestry.

Results and discussion

Analysis of the improvement options

The guidelines for nature protection suggest the monitoring of populations of autochthonous flora and natural habitats along with the education and popularisation of preserved values of the entire biological diversity of the reserve, as well as fostering development of naturally emerging forests on recent Danube deposits (Panjković *et al*., 2010). On the other hand, the same Study of protection and the Protection act (Panjković *et al.*, 2010, SG of RS 27/98, 91/06, 81/08) limits the actions in the first, and in all, protection regimes, but also prescribes some measures to be taken. The question is whether or not these actions support the natural succession of forest vegetation in the strict zone of protection?
Since the autochthonous forests of willows and poplars, and also the communities of pedunculate oak are really rare, and remained only in fragments or very small areas, they should also be protected. Dredging of the canals is a highlighted activity since the protection was proclaimed (Puzović *et al.*, 2015). But, on the other hand, dredging of canals and other linear wetland depressions change the actual natural transport and deposition of flooded material, the soil formation is also altered, and finally formation of higher sites is questioned. Dredging of meanders of the old Danube, ecological restauration of wet habitats, revitalization of wet and swamp habitats is favourable for some ecosystems (Stojnić *et al.*, 2015, Puzović *et al.*, 2015), but their impact on forest ecosystems and further formation of forests of autochthonous tree species along the excavation is questioned.
Reviewing reference data and contacting the relevant professionals hasn't been found any concrete taken or planned activity with the aim of restoration of natural, autochthonous forests. The Study of protection, the forest management plans, management program of the protected area all recognise the importance of protection of natural forests. Particularly, the Study of protection prescribes filling the secondarily opened sites with autochthonous tree species, but none of the documents prescribes real measures with the aim of enabling the natural processes form the soils and micro habitats convenient for native forest vegetation of the area.
The Study of protection claims that regular removing of deposits and maintenance of water courses in the canals significantly slows raising of the ground and succession of vegetation, which contributes to the preserving of natural values of the area (Panjković *et al.*, 2010). In contrary, selecting parts of the first protection regime and creating favourable conditions for natural forest formation would improve and accelerate the restoration of autochthonous forests, which are also natural values of the area. It would be necessary to leave the processes of deposition and soil formation flow undisturbedly. The invasive and alochthonous tree species should be removed, leaving the space for autochthonous tree species. Permanent monitoring and acting accurately if needed would obviate disturbing the natural processes of forest restoration, and also obviate disturbing the preservation of other natural habitats and ecosystems in the close sites.
The Study of protection (Panjković *et al.*, 2010) recognises the importance of the preservation of forests and prescribes measures mostly oriented towards the protection and reintroduction of autochthonous tree species. It highlights that the species of pedunculate oak, narrow-leafed ash, smoothleaf elm, European white elm and black poplar should be preserved, because of

their rare prevalence, even if they are native in alluvial forests. The Study also suggests the consideration of the possibility of planting these species on higher sites or places where euroamerican hybrid poplars have taken their place.

Revising the forestry and the protected area management plans and the abovementioned documentation, it has not been found any exact locations of the mentioned species. Neither the exact locations of the trees, nor the ecological - pedological conditions of the sites are known. This suggests, that further analysis of the natural spread, the ecological characteristics of the site conditions are needed to be discovered. Mapping of the tree spread, together with soil characteristics, a database with exact GPS coordinates of the remaining trees of these species, would give an exact data convenient for further management. It would also enable us the monitoring of the situation in the field which would answer to the demand defined in the "Possible perspectives of sustainable development" of the Study of protection that "sustainable management of forests and development of forestry as part of economy is possible to achieve only by constant monitoring and determination of the state of forest fund, professional planning for long and short term and effective realisation of plans".

Forests of High Conservation Value (HCV forests) are proclaimed when some of their environmental or social values are dominatingly important on global, regional or local level (Laketić *et al*, 2012). Management should be oriented towards the conservation and promotion of their specific values. Review of the relevant documentation has shown, that in the process of forest certification all forests in the first protection regime are proclaimed as HCV forests (PE Vojvodinašume archive, 2018). On the other hand the forest management plans in the Republic of Serbia doesn't recognise HCV forests as management class, and does not classify them by this name (OG of RS 122/03, 35/10, 30/10, 93/12 and 89/15). Revision of the management plans actually shows their similar management status, but by other name. The data revealed shows the need of harmonisation of the terminology and management options in forest management with the international standards of certification.

Conclusions

Selecting sites and creating favourable conditions for natural forest formation in the first protection regime would possibly lead to natural formation of communities of pedunculate oak and other autochthonous species. Monitoring of the forest formation processes would give valuable data regarding the really rare appearance of such natural forests. The actions would be as prerequisite need either the change of the protection zone (to one where land management is allowed) or amendments in the higher policy.

Creating a database with GPS coordinates of the spread of foundation species like pedunculate oak, narrow-leafed ash, smoothleaf elm, European white elm and black poplar could contribute to further management planning and monitoring of the situation in the field.

All the forests in the first protection regime are classified as HCV forests, management options are actually accurate to the demands of the specific needs, but the forest management plans doesn't recognise this management category.

COMPARATIVE EFFECTIVENESS OF SOME INSECTICIDES IN CONTROLLING *IPS TYPOGRAPHUS*

Mara TABAKOVIĆ-TOŠIĆ*, Marija MILOSAVLJEVIĆ

Department of Forest Protection, Institute of Forestry Belgrade, Serbia
*Corresponding author: mara.tabakovic@gmail.com

Abstract

In the field (Golija Mountain, spruce forest approximately 80 years old, outbreak of *Ips typographus*) and semi-controlled laboratory conditions (Institute of Forestry in Belgrade), studies of the biological efficacy in the control of *I. typographus* adults, two concentrations (2% and 3%) of selected chemical (Fastac®Forst – active ingredient Alpha-cypermethrin) and biological insecticides (Naturalis Biogard® – active ingredient spore of *Beauveria bassiana*), were conducted. On June 13th, 2017, five TRIPODs in three repetitions, were installed along the edge of a forest stand, alternating in a single line with 10 m spacing. TRIPODs comprised of three spruce logs, 1.5 m in length and minimum 19 cm in diameter. Logs were taken from freshly cut healthy spruces. Trap logs were treated with insecticides diluted in water. The TRIPODs were baited with aggregation pheromone dispenser IT Ecolure that was attached to the top. After two months, bark beetles were sampled together with bark. Three samples approximately 34 x 13 cm in size, were taken from the upper, central and lower part of each log. The samples were placed in plastic boxes, stored in the laboratory and controlled at seven-day intervals. Experiments was established in the complete random block pattern in three repetitions, where the blocks for each variant present 3 samples. Fastac®Forst, in accordance with its functioning, caused 100% mortality of the adult *I. typographus* before their boring in the logs. No evidence of *B. bassiana* infection was reported in the collected individuals. The percentage of *I. typographus* individuals infected with *B. bassiana* on logs treated with Naturalis Biogard® 2% was 45.9%, and for Naturalis Biogard® 3% - 39.3%.

Key words: *Fastac®Forst, Naturalis Biogard® biological efficacy, Ips typographus*

Introduction

The epidemic desiccation of mainly autochthonous spruce stands, the uniform and mixed ones, as the modern phenomenon, is present in the most countries of Southeastern and Central Europe, and in the Republic of Serbia, due to the very unfavorable, extreme climatic conditions over the period 2011-2012, gained unprecedented scope in the forest areas which are under the special regime of protection, such as the Nature Park and the "Golija-Studenica" Biosphere Reserve. The changes in the trees induced by the desiccation, the reduction of the transpiration, of the carbon assimilation, have significantly reduced their natural, mainly chemical resistance to the attacks of the various xylophagous insects, so the population size of *Ips typographus* L. (Coleoptera: Curculionidae) was extremely increased over the period 2015-2017 (Tabaković-Tošić & Milosavljević, 2016, 2018).

In the Serbian forestry the certification based on the principles of the sustainable forest management was adopted in 2006. During the preparation of it, the FSC Criteria (FSC-STD-01-001, 2004), relating to pesticide use (Criterion 6.6, 10.7, 10.8), proved to be particularly interesting. FSC has a list of chemicals that are prohibited, and almost all previously registered and applied chemical insecticides are on this list. A company applying for certification would normally have to stop using these chemicals before it can receive an FSC certificate. One of the steps on the path towards obtaining the permission for putting into circulation and for application of some insecticide is the study of the biological efficacy of it,

i.e. of its ability to reduce a number of economically harmful insects to the normal level, which is considered to be safe.

The main aim of this research was to compare the biological efficacy of two insecticides (chemical and biological), both in two concentrations (2 and 3%) in the control of adults of *I. typographus*.

Material and method

In the field (Golija Mountain, spruce forest approximately 80 years old, outbreak of *I. typographus*) and semi-controlled laboratory conditions (Institute of Forestry in Belgrade), studies of the biological efficacy in the control of *I. typographus* adults, two concentrations (2% and 3%) of insecticides Fastac®Forst and Naturalis Biogard®, were conducted. Based on the technical documentations, Fastac®Forst (active ingredient - 1.5% Alpha-cypermethrin) is non-systemic chemical insecticide with contact and digestive action, in the form of a liquid concentrated suspension (SC). The formulated product, bionisecticide Naturalis Biogard® is a concentrated suspension of at least 2.3 x 10^7 spores/ml of *Beauveria bassiana* (Balsamo) Vuillemin strain ATTC 74040. It is a suspension of conidiospores in vegetal oil, which improves spore germination and UV protection, enhancing the efficacy of the antagonist in the field. *B. bassiana* acts primarily by contact. According to technical documentation for Naturalis Biogard®, once attached to the insect's cuticle, its conidia germinate producing hyphae, which penetrate the cuticle and proliferate inside the insect's body and causes their death within 3-5 days. After the host's death, new conidia may be produced and released on the outside of the insect cadaver. *B. bassiana* strain ATTC 74040 does not produce any toxins: the infected host dies due to dehydration and/or depletion of nutrients. On June 13th, 2017, five TRIPODs in three repetitions, were installed along the edge of a forest stand, alternating in a single line with 10 m spacing. TRIPODs comprised of three spruce logs, 1.5 m in length and minimum 19 cm in diameter. Logs were taken from freshly cut healthy spruces. Trap logs were treated with insecticides diluted in water. The TRIPODs were baited with aggregation pheromone dispenser IT Ecolure that was attached to the top and covered with spruce branches (Figures 1-3).

Figures 1-3: Treated TRIPODs (Original)

After two months, bark beetles were sampled together with bark. Three samples approximately 34 x 13 cm in size, were taken from the upper, central and lower part of each log. The samples were placed in plastic boxes, stored in the laboratory (Figures 4-6) and controlled at seven-day intervals.

Figures 4-6: Samples and second part of experiment in semi-controlled laboratory conditions (Original)

Table 1. Scheme of the experiment in the field - the complete random block pattern in three repetitions.

BLOCK I			**BLOCK II**			**BLOCK III**		
Fastac®Forst 2%			Naturalis Biogard® 2%			Naturalis Biogard® 3%		
12	25	41	16	32	33	5	21	36

Experiments was established in the complete random block pattern with five treatments in three repetitions (Table 1), where the blocks for each variant present 3 samples. Mean daily temperature and relative humidity for the June and July 2017 [data of the Republic Hydrometeorological Service of Serbia, Zlatibor (α: 43°44' N; δ: 19°43' E; the altitude of 1029 m)] are presented in the Fig. 7 & 8.

