Callicarpa bodinieri is an ornamental, deciduous shrub that can be easily grown in well-drained soil in full sun to part shade. It is suitable for landscape use, for planting in group or mass, in bird gardens or in open woodland areas. For this research, two types of hardwood cuttings were used: t-cuttings with a part of two-year old wood and standard hardwood cuttings. The cuttings were treated with 0.8 % IBA (indole butyric acid) using a quick dip method. After rooting in mixture of peat and sand (2: 1), following parameters were recorded: number and length of primary roots, and presence of secondary roots. Considerably better results were achieved with t-cuttings, and there were no significant difference among those cutings treated with IBA and control. Rooting percentage was high, 95.3 % (IBA treatment) and 96 % (control), and there were no significant difference regarding other parameters, except root length. T-cuttings treated with IBA formed longer roots. Rooting rate of cuttings without two-year old wood was low - 21.3 % (IBA treatment) and 17.3 % (control). These results indicated that carbohydrate and endogenous hormone levels possibly significantly influenced rooting of hardwood cuttings of this species.

Keywords: *Bodinier beautyberry, vegetative propagation, cuttings, rooting medium, auxine.*

Introduction

Callicarpa bodinieri is an ornamental, deciduous shrub, native to Sichuan, Hubei and Shaanxi provinces in central and western China (Zhou *et al,* 2013). It grows up to 3 m, with upright slender branches covered with dark green leaves turning golden yellow and red in autumn. Bodinier beautyberry blooms in summer, producing small lilac flowers in the leaf axils, followed by small, decorative violet-purple berries in September and October. *C. bodinieri* can be easily grown in well-drained soil in full sun to part shade. It is suitable for landscape use, for planting in group or mass, in bird gardens or in open woodland areas (Brickell, 2008; Zhou *et al,* 2013). Bodinier beautyberry is a non-native species in Serbia, but due its low invasive potential (Hauser, 2017) it is suitable for use in green areas in the conditions of climate changes. *C. bodinieri* can be propagated by seed or cuttings (Brickell, 2008), but vegetative propagation is more convenienet in order to produce desired genotypes. There is no available records about detailed vegetative propagation of this species. There are recommendations that this species can be propagated by softwood cuttings or semi-hardwood cuttings (Tripp, 1995; Segall, 1997; Vermeulen, 1997; Brickell, 2008), but there is no data about expected rooting percentage of cuttings or suggested auxine pretreatments for this species. Also, there is no data about possibility of its propagation using hardwood cuttings. For this reason, we decided to investigate vegetative propagation of *C. bodinieri* using hardwood cuttings.

Material and Methods

The hardwood cuttings were collected early in the morning, at the begining of March. For this research, two types of hardwood cuttings were used: t-cuttings with a part of two-year old wood and standard hardwood cuttings; both types 4-7 cm long with 2 nodes. The cuttings

were disinfected with 0.6% solution of fungicide Benomyl (Benlate®). The bottom of cuttings was wounded and the cuttings were dipped in a 0.8% (8000 ppm) IBA (indole-3-butyric acid) solution for 3-5 seconds, using a quick dip method. After that, the cuttings were sticked in a mixture of peat and sand (2: 1) and kept in the Greenhouse of the Faculty of Forestry under intermittent mist (5 seconds mist with 15 minutes interval). Three replications of 50 cuttings per treatment were used.

After 5 weeks, the following parameters were determined: number and length of primary roots, and presence of secondary roots. The significance of differences between the means was determined by the analysis of variance (ANOVA, $p < 0.05$) and the least significant difference (LSD) test. Before the statistical analysis, the percentage data were converted using arcsine transformation.

Results and Discussion

After 5 weeks, rooting percentage was high, reaching more than 90% rooted cuttings (Table 1). Cutting type significantly influenced rooting, and t-cuttings with a part of two-year old wood rooted in a high percentage uncorrelated with the IBA pretreatment. Those cuttings also formed well developed root system, and more than 85% of rooted cuttings also developed secondary roots. As opposed to that, cuttings without a section of of two-year old wood rooted poorly, and IBA pretreatment also didn't influence rooting, because there was no significant difference among treated cuttings and a control (Table 1).

Table 1. State of cuttings after 5 weeks

Cutting type	treatment	Rooting (%)	No of primary roots	Length of primary roots (cm)	Secondary roots frequency* (%)
t-cuttings	0.8% IBA	95.3[a]	5.82[a]	1.77[a]	0.89[a]
t-cuttings	control	96.0[a]	5.37[a]	1.47 [b]	0.86[a]
standard cuttings	0.8% IBA	21.3[b]	0.66[b]	0.18[c]	0.07[b]
standard cuttings	control	17.3 [b]	0.53[b]	0.17[c]	0.09[b]

Values followed by different letters are significantly different at the $P < 0.05$ level according to the LSD test

*Frequency represent the percentage of rooted cuttings which have formed secondary roots

Contrary to our findings, results obtained with some other *Callicarpa* species indicates that use of plant growth regulators (PGRs) is neccessary in their vegetative propagation (Fang, 2010; Zhang *et al.,* 2013; Chen *et al.,* 2010). Thus, Fang (2010) reported that the rooting rate, root length and root number of *C. macropylla* were greatly improved with the treatment of NAA (naphthalene acetic acid) and IBA, and similarly Chen *et al.* (2010) found that addition of NAA was neccessary for successful rooting of *C. dichotoma*. Additionaly, Zhang *et al.,* (2013) showed that rooting percentage could be significantly increased from 38.6% (control) to 94.6% by using a rooting agents during propagation of *C. nudiflora*. They also obtained better results with 2 year old cuttings, which is in accordance with our findings that 2 years old cuttings have a higher rooting percentage than younger ones, but Zhang *et al.,* (2013) also found that cutting diameter influenced rooting, and cuttings with 0.8 cm diameter had a higher rooting percentage than cuttings with 0.6 cm diameter. This can be expected probably due to higher carbohydrate reserves in cuttings with greater thickness relative to thinner cuttings (Biondi et al., 2008; Zhang et al., 2010), however there are also reports that rooting percentage of some species could decrease with increasing cutting diameter (Howard and Ridout, 1991). The cutting diameter could influence rooting differently, and for example,

during propagation of *Actinidia arguta*, thiner cuttings (<2 mm) had higher rooting percentage, but thicker cuttings (2-8 mm) developed longer roots in a higher number (Beyl *et al*., 1995). The cuttings used in our research were uniform, with 2 nodes, and some additional research could be conducted using a single node cuttings in order to obtain higher multiplication rate. However, rooting of single node cuttings can be poor, because cutting length can also significantly influence rooting and longer cuttings usually have a better rooting rate and root system is better developed (Gerrakakis and Özkaya, 2005; Gopale and Zunjarrao, 2011).

Besides PGRs, Bai *et al.* (2015) showed that rooting substrate can significantly influence the rooting of *Callicarpa bodinieri* Levl. var. *bodinieri* semi-hardwood cuttings, and they recommend use of perlite, riversand and the garden soil (1: 1: 1), but taking into account that rooting percentage obtained in our research was high, there is no need for further investigation of effect of other rooting media on rooting of *C. bodinieri.*

Conclusions

Obtained results indicated that *Callicarpa bodinieri* can be successfuly propagated using a hardwood t-cuttings with a part of two-year old wood, 4 - 7 cm long, with 2 nodes, wounded at the bottom. These cuttings should be rooted in a mixture of peat and sand (2: 1), under mist system, without addition of PGRs. Using this method, rooting percentage was high - 96%, and root system was well developed.

Acknowledgments

This work was supported by the Ministry of Education and Science of the Republic of Serbia within the project no. 43007 for the period 2011-2015.

Abstract

Over the course of the last decade, surfaces under hazelnut cultivation in Serbia have been under significant expansion thanks to the new market possibilities. Given the high investment required for establishment of hazelnut plantation, proper and thorough examination of agroecological conditions, above all climate and soil, is necessary for this type of cultivation. Research was, therefore, carried out in 2017 and 2018, including 120 agricultural plots in AP Vojvodina where 240 samples were collected from the depth of 0 – 30 cm and 30 – 60 cm. The tested parameters included the main agrochemical soil properties (pH, total $CaCO_3$, humus content, total nitrogen and content of readily-available phosphorus and potassium), content of active lime ($CaCO_3$) and mechanical content. The most important limiting factor of the research was high content of active $CaCO_3$, resulting in adverse conditions for hazelnut tree growing at 1/4 of the tested plots. A few plots had an acidic pH reaction, while 1/4 of the tested plots had very low humus content (below 2 %). Since most of the tested plots were used for field crop cultivation, nutrients were mainly concentrated within the surface soil horizon; deep tillage should therefore be encouraged, so that the nutrients were transferred into the active rhizosphere which was suitable for growing perrenial plants such as hazelnut trees. In addition, nine pedological profiles were open and the results showed that the tested soils belong to chernozem soil type, or its subtype or form. Having conducted the detailed research, we can conclude that the soils in AP Vojvodina are suitable for contemporary and intensive hazel growing, with the good prospect of obtaining high, top-quality hazelnut yields.

Keywords: *hazelnut, lime, basic agrochemical properties, soil.*

Introduction

Vojvodina is an important agricultural region in Southeast Europe and a gem of the Pannonian Plain for its soil properties. It provides a surplus of wheat, maize and industrial crop production (Živković *et al*., 1972). Thanks to the considerably improved market conditions in the recent years, an increasing number of perennial fruit and vine plantations have been established in many locations. A total of 2,239 ha of cultivated land was estimated in an agricultural survey conducted in 2012 (Keserović *et al*., 2014). Hazel cultivation has significantly expanded in recent years, amounting to 4,000 ha of hazel plantation surface according to unofficial estimates, and 1,200 ha more planned for 2018 according to contract with Agriser Ltd. Serbia and Ferrero as its parent company.

Hazel has long been grown in an extensive production system, mostly in private backyards without the application of suitable cultivation practices. However, new markets demand the security of product placement, and high standard of both the quantity and quality of product. To meet these requirements, production needs to be improved and adapted to specific agro-ecological conditions. High quality of soil is one of the most important preconditions for hazel production. Soil is a natural source of organic matter and primary base for organic matter production by cultivation of different plant species. It consists of mineral and organic substances, soil solution and soil air. Soil is a natural environment of plants, animals and

microrganisms, limited in its surface and destructable by nature. Soil formation is slow and gradual, but soil destruction can be very fast.

High-quality fruit production begins with the optimal use of soil with regard to local climate conditions (Keserović *et al.*, 2008). Human activities can have a significant influence on soil properties, primarily during plantation establishment. Although agro-ecological conditions in Vojvodina are suitable for intensive hazel production, certain existing limitations are the reason for soil quality testing of each plantation.

The aim of the paper is to put together a document on the global estimate of fertility and quality of soils under hazel cultivation in Vojvodina, as well as completely adopt the fertility control system and rational use of fertilizers by end users - producers and authorities, through education, promotion and dissemination of research results.

Material and Methods

Hazel production was chosen as the research subject due to the recent significant increase in its growing surfaces and ongoing tendencies for hazel cultivation, primarily at the territory of AP Vojvodina. The paper aims to examine research results obtained at 120 control plots, and 240 soil samples.

Picture 1. Soil sampling localities under hazel cultivation

Control plot is a plot with the uniform history, terrain, and cultivation practices. The samples were collected in 2017 and 2018 using an agrochemical probe at the depth of 0-30 and 30-60 cm, according to fertility control methodology, so that one submitted sample consisted of 20 individual sub-samples. Complete laboratory research was conducted at the Laboratory for Soil and Agroecology of the Institute of Field and Vegetable Crops. The applied research methods were:

- determination of soil mechanical structure by the international pipette method (with Na-pyrophosphate)

- determination of potential soil acidity - pH in 1 M KCl – in soil suspension (10g:25cm^3) with potassium chloride, potentiometrically, with pH meter.
- determination of calcium-carbonate ($CaCO_3$) content – volumetric method, using the Scheibler calcimeter.
- determination of physiologically active calcium-carbonate ($CaCO_3$) by the Drouineau – Galet method (with ammonia oxalate)
- determination of humus (organic matter) content - by the method of Turin (with $K_2Cr_2O_7$)
- determination of ammonium lactate P_2O_5 – spectrophotometric determination of readily available phosphorus.
- determination of ammonium lactate K_2O –flamephotometric determination of readily available potassium.

Results and Discussion

Hazel has the widest growing areal of all woody fruit species, reaching over 1500 m.a.s.l. It grows on different types of soil, from the fertile humus soils to the poor alkaline skeletal soils. However, high-yielding and cost effective production requires cultivation in deep, fertile soils with an optimal water and air regime, such as different types of chernozem, alluvial soils and eutric cambisols. High – yielding cultivars have specific soil quality requirements (Šoškić, 2016).

Mechanical content (Granulometric analysis)

The solid phase of soil is a polydisperse system composed of different sized particles. Soil mechanical structure is therefore a quantitative content of variable soil particles, grouped into mechanical fractions by their limit fractal dimensions. The method of Atterberg and IUSS distinguishes clay (<0,002 mm), silt (0,002-0,02 mm), fine sand (0,02-0,2 mm), and rough sand (0,2-2 mm) (IUSS-International Union of Soil Science). The two fractions observed at the tested plots were loamy clay and clay loam, with the prevailing content of the first fraction.

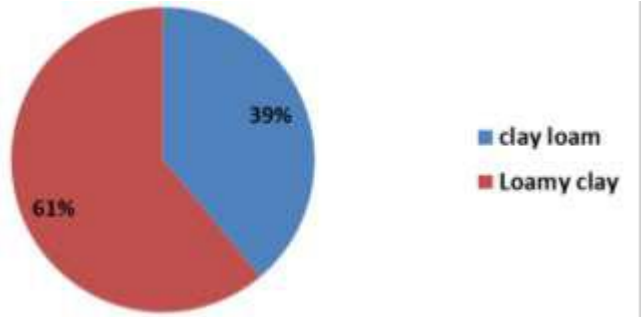

Figure 1. Granulometic content

Soil pH, total and active lime ($CaCO_3$)

The results of substitutional acidity tests and total $CaCO_3$ content confirm the fact that slightly alkaline soils are predominant in the territory of Vojvodina. The development of such soils occurs because of their geological substrate i.e. loess, which is rich in $CaCO_3$ and directly correlates to soil pH thus affecting its higher value. However, the content of physiologically active soil lime as determined by the method of Droineau – Galet (Hadžić *et al*., 2004) is not highly correlated with the total content but with its mean (r=0,62). This soil property should be given special attention as one of the most significant limiting factors of hazel production in Vojvodina. High $CaCO_3$ content in soil causes blockage of plant nutrients and, as a result, prevents their adoption by plants and leads to mild (in active lime values of 5-8 %) or strong chlorosis (in active lime values above 8 %) (Magazzini, 2018). Active lime content increases

with soil depth. The highest root mass of hazel and other perennial woody plants is in the soil layer of 30 to 60 cm. According to our research, one of the four tested plots has an active lime content above 8 %, which is unsuitable for hazel production.

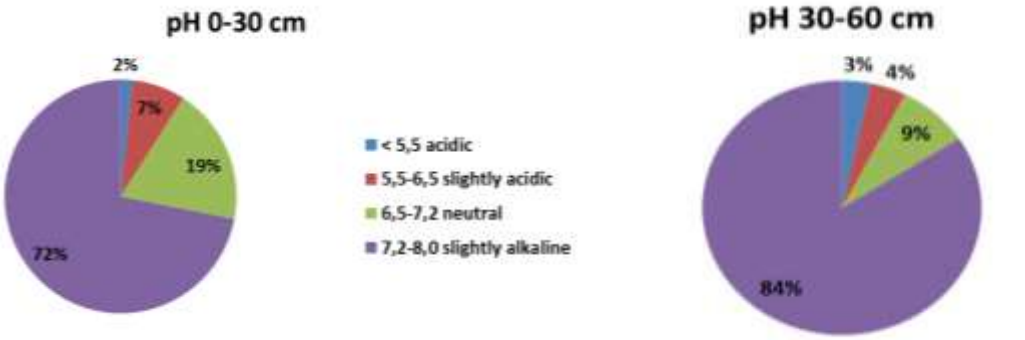

Figure 2. pH value in KCl (classification: Belić *et al., 2014)*

Figure 3. Total $CaCO_3$ (classification: Belić *et al., 2014)*

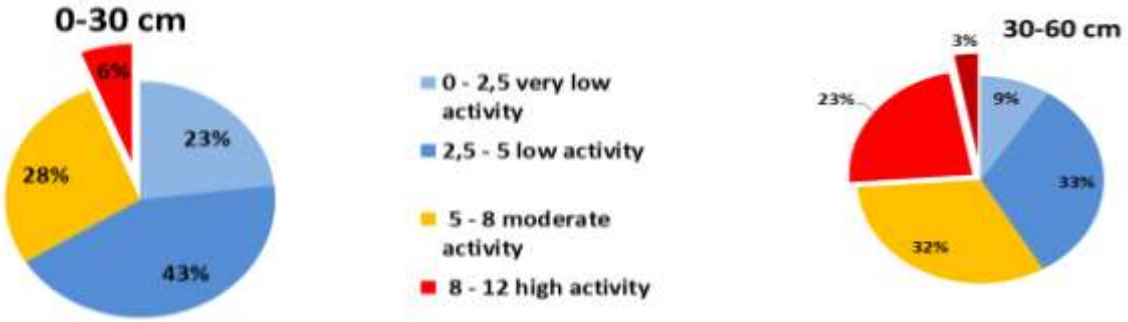

Figure 4. Active $CaCO_3$ (classification: Magazzini, 2018)

Content of organic matter

Humus is an important soil fertility indicator, the source of nutrients and factor of soil fertility preservation. Vojvodinian soils are still well-supplied with organic substances, regardless of the dramatic decrease observed in the last few decades due to minimalized use of organic fertilization and harvest residue burning.

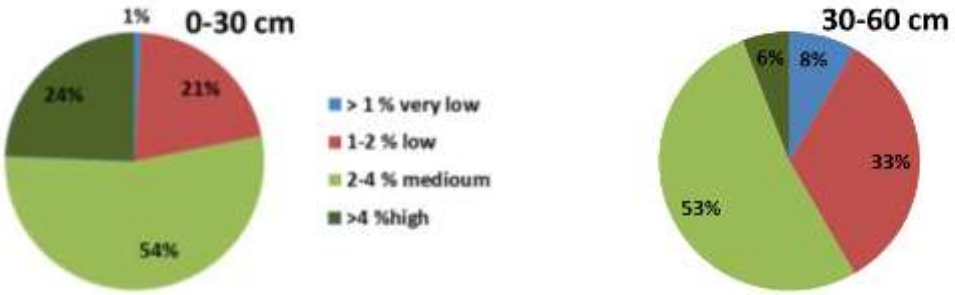

Figure 5. Content of organic matter (classification: Ninkov *et al.*,2014)

Content of readily available macronutrients – phosphorus and potassium

Phosphorus and potassium have a major role in plant growth and therefore belong to the group of primary nutrients (NPK). The tested soils are mostly well-supplied with the primary minerals, but there is a substantial difference between their content in the upper and lower soil layers. The upper soil layer generally prevails in terms of nutrient sufficiency, which can be explained by the previous use of the tested plots for field crop cultivation, focusing mainly on fertilization of the upper soil layer. Incorporation of nutrients into deeper soil layers is vital due to rooting depth of 30 to 60 cm found in perennial fruit plantations.

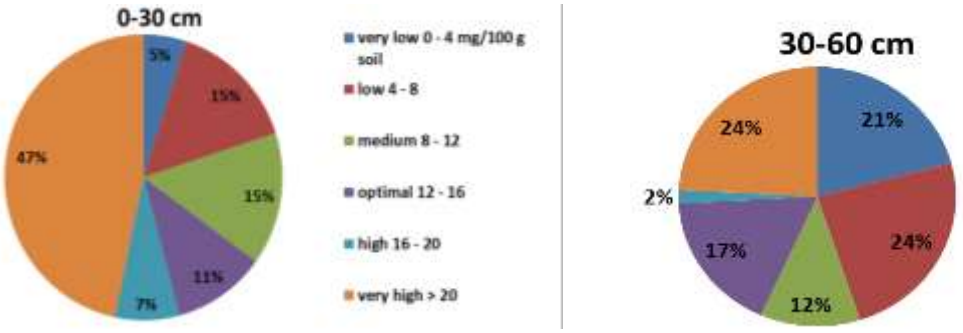

Figure 6. Readily available **phosphorus (P_2O_5)** (classification: Ninkov *et al.*,2014)

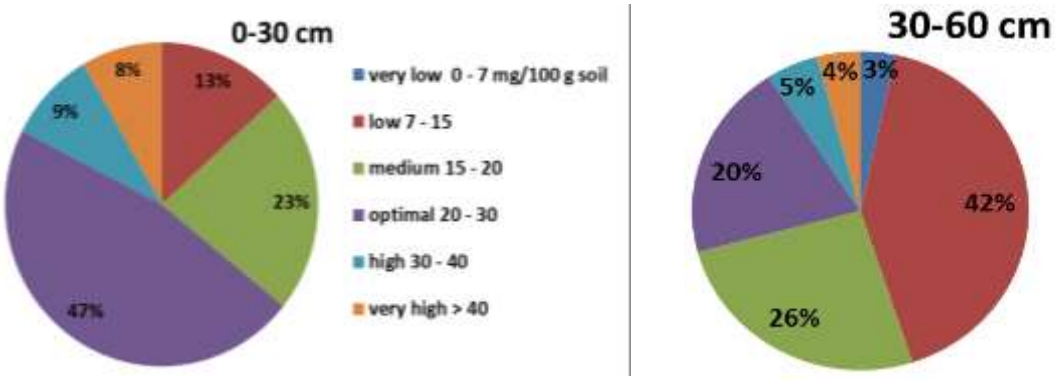

Figure 7. Readily available **potassium (K_2O)** (classification: Ninkov *et al.*,2014)

Conclusions

Only the well-prepared soils can provide optimal nutrition for economically viable yields of hazel, and ensure satisfactory resistance to attacks of pests and diseases. Mistakes made during the establishment of plantations are costly and very difficult to remove. All the factors directly or indirectly affecting this type of production must therefore be taken into consideration when hazel plantations are established. High content of physiologically active $CaCO_3$ and high levels of ground water, determined in additional field research by opening soil pedological profiles, are the major limiting factors for hazel production in Vojvodina.