Figures 7-8: Mean daily air temperature (7) and relative humidity (8) for the June and July 2017 (Zlatibor Meteorological station).

Results and discussion

After 40 days of exposure, Fastac®Forst, concentration 3%, in accordance with its mode of action, caused 100% mortality of the adult *I. typographus* before their boring in the logs (Table 2, Fig. 9&10). No evidence of *B. bassiana* infection was reported in the collected individuals.

1 – First evaluation after 15 days; 2 – Second evaluation after 40 days

Figures 9 & 10: Dead adults of *Ips typographus* on the spruce log treated with insecticide Fastac Forst® (First evaluation) (Original)

All the samples taken from logs treated with *B. bassiana*, manifested occurrence of the pathogen in direct association with adults of *I. typographus* at frequencies higher than in samples taken from untreated logs. The percentage of *I. typographus* dead and alive individuals infected with entomopathogenic fungus *B. bassiana* on logs treated with Naturalis Biogard®, concentracion 2%, was 45.9%, and for Naturalis Biogard®, concentracion 3% - 39.3%, and it were significantly higher than in the case of control (4.0%). Logs treated with

insecticide Fastac®Forst, concentrations 2% and 3%, were without attack of *I. typographus* (Table 3).

Fungal activity is strongly influenced by the biotic and abiotic environment. The unfavorable condition (temperature, relative air humidity, precipitation…) hindering the pathogen to develop as saprophyte on host cadavers. These aspects must be considered in evaluation of results. During the experiment, the mean daily air temperatures and the mean daily values of relative humidity were mostly found below the optimum values, which contributed to the reduction of the biological efficiency of insecticides Naturalis Biogard® (Fig. 7&8).

In the conditions of high humidity, the mortality strongly depends on the temperature and the *B. bassiana* dosage (Wegensteiner, 1992). Kreutz (2001) have applied biopreparation of *B. bassiana* and insecticidae Fastac®Forst on spruce logs just after finishing of their colonization by *Ips typographus* an achieved 100% mortality in the case of insecticide and 93% mortality in case of biopreparate. Vaupel and Zimmermann (1996) and Jakuš & Blaženec (2011) in the similary experiment achived the lower mortality. Their results are more similar to mortality achieved in our experiment. The timing of biopreparation application, before or after colonization of *Ips typographus* is probably the critical factor.

Acknowledgments

The study was partly financed by the Ministry of Science of the Republic of Serbia, the Project 31070 - SUBPROJECT: New technological methods in the integral protection of forests with the focus on the entomopathogenic fungus *Entomophaga maimaiga*, as the possible solution to the problem regarding the frequent occurrences of the outbreak of gypsy moth in the forest ecosystems of Serbia.

CHARACTERISTICS AND INITIAL EFFECTS OF THINNING IN A POPLAR PLANTATION OF THE PANNONIA CLONE

Siniša ANDRAŠEV[1*], Martin BOBINAC[2], Vladislava GALOVIĆ[1]

[1]Institute of Lowland Forestry and Environment, University of Novi Sad, Serbia

Abstract

Research was performed in a plantation of the poplar clone Pannonia on alluvial soil of the Danube River, with a planting distance of 4.25×4.25 m. At the age of 10 years a field experiment was established comprising two experimental plots with moderate and heavy thinning and one control plot in three replications within a randomized block design, each area of 0.1 ha. The mean height grew to 26.2 m, and breast height diameters from 22 to 22.2 cm. On the experimental plots were recorded from 522 to 542 trees per hectare, i.e. the survival amounted from 94.1 to 97.7%, with a basal area of 19.9-20.7 $m^2 \cdot ha^{-1}$. On the experimental plots with moderate thinning an average of 130 trees per hectare (24.0%) were felled in total with the basal area of 3.61 $m^2 \cdot ha^{-1}$ (17.4%), and on the experimental plot with heavy thinning an average of 247 trees per hectare (47.3%) were felled with the basal area of 8.21 $m^2 \cdot ha^{-1}$ (41.2%). The diameters of all trees were measured after 11 years to determine the initial effects of thinning. The trees showed higher diameter increment by 4-11% and basal area by 11-21% on the thinned experimental plots compared to the control plot, but the differences were not significant. The growth of the basal area per hectare was highest in the control plot, 1.66 $m^2 \cdot ha^{-1} \cdot year^{-1}$, while in the experimental plot with moderate thinning it was 1.51 $m^2 \cdot ha^{-1} \cdot year^{-1}$, and the differences were not significant. The increment of the basal area per hectare was lowest in the experimental plot with heavy thinning, 1.06 $m^2 \cdot ha^{-1} \cdot year^{-1}$, and the differences were significant in relation to the control plot.

Key words: *Clone Pannonia, alluvium of the Danube River, thinning, diameter increment, basal area increment*

Introduction

Poplars are fast-growing and light-demanding tree species whose growth significantly determines the density of plantations, i.e. the space for tree growth. This allows establishment of plantations with different densities, depending of the purpose, such as plantations for the production of logs, plantations for the production of cellulose wood and energy plantations (Marković *et al.*, 1997). In the practice today, the plantations for the production of technical wood are dominant, which is a consequence of the market demands for more valuable assortments.

Thinning in poplar plantations are not mandatory silvicultural measures and are implemented in case where the plantations are established in denser spacing with the aim that at a certain age the tree number, which carry the production and its value by the end of the production cycle, are decreased. They are mostly schematic and are performed by removing of every second rows (Marković *et al.*, 1994). However, recent research highlights the importance of a selective approach in the thinning, because in this way the collective of the remaining trees, which carry the production and value of the plantation until the end of the production cycle, is homogenized (Andrašev *et al.*, 2011; 2012; 2015).

Thinning, as very sensitive silvicultural measures in poplar plantations, are defined by the knowledge of the biological characteristics of tree growth and the maximum reaction of the

trees to thinning can be expected in the period when the trees are in the phase of intensive height increment (Marković *et al.*, 1994; Andrašev *et al.*, 2011; 2015).
Previous research, as well as experience gained in practice, suggests that in poplar plantations should be used several registered varieties (clones) with the permanent change of existing clones susceptible to pathogens with newly registered clones which should be established in polyclonal plantations or mixtures of several monoclonal plantations on smaller areas (Andrašev, 2008).
The objective of this study is to show characteristics of moderate and heavy thinnings and their initial effects after one year in a poplar plantation of the Pannonia clone having in mind that this clone has a higher representation and the tendency of expansion in practice in Serbia.

Materials and methods

The research was carried out in the experimental trial of the Pannonia clone (*Populus* × *euramericana* Dode Guinier), the working name M-1, established on the planting distance of 4.25×4.25 m. The trial is located in the area of Public company Vojvodinašume, Forest holding Sombor, Management Unit „Kamarište", department 5, section a (latitude 45°29', longitude 19°03'). At the age of 10 years an experimental trial in randomized block design with three repetition was established. Each block consists of two experimental and one control plot (CP) with an area of 0.10-0.12 ha separated from each other by a single row. On the plots, selective moderate (EP1) and heavy (EP2) thinnings were performed. All trees were numbered and their breast height diameter was measured. The heights of the trees were measured with the Vertex III hypsometer, as well as with tape on all felled trees in the thinning, on at least 10 trees in each diameters class of 5 cm wide, and used to construct a height curve. In order to examine the initial effects of performed thinnings on diameter and basal area increment all trees were measured in the diameter at the breast height at the age of 11 years. To reconstruct the height growth, the height (length) of each whorl of branches were measured with tape on three mean trees felled in the thinning, which correspond to heights of these trees in each previous years.
Data processing consisted of a standard procedure for determining the elements of growth of mean and dominant trees, where the height curve was previously constructed. The volume of trees was obtained using volume table by Pantić *et al.* (2009), while the basal area and volume per hectare were obtained as the sum of the basal areas and the volumes of the trees on the experimental plots and multiplying with the corresponding coefficient of the area of each plot. For the objective comparison of growth elements, the ANOVA and $LSD_{0.05}$ test were used.

Results and discussion

Trees of poplar clone Pannonia in the researched conditions after 10 years of development achieved uniform growth in height on all plots. The dominant heights are 27.2-27.3 m, and the mean heights are the same, 26.2 m. Similar to heights, the mean and dominant breast height diameters are uniform in the plots and range from 22.0-22.2 cm (d_g) to 25.1-25.5 cm (D_{100}). In the plantation were found 522-542 trees per hectare, i.e. the survival was 94.1-97.7%. The total basal area was 19.9-20.7 $m^2 \cdot ha^{-1}$, and the total volume was 225.2-233.7 $m^3 \cdot ha^{-1}$. The ANOVA test did not determine the significant variation of the elements of growth of trees and plantations between experimental plots at the age of 10 years (Table 1).
The high intensity of height increment continued to 7 years of planting age, after which height increment decreased, which is expected biological characteristics of poplar clones (Marković *et al*, 1994, Andrašev, 2008). The growth of trees in height was intense in the period from 3 to 5 year, and in the age of 6 years a significant decrease was caused by exogenous influence (Figure 1).

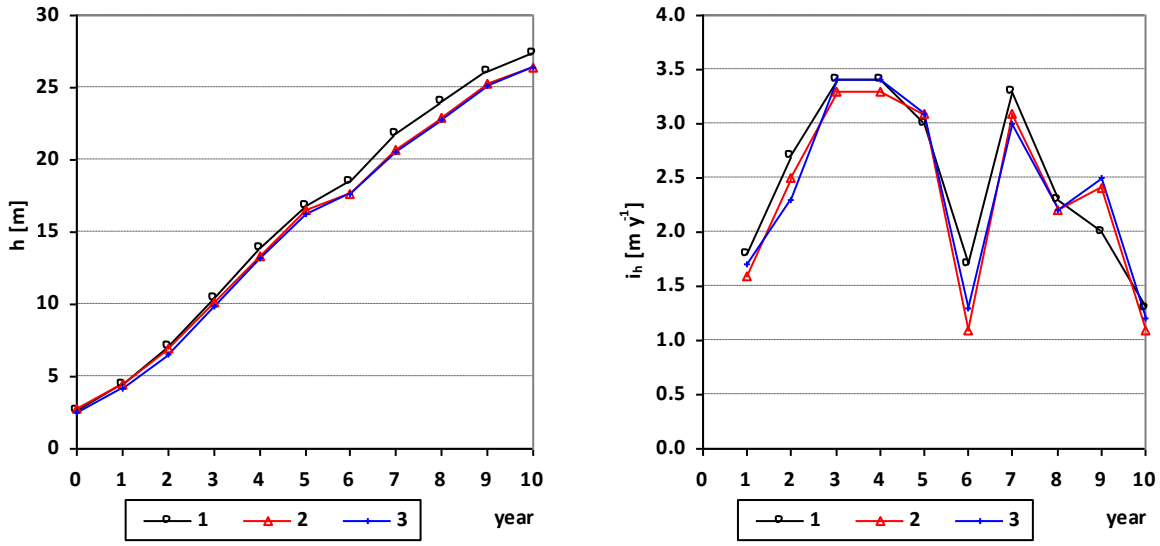

Figure 1. Height growth (left) and current height increment (right) of three mean trees.