Abstract

Humanity is facing the population growth, environmental erosion, and climate changes. Dramatic challenges require resolute solutions in agriculture. The agro-industrialization was the main goal of the 20th Century Green Revolution (GR). A new plant ideotype capable to respond to the new requirements was created. Though GR mitigated the hunger in the world, it opened some other problems. The prize was environmental erosion, climate changing, and over population. Using long term results of wheat breeding in the Institute of Field and Vegetable Crops in Novi Sad, Serbia, the authors comment plant breeding goals and selection criteria that were established to meeting growing demand for food, through the variation of some yield and quality marker in wheat, plant stature variation and creation a novel genetic variability for overcoming stressful growing conditions. Allelic variation of seed storage protein loci on 1B, wheat rye translocation, and 1D chromosomes, HMW glutenin alleles, mostly, as a consequence of selection pressure in wheat breeding showed that the main effort through selection criteria was to reconciling negative correlation between high yield and good quality. The variation of sink/source ratio and its effects studied, as well. On the basis of GR legacy, authors tried to anticipate future trends in agriculture. Whether a further genotype by environment interaction minimization by more controlled agro-production conditions in closed growth systems could be the next level? In order to feed more than 10 billion people are we forced to seek for radical solution in food production increment, rather than step by step improvements?

Keywords: *Agriculture, food, wheat, breeding, future.*

Introduction

The elephant in the room. The human population grew slowly for thousands of years, but in recent centuries, it has jumped dramatically. Between 1900 and 2000, the increase in world population was three times greater than during the entire previous history of humanity giving an increment from 1.5 to 6.1 billion in just 100 years (Roser, M., and Ortiz-Ospina, E., 2018). How to feeding 10 billion people sustainably in the late 21st century? In just 30 to 40 years, about 600 quadrillion calories every single day is going to be required. This is twice as much as today. The mass of 7-8 billion people will be squeezed in cities spending around 2800km^3 of fresh water a year. That is more than the whole of irrigation farming is using, today. Every second 750 tons of topsoil is lost even, today giving a warning that present food production is unsustainable in the long term. Moreover, we have lost 24% of our land, already, and we keep on losing 1% a year. The UK's Hadley Climate Centre projects that 40 per cent of the planet could be in regular drought by 2100. The hunger breeds war. If we failed to prevail what is coming, the consequences would affect every person on the planet. Fortunately, to some opinions, humanity has potentials and the technical ability to do limit the danger of extinction and the end of civilization, but things have to change. (Cribb, 2010, 2016). However, world demand for staple food, from 2010 to 2050, is projected to grow by 60%, contrasting about 10% growth of crop area in the same period and the trend of linear increment of wheat, rice and soybean yield that have started to gradually decline (Fischer *et al*., 2014). Furthermore, the ongoing processes are urbanization, environmental erosion including arable land degradation and climate change (Myers *et al*., 2017). Despite alarming voices, there is an

impression that neither agricultural scientific community, nor broader public do not address the issue adequately. That has to be changed. Mortal danger requires resolute and joint action, because if we had no ability to do so, there would be no one to light up the light in celebration of the next millennium, maybe the next century, even.

The road to hell is paved with good intentions. "The Earth provides enough to satisfy every man's need, but not enough for every man's greed" (*cit.* Mahatma Gandhi). The full intensification of agricultural production began in the middle of the previous century. The second half of the twentieth century was marked by the "green revolution", which significantly increased the yield of basic agricultural crops by a significant change in plant architecture. It was a project of great American foundations (Rockefeller, Ford) and governments of developing countries. The intensive agricultural production was based on new genotypes that were more distanced from their wild relatives, and highly dependent on human nursing. Though, the "Green agricultural revolution" has never solved "hunger problem in the world" as the proclaimed goal, the road of agricultural production was traced.

Evolution on steroids. The road of industrialization has started from instinctive selection and breeding that farmer did on the bases of field experience and personal goals. However, this was not fast enough. Controlled evolution required to be accelerated. The Green Revolution (GR) was a game changer, not only in primary food production as well as in plant breeder's philosophy, but also in relations of humans to nature, economic and political relations both locally and globally. It is widely spread opinion that genetics and plant breeding were the foundation of GR, particularly because American scientist and plant breeder Norman Borlaug was the symbol and a Nobel Prize laureate of this revolution (Borlaug, 2002). However, the real bases of GR were fertilizers, nitrogen in particular. The nitrogen is principal factor for crop productivity. Cheap nitrogen from industrial ammonium was available in great quantities after the WWII, since the explosives were not in high demand, any more. The synthetic fertilizer industry blossomed. Unfortunately, tall stature of landraces and "old" bred varieties were not suitable to withstanding large amount of nitrogen fertilizers application without logging. Beside N-fertilizers, density (the number of plants per unit area) was another corner stone of GR. The role of population significantly prevailed the role of an individual, in crops yield formation. But, the tall stature of plants could not follow the increment of sowing rate without logging. In order to solve the logging problem, new plant ideotype was required. Evolution had to be artificially accelerated. Newly designed GR plant ideotype had to be of shorter stature to overcome logging. Bread wheat and rice, are éclatant examples of these scientifically induced evolution in agriculture. Using genetic variation of wild relatives and landraces, as *Rht* (reduction of height) genes in wheat, new plant type was born. The type capable to put forward industrialization in agriculture.

The aim of this article is to summarize the impact of GR philosophy on wheat breeding program of the Institute of Field and Vegetable Crops in Novi Sad, Serbia, and to look at future trends.

Material and Methods

A research has been conducted on large sample of wheat genotypes consisting on varieties, landraces and wild relatives from the Wheat breeding program of the Institute of Field and Vegetable Crops in Novi Sad (IFVCNS), and accompanying genetic collection listed in Dimitrijević (1987), and Dimitrijević (1997). A wide palette of results processing was applied, mainly statistical models and laboratory analysis after Steel and Torrie (1960), Singh and Shepherd (1985), Gauch and Zobel (1997), Ng *at al*. (1988).

Results and discussion

The Harvest index - Truth or Dare. Harvest index is a synthetic parameter representing the ratio of grain yield and total biomass yield. Introduced by Donald (1962), HI represents effectiveness of assimilative translocation from vegetative to generative plant parts, towards grain filling, and hence high grain yield. This parameter was paradigm of GR philosophical approach materialized in Donald's "communal" ideotype that performs poorly as individual, but gives its best in interplant competition provoked by crop population density (Donald, 1968). Hence, radically changed plant architecture, particularly the reduction of plant stature resulting in better sink to source ratio expressed through higher HI value is the main cause of 3 to 5 time higher grain yield due to the GR. The HI, as a selection criterion, was widely used in plant breeding and investigated in scientific papers, but rarely criticized. Ismail (1993) had a case contemplating usefulness and credibility of this parameter that relies on complex quantitative genetic influence. Moreover, analyzing data of 22 divergent wheat genotypes the trend could be denoted that HI appeared to be quite insensitive to reduction of plant height (Petrović, 2000; Petrović *et al.*, 2000), fig. 1. The sink to source ratio did not vary much, because the key seems to be overall robustness, and its proportional downscaling rather than height reduction *per se*. The previously stated trend was observed in investigation of very divergent wheat sample consisting of 41 genotypes, about half varieties and half wild relatives (Dimitrijević *et al*., 2001), fig. 2. The plant stature did not influenced average spike yield formation followed through grain weight per spike. Consequently, it seems that the dwarfing genes introduction brought by GR was not primarily for more efficient assimilative translocation to generative part of the plant, but mostly because of production intensification by fertilizers application increment, nitrogen in particular, and the plant ability improvement to withstand higher sowing density. The key words of GR were "chemistry" rather than "genetics", "logging", rather than "translocation", and "collectiveness", rather than "individuality".

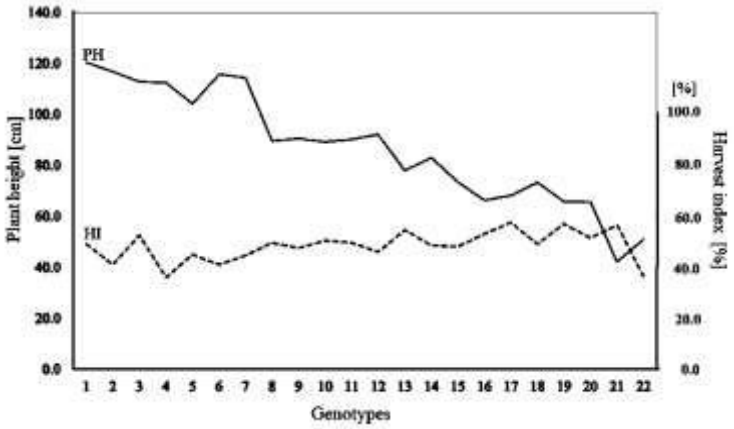

Figure 1. The relation of plant height (PH) and harvest index (HI) of 22 wheat genotypes from different foreign wheat breeding centers and IFVCNS, from tall old varieties, via semi-dwarf modern varieties to dwarf Aibian and Tom Thumb. Data from Petrović (2000)

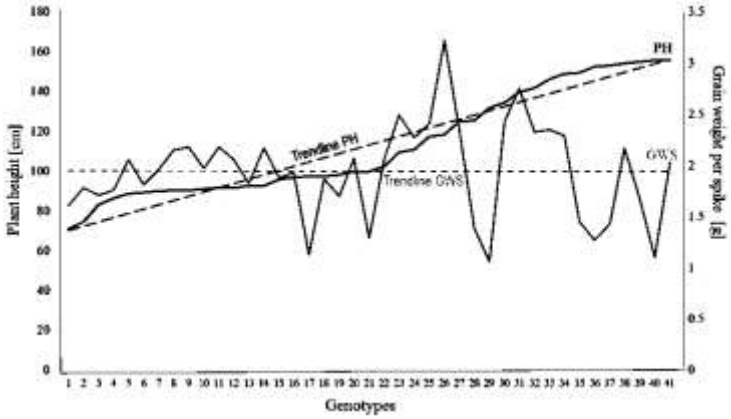

Figure 2. The relation of plant height (PH) and average spike yield given through grain weight pre spike (GWS) of 41 wheat genotypes of different ploidy level (4x=28 and 6x=42) and origin (modern varieties foreign and from IFVCNS, as well as, wild relatives). Data from Dimitrijević *et al*., 2001.