The plantations had a good growth and the achieved mean height of 26.2 m at the age of 10 years is by 5.8 m higher than the same clones on a medium favorable habitat in the middle Danube region established at the spacing of 5×5 m (Andrašev, 2008). Also, the achieved mean heights of the Pannonia clone is higher by 1.9 m from the heights of clone I-214 at the same planting space on a favorable habitat (Pudar, 1982), and by 3.7 m on medium favorable, or by 6.3 m to less favorable habitat (Pudar, 1986). This suggests that the researched habitat belongs to the category of favorable habitats for poplar growth. However, the mean diameter of 22.1 cm at the age of 10 years is less than 0.5 cm from the mean diameter of the same clone at a medium favorable habitat in the middle Danube region established at the 5×5 m planting distance (Andrašev, 2008), as well as from clone I-214 at the same planting distance at a favorable habitat where is less 6.3 cm (Pudar, 1982) and on medium favorable where is less 1.4 cm, while they are 0.9 cm higher in a less favorable habitat (Pudar, 1986). The different dynamics of the height and diameter growth of the clone Pannonia is due to in part the different growth characteristics of poplar clones (Andrašev, 2008), but also the influence of density, i.e. the competition between trees in the zone of crowns. The decrease in current height increment after 7 years, and especially at the age of 10 years can be related to the impact of the density of the researched plantation. This indicates that the thinning was to be carried out at the age of 8-9 years, when the current height increment was still high and when the trees are expected to best respond to increase of growing space.

On the plots with moderate thinning (EP1) an average of 130 trees per hectare were felled, with total basal area of 3.6 m^2·ha^{-1} and total volume of 38.7 m^3·ha^{-1}, i.e. the harvest was 24%

by number of trees, 17,4% per basal area and 16.6% by volume. On the plots with heavy thinning (EP2) an average of 247 trees per hectare were felled, with total basal area of 8.2 $m^2 \cdot ha^{-1}$ and total volume of 90.9 $m^3 \cdot ha^{-1}$, i.e. the harvest was 47.3% by number of trees, 41.2% per basal area and 40.4% by volume. The mean diameter and the mean height of the allowable cut are smaller than the mean height and mean diameter of plantation before the thinning, which indicate that the thinnings on both experimental plots (EP1 and EP2) had the character of a low thinning. The ANOVA test did not confirm a significant difference between average diameters and heights of the allowable cuts on the plots, while the total number of trees harvested per hectare, as well as their total basal area and volume, are significantly higher on the EP2 plots (Table 2).

Table 2. Growth elements of felled trees, characteristics of allowable cut at the age of 10 years, and results of ANOVA test.

Exper.	h_L	d_g	N	G	V	Percentage of the initial state				
plot	[m]	[cm]	[trees·ha^{-1}]	[$m^2 \cdot ha^{-1}$]	[$m^3 \cdot ha^{-1}$]	h_L	d_g	N	G	V
EP1	24.5	18.8	130	3.61	38.73	93.5	85.5	24.0	17.4	16.6
EP2	25.4	20.5	247	8.21	90.88	96.9	93.2	47.3	41.2	40.4
F test	1.49	1.87	72.36	15.41	13					
p value	0.2893	0.2431	0.001	0.0172	0.0226					

The intensity of thinning at the age of 10 years in EP2 of 47% by number of trees is a procedure that is usually carried out in plantations with schematic thinning. The intensity of thinning by volume is lower (40%) and indicates that it has the character of a low thinning and differs from the typical schematic thinning. The achieved allowable cut on EP1 of 91 $m^3 \cdot ha^{-1}$ is smaller than allowable cut of the clone I-214 on a favorable habitat conducted after 6 (Marković *et al.*, 1994) and 8 years (Pudar, 1986) at the same planting distance, and higher than allowable cut of the clone I-214 on medium and less favorable habitat after 8 years (Pudar, 1986). In the researched plantation allowable cut is also higher than that obtained in the thinning of the clone I-214 with wide spacing (6×6 m) after 11 years (Andrašev *et al.*, 2012), as well as in the thinning after 8 years in the plantation of the clone B-229 established at a distance of 5×5 m on a medium favorable habitat (Andrašev *et al.*, 2011).

The implemented silvicultural treatment of moderate thinning is rarely applied in the practice. The obtained allowable cut of 39 $m^3 \cdot ha^{-1}$ on EP1 is twice lower than that obtained in the moderate thinning of the clone I-214 after 9 years established on a favorable habitat at a wide spacing of 6.5×5.63 m (Novaković, 1981).

After thinnings, which were performed on the plots EP1 and EP2, mean heights and mean diameters are slightly larger than these values befores the thinnings, while the dominant heights and the dominant diameters remained almost unchanged. The ANOVA test did not reveal significant differences between mean and dominant diameters and heights on plots. However, a significant difference was found in growth elements of plantations per hectare (N, G, V) (Table 3).

At the age of 11 years the mean diameters were the smallest on the control plots, on average 23.1 cm, they were somewhat larger on plots with moderate thinning (EP1), on average 24 cm, and the highest on plots with heavy thinning (EP2), on average 24.3 cm. The dominant diameters were less variable compared to the mean diameters. The ANOVA test did not confirm the significant difference between the mean and dominant diameters on the plots at the age of 11 years. The number of trees per hectare decreased on control plots, due to exogenous influence, and on plots it remained unchanged. The total basal area is the highest on the control plots, on average 21.9 $m^2 \cdot ha^{-1}$, on experimental plots it is significantly lower, and on average amounted 18.6 $m^2 \cdot ha^{-1}$ in EP1, and in EP2 amounted 12.8 $m^2 \cdot ha^{-1}$ (Table 4).

*Letters indicate different homogeneity groups according to the $LSD_{0.05}$ test.

At the age of 11 years the current diameter increment of mean trees was approximately 1 cm on all experimental plots, or from 0.93 cm (CP) to 1.03 cm (EP2). The differences are not statistically significant, nor are the differences in the increment of dominant trees (i_{D100}). Basal area increment of the mean trees (i_g) were uniform, from 31.8 cm^2·year^{-1} (CP) to 38.7 cm^2·year^{-1} (EP2), as well as the basal area increment of the dominant trees (i_{G100}). However, the basal area increment per hectare (I_G), on average 1.61 m^2·ha^{-1}·year^{-1}, is the highest on the control plots and significantly differs from the basal area increment on experimental plots with a heavy thinning, where is on average 1.06 m^2·ha^{-1}·year^{-1} (Table 4).

The annual effects of the thinnings expressed by a tree are positive in comparison with the control plot. Diameter increment of the mean tree is larger by 7-15%, and the basal area increment by 11-21%, indicating that the remaining trees reacted to the increased growing space. On the reaction of the remaining trees after the thinning clearly indicates the amount of basal area increment per hectare being higher by 51% on the control plot than on the plot with heavy thinning, while the number of trees on the control plot is higher by 89%.

The obtained results are in agreement with previously published results that poplar clones strongly respond to increased growing space already after 3 years (Andrašev *et al.*, 2015), and 5 years after the conducted thinning (Andrašev *et al.*, 2012), under conditions that the remaining trees were in the stage of intensive height and diameter increment.

Conclusions

In the plantation of poplar clone Pannonia, established on the planting distance of 4.25 × 4.25 m, at the age of 10 years the mean height was 26.2 m indicating favourable habitat conditions for the poplar growth. The mean diameter was 22.1 cm and is the result of the influence of tree competition that shows a clear influence on the current height increment of mean trees at the age of 8 years when from biological aspect was supposed to make a thinning in order to achieve the maximum effects.

Realized low thinnings with moderate and heavy intensity were achieved the allowable cut of 39 $m^3 \cdot ha^{-1}$ and 91 $m^3 \cdot ha^{-1}$ which are within the limits of the realized allowable cuts in poplar plantations of other clones.

The initial effects of thinning after a year are reflected in the intensification of the diameter and basal area increment of mean tree by 4-11%, ie by 11-21%, compared to the control plot, and the differences are not significant. However, the basal area increment per hectare of 1.61 $m^2 \cdot ha^{-1}$ is the highest on the control plot and is significantly different from the basal area increment on the plot with a heavy low thinning where it was 1.06 $m^2 \cdot ha^{-1}$.

Abstract

The paper presents the characteristics of the increment of tree growth elements (height, diameter, basal area and volume) in the monoculture of the spruce (*Picea abies* Karst.) in the period of 33-40 and 41-50 years, after the application of heavy selective thinnings. In both periods, the trees with larger dimensions, i.e., breast height diameter, had greater increments of growth elements compared to the smaller trees. By grouping trees in the group of 200 trees per hectare sorted by their diameters showed that after the first thinning the 600 thickest trees per hectare had uniform increments of diameter at breast height, basal area and volume being significantly larger than the next group of thinner trees. In the period after the second thinning, the groups of the 200 thickest trees per hectare had significantly higher increments of diameter, basal area and volume in relation to the next groups of 201 to 600 thickest trees that had a uniform and significantly greater increments from the following groups of the thinner trees. The results indicate that in the studied spruce plantation only 600 thickest trees per hectare singled out according to the size of the increment in the period after the first thinning. In the period after the second thinning, only the 200 thickest trees were singled out according to the size of the increment in diameter at breast height, basal area and volume, which indicates to intensive differentiation of trees according to the increment potential under the influence of heavy selective thinning.

Key words: *Picea abies* Karst., increment of growth elements, differentiation of trees, increment potential.

Introduction

In Serbia excluding Kosovo, Norway spruce cultures cover an area of 32,400 ha (Banković et al, 2009). A large number of these cultures typically had a spontaneous development in the first decades after the establishment. The first thinnings were usually carried out at the age when economically viable assortments were most likely to be obtained. Such a trend has also been a characteristic of other conifer cultures throughout Europe because late crown thinnings provide higher and more valuable cutting yields (Slodičak et al, 2005).

The results of long-term research of the effects of thinnings in spruce cultures generally indicate that the stands have a positive reaction to the thinnings, regardless of the age when commercial thinnings are performed (Mäkinen and Isomäki 2004a, 2004b). Based on the results of the research on the application of two heavy selective thinnings on a permanent experimental plot in Serbia, a positive reaction of the tree for tending, *i.e*. the future trees, was determined at the age from 32 to 50 years (Bobinac et al., 2017). However, under conditions of ice and snow breaks to which the researched stand was exposed, a permanent selection of trees for tending based on the approach introduced by Schedelin (1934) was applied, and the reaction of trees depending on their dimensions was not clearly defined.

The aim of the paper is to point out to the characteristics of the increment of the growth elements (height, diameter, basal area and volume) of trees under the influence of two heavy selective thinnings depending on their dimensions, *i.e.* their breast height diameters, and to

define groups or the number of trees in certain stages of development with a similar reaction of the increment of growth elements to thinnings.

Materials and methods

The research was conducted in a Norway spruce culture on Velika Brezovica of the Kučaj mountain range in northeastern Serbia (MU Bogovina I, compartment 87a) which was established by afforestation of pasture with dense planting (2×1 *m*), and according to the available data from the management records it had not been thinned before the age of 32 years. A permanent experimental plot was established in the culture in 1994 when it was at the age of 32 years and in which strong heavy selective thinning was carried out. The second thinning, which was also a heavy selective thinning, was carried out when the culture was 40 years old. In the first thinning 1,378 trees were cut per hectare (35.2%), with a volume of 115.1 $m^3 \cdot ha^{-1}$, while in the second thinning 911 trees per hectare (46.1%) were felled down with the volume of 142.3 $m^3 \cdot ha^{-1}$ (33.7%) (Bobinac *et al*, 2017). All trees on the experimental plot were numbered and at the age of 32, 40 and 50 years two cross diameters at breast height, with an accuracy of 1 mm, were measured. For the construction of the height curve, the heights of the trees are measured with a Vertex III type hypsometer.

The influence of the thinnings on the current (average periodic) height increment (i_h), diameter increment (i_d), basal area increment (i_g) and volume increment (i_v) was analyzed with an identical group of trees that grew after the thinning in the period from 33 to 40 years and in the period from 41 to 50 years.

Testing the differences between mean increments of growth elements among the observed two periods was done with a t-test. The ANOVA and least significant difference ($LSD_{0.05}$) tests were used for testing differences between the average size of the increment of growth elements of trees grouped by the size of their breast height diameters in groups of 200 trees per hectare.

Results and discussion

The mean value of the current height increment of 52 $cm \cdot year^{-1}$ was significantly higher in the period from 33 to 40 years, compared to 42 $cm \cdot year^{-1}$ in the period from 41 to 50 years. However, the mean value of diameter increment (5.1 $mm \cdot year^{-1}$), as well as basal area (18.98 $cm^2 \cdot year^{-1}$) and volume increment (24.12 $dm^3 \cdot year^{-1}$) per tree, was significantly higher in the period from 41 to 50 years in relation to the mean value of diameter (3.1 $mm \cdot year^{-1}$), as well as basal area (8.92 $cm^2 \cdot year^{-1}$) and the volume increments (11.23 $dm^3 \cdot year^{-1}$) per tree in the period from 33 to 40 years (Figure 1).

Increments of growth elements grouped by the size of their breast height diameters into groups of 200 trees per hectare significantly differ in all increments and in both researched periods (Table 1).

The mean values of current height increments by groups of 200 trees per hectare, sorted by its diameters, show that the thickest trees have the highest current height increments in both periods and that increments are decreased in the thinner trees. The height increments of 600 thickest trees per hectare are uniform in both periods, and there are no significant differences between them. The mean values of current diameter increments, as well as basal area and volume increments per tree, are the highest in the thickest trees and are reduced in the thinner trees in both researched periods after the implementation of a heavy thinning. However, in the period after the first thinning a group of 600 thickest trees per hectare had a uniform diameter increment of 4.9-5.2 $mm \cdot year^{-1}$, a basal area of 15.5-17.4 $cm^2 \cdot year^{-1}$ and a volume of 18.5-23.4 $dm^3 \cdot year^{-1}$, as opposed to the period after second thinning, in which a group of 200 thickest trees per hectare with a current diameter increment of 7.5 $mm \cdot year^{-1}$, a basal area of 33.5 $cm^2 \cdot year^{-1}$ and a volume of 44.3 $dm^3 \cdot year^{-1}$, are separated. A group of 201-600 trees per hectare, sorted by their diameters, has significantly less current increment compared to the

group of 200 thickest trees per hectare, but also significantly higher than the next groups of thinner trees (Figure 2).

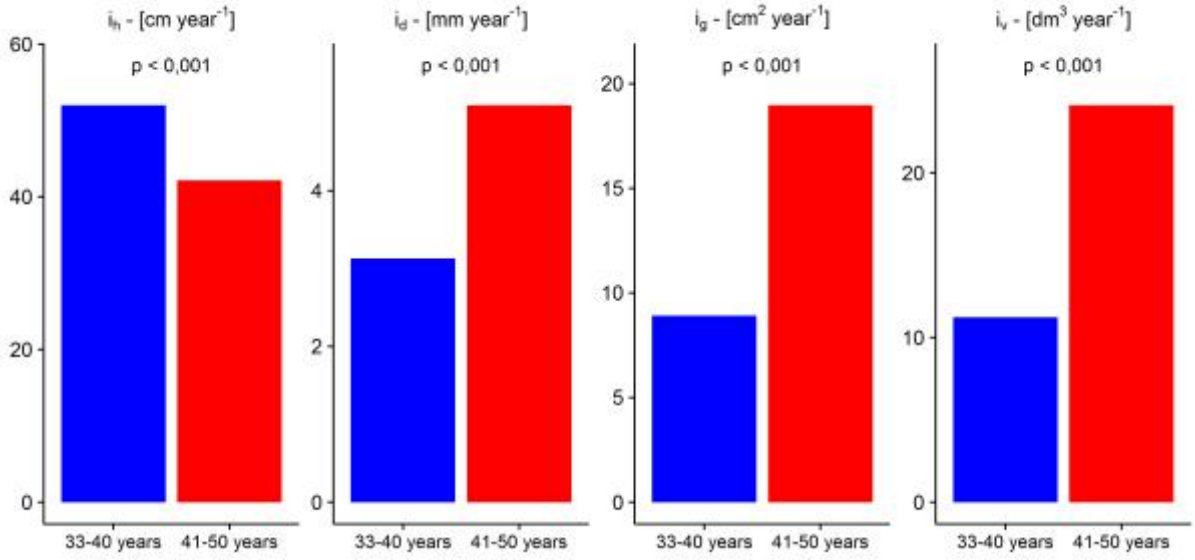

Figure 1. Average values of current increments of height, diameter, basal area and volume per tree in periods 33-40 and 41-50 years.

Table 1. Results of the ANOVA test (F coefficient) of the comparison of height, diameter, basal area and volume per tree of different breast height diameters by groups of 200 trees per hectare.

Period	Current increment of the growth elements			
	i_h	i_d	i_g	i_v
33-40 god.	595.68***	217.16***	294.58***	413.20***
41-50 god.	88.35***	108.30***	148.57***	164.22***

The thinning made in 32 years was the first intervention in the researched stand and was carried out in a period that does not significantly differ from the period when the first commercial thinnings in Europe were performed (Slodičak, Novak, 2003). Based on the characteristics of increments of the diameter and height of the dominant trees, the thinning is characterized as a delayed tending measure (Bobinac, 2004). However, the dominant trees, in particular 400 thickest trees per hectare, were in the phase of significant height increments at the time of the thinning, which conditioned the maintenance of high height increments in the period from 33 to 40 years. The mean height increment of 0.5 m·year^{-1} is in agreement with the growth characteristics of spruce trees at a similar age when the thinnings begin (Stojanović and Krstić, 1984, Orlić, 1991). However, the current height increment of the mean tree in the researched culture is higher compared to the height increment of the trees after the application of different thinnings on several series of experimental trials in the Czech Republic at a similar age (Slodičak, Novak, 2003). Makinen and Isomaki (2004a) state that the height increment does not depend on the intensity of the thinning and decreases with the age of trees, which is in line with our results.

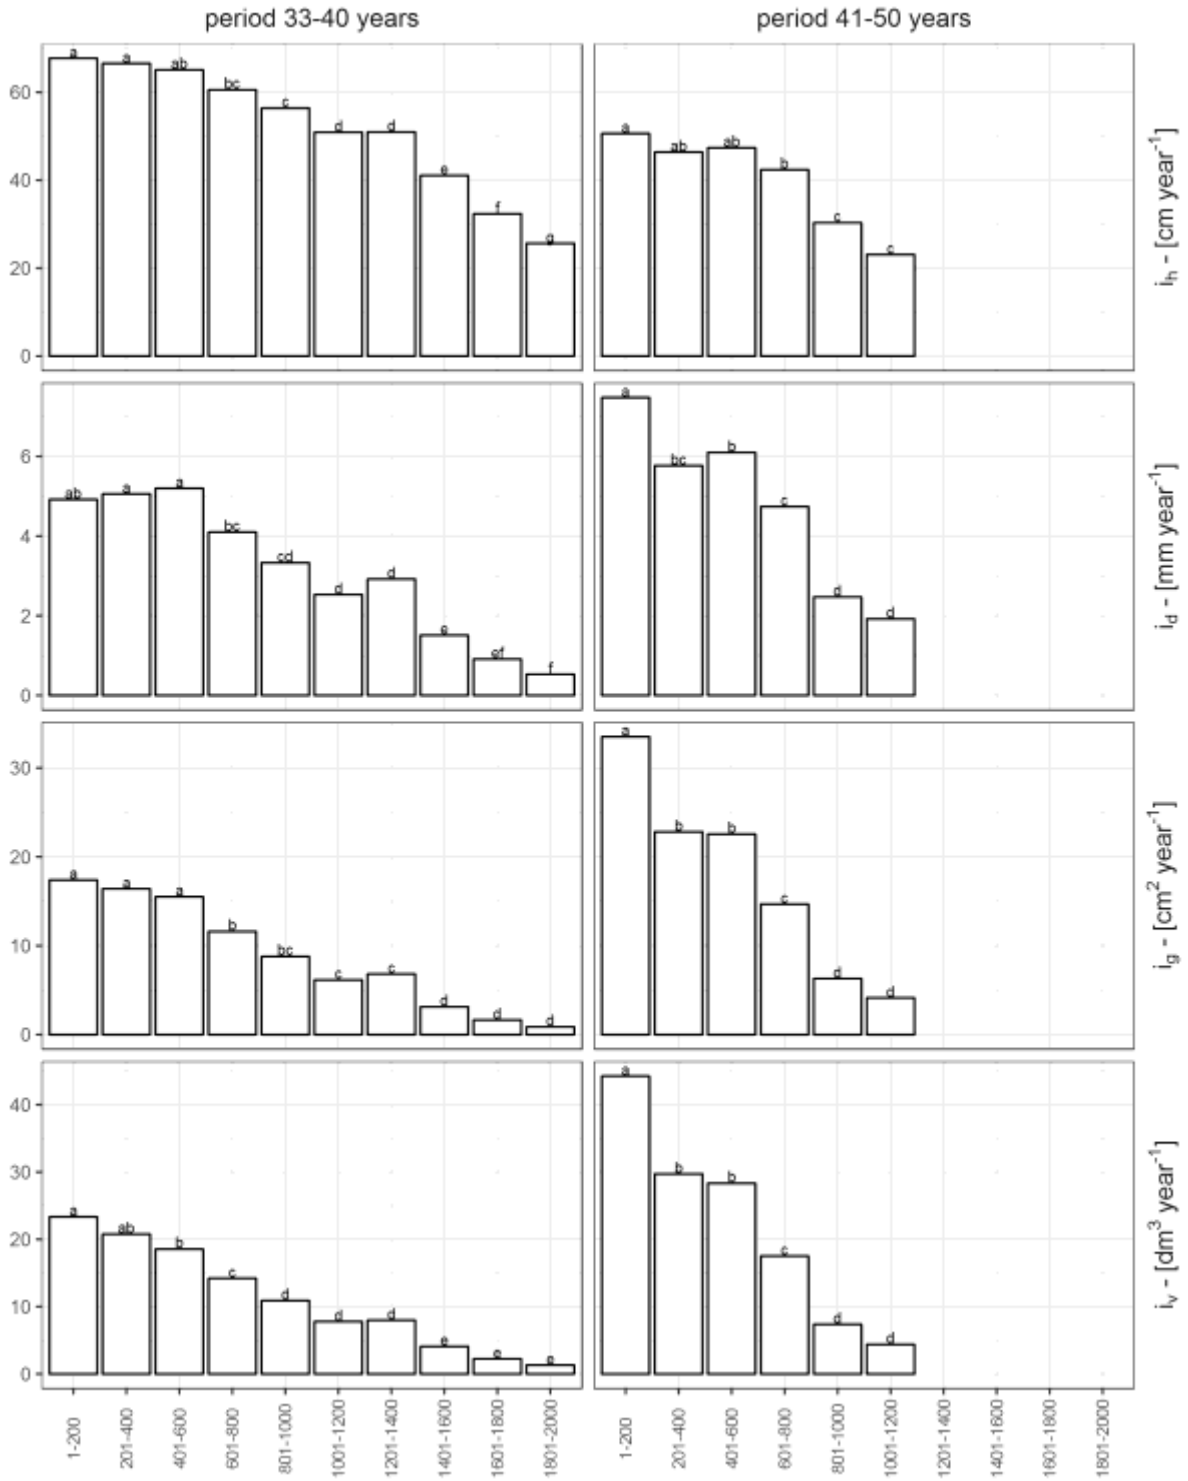

Figure 2. Current increments of height, diameter, basal area and volume of trees grouped according to the size of their breast height diameters in groups of 200 trees per hectare in the periods 33-40 and 41-50 of culture age.