Green Revolution - Winners and losers. If yield was the winner of GR, biodiversity was definitely it's looser (Dimitrijević *et al.*, 2011). The pedigree of 23 bread modern wheat varieties from Yugoslavia (18) with 14 from IFVCNS, consisting of 123 varieties from all over the world illustrates that the vast number of heat varieties created within the GR philosophy, particularly in American, Australian and European wheat breeding centers originate from single cross of Squarehead, an early English cultivars, introduced in Holland around 1870 and Duch landrace Zeeuwse Witte. In 1886 Luitje Broekema, Director of the Government Agricultural School at Wageningen crossed Squarehead x Zeeuwse Witte, getting variety Spijk. In 1889, Broekema backcrossed a F_3 generation plant with maternal parent Squarehead obtaining the variety Wilhelmina, released in 1901. The general idea was to combine quality and good yield of Zeeuwse Witte and good spike architecture of Squarehead, as well as, it's good baking quality (de Haan, 1957). The real father of GR, Italian breeder Nazareno Strampelli crossed in 1913, Wilhelmna Tarwe with local landrace Rieti, mixing superior Dutch variety with rust resistant Rieti, and then top-crossing this combination with Japanese agronomically poor variety Akago-mughi of short stature up to 65cm tall (*Rht8*), therefore resistant to logging, and of early maturation (*Ppd1*) (Salvi *et al.*, 2013). The cornerstone of the GR was set. This combination played the fundamental role in Yugoslavian, Serbian and Novi Sad wheat breeding program, as well (fig. 3). Beside this crucial Anglo-Dutch cross combination, there were some other principal sources of genetic variation, so called, "common ancestors" in pedigree, like Barletta, landrace from Argentina, ancient Italian genotypes Gentil Rosso and Inallettabile, Japanese genotypes Akago-mughi, Soyiku-akage and Kaya-komughi *via* Saitama 27, English populations with a common name Prince Albert etc., but the role of landrace named "Banatka", after the Banat region divided between Serbia, Romania and Hungary. In Serbia, landrace Banatka (Old Banatka) was well spread, not only in Banat and Vojvodina, but also in Šumadija, Kosovo and Metohija, until the 30's of the XX century wheat landraces had been gradually replaced by "scientifically" bred varieties (Petrović and Dimitrijević, 2012). Beside Serbia, Banatka was grown in Hungary, Poland, Ukraine, Russia. In Ukraine, the landrace Banatka was the progenitor of variety Bezostaja 1, contributing 12.5% to its nuclear gene fund (fig. 4). Bezostaja 1 was a very important source of genetic variability for modern high yielding semi-dwarf varieties in wheat breeding programs in Europe, and beyond. However, following pedigrees of 139 wheat varieties and lines from comparative trials, from mid-60's to early 90's, the breeding source of variability changed, which could be denoted in studying IFVCNS wheat breeding program trends. As the domestic wheat breeding developed, the principal source of genetic variability has gradually shifted from foreign gene pool to newly formed domestic wheat varieties gene fund. By the end of 80's the novel advanced genetic variation

Figure 3. Combination Squarehead x Zeeuwse Witte, "Adam and Eve" of the most European, and even broader, wheat varieties. Akagomughi, Japanese wheat variety was donor of earliness and dwarfism (*Ppd1+Rht8*). The pedigree of a sample of Yugoslavian semi-dwarf varieties, in the background (Dimitrijević, 1987).

Figure 4. Landrace Banatka the progenitor of variety Bezostaja 1. Full Pedigree in Dimitrijević, 1987.

had been searched in fixation of small improvements obtained from recombination of domestic varieties. Having in mind decades of selection under the same criteria, the narrowing of genetic variability in producing new superior varieties, primarily in yield, was inevitable (data Dimitrijević, 1997). The advancement was slower and slower, and a new breakthrough is desperately needed.

Trying harder or the border is reached. The crucial question, facing the human population of 10 billion and rising, is are breeders trying hard enough or they just reached the limit of what vertical gene transfer could offer them? According to some data there is no place to put a question like this. Holt-Giménez *et al.* (2012), analyzing FAO 2009 reports state that "the world produces more than 1½ times enough food to feed everyone on the planet. That's already enough to feed 10 billion people". FAO (2017a) declares that "After a prolonged decline, world hunger appears to be on the rise again". The general cause is not in inadequate quantity of world's food production, but in poorness on the rise in some parts of the World. Anyhow, FAO estimates, relying on UN projection that the "world's population would reach 9.73 billion in 2050", "to meet demand, agriculture in 2050 will need to produce almost 50 percent more food, feed and biofuel than it did in 2012", cereals should increase production 43.4% by 2050 comparing to production 2005-07. The assumption is that 80% of this increment should come from yield increases meaning that yield should increase 35% by 2050, however, "yield increases are slowing, despite overall improvements in agricultural efficiency" (Alexandratos & Bruinsma, 2012; FAO, 2017b). The "contractor" of GR predicted that in the foreseeable future food security is to rely on plants, cereals in particular, estimating that world food production should increases 57% by 2025, comparing to 1990 production (Borlaug, 2002). So, following the domestic wheat breeding trends, as an illustration, it could be stated that the dramatically yield increment in wheat has been achieved by the introduction of *Rht-Ppd* genes combination. The smaller, but still remarkable, gran yield enhancements were achieved using chromosome engineering through translocations. The seed storage protein genetic variation of the representative sample of 139 wheat varieties of the IFVCNS indicates that by the end of 70's parental gene pool genetic variation should be renewed in order to continuing step by step yield improvement. At that time wheat rye translocation 1Rs.1Bl was introduced to wheat breeding program in Novi Sad through Soviet varieties Aurora, Kavkaz and Skorospelka 35. According to Dimitrijević (1997) and Dimitrijević *et al.* (2008), the novel variability brought by this chromosomal aberration enhanced potentials to rusts resistance, as well as hectoliter and absolute mass, and consequently the rain yield up to 10% comparing to averages of genotypes without this translocation. Negative effects were denoted in the higher susceptibility to powdery mildew and adverse effect on rheological dough properties. However, dough stickiness which is the main deleterious effect of 1Rs.1Bl was not observed. According to Dimitrijević (1997) results, there is a strong possibility of deletion in the 1Rs.1Bl translocation region that happened spontaneously in IFVCNS wheat breeding program, diminishing the dough

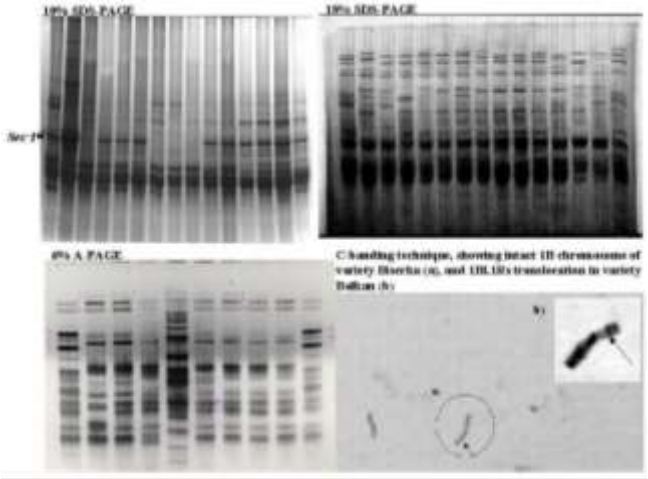

Figure 5. Seed storage protein and chromosomal aberration analysis illustrate the selection criteria of an advanced wheat breeding program based on the Green revolution philosophy (illustrations from Dimitrijević, 1997, given in Dimitrijević (2008).

stickiness as adverse effect. Moreover, there is another momentum concerning high molecular weight glutenin subunits genetic variation (HMW Glu) which made possible rather successful combination of high yield and good quality. The negative effect of 1Rs.1Bl translocation highly depends on genetic background, particularly on quality genetic background in which HMW Glu genes on 1D chromosome play an important role. The introduction of 1Rs.1Bl translocation was followed by favoring higher quality genetic background through selection of 5+10 HMW Glu subunits composition over 2+12. Hence in the representative sample of 139 about 40% had 1Rs.1Bl wheat-rye translocation and about 66% 5+10 HMW Glu subunits composition. Varieties that shared both genetic variations in the same time made about 50% of studied genetic variation, (fig. 5). This example shows that after reaching a satisfactory yield level, the main selection criterion was shifted from the "Stakhanov's grain yield" achievement to breaking a negative correlation between high grain yield, and the quality. Was it too soon? Was it a voluntary decision, or imposed by force of reaching the yield border, limitations of GR wheat ideotype? Anyway, the yield is a winner of GR, but overall genetic variability is a looser, plant breeding programs, included. To reach new heights in yield and food production, facing a human population growth challenges a novel genetic variability should be created.

Conclusions

Was the GR humanitarian effort or mammonic deed in its essence? Judging the results, after 60 years, there is a space for discussion. However, the fact is that hard working geneticists and plant breeders, all over the World, did their best to meet the demands for food. This is a gigantic task, and here is elaborated the tip of the iceberg. The swing of GR is weakening, going to halt. In the meantime demands for food are rapidly growing since the human population is still not at its peak. The Green revolution had the convenience not to take care about environment, but "Anyone who believes in indefinite growth in anything physical, on a physically finite planet, is either mad or an economist." (*cit.* Kenneth E. Boulding). The GR legacy is to continue food production increment without further environmental damages. The genetic variability meant to carry out the yield regardless of costs is exhausted. The trying in breeding for special purposes, like to prevail stress conditions and seize new areas for food production, or revive a branched wheat could appear insufficient. Are we to find new genetic variability capable to speed up food production, which is inadequately slow, now, making more turns. Are we to go NASA way, and try to avoid climate changes and field stresses in closed production systems? Does the vertical gene transfer reach the border of its potentials? Is the horizontal gene transfer, we still know so little about, the path of salvation? While vertical gene transfer has its limits relying on reproductive mechanisms and chromosomal compatibility in creating novel genetic recombination, horizontal gene transfer bypasses all these obstacles recombining at nucleic acid level, directly. Anyway, in order to prevail, it seems that new "revolution" is required, not only in doing, but also in thinking. The elephant is in the room, and we cannot ignore it, trying to solve the problem rearranging old furniture. Dramatic challenges require resolute response.

Abstract

Every single-cross maize hybrid can be produced in its original and reciprocal variant depending on the choice of the maize inbred line to serve as a maternal, or paternal component. Due to the manifestation of maternal effects, significant differences for various traits can be exhibited between the two variants of the same hybrid. The goal of this experiment was to examine a possible influence of reciprocal crosses on grain yield and some morphological traits in maize. Ten commercial ZP maize hybrids belonging to the maturity FAO 500-600 group were examined. All hybrids share a common parental line T1 which is used as a paternal line in original and as maternal in the reciprocal variants of investigated hybrids. The trial was set on two locations during 2015 and 2016. Grain yield, plant height , ear height and total number of leafs per plant were recorded. Location, year and reciprocal crosses were significant factors for all examined traits. Hybrids ZPH2, ZPH7 and ZPH8 had significantly higher grain yield in their reciprocal compared to the original variants with the difference ranging from 4.5 to 6.87%. Plant height was significantly higher in reciprocal variants of hybrids ZPH7 and ZPH9, and original variants of hybrid ZPH3 and ZPH6 (3,9 and 5,1% respectivily). Hybrid ZPH7 exhibited the highest difference in leaf number in reciprocal variant, compared to the original (11,6%). Hybrids ZPH1, ZPH4 and ZPH10 weren't influenced by the reciprocal crosses for neither of the investigated traits.