During the period from 33 to 40 years, there was noted a weak reaction of diameter increment on the remaining trees, which is a consequence of a large number of trees, i.e., the absence of thinnings in the previous period. The current diameter increment of the remaining trees after thinning in the researched culture (0.31 cm·year^{-1}), compared with the results of Stojanović and Krstić (1984), is similar to the diameter increment on the control plot in two five-year

periods (0.34 cm·year^{-1}) with a 30% higher number of trees per hectare in the period from 32 to 42 years.
The second thinning at the age of 40 years caused a significantly higher diameter increment, i.e. a better reaction of diameter increment on the remaining trees compared to the thinning in the age of 32 years. The difference in the diameter increments between the two observed periods in the examined stand agrees with the results of other authors that spruce trees in the stands at favorable habitats and with a number of trees that are not too large for the appropriate age positively respond to thinnings and in the later period (Mäkinen and Isomäki, 2004a; 2004b; Preuhsler and Schmidt, 1989).
The increments of different elements of tree growth (height, diameter, basal area and volume) are reduced with decreasing breast height diameter of trees that are in line with previous research (Mäkinen & Isomäki, 2004b). This means that the effects of the thinnings are greatest in the trees of larger dimensions in the stand, that is, smaller trees are not able to react to the increasing space for growth as strongly as the larger trees can do.
The diameter increments of 200 and 400 of the thickest trees in the examined stand from 4.9 to 5.2 mm·year^{-1} in the period after the first thinning are somewhat higher (5-20 %) than the increment of the same group of trees in several series of experimental plots with a heavy crown thinnings in Sweden (Karlsson, 2006). Compared to the above results, *i.e.* diameter increments of the same collective of trees after the application of heavy low thinnings, the diameter increments at the experimental plot after the first thinning are smaller by 50% and are in the range with the obtained diameter increments at the control plots. Also, the diameter increments of 200 and 400 thickest trees per hectare in the period after the second thinning on the series of experimental plots where low thinnings were performed, as well as on the control plots, are smaller than in the period after the first thinning, and are larger only on the experimental plots with a heavy crown thinning, which is in line with our research.
Diameter increment of the 600 thickest trees per hectare in the examined culture in the period of 33-40 years was significantly smaller than the increment of the similar number of future trees per hectare when the first thinning is carried out at the age of 20 years (Štefančik, 2012). However, the diameter increment of 200 thickest trees per hectare of 7.5 mm·year^{-1} on our examined plot in the period after the second thinning is in agreement with the results stated by Štefančik (2012).
Basal area increment per tree of the 600 thickest trees in the stand after the thinning in the year of 32, from 15.5 to 17.4 cm^2·year^{-1}, is in the ranking with the increment of the basal area of the 300 thickest trees per hectare in the spruce stands in Finland in which heavy low thinnings were carried out in the early period of development, *i.e.*, they are in the ranks with increments of the 100-150 thickest trees when heavy low thinnings performed in the later period (Mäkinen and Isomäki, 2004b).

Conclusions

The results of the study show that the characteristics of increments of the growth elements (height, diameter, basal area and volume) of the spruce trees vary depending on the condition and intensity of the thinnings. In the period after the first thinning in the age of 32 years compared to the period after the second thinning in the age of 40 years, it is a significantly higher increment of height, which is a consequence of high height increments after culmination. In contrast, diameter increment, as well as basal area and volume increments, are significantly smaller, which is a consequence of a large number of trees and the absence of thinnings in the earlier period.
By grouping the trees into groups of 200 trees per hectare sorted by their breast height diameter after the first thinning was shown that the 600 thickest trees per hectare have a uniform reaction of diameter, basal area and volume increments, that is, those trees that had

the greatest increment potential. The second thinning allowed a more intense reaction of all the remaining trees, but the highest diameter, basal area and volume increment had only the 200 thickest trees per hectares. This indicates to intensive tree differentiation according to the increment potential under the influence of heavy selective thinning and that the increment potential of the tree is related to their dimensions.

Abstract

This paper presents the results of the morphometric analysis of seed and one-year-old seedlings of different genotypes of Pedunculate oak (*Quercus robur* L.). The seed was collected in the pure stand of Pedunculate oak with 10 mother trees which are minimum 50 meters away from each other. The length, width and weight of the acorn have been measured on the sample of 50 acorns per tree and based on the measured values of the length and the width the volume and the shape index of the acorn have been calculated. The collected seed was planted in the seedling nursery of the Institute of Forestry in Belgrade (Serbia) and the seedlings were produced in equable environmental conditions. At the end of the first vegetation season the root collar diameter and the height of the seedlings were measured on the random sample of 50 seedlings per mother tree, and on the basis of the measured values the ratio height : root collar diameter was calculated. The detailed data on morphometry and variability of several traits of seed and seedlings have been presented using the comparative analysis of 10 mother trees. On the basis of the obtained statistical parameters it can be concluded that the genetic variability exists both within and between analyzed mother trees. The analysis of variance for a single factor (One-Way ANOVA) was performed for the purpose of determination of existence of the statistically significant differences for all observed traits. The results of the analysis of variance showed that there are statistically significant differences between studied mother trees for the observed morphometric traits.
The obtained results contribute to acquiring knowledge on analyzed traits, give preliminary assessment of the genetic variability of the studied mother trees and represent a good start point for future researches of the species breeding; the results can also be used for the improvement of the production of good quality raw material of Pedunculate oak.

Keywords: *Pedunculate oak, seed, seedlings, morphometry, variability*.

Introduction

Pedunculate oak (*Quercus robur* L.) is one of the most valuable and most important tree species in the growing stock of the Republic of Serbia. The Pedunculate oak belongs to the genus *Quercus* and Fagaceae family (Nixon, 1993). It is a long-lived species, which can reach an age of more than 1000 years, reaching a height of over 40 m and a diameter at breast height of 2-2.5 m. It starts to produce fruit at age between 40 and 100 years. The seed quantity varies at the level of individual trees, populations and seed yield on harvest year (Ducousso and Bordacs, 2004). The Pedunculate oak is one of the most valuable species of forest trees due to its high quality wood. Specifically because of this characteristic, as well as the fact that it grows on very quality types of soil ideal for agricultural purposes, the oak forests have been significantly reduced in the last century (Yakovlev and Kleinschmidt, 2002; Thomas *et al.*, 2003; Balboa- Murias *et al.*, 2006; Kutnar, 2006; Helama *et al.*, 2009; Tikvić, 2011). It occurs in the moderate zone of the Northern Hemisphere, in almost all European countries, from northern Spain to southern Scandinavia and from Ireland to Eastern Europe. Environmentally, the species is adapted to both continental and forest-steppe climate as well as to mediterranean and submediterranean climate in the south of its distribution area. In relation to the soil, the Pedunculate oak is tolerant, but it prefers deep and fertile soil influenced by

groundwater, which is occasionally flooded. Large variability within species is a consequence of the wide distribution area of this species, as well as the occurrence of spontaneous hybridization with Sessile oak (*Q. petraea* L.), which greatly complicates its determination in the stand conditions (Ducousso and Bordacs, 2004). In Serbia, the largest areas under the Pedunculate oak forests are in the valleys of large rivers: Sava, Danube and Great Morava (Velika Morava).

An increasing number of researchers in the country and abroad study the quality and quantity of forest tree yield and the quality of seedlings. The degree of study of the genetic variability of the quantity and quality of seeds of different forest tree species and the possibility of their use in our conditions is still under real needs and it is not in accordance with the economic significance that this scientific field can provide (Popović *et al.,* 2015). The researches of the following authors: Tucović, (1975), Tucović and Stilinović, (1982), Lucic *et al.,* (2011), Popovic *et al.,* (2012, 2015), Nonic *et al.,* (2012) etc. contributed to gradual completion of knowledge related to the variability within and between populations of different forest tree species at the level of seed and juvenile stage of development.

The aim of the research in this paper is to determine the variability within population of Pedunculate oak in terms of morphometric traits of seed and one-year-old seedlings. The morphometry and variability of seed and seedlings are of a great importance for understanding the variability and taxonomy of species, production of seedlings and cultivation in stand conditions. The obtained results can serve for acquiring knowledge on the genetic variability of the studied population and for the improvement of the production of high quality seed and planting material of the Pedunculate oak in Serbia.

Material and Method

The seed intended for the examination of traits and variability of seeds and one-year-old seedlings of different genotypes of the Pedunculate oak (*Quercus robur* L.) was collected in a pure Pedunculate oak stand in the memorial park Šumarice in city of Kragujevac (Serbia). 10 mother trees which are at least 50 meters away from each other were selected for the test trees using individual selection. The seed was collected from each tree for the purpose of breeding half-sib lines where mother is known and the other parent is not, according to the method of the genetic analysis of trees (Isajev and Mančić, 2001). About 5 kg of ocularly healthy and undamaged acorns were collected as per tree, regardless of the acorn size. After collection, the acorn was dried to a moisture content of 35% and stored at a temperature of 3-5º C. The collected seed separated by mother trees was sown in April 2017 in the seedling nursery of the Institute of Forestry in Belgrade (Serbia) and the seedlings were produced in the equable environmental conditions in a hotbed size of 1x10 meters. The row spacing is 15 cm, the rows are parallel with the shorter side of the hotbed.

The length, width and weight of an acorn were measured on the sample of 50 acorns per test tree, and based on the measured values of the length and the width the volume and the shape index of the acorn were calculated. The length and the width of the acorns were measured with a vernier calliper with an accuracy of 0.01 mm and the acorn weight with an electronic scale with an accuracy of 0.01 g. The following traits were calculated based on the measured values: shape index, volume of acorn and average number of acorns per kilogram. The shape index of the acorn was calculated as a quotient of the acorn length and width. The volume of the acorn was calculated using formula for calculating volume of a cylinder (the shape of the acorn is approximated as a cylinder).