Key words: *maize, reciprocical effect, grain yield, morphological traits.*

Introduction

The choice of the maize inbred line to serve as a maternal, or paternal component in any specific maize hybrid combination can have a considerable impact on some phenotype characteristics of the hybrid. Due to the manifestation of maternal effects, significant differences for various traits can be exhibited between the two variants of the same hybrid. The maternal effect is in theory usually defined as the contribution of the maternal parent to the phenotype of its offspring beyond the equal chromosomal contribution expected from both parents. To understand the nature of maternal effect it is important to distinguish different classes of it. Roach and Wullf (1987) distinguish three different classes of maternal effects in plants: cytoplasmic genetic, endosperm nuclear and maternal phenotypic. Cytoplasmic genetic effect are based to the fact that maternal cytoplasm is transferred to the offspring including organelles such as plastids and mitochondrias containing genetic material. It's important to note that some research point the possibility of male cytoplasm to influence the hereditary expression in the progeny as a small quantity of male cytoplasm can be incorporated in the zygote from the male gamete or the male gametophyte during fertilization (Fleming, 1975). Endosperm nuclear effect is based to the fact that the maternal plant contributes with two nuclei in the formation of 3N endosperm. The larger proportion of maternal genes in endosperm which contains important enzymes for germination and is the source of nutrient for the future plant may greatly influence the development of the plant and the traits that it will exhibit.

Differences between reciprocal F1 crosses for important characters can influence decisions at many steps in a breeding program (Hansen and Baggett, 1977). Differences between reciprocal crosses for important agronomic traits of maize due to maternal effects were reported by many researchers (Garwood et. al., 1970; Kalsy and Sharma, 1971; Khehra and Bhalla, 1976; Pollmer et. al., 1978; Seka and Cross, 1995; Revilla et al., 1999; Gonzalo et. al., 2007; Pepo et. al., 2007).

Materials and methods

Ten commercial ZP maize hybrids belonging to the maturity FAO 500-600 group were examined (Table 1.). Ten inbred lines belonging to different heterotic and maturity groups serve as maternal component of each original hybrid variants. All hybrids share a common parental line T1 which is used as a paternal line in original and as maternal in the reciprocal variants of investigated hybrids. T1 inbred line belongs to the lancaster heterotic group and FAO 500 maturity group.

The trial was set on two locations (Zemun Polje-Institut and Zemun Polje- Skolsko dobro) during 2015 and 2016. The trial had an RCBD design in two replications for each original and reciprocal hybrid combination.. Grain yield (kg/ha), plant height (cm) , ear height (cm) and total number of leafs per plant were recorded. Grain yield was adjusted at 14% grain moisture. The data for vegetative traits were recorded on ten average plants for each replication. The statistical significance of the difference in traits values between original and corresponding reciprocal crosses were tested using ANOVA.

Results and discussion

The ANOVA results show that years, locations and genotypes were significant factors for most of examined traits (table 2.). Years and genotypes influenced all traits at 1% level of significance. Different locations didn't affect variations in plant and ear height. Year x Location interaction was signicficant for ear height and leaf number, whileyear x genotype interaction influenced all four examined traits. The variation coefficient ranged from 1.75% for plant height to 3.55% as recorded for ear height.

Table 3 shows mean values for grain yield and the difference between the original and reciprocal variants of the same hybrids. Highest yield hybrid were the reciprocal ZPH 2 R (12665 kg/ha) and ZPH (12453 kg/ha) and ZPH 7 R (12453 kg/ha) hybrids. Smallest differences between original and reciprocal hybrids were recorded for ZPH 4 / ZPH 4 R and ZPH 9 / ZPH 9 R hybrids, 0.6 and 0.62% respectively. Significant reciprocal effects were recorded for hybrids ZPH2, ZPH7 and ZPH8 with the difference ranging from -4.5 to 6.87%.

Plant height mean values for original and reciprocal hybrids and their difference is presented in table 4. Six hybrids exhibited significant reciprocal effect for plant height . Plant height was significantly higher in reciprocal variants of hybrids ZPH7, ZPH8 and ZPH9, and original variants of hybrid ZPH3, ZPH5 and ZPH6. Highest reciprocal difference was exhibited in hybrid ZPH 6 and ZPH7 (5.13 and -5.68, respectivily). Reciprocal effect for maize plant height was Greatest ear height was recorded in reciprocal hybrid ZPH 6 R (127cm) and his original ZPH 6 (124cm). Significant reciprocal effect was noticed for hybrids ZPH 7 and ZPH 8. Original ZPH 7 hybrid had on average 9,5 cm higher positioned main ear compared to his reciprocal variant. Contrary to that reciprocal ZPH 8 R had significantly greater values for ear height compared to the original variant of the same hybrid.

Hybrids ZPH1, ZPH4 and ZPH10 weren't influenced by the reciprocal crosses for neither of the investigated traits.

Conclusion

The maternal effect is a complex phenomena and more research should be done to understand its nature. While some maize hybrids seems unaffected by the reciprocal effect, others exhibite significant differences between their original and reciprocal variants for important traits that can affect hybrid performances. Taken in consideration the correlations between

different traits of maize (morphological traits, yield components), the possible significant influence of maternal effect should be regarded as one of the important factors in the planning of maize hybrid seed production, together with yield potential of the mother inbred line, pollination capabilities of the father line and others.

Abstract

The aim of this research was to examine the impact of the application of different nitrogen amounts and the timing of nitrogen fertilizer applications on morphological characteristics, yield and yield components and grain quality of the winter oats. The research was performed in 2015/2016 production year, with the domestic variety Vranac, on the eutric cambisol soil type, according to the randomized block system with four replications. Two factorial trial was based on the following variants: A) Time of fertilization (1. February, 2. March, 3. February and March); B) Nitrogen content (1. Control (without fertilization), 2. 50 kg ha^{-1} N; 3. 100 kg ha^{-1} N; 4. 50 + 50 kg ha^{-1} N). Combinations i.e. variants were as follows: Control, February 50 kg N ha^{-1} (F_{50}); March 50 kg N ha^{-1} (M_{50}), February 50 kg N ha^{-1} + March 50 kg N ha^{-1} (F_{50} + M_{50}); February 100 kg N ha-1 (F_{100}) and March 100 kg N ha-1 (M_{100}). The highest values of plant height (82.6 cm), number of internodes (4.6), panicle length (20.8 cm), number of spikes in a panicle (30.2), number of grains (66.4) and grain weight (1.78 g) per panicle were obtained in the variant F_{50} + M_{50}. The highest values of the 1000-grain weight (32.4 g) and the hectoliter weight (51.6 kg) were measured when fertilization was carried out in March with 50 kg N ha-1. The largest grain yield (4.23 t ha^{-1}) and grain protein content (8.6 %) were observed for the variant F_{50} + M_{50}.

Keywords: *Oats, nitrogen, morphological and production characteristics, protein content*

Introduction

Oat (*Avena sativa* L.) is an annual field crop from the grass family (*Poaceae*). It is originated from Eastern and Southeast Asia. Thanks to the high energy and nutritional value of the grain, it has a great economic importance. Oats are used in the diet of humans, domestic and fattening animals (Glamočlija, 2012). Secondary metabolites of oat grain exhibit antioxidant properties (Rakić *et al*., 2014). Compared to other cereals, oats are better adapted to the production in less favorable, colder and humid conditions, as well as on less fertile soil (Hoffman, 1995). It is particularly important for growing in mountainous areas where growing of other field crops is less successful (Maksimović, 1998). Requirements of oats regarding soil quality are modest, compared to other cereals (except rye). Because of the good suction power of the root system, oats can perfectly use the remaining nutrients after first crop harvesting, and it is usually the last crop in the crop rotation, when the high grain yields can not be expected. However, although oats can be grown on less fertile soils, with somewhat reduced yields, better results are achieved on more fertile land (Reiner *et al.*, 1983; Malešević, 2008). In the past years areas under the oats in the world ranged between 10 and 14 million ha, with an average grain yield of around 2.3 t ha^{-1}. In Serbia, oats are grown on the area of about 35,000 hectares with the average grain yield of 2.2 t ha^{-1} (Glamočlija, 2012). Nitrogen is the key element for yield and most often is the limiting factor for achieving high yields. As the constituent of vitamins and chlorophylls, it indirectly participates in the photosynthesis process (Jevtić, 1986). Nitrogen

fertilization is specific because the mineral, accessible form of nitrogen can be decreased by washing out due to its mobility in the soil and denitrification, and on the other hand, it is increased by the mineralization of soil organic matter (Kastori, 2005). In order to determine the optimum amount of nitrogen from the fertilizer, it is necessary to know the dynamics of the nitrogen absorption by the crop and the N - NO_3 dynamics in the soil, as well as the time of application or the type of nitrogen fertilizer. Oat strongly responds to supplemental nutrition, especially with nitrogen. Nitrogen fertilization significantly increases the yield and quality of oats, as well as the production of overhead biomass, while phosphorus and potassium have significantly less effect on the yield increase. Halezov and Anisimov (1982) recommend from 30 to 60 kg N for oats fertilization ha^{-1}, Sawicki (1982) 60 kg N ha^{-1}, Hmurec and Markovec (1982) 90 kg N ha^{-1}. Based on the investigation of the influence of different amounts of nitrogen on the yield of three varieties of oats, Pržulj *et al.* (2010) found that the highest grain yield in all varieties was obtained with 30 kg N ha^{-1} while Burke *et al.* (2001) stated that the effects of different doses of nitrogen and density of the sowing have had a less effect on the yield and quality compared to the variety of oats. The same researchers pointed out that the yield of the oats increased by increasing the amount of nitrogen up to 160 kg N ha^{-1}. However, the percentage of lodging significantly increased in treatments with more than 100 kg N ha^{-1}. For agro-ecological conditions of Vojvodina Aćin *et al*. (2012) recommend 60 kg N ha^{-1} for oats fertilization, as they did not establish statistically significant differences between 60 and 90 kg N ha^{-1}. Accordingly, the amount of nitrogen in the oats fertilization depends on the resistance of the variety to the lodging and low temperatures, fertility and physical properties of the soil, the agro-ecological conditions of the area, the planned yield and the financial status of the producer (Maksimović, 1998). When planning this research, it was assumed that the investigated amounts of nitrogen and different fertilization timing would have different impact on morphological characteristics, yield components, yield and grain quality of the winter oats.

Materials and Methods

Testing of the winter oats productivity in the dependence from fertilization time and the amount of nitrogen was carried out on the private farm near Sopot (village Drlupa), Serbia, in 2015/16 production year. The field trial was performed on the eutric cambisol soil type, according to the randomized block system with four replications. At the profile depth of 0 - 30 cm the soil was characterized by the following agrochemical properties: pH in H_2O – 4.99; pH in KCl - 4.15; humus - 4.26%; nitrogen - 0.213%; P_2O_5 - 9.60 mg/100 g and K_2O - 26.60 mg/100 g of soil. The actual plot area for grain yield was 6.0 m^2 (3.0 x 2.0 m). Two factorial trial was established, comprising the following variants: A) Time of fertilization (1. February, 2. March, 3. February and ?. March). B) Nitrogen content (**1**. Control (without fertilization); **2.** 50 kg ha^{-1} N; **3.** 100 kg ha^{-1} N; **4.** 50 + 50 kg ha^{-1} N). Combinations i.e. variants were as follows: Control, February 50 kg N ha^{-1} (F_{50}); March 50 kg N ha^{-1} (M_{50}), February 50 kg N ha^{-1} + March 50 kg N ha^{-1} (F_{50} + M_{50}); February 100 kg N ha-1 (F_{100}) and March 100 kg N ha-1 (M_{100}). Crop previous to oats was winter wheat. After the harvest of wheat, the stubble field was ploughed down to the depth of 10 - 15 cm. The sowing of winter oat variety Kg - Vranac was performed in the second half of October 2015, according to the plan of the sowing, with 500 seedlings per square meter or about 160 kg ha^{-1}. Within the cultivation measures, the protection of the crop with the herbicide based on *Bentazone* and the protection of the grain from cereal leaf beetle with insecticide based on *Deltamethrin* were carried out. Nitrogen fertilizer AN (33.5% N) was applied in the second half of February and the second half of March. The harvest of the oats was done manually in physiological maturity, in the second half of July. Immediately after the harvest, necessary measurements of the oats yield basic indicators and productivity were made. The chemical composition (quality) of the grain

was determined on the apparatus DICKEY - JOHN, NIR Analyzer. Data on the weather conditions were obtained from Mladenovac meteorological station.

Meteorological conditions. Oats, as a plant of the northern chilly areas, does not have a great need for warmth, so the heat sum for winter varieties is about 1,900°C (Glamočlija, 2012). Average monthly air temperature, monthly and annual amount of rainfall for the vegetation period of winter oats in the year of the study, as well as the multi-annual average of air temperature and rainfall (2009 - 2014) are shown in Table 1.

Table 1. Average monthly air temperature (°C), monthly and annual sum of rainfall (mm) for the vegetation period of the winter oats and the multi-annual average (Mladenovac)

	Month									
	X	XI	XII	I	II	III	IV	V	VI	Average/ Sum
Air temperature (^{o}C) 2015/2016	11.2	6.9	3.3	0.2	7.3	7.8	14.1	16.1	21.4	9.8
Multi-annual average 2009-2014	11.8	9.7	2.8	2.0	1.2	7.5	12.5	16.4	20.7	9.4
Rainfall (mm) 2015/2016.	42.4	54.3	4.4	47.2	97.0	95.8	67.8	90.0	106.6	605.5
Multi-annual average 2009-2014	53.7	25.5	58.3	49.4	56.2	47.0	68.8	93.6	68.1	520.6

The average air temperature in the investigated year did not differ significantly compared to the multi-annual average of 9.8°C. The total sum of the precipitation for the vegetation of the winter oats in the year of investigation was significantly higher (by 84.9 mm) in comparison to the multi-annual period for Mladenovac area, and it was 605.5 mm, which certainly affected the obtained results, i.e. the nitrogen fertilizer had stronger effect.

Results and Discussion

Within the morphological characteristics of the oats, the influence of timing of fertilization and amount of nitrogen on the plant height and the number of internodes of the stem were examined. Average plant height for investigated variants was 70.9 cm (Table 2). The lowest plant height (50.8 cm) was noted in control (variants without fertilization) and the highest one (82.6 cm) was measured in variant where nitrogen was applied twice (February+March) in the quantity of 50 + 50 kg N ha^{-1}. Higher plant height was achieved by nitrogen fertilization in February compared with that in March. The average number of internodes was 3.8 (Table 2). Also, the smallest number of internodes was counted in the control variant (2.6), while the largest number of internodes was recorded on F_{50} + M_{50} (4.6), followed by the F_{50} variant (4.2).

Table 2. Influence of fertilization timing and nitrogen amount on the plant height (cm) and the number of internodes

Fertilisation variant	Plant height (cm)	Index (%)	Number of internodes	Index (%)
Control	50.8	100.0	2.6	100.0
F_{50}	72.9	143.5	4.2	161.5
M_{50}	68.6	135.0	3.7	142.3
F_{50} + M_{50}	82.6	162.6	4.6	176.9
F_{100}	75.7	149.0	4.0	153.8
M_{100}	74.7	147.0	3.9	150.0
Average	70.9	-	3.8	-

The average length of the panicle was 16.7 cm (Table 3). The minimum panicle length (11.7 cm) was detected in control, while the highest value (20.8 cm) of this parameter was registered in the combination F_{50} + M_{50}. The average number of spikes per panicle was 25.1 (Table 3). Fertilization in March, on average for nitrogen amounts, resulted in 1.2% higher number of spikes compared to the February fertilization. Furthermore, by using 100 kg of N ha^{-1}, a larger number of spikes (3.9) was found compared to the smaller amount of nitrogen (50 kg N ha^{-1}).

Table 3. Influence of fertilisation time and nitrogen quantity on the lenght of panicle (cm) and the number of spikes in panicle

Fertilisation variant	Lenght of the panicle (cm)	Index (%)	Number of spikes per panicle	Index (%)
Control	11.7	100.0	16.7	100.0
F_{50}	14.6	124.8	22.7	135.9
M_{50}	16.2	138.5	25.1	150.3
F_{50} + M_{50}	20.8	177.8	30.2	180.8
F_{100}	18.3	156.4	28.7	171.8
M_{100}	18.3	156.4	26.9	161.1
Average	16.7	-	25.1	-

The average number of grains in the panicle was 51.2 (Table 4). The smallest number of grains in the panicle (30.9) was counted in the control and the largest (66.4) in the variant F_{50} + M_{50}. The average grain weight per panicle was 1.38 g. The application of larger amounts of nitrogen (100 kg N ha^{-1}) caused the increase of grain weight per panicle by 16.4%, while fertilization in March, on average for nitrogen amounts, increased grain weight per panicle by 6.9% (Table 4).

Table 4. Influence of fertilisation time and nitrogen quantity on the number of grains per panicle and grain mass per panicle (g)

Fertilisation variant	Number of grains per panicle	Index (%)	Grain weight per panicle (g)	Index (%)
Control	30.9	100.0	0.85	100.0
F_{50}	48.8	157.9	1.20	141.2
M_{50}	50.8	164.4	1.42	167.1
F_{50} + M_{50}	66.4	214.9	1.78	209.4
F_{100}	55.0	178.0	1.54	181.2
M_{100}	55.2	178.6	1.51	177.6
Average	51.2	-	1.38	-

The average 1000-grain weight was 31.4 g (Table 5). The minimum 1000-grain weight (29.3 g) was detected in control and the largest (32.4 g) when fertilization was carried out in March with the amount of 50 kg N ha^{-1}. Average hectoliter weight was 49.9 kg. In this case, a higher hectoliter weight was achieved with a smaller amount of nitrogen (50 kg N ha^{-1}) both in February and March, while the greatest hectoliter weight (51.6 kg) was measured when fertilization was carried out in March with 50 kg N ha^{-1}.

Table 5. Influence of fertilisation time and nitrogen quantity on the 1000-grain weight (g) and hectoliter weight (kg)

Fertilisation variant	1000-grain weight (g)	Index (%)	Hectoliter weight (kg)	Index (%)
Control	29.3	100.0	48.2	100.0
F_{50}	31.9	108.9	51.2	106.0
M_{50}	32.4	110.6	51.6	107.1
$F_{50} + M_{50}$	30.7	104.8	49.1	101.9
F_{100}	31.7	108.2	49.9	102.9
M_{100}	32.1	109.6	50.2	104.1
Average	31.4	-	49.9	-

The average grain yield was 3.71 t ha^{-1} (Table 6). The lowest grain yield (2.77 t ha^{-1}) was achieved in the variant without nitrogen supplementation and the largest (4.23 t ha^{-1}) in combination $F_{50} + M_{50}$. The same tendency was observed for the protein content of the grain. On average for nitrogen amounts, the higher protein content in the grain (by 14.05 index points) was achieved in the variant of nitrogen utilization in March compared to the fertilization in February. On the other hand, by applying a larger amount of nitrogen (100 kg ha^{-1}) in March, the protein content in grains was higher by 6.2 index points compared to 50 kg N ha^{-1}.

Table 6. Influence of fertilisation time and nitrogen quantity on the grain yield (t ha^{-1}) and grain protein content (%)

Fertilisation variant	Grain yield (t ha^{-1})	Index (%)	Grain protein content (%)	Index points
Control	2.77	100.0	6.4	100.0
F_{50}	3.60	130.0	6.8	106.3
M_{50}	3.77	136.1	7.8	121.9
$F_{50} + M_{50}$	4.23	152.7	8.6	134.4
F_{100}	3.97	143.3	7.4	115.6
M_{100}	3.90	140.8	8.2	128.1
Average	3.71	-	7.5	-

Conclusion

On the basis of the obtained results the following conclusions can be drawn:

Meteorological conditions during the vegetation period were favorable for the growth and development of the winter oats. Both investigated factors - amount of nitrogen and the timing of nitrogen fertilizer application had an effect on the parameters involved in the research.

Regarding morphological characteristics of the oats, the plant height was more dependent on the amount of nitrogen compared to the timing of application, while the its influence on the number of internodes was opposite. By increasing the nitrogen amount from 50 to 100 kg N ha^{-1}, plant height increased by 6.2%. Fertilization in February resulted in increased plant height (by 3.3%) compared to March. There was no significant difference in the number of internodes for 50 and 100 kg N ha^{-1}, but earlier fertilization (in February) resulted in the higher number of internodes compared to nitrogen supplementation in March. Regarding yield components, by applying the larger amount of nitrogen (100 kg N ha^{-1}), a greater panicle length (by 18.8%) was measured and the greater number of spikes (by 16.3%) compared to the application of the amount of 50 kg N ha^{-1}. Fertilization in March resulted in higher panicle length (by 4.8%) and the greater number of spikes (by 1.2%) compared to the nitrogen utilization in February. The 1000-grain weight, as well as the hectoliter weight, showed low dependence, both from the timing of fertilization and the amount of nitrogen. The applied

nutrition with nitrogen had the strong influence on the yield and quality of oat grains. Compared to the non-fertilized variant, two-fold nitrogen utilization in the amount of 50 kg N ha^{-1} (variant F_{50} + M_{50}) increased grain yield by 52.7% or 1.46 t ha^{-1}, as well as protein content (34.4 index points or 2.2%). This is also a recommendation to the winter oats producers when deciding about timing of fertilization and the amount of nitrogen for the investigated area.