The root collar diameter and the seedling height were measured at the end of the first vegetation season on the random sample of 50 seedlings per mother tree, and based on measured values the ratio height : root collar diameter was calculated. The root collar

diameter was measured with the vernier calliper with an accuracy of 0.01 mm and the seedling height with a ruler with an accuracy of 0.1 cm.
The morphometric traits of the acorns and the one-year-old seedlings were described using descriptive statistical indicators: arithmetic mean (x), standard deviation (SD), coefficient of variability (CV %). The analysis of variance (ANOVA) was used for the purpose of determining variability within population. The analyzed variability factor was a tree. All statistical analyses were performed using the statistical software package STATISTICA 7.0 (StatSoft Inc. 2004).

Results and Discussion

The average value of the acorn width on its widest part at the level of the studied genotypes is 16.42 mm, with a range from 15.02 mm (test tree 9) to 17.72 mm (test tree 3) and the standard deviation from 0.78 mm to 1.25 mm (Table 1). Nikolić and Orlović, (2002) determined the average acorn width from 13.9 mm to 18.0 mm. Ivanković *et al.,* (2011) determined the average acorn width ranged from 14.1 mm to 17.5 mm. In the studies of Franjić *et al.,* (2001) the results of the average width from 13.0 mm to 17.8 mm were obtained. The average acorn width on the sample from the recognized and selected stands in Croatia ranged from 16.6 mm to 18.4 mm (Roth, 1999). The acorns originated from seed stands in Serbia have the average width of 17.4 mm (Popović *et al.,* 2016).
The average value of the acorn length at the level of the studied genotypes is 30.68 mm and ranged from 28.65 mm (test tree 5) to 33.20 mm (test tree 6) and the standard deviation from 1.21 mm to 3.22 mm (Table 1). The acorns of the Pedunculate oak are 20-40 mm long, rarely longer (Jovanović and Vukićević, 1983). The average acorn length on the sample from the seed orchard Banov Brod ranged 23.8 - 32.3 mm (Nikolić and Orlović, 2002). The average value of the acorn length of 1.2 - 3.6 cm can be found in the paper on importance of morphometric characteristics for identification of oak species (Smole *et al.,* 1992). The average length of the acorns originated from seed stands in Croatia ranged from 26.8 to 32.4 mm (Ivanković *et al.,* 2011). In the paper about variability of the Pedunculate oak acorn shape in Croatia the obtained average values of the acorn length were 26.2-31.9 mm (Franjić *et al.,* 2001). In the researches of the Pedunculate oak acorn morphology from different seed stands in Croatia, the measured average values of the acorn length ranged 30.5-37.0 mm (Roth, 1999). The average length of acorns from seed stands in Serbia ranged from 15.02 mm to 17.72 mm (Popović *et al.,* 2016).
The greatest average value of the acorn weight is 7.05 g (test tree 1), and the lowest is 4.38 g (test tree 6), while the average value at the level of the studied genotypes is 5.52 g with the standard deviation from 0.68 g to 1.19 g (Table 1). The average weight of an acorn in the research of Ivanković *et al.,* (2011) ranged from 3.89 g to 6.11 g. Nikolić and Orlović, (2002) indicated that in their research the average value of the acorn weight ranged from 2.8 g to 6.1 g. In the studies of Popović *et al.,* (2016) the determined average acorn weight ranged from 3.6 g to 7.5 g.
The shape index of the acorns ranged from 1.63 (test tree 10) to 2.14 (test tree 6) with the average value of 1.88 at the level of the studied genotypes and the standard deviation from 0.07 to 0.15 (Table 1). Krstinić, (1996) in his researches indicated that the shape index of the Pedunculate oak acorn is greater than 1.6. The researches of Ivanković *et al.,* (2011) showed that the shape index ranged from 1.74 to 2.12. The average values of the shape index from 1.68 to 2.35 were determined in the studies of Franjić *et al.,* (2001). Roth, (1999) indicated that in his researches the average values of the shape index ranged from 1.7 to 2.2. Popović *et al.,* (2016) determined the average shape index of 1.9.
The average value of the acorn volume at the level of seed stand was 6.56 cm^3 and ranged from 5.31 cm^3 (test tree 5) to 7.96 cm^3 (test tree 1) with the standard deviation from 0.78 cm^3

to 1.28 cm^3 (Table 1). The average value of the acorn volume in the studies of Ivanković *et al.*, (2011) ranged from 4.4 cm^3 to 7.8 cm^3, while in the studies of Popović *et al.*, (2016) the average value of the acorn volume ranged from 4.8 cm^3 to 9.7 cm^3.
The obtained results of the averages values of the morphometric traits of acorns that were determined in this paper are to a large extent similar to the mentioned literature data, which was expected because a similar work methodology was used.

Table 2 shows the results of the analysis of variance where the studied source of variability was the tree (family) within the population. Statistically significant differences caused by the observed source of variability were determined for all the studied morphometric traits of the acorn, and that confirmed the assumption of significant differentiation within population. High statistically significant differences between the studied genotypes indicate a high level of genetic diversity within population. The occurrence of a high degree of variability within population is characteristic for most species of forest trees and can be explained by the process of migration of genes (change of genes between different populations through natural processes, but also by human action) and low degree of local adaptation (Bogdan, 2009).

The average value of the root collar diameter of the studied half-sib lines was 3.4 mm and ranged from 3.1 mm (half-sib line 5) to 3.7 mm (half-sib lines 3 and 10) with the standard deviation from 0.4 mm to 0.7 mm. According to the root collar diameter the half-sib line 3 is the most homogeneous (13.1%) and the most heterogeneous is the half-sib line 7 (21.9%). The average value of the seedling height at the level of the studied half-sib lines is 27.5 cm and ranged from 20 cm (half-sib line 6) to 33.8 cm (half-sib line 3) with the standard deviation from 4.4 to 8.4. According to the seedling height the half-sib line 10 is the most homogeneous (16.9%) and the most heterogeneous is the half-sib line 7 (27.8%). The average value of the seedling sturdiness coefficient is 8.1 and ranged from 6.1 (half-sib line 6) to 9.2 (half-sib line 3) with the standard deviation from 1.2 to 2. According to the seedling sturdiness coefficient the half-sib line 2 is the most homogeneous (15.3%) and the most heterogeneous is the half-sib line 1 (22.1%).

Table 4: The analysis of variance for the measured morphometric traits of seedlings

	SS Effect	df Effect	MS Effect	F	p
d	9.59	9	1.07	2.88	0.0028
h	3756.20	9	417.40	9.49	0.0000
h/d	210.95	9	23.44	9.53	0.0000

In order to determine the existence of the statistically significant differences for all measured traits of seedlings, the analysis of variance for a single factor was performed (Table 4). The results of the analysis of variance showed the existence of the statistically significant differences between 10 half-sib lines for all measured morphometric traits of seedlings.

Conclusion

The obtained results contribute to the knowledge of the analyzed traits, the preliminary assessment of the genetic variability of the studied test trees and represent a good starting point for future researches in the breeding of the species.

The existence of the statistically significant differences between the studied test trees and the half-sib lines for all the analyzed morphometric traits of the seed and the seedlings clearly indicate a genetic differentiation and a high degree of variability within population. Based on the obtained statistical parameters, it can be concluded that there is a genetic variability both within and between the analyzed test trees and half-sib lines. The analyzed traits of the seed and the seedlings have a quantitative character and they are controlled by polymeric genes whose effects are summed up. The variability of the quantitative traits is wide and has a continuous character, and it is conditioned by the interaction of polymeric genes and environmental factors.

For preservation and directed use of the available gene pool of the studied Pedunculate oak test trees it is necessary to know their genetic variability. The determined variability of the morphometric traits of the seed and the seedlings can serve as an indicator of the further development of the seedlings of the selected half-sib lines, and can also serve for improvement the production of high-quality raw material of the Pedunculate oak.

Abstract

Agroforestry is a land use system that includes the use of woody perennial, agricultural crops and animals in combination to achieve beneficial ecological and economical interactions for food, fiber and livestock production. However limited understanding, incorrect information and a negative mindset could hinder the competitiveness of this practice. This case study of smallholder farmers in Limpopo Province attempted to explain the farmers' constraints to agroforestry competiveness by analysing their perception on agroforestry. The survey was conducted in Limpopo Province by the Agricultural Research Council, University of Venda and Water Research Commission. The research is fully funded by the Water Research Commission. The aims of the survey were to document smallholder farmer's perception on constraints to agroforestry competiveness in Limpopo Province and to review the current knowledge on Agroforestry in the province. A total of 65 smallholder farmers participated in the study and were spread in districts as follows: Vhembe (40), Capricorn (21) and Mopani (4). Quantitative and qualitative designs were used as a questionnaire, stakeholder's discussion and field observations were part of the data collection. A purposive sampling technique was used to select 65 potential agroforestry farmers from the list provided by the Department of Agriculture, Forestry and Fisheries and Forestry South Africa Limpopo. Data was coded, captured, and analysed using SPSS. The results indicated the following as the most important constraints identified by farmers: cost of production (13.92%); labour (13.92%); distance to the market (10.7%); cost to the market (11.36%); financial institutions (12.81%); suppliers (11.8%); indirect support (12.04%), fiscal policy (9.8%) and labour policy (12.6%).The identified farmer's perceptions were in line with some of the researcher field observations. It is thus recommended that stakeholders should take note of the constraints identified by farmers in an attempt to increase agroforestry competitiveness.

Keywords: *Smallholder Farmers, Agroforestry, Perceptions, Limpopo Province and South Africa.*

Introduction

Results from several studies have indicated that agroforestry practices are perceived in different ways. According to (Lundgren and Raintree 1982) agroforestry is viewed as the set of land-use practices which involves the combination of trees, agricultural crops and/or animals on the same land management unit. Nair (1993) emphasized that although cultivating trees in combination with crops and livestock is considered an ancient practice, factors such as the deteriorating economic situation in many parts of the developing world, increased tropical deforestation; incorrect agricultural practices; degradation and scarcity of land because of population pressures; and growing interest in farming systems, intercropping and the environment have contributed to a rising interest in agroforestry since the 1970s. Based on the above mentioned factors (Mercer and Miller 1998) further acknowledged that most research

on agroforestry has been conducted from the biophysical perspective, but socio-economic aspects in relation to perception of farmers should be given much attention.

According to Combe (1982) classified agroforestry systems into three broad groups, namely agrosilvicultural (mixing trees and crops), silvopastoralism (mixing trees, pastures and animals) and agrosilvopastoralism (mixing trees with crops and animals). According to Rethman *et al.,* (2007) these groups can further be subdivided as either simultaneous (where trees and crops are grown simultaneously), or sequential (where trees and crops are grown separately, temporally, over a number of seasons, as with improved fallows). According to DAFF (2017) Agroforestry is a land use system that includes the use of woody perennial and agricultural crops and animals in combination to achieve beneficial ecological and economical interactions for food, fiber and livestock production. It is further emphasized that properly managed Agroforestry system provides multiple benefits and contribute to improved livelihoods and income generation (DAFF, 2017). It is against the above background that a comprehensive survey was conducted in Limpopo Province to identify farmer's perception on agroforestry competitiveness. The aims of the survey were to document smallholder farmer's perception on constraints to agroforestry competiveness and to review the current knowledge on Agroforestry in the Limpopo Province of South Africa.