Abstract

The human population has increased more than 200% during the 20th Century. UN projection is 10 billion people in 2055 demanding food. To meet the challenge, contemporary agriculture is to using all its resources to increase the food production. In order to investigate the way to enhance productivity level of marginally suitable land multi-environment trials has been established. A portion of these multiyear trials is analyzed in this article. Six bread divergent wheat varieties were grown 4 environment trials (2 years x 2 localities). The first year was extremely humid and rainy, and the second could be considered as an average year. Two localities differed in soul type. One locality was characterized by chernozem, and the other by solonetz soil. The paper presents the results of the plant height (cm), the spike length (cm), the mass of the spike (g), the grain mass per spike (g), the number of grains per spike and the spike index of 6 bread wheat varieties (Renesansa, NSR5, Pesma, Banatka, Jugoslavia and Bankut 1205). The results are presented via the GGE biplot in order to analyze the common genotype effect and the genotype by environment interaction (G + GE). GGE biplotes were used to distinguish genotypes with the highest GGE effect. Graphs are constructed based on PCA results. For all tested traits, the first principal component (PC1) has explained more than 50% of the total variation of the trial. The genotype by environment interactions (GEI) for each examined variety varied depending on variety and trait.

Keywords: *wheat, MET, GEI, GGE, yield components.*

Introduction

Bread wheat (*Triticum aestivum* L.) is one of the most widespread agricultural crops. It represents a portion of human diet of about 25% in developed, and even up to 80% in developing countries comparing to all the cereals use being the main source of minerals and vitamins. According to UN data, human population is growing at the rate of 83 million individuals per year, and up to 2055, the projection is that it would be about 10 billion people on Earth (United Nations, 2018). General view is that the food production *per capita* of today is sufficient enough to feed the World, however the basic problem is unevenly distributed production and consumption. Hence, about 2.3 billion people in the World are not fed enough or intake less than required 2000kcal/day, while 1.9 billion people consume more than 3000kcal/day *(TEEB, 2015)*. Consequently, contemporary agriculture faces great challenges not only in increased requirement for food production, but also in finding and reaching for new agricultural resources.

Plant breeding, including the breeding of wheat, is of crucial importance in achieving high and stable yield, as well as, in searching for usable genetic variability for crop growing in limited conditions of less convenient, stressful environments. One of the important plant breeding directions is broadening production area by putting in good use less productive soil, by producing usable genetic variation that could be utilized in wide range of agro-ecological conditions including different soil types. In phenotypic variability components estimation the important is the role of genotype by environment interaction (GEI), not only in respect of

stable genotype reaction to environmental variation that is one of the selection criteria, but also in identifying the main sources of phenotypic variability in order to find optimal growing conditions where a given genotype is going to perform to the best of its genetic background.
The aim of the article is to estimate GEI of different wheat varieties in multi environmental trial (MET) seated on chernozem and solonetz soil in order to assesing grain yield performance and identifying the most valuable genetic variation, through grain yield component traits, using genotypes (G) and genotype/environment (GE) interaction biplot model (GGE).

Material and methods

The 2Lx2Y MET trial was set at two locations (2L), Rimski Šančevi, near Novi Sad (45.322°N and 19.839°E), on chernozem soil at the Experimental field of the Institute of Field and Vegetable Crops in Novi Sad (EFIFVC - NS), as control locality, and on the soil type solonec, in Banat region, in the village of Kumane - KU (45.539°N and 20.228°E), in two vegetation seasons (2Y - 2014/15 and 2015/16). The first season was characterized by exceptionally high averages of monthly rainfall and humidity, while the second season was within the average values for the observed region. In the study, six varieties of bread wheat (Renesansa, NSR 5, Pesma, Banatka, Jugoslavija and Bankut 1205) were investigated, in the full maturity phase, for the phenotypic variation of the following yield components: plant height (cm) - PH, spike length (cm) - SL, spike weight (g) - SW, grain mass per spike (g) - GMS, grain number per spike - GNS and the spike index - SI, defined as the ratio between the mass of grains per spike and the total mass of spike (Denčić and Borojević, 1992). Varieties Renesansa, NSR 5, Pesma, and Jugoslavija are of Green revolution (GR) ideotype, semi-dwarf wheat varieties, where NSR 5 (Novi Sad's early) is considerably earlier than other three. Variety Bankut 1205 is and pre GR bred variety of taller stature, showing 120cm of height on average. Finally, Banatka, or Old Banatka is a landrace from Banat area that had been grown in Banat region by small farmers before the introduction of Hungarian variety Bankut 1295. At both localities, labeled as NS and KU, varieties were sown in 6 rows of 2m length, with the raw spacing of 15cm. Before sowing, 130kg/ha of mineral fertilizer NPK (15:15:15) was applied, while 200kg/ha KAN mineral fertilizer was additionally applied.
The data were analyzed using the GGE biplot software (http://www.ggebiplot.com/software), and genotype (G) variation and GE interaction interpreted according to the model for the GGE biplot based on singular value decomposition (SVD) of first two principal components:

$$Y_{ij} - \mu - \beta_j = \sum_{k=1}^{K} \lambda_k \xi_{ik} \eta_{jk} + \varepsilon_{ij}$$

Where Y_{ij} = the mean yield of genotype i (= 1,2,…,g) in environment j (= 1,2,…e), μ = the grand mean, β_j = the main effect of environment *j*, ($\mu + \beta_j$) = mean yield of environment j, λ_k = the singular value (SV) of k^{th} principal component (PC), ξ_{ik} = the eigen-vector of genotype i for PC_k, η_{jk} = the eigen-vector of environment j for PC_k, K is the number of PC axes retained in the model ($K \leq \min(g,e)$ and $K = 2$ for a 2-dimensional biplot) and ε_{ij} = the residual associated with genotype i in environment j (Yan, 2001; Yan and Holland, 2010).

Results and discussion

Plant height. Variation for plant height highly depended as expected, on locality and on vegetation period. The season of 2015/16 (sowing 2015) was meteorologically more favorable for wheat than 2014/15

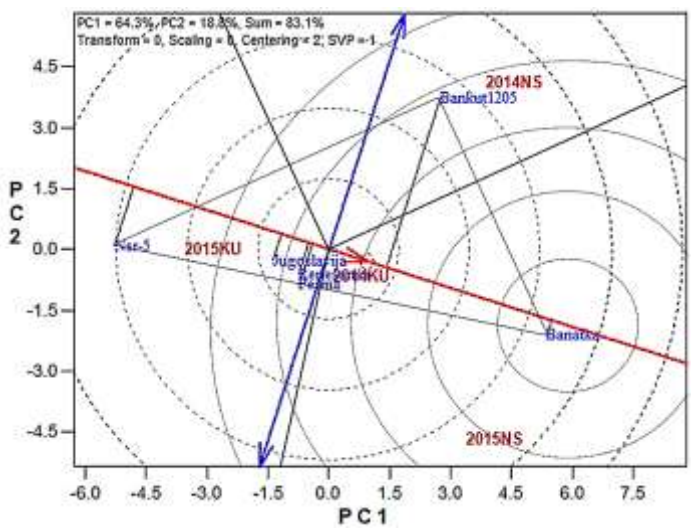

Figure 1. GGE biplot of two Principal Components (PC) based on 2Lx2Y MET trial with 6 bread wheat genotypes for plant height (cm). The GGE biplot showing genotype variability and GE interaction in each environmental variation.

(sowing 2014), where the weather was unstable with a lot of precipitations that followed dry period in spring. The complex nature of environmental variation caused that almost every environment represented a distinct environmental sector. The locality more suitable for agricultural production, EFIFVCNS (labeled as NS in the graph) exhibited higher level of GEI, meaning that in favorable agro ecological conditions varietal response to environmental variation is more prominent comparing to solonetz soil condition at locality Kumane (KU) combined with less favorable over all meteorological conditions. The smaller GEI variation in Kumane showed that, concerning PH variation, more abiotic stressful conditions lessen the differences between varietal reactions to environmental variation. Modern varieties, created after Green revolution projected ideotype in wheat expressed low level of GEI variation, three semi-dwarf varieties of medium maturity, particularly. As expected "ideal environment" was 2015/16 (2015NS). Landrace Banatka took the position of the most adaptable variety concerning PH, similarly behaved pre GR variety Bankut 1205 reacting with full PH performance on NS favorable environmental conditions, however the most stable modern varieties, Jugoslavija, Renesansa and Pesma were distributed near to average environment. NSR 5 appeared the best suited for unfavorable conditions both years and soil type, since this is the only variety bred for early maturity in the trial (fig. 1).

Spike length. Though the variability of SL and PH is influenced by the same gene system, in this case a cocktail of major *Rht* genes, and minor genes genotypes in MET exhibited different but expressly GEI variation for SL comparing to PH. According to sector division, as well as array of environments, locality was predominant variation source of SL. This could be as a consequence of selection criteria, where PH is commonly more in focus than SL, *per se*. Hence, GEI is more variable than PH, regardless of genotype origin. So, locally well adapted instinctively selected landrace Banatka, appeared to be the best suited for an average environment. Moreover, modern varieties Jugoslavija and NSR 5 exhibited potentially desirable variation of SL in the list favorable production conditions in this trial (2014KU), fig. 2.

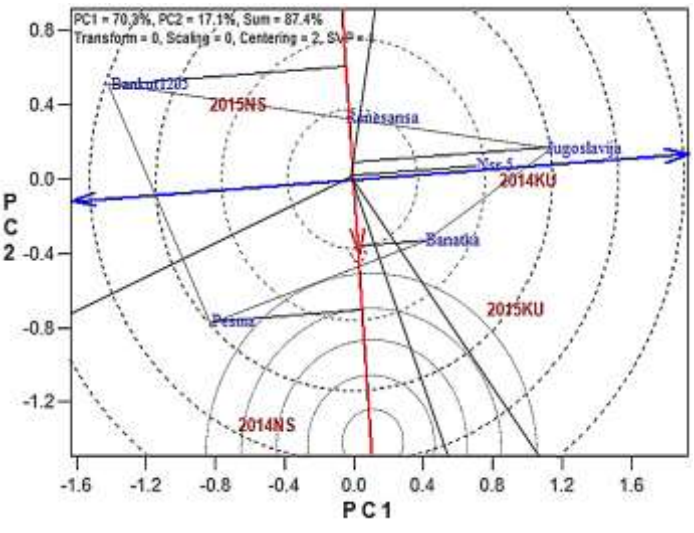

Figure 2. GGE biplot of two Principal Components (PC) based on 2Lx2Y MET trial with 6 bread wheat genotypes for spike length (cm). The GGE biplot showing genotype variability and GE interaction in each environmental variation.