Materials and Methods

All research done so far with partners is focused on achieving or working towards a participatory research approach since the researcher, collaborators, extension officers, farmers and funder were actively involved in all phases. According to Backeberg and Sanewe (2010) the method of participatory action research is most appropriate since people especially farmers benefit while the research is ongoing. The participatory action approach was also recommended by various researchers who emphasised that the participatory action approach is a good alternative to the traditional "transfer of technology" or" top - down approach" to agricultural research and extension. It is against this background that the approach was used to achieve the research aims, deliverables and phases. The research used quantitative and qualitative methods. A detailed questionnaire written in English was developed as a quantitative data collection method and data was collected from 04th to 15th September 2017 in Vhembe, Capricorn and Mopani Districts. The questionnaire used both open and closed ended questions. Qualitative data collection method included focus group discussions and field observations. The two methods were also used to identify the smallholder farmers and potential agroforestry systems in Limpopo Province as indicated in Figure 1. A purposive sampling technique was used to select 65 potential agroforestry farmers from the list provided by the Department of Agriculture, Forestry and Fisheries and Forestry South Africa Limpopo. As indicated in Figure 1, Vhembe district is dominant as a location for smallholder farmers with interest in agroforestry systems establishment. The same trend is observed at a local municipality level where Thulamela local municipality in Vhembe district had the most potential agroforestry systems followed by Molemole local municipality in Capricorn district. Data collected was analysed quantitatively using the Statistical Package for Social Sciences (IBM SPSS Statistics) Windows version. The top three farmers perceptions on agroforestry competitiveness were calculated as follows: (Agree x Total Average) + (Strongly Agree x Total Average).

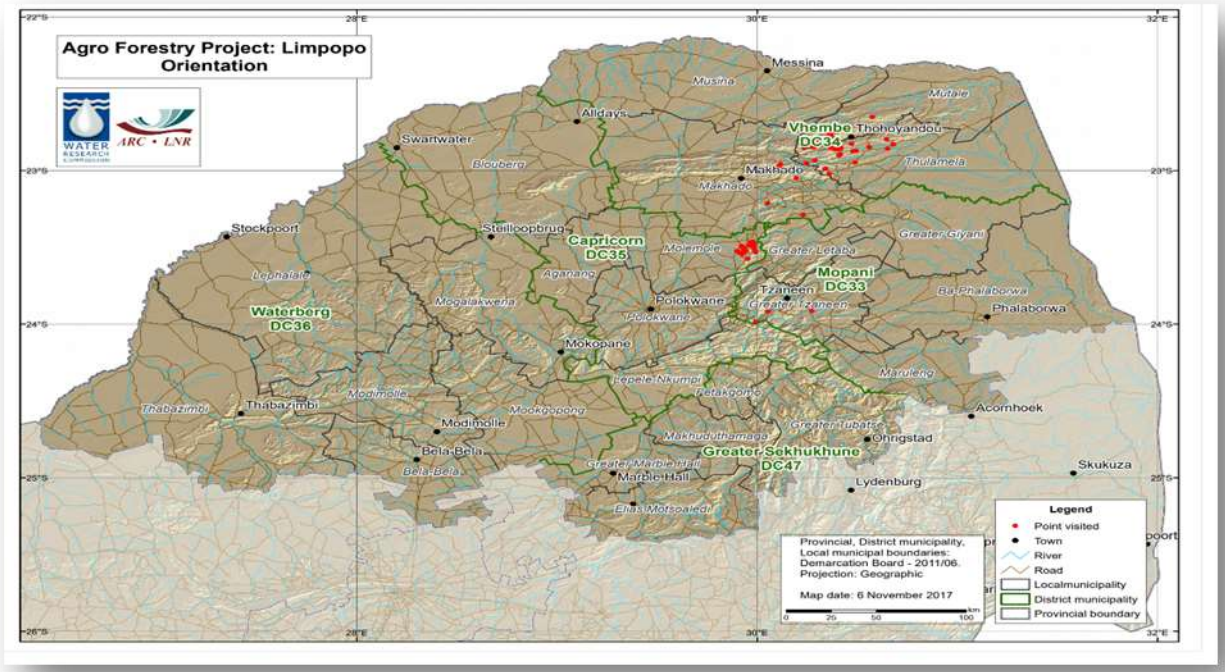

Figure 1: Limpopo Province Orientation (ARC ISCW, 2017)

Results and Discussions

The results from Figure 2 showed different ages of beneficiaries. As indicated in Figure 2, the average age of the beneficiaries was 52 years, which indicated the need for youth involvement in agroforestry business as any future agricultural development in the identified districts should be tailor made to attract youth. There's a need to formulate strategy in order to involve youth on agroforestry issues, various market incentives need to propose by all key role players within the agroforestry sector as a way of attracting young people.

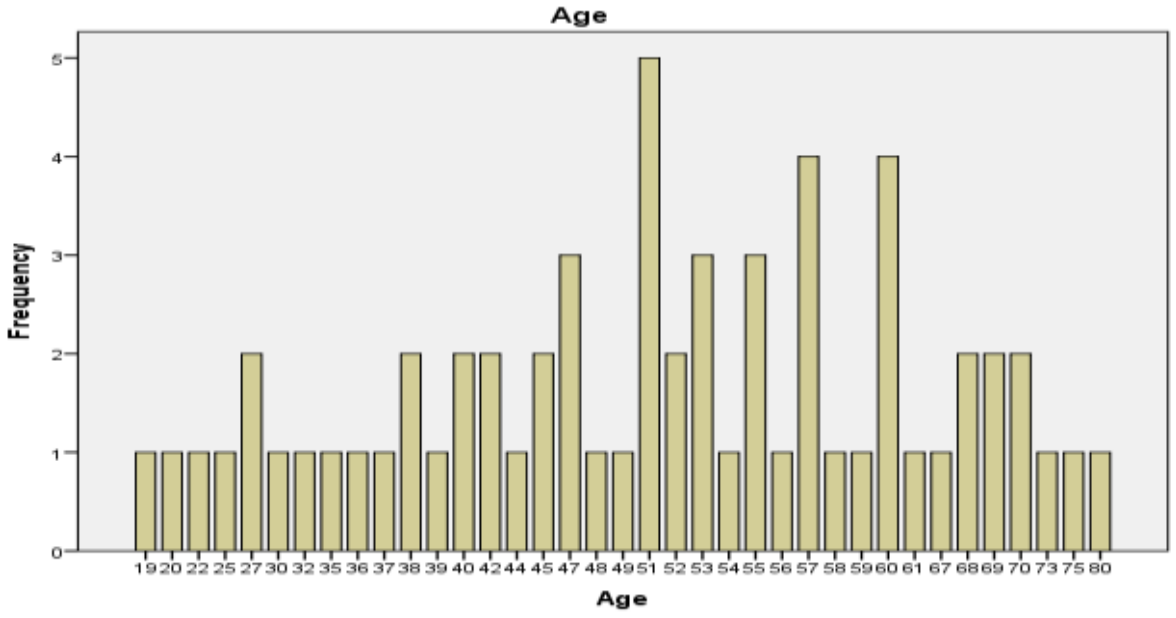

Figure 2: Age Categories of Farmers

The majority of farmers interviewed were men. According to Table 1, fifty one men were interviewed as compared to fourteen females. As shown in Table 1 there is a huge difference between the number of female and male farmers, which implied that any developmental strategy for the farmers in the areas will benefit more males than females. All farmers interviewed were black South African citizens. In terms of educational attainment (Table 1), 9 farmers had no education, 20 of the farmers completed primary education, 27 secondary education and 9 tertiary education. The educational levels of the farmers was generally good. Almost all farmers attended secondary and tertiary education level. These results indicated that educational level of the selected farmers is generally adequate to enable interpretation and understanding of basic farming activities. It is expected of farmers with tertiary education to interpret, understand different farming principles to make informed decisions on general farming operations and to be able to negotiable contracts better than beneficiaries with lower education levels. The lower educational levels among the farmers implied that written information might be of minimal benefit to such farmers and alternatives will have to be developed.

According to Maponya *et al.,* (2016) training and education plays an important role in smallholder farmer development. Failure to address some of the training needs has led to constrained agricultural growth in some districts in South Africa (Maponya *et al.,* 2014 and Maponya *et al.,* 2015). As indicated in Table 1; only 24 farmers received training and whereas the majority of farmers did not receive any training. The results showed farmers variation in terms of potential agroforestry experience acquired over time (Table 1). The majority of farmers (30) had more than ten years' experience while 21 and 14 farmers had less than five years and six to ten years' experience respectively. Results on land acquisition (Table 1) indicated that the majority of farmers got land through Permission to Occupy (PTO) (25) while others received land through the following: government (14), leased (11), renting (6) and inheritance (2). The role of traditional leaders must be applauded as the majority of farmers had PTO.

Perceptions on constraints to competitiveness to Agroforestry

Table 2 indicates that an average of 42% farmers strongly agreed/agreed that production factors were causing a decrease in agroforestry competitiveness. Among factors of production: cost of production (13.92%), labour (13.92%) and availability of skilled labour (13.32%) were perceived as the most important factors causing decrease in agroforestry competiveness. However, 36% of farmers perceived production factors as not causing any decrease in agroforestry competiveness and 22% of farmers were not sure.

Table 2: Production factors causing decrease in agroforestry competitiveness

Views The following production factors are causing the decrease in competitiveness of Agroforestry	**Responses (65)**				
	Strongly disagree	Disagree	Not sure	Agree	Strongly agree
Cost of production	17%	15%	15%	11%	42%
Labour	11%	22%	15%	11%	42%
Cost of unskilled labour	20%	14%	23%	9%	34%
Quality of unskilled labour	9%	29%	23%	11%	29%
Availability of unskilled labour	6%	23%	31%	14%	26%
Cost of skilled labour	9%	20%	20%	14%	37%
Availability of skilled labour	5%	31%	14%	11%	40%
Administration cost associated with labour matters	11%	25%	23%	8%	34%
Insufficient source of water	11%	29%	23%	9%	28%
Infrastructure	20%	23%	19%	8%	31%
Lack of knowledge	6%	29%	23%	15%	26%
Lack of Technology	11%	26%	31%	9%	23%
Capital / Finance	14%	20%	22%	19%	26%
Average Total	**12%**	**24%**	**22%**	**12%**	**30%**

Table 3 indicates that an average of 40% farmers strongly agreed/agreed that demand factors were causing a decrease in agroforestry competitiveness. Among demand factors: distance to market (10.7%), cost to the market (11.36%) and quality of products (9.19%) were perceived as the demand factors causing decrease in agroforestry competiveness. However 35% of farmers perceived demand factors as not causing any decrease in agroforestry competiveness and 25% of farmers were not sure. It was highlighted several times that market access, distance from the agroforestry site to market and quality of the products were cited as some of the key factors hindering the development of the agroforestry sector across the country (DAFF, 2017).

Table 3: Demand factors causing decrease in agroforestry competiveness

Views The following demand conditions are causing the decrease in competitiveness of Agroforestry	**Responses (65)**				
	Strongly disagree	Disagree	Not sure	Agree	Strongly agree
Distance to market	12%	25%	23%	5%	35%
Market information	22%	17%	23%	9%	29%
Cost to the market	8%	20%	26%	11%	35%
Quality of products	9%	22%	28%	15%	26%
Market for Agroforestry	12%	25%	25%	14%	19%
Average Total	**13%**	**22%**	**25%**	**11%**	**29%**

Table 4 indicates that an average of 45% farmers strongly agreed/agreed that related and supporting industries were causing a decrease in agroforestry competitiveness. Among related and supporting industries: financial institutions (12.81%), research institutions (11.28%) and suppliers (11.8%) were perceived as related and supporting industries causing decrease in agroforestry competiveness. However 35% of farmers perceived related and supporting industries as not causing any decrease in agroforestry competiveness and 20% of farmers were not sure.

Table 4: Related and supporting industries causing decrease in agroforestry competitiveness

Views The following Related and supporting industries are causing the decrease in competitiveness of Agroforestry	**Responses (65)**				
	Strongly disagree	Disagree	Not sure	Agree	Strongly agree
Financial institutions	9%	25%	17%	14%	35%
Research institutions	17%	15%	19%	23%	26%

Electricity suppliers	17%	23%	23%	9%	28%
Average Total	**14%**	**21%**	**20%**	**14%**	**31%**

Table 5 indicates that an average of 45% farmers strongly agreed/agreed that government support were causing a decrease in agroforestry competitiveness. Among government support: labour policy (12.6%), fiscal policy (9.9%) and indirect support (12.04%) were perceived as government support causing decrease in agroforestry competiveness. However 36% of farmers perceived government support as not causing any decrease in agroforestry competiveness and 19% of farmers were not sure.

Table 5: Government support causing decrease in agroforestry competitiveness

Views The following production factors are causing the decrease in competitiveness of Agroforestry	**Responses**				
	Strongly disagree	Disagree	Not sure	Agree	Strongly agree
Poor interaction and support between Government	17%	25%	17%	9%	32%
Indirect support	23%	14%	17%	11%	35%
Trade policy	9%	26%	19%	12%	34%
Land reform policy	9%	28%	14%	20%	29%

Labour policy	9%	22%	17%	22%	31%
Fiscal policy	2%	28%	31%	14%	26%
Average Total	**12%**	**24%**	**19%**	**15%**	**30%**

Conclusions

This research evaluated selected potential agroforestry farmers' perceptions on constraints to agroforestry competitiveness in the Limpopo Province. Based on the findings of the research it can be concluded that most of the farmers in the study area agreed that production factors, demand conditions, related and supporting industries and government support were causing decrease in agroforestry competitiveness. The most important constraints identified by farmers include: (a) cost of production; labour; (b) distance to the market; (c) cost to the market; (d) financial institutions; suppliers; (e) indirect support; (f) labour policy and (g) fiscal policy. The identified farmer's perceptions were in line with some of the researcher field observations. It is thus recommended that stakeholders should take note of the constraints identified by farmers in an attempt to increase agroforestry competitiveness.

Abstract

A great relevance of the problem of studying and conservation of biological diversity of the Earth is reflected in International Convention on Biological Diversity signed at the United Nations (UN) conference in Rio de Janeiro in 1992 by representatives of 180 countries. An important direction of solving this problem is monographic study of taxa of living organisms, the identification of globally and regionally endangered and vulnerable species and their inclusion in the International Union for the Conservation of Nature (IUCN) Red List of Threatened Species, national and regional Red Books. Fungi as a heterotrophic component of ecosystems present an important component of global biota. In nature, the fungi decompose plant debris and are included into the humification processes. The purpose of the present paper is a survey of macromycetes in forest ecosystems of specially protected natural areas of Abkhazia. The research was carried out in broad-leaved forests, pine forests, fir-beech forests and sub-alpine birch forest, the height interval was 5 to 1980 m above sea level. In the examined forests, 237 species of fungi belonging to 139 genera, 53 families, 21 orders and 6 classes were identified. The task of the present work includes an identification of rare species of fungi, with the aim to organize further protection in conjunction with their habitat. In our studies, 62 species fall under Rare category. The list of rare species recommended for inclusion in the Red Book of the Republic of Abkhazia when preparing its publication is given in this paper. The list includes such species as *Amanita caesarea, Clathrus ruber, Pseudocolus fusiformis, Geastrum triplex, Geastrum fimbriatum, Cortinarius violaceus*.

Keywords: *Rare macromycetes, Republic of Abkhazia, Forest ecosystems, Red Book.*

Introduction

The biodiversity conservation belongs to one of basic directions of environmental policy on global and regional scale. This is also an important task of the World Conservation Strategy adopted by International Conference in Rio de Janeiro in 1992. A sufficient aspect of this activity is study of regularities in development and distribution of various taxa of living world, whose representatives play an important role in the processes of recycling in nature ecosystems. A biodiversity conservation practice includes a foundation of networks of nature reserves and specially protected natural areas.

The Republic of Abkhazia is located in South-Western part of the Greater Caucasus and situated between 43°35'–42°27'N and 40–42°08' E. The total area of the republic consist 8665 km^2. Due to its unique geographical position on the border of temperate and subtropical zones and rather diverse relief varying from 0 to 4000 m above sea level, this area is characterized by local climates echoes all the zonal ones of the Northern Hemisphere, excluding tropical. Being a part of Colchis floristic refugium, the Abkhazia Republic is rich by various types of vegetation and a relic and endemic plants (Adzinba, 2011). On the Abkhazia territory there are three large areas having status of specially protected natural areas – the Pitsunda-Musser Scout Reserve, the Pskhu-Gumista Reserve, and the Ritza Relic National Park (RRNP).

Material and Methods

The main subject of the present study is macromycetes. This is a non-formal group of higher fungi that develop a huge mycelium biomass in the substrate and form macroscopic fruiting bodies as a rule more than 1 mm large. In nature ecosystems, the macromycetes are the main regulator of recycling processes (Burova, 1986). These fungi regulate a wide range of important ecosystem functions as primary and secondary production of ecosystems, regeneration of biogenic elements, wood humification and related aspects of forest environment formation (Bondartseva, 2001; Mukhin et al., 2000). The macromycetes is an integral component of forest ecosystems playing a key role in enzymatic degradation of the wood and herbaceous plants with formation of forest litter and underlying soil strata on the one hand and involved to mineral nutrition of forest plants through mycorrhizas on the other (Burova, 1986). The studied forest ecosystems in the Musser Scout Reserve and RRNP occupy heights varying between 5–134 and 376–1817 m, being presented by pine forests, deciduous mixed forests, hornbeam-box forests, chestnut-hornbeam forests, fir (or beech-fir) forests, and birch woodland. Radial routes and stationary search methods were used by us. Stationary plots measure 25 × 25 (625 m^2) and 50 × 50 (2500 m^2). A fungal diversity and ecology monitoring was carried out during all the vegetation season (Khacheva, Dbar, 2013; Khacheva, 2015; Khacheva, 2018; Yupina et al., 2011).

The material collected was identified using basic key-books for some groups of macromycetes (Perevedentseva, 2015; Eriksson, Ryvarden, 1973, 1975, 1976; Eriksson et al., 1978, 1981, 1984; Bondartseva, Parmasto, 1986; Kõljalg, 1996; Hansen, Knudsen, 1997; Bondartseva, 1998; Zmitrovich, 2008). The taxonomy on generic level corresponds to 10th edition of the Ainsworth and Bisby's Dictionary of the Fungi (Kirk et al., 2008). The species names are giving according to the "Index Fungorum" nomenclatural database (http://www.indexfungorum.org).

Results and Discussion

A total of 237 species of macromycetes belonging to 139 genera, 53 families, 21 orders, and 6 classes were revealed in the forests under study. It was established that the group of highly adaptive and widely distributed species have a dominant position in studied forest communities. Also, were found sporadically distributed species, represented by single finds or found constantly, but in a limited specimens number (Mukhin, 1993).

In our studies, a total of 62 macromycetes species seem to be having a rare status. In establishing a rare status, such attributes adopted to conservation status scale of Red Book of the Russian Federation are taken into account as geographical distribution, habitat specificity, sizes of local population. Species can have a local, regional, national and international rarity status (IUCN Red List Categories and Criteria, Version 3.1, 2001).

When analyzing a rare species of the Musser Scout Reserve and RRNP, the distribution of species throughout whole area, the rarity of species in studying area, and the inclusion of species to international, national and regional Red Data Books were taken into account. The list of rare species of macromycetes of the protected natural areas of the Republic of Abkhazia is given in Table 1.

Table 1. Rare species of macromycetes of the protected natural areas of the Republic of Abkhazia.

Species	Conservation status (category)	
	Abkhazia	IUCN or regional status
Amanita caesarea (Scop.) Pers.	3	EN (IUCN)
Amyloporia crassa (P. Karst.) Bondartsev et Singer	2	VU
Amylocorticium subincarnatum (Peck) Pouzar	3	EN
Antrodia malicola (Berk. et M. A. Curtis) Donk	3	
A. gossypium (Speg.) Ryvarden	2	CR (IUCN)
A. romellii (Donk) Niemelä	3	
Antrodiella fissiliformis (Pilát) Gilb. et Ryvarden	2	
Ceriporia excelsa S. Lundell ex Parmasto	3	NT
C. purpurea (Fr.) Donk	3	
C. tarda (Berk.) Ginns	3	
C. viridans (Berk. et Broome) Donk	3	
Ceriporiopsis mucida (Pers.) Gilb. et Ryvarden	3	
Clathrus ruber P. Micheli ex Pers.	3	NT (IUCN)
Climacodon pulcherrimus (Berk. et M. A. Curtis) Nikol.	3	
Cortinarius violaceus (L.) Gray	3	
Crustoderma dryinum (Berk. et M. A. Curtis) Parmasto	3	VU
Crustomyces expallens (Bres.) Hjortstam	3	
C. subabruptus (Bourdot et Galzin) Jülich	3	
Cystostereum murrayi (Berk. et M. A. Curtis) Pouzar	3	
Elmerina caryae (Schwein.) D. A. Reid	2	
Emmia latemarginata (Durieu et Mont.) Zmitr., Spirin et Malysheva	3

Tyromyces kmetii (Bres.) Bondartsev et Singer	3	NT

Note. Conservation status according to the Red Data Book of the Republic of Abkhazia: 2 – endangered, 3 – rare, 4 – having indefinite status. Conservation status according to IUCN: CR – critically endangered, EN – endangered, VU – vulnerable, NT – near threatened, DD – data deficient.

Conclusion

The data obtained show a necessity for further comprehensive study of macromycetes and protection of both individual species and entire natural complexes of the Republic of Abkhazia. The macromycetes biota of area under study is characterized by a high level of biological diversity and the presence of species confined to specific habitats. The old-growth beech and fir forests, where a significant number of rare species (69.4%) was identified, present a great conservation value. To date, the transformation of natural complexes is intensifying, since an irrational nature management leads to reduction in species diversity of native mycobiota and complexity of ecosystem structure. The main threatening factors for the macromycetes of Abkhazia are the recreational load on biotopes, the intensive exploitation of forest ecosystems and the uncontrolled forest cutting. The presented list of species is recommended for inclusion in the Red Data Book of Abkhazia. This list reflects the rarity categories, the basis for special protection measures, and the population state due to their vulnerability. Also, it is necessary to compile a complete list of rare species on the basis of expanding studies on the Abkhazia territory, since the presented list is limited to protected areas of the republic, only.