Spike mass. This is the first of three of distinctively quantitative traits. The SM

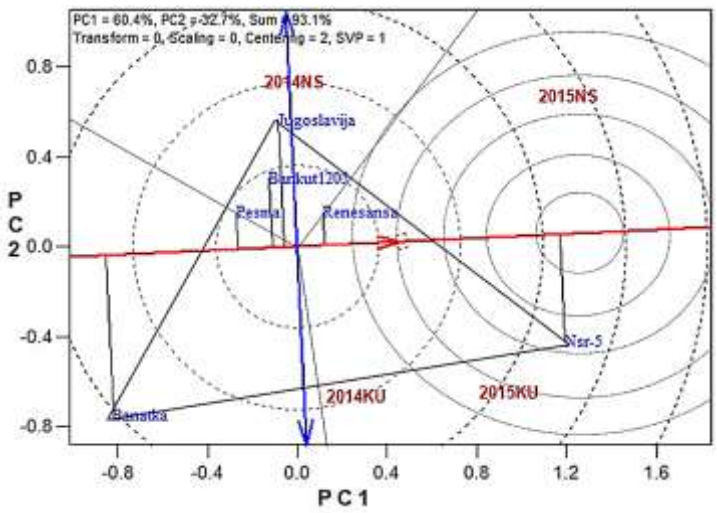

Figure 3. GGE biplot of two Principal Components (PC) based on 2Lx2Y MET trial with 6 bread wheat genotypes for spike mass (g). The GGE biplot showing genotype variability and GE interaction in each environmental variation.

polygenic genetic background caused more even distribution of variation percentage brought out of total trial variability by first two principal axes comparing to PH and SL. According to environmental array, the first variation source of SM variability was soil type, the second was variation of physical weather factors thru vegetation periods, where 2014/15 (2014KU, and 2014NS) where on unfavorable side for the SM formation. The position of EFIFVC (NS) locality in the upper part of the graph regardless of year witnessed that chernozem, as expected, was more productive substrate for SM formation in all varieties except NSR 5, where earliness helped to prevail unfavorable conditions of solonetz soil, but with a help of more convenient meteorological conditions in second season of the trial (2015KU). Landrace Banatka was the best adapted to unfavorable conditions both of year and soil type for SM (fig. 3).

Grain mass per spike. The similarity of gene system responsible for SM and GMS was the main cause of similar variation pattern of these two traits. The additive variation component brought out by PC1 reflected genotype differences in spike yield trough their GMS averages where the influence of the year dominated the effect of location. However, the environmental array along multivariate PC2 showed that GEI variation relied on the soil type variation (locality) rather than on yearly meteorological conditions variation. Bred varieties obtained in breeding institutions, behaved quite alike responding well to favorable production conditions, all except NSR 5, that was more resilient in somewhat less favorable conditions of solonetz soil, at the locality of Kumane. Landrace Banatka expressed the same GMS variation as in it was the case for previously reported SM (fig.4).

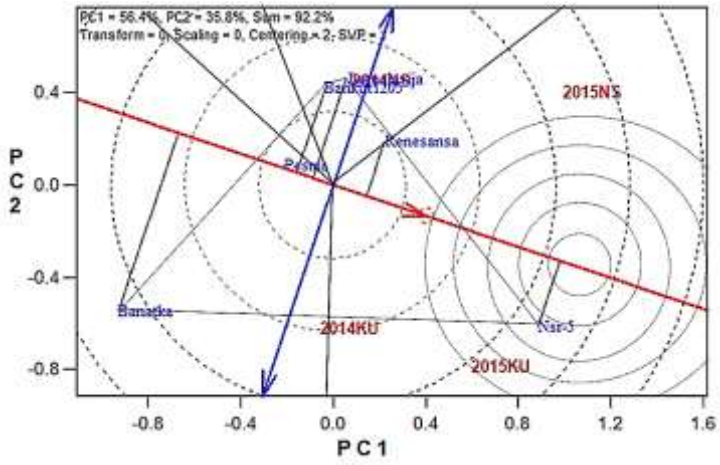

Figure 4. GGE biplot of two Principal Components (PC) based on 2Lx2Y MET trial with 6 bread wheat genotypes for grain mass per spike (g). The GGE biplot showing genotype variability and GE interaction in each environmental variation.

Grain number per spike. The individual plant traits, especially spike traits are fading in its importance in favorable agro-ecological conditions, where the population behavior has the decisive role in grain yield formation. However, in less favorable even stressful production conditions individual plant variation gains in significance. Consequently, GNS complements the triad of quantitative spike traits SM and GMS, expressing the phenotypic variation of the most

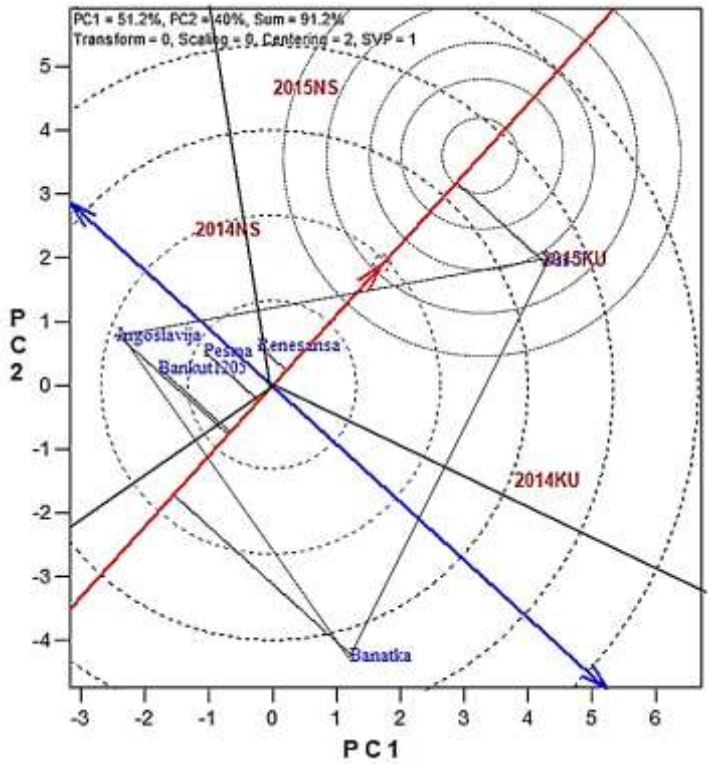

Figure 5. GGE biplot of two Principal Components (PC) based on 2Lx2Y MET trial with 6 bread wheat genotypes for the number of grains per spike. The GGE biplot showing genotype variability and GE interaction in each environmental variation.

complex nature. Though, the first two PCs explained up to 91.2% of total variation, the share of each PC was almost evenly distributed PC1 51.2% and 40% for PC2. This was the highest influence of multiplicative component of total variation denoted in this trial. Consequently, the influence of meteorological physical factors variation appeared to be more influential cause of phenotypic variation for GNS than soil type that should be taken into consideration when forming selection criteria to getting desirable genetic variation in wheat breeding aimed to overcome alkaline soil stress conditions. Bred varieties expressed similar variation pattern both in additive and multiplicative part of total variation. Early variety NSR 5, and the landrace Banatka differed in main, as well as, in multiplicative variation, Banatka performing better in less favorable locality and in less favorable year (2014KU), and NSR 5 expressing good use of better meteorological conditions at the solonetz soil locality in 2015 (2015KU), fig. 5.

Spike index. In modern bread wheat varieties SI is significantly positive correlated to harvest index that quantify the economic (grain) yield versus the total amount of produced biomass (total biological yield), representing sink to source ratio, hence, varietal productivity (Donald, 1962; Petrović *et al*., 2000). The most challenging environments for GEI variation of SI appeared to be 2015KU and 2014NS, but of quite different nature. Genotypes reacted positively to meteorological conditions improvement on solonetz soil in 2015, while less favorable weather conditions in 2014, provoked negative effect on GEI for SI of the genotypes in the experiment on chernozem. According to the environmental array along PC1 it could be observed that the most unfavorable environment (2014KU) provoked better relative efficiency in grain formations, particularly in a group of genotypes landrace Banatka. The perseverance of early maturity variety NSR 5 could be witnessed for SI, as well, while poor behavior of old variety Bankut 1205 for SI parameter variation could be a consequence of the tall stature

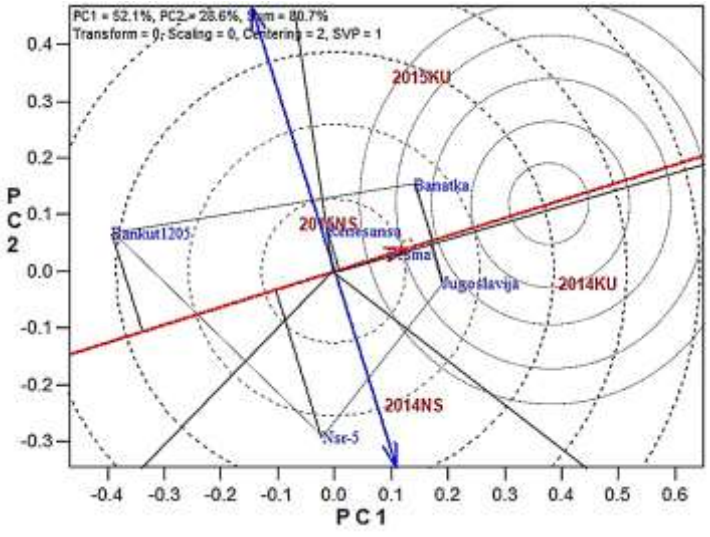

Figure 6. GGE biplot of two Principal Components (PC) based on 2Lx2Y MET trial with 6 bread wheat genotypes for spike index. The GGE biplot showing genotype variability and GE interaction in each environmental variation.

resulting in less efficient translocation of nutrients from sink to source (Dimitrijević *et al*., 2001; Petrović *et al*., 2011), fig. 6.

Conclusion

The investigation presented in this article relay on plant breeding strategy aimed to high and stable grain yield utilizing indirect selection for the traits of interest, the yield components. This approach could be quite efficient in an *in situ* breeding programs for getting usable genetic variability for agricultural production in stressful ecological conditions. For the effectiveness of indirect selection, one of the requirements is the simplicity of testing, accuracy of the results, as well as economical and rapid approach (Yan and Kang, 2001). The results of this trial led to conclusion that the GGE biplot analysis fulfils all the postulated requirements in handling experimental data and drawing in plant breeding applicable conclusions. Though, Kaya *et al*. (2006) commented that favorable environments were more representative of the overall environments and more powerful to discriminate genotypes than the unfavorable ones, according to this results the combination of unfavorable environments using favorable as a parallel control part of the trial, could be of use not only to study varietal behavior, but also to catch sight of usable genetic variation in breeding programs for special purposes. The sources of genetic variation for broadening genetic variability in selection of genotypes suitable for growing on solonetz soil could be found not only in existing commercial genetic variation, but also in landraces and old bred varieties.

Abstract

Improving agricultural productivity in Karamoja, Uganda commenced with implementation of a comprehensive program for seed revitalization system through: creating a multi stakeholder innovation platform for commercial seed production, training and equipping farmers with practical grower knowledge, quality control and marketing of pure quality seeds in a sustainable venture, and increasing seed volumes through block farming. Successes achieved involved application of effective methodologies including: establishing an inter-linkage platform for sourcing production and marketing information used in seed system, application of nucleus and farmer field school (FFS) perspective for practical farmer training, application of isolations (time and distance) and half-sib methods for genetic purity maintenance, and establishing block fields for seed production. Four farmer groups were formed each comprising of 25 farmers across selected districts. Farmers started with foundation seed stocks and produced quality declared seed and finally pure quality seeds after three seasons. The project registered the following benefits including: platform for seed enterprise established and functionalized, favorable contract agreements for commercial seed scheme developed and operationalized, model for seed profit margin analysis for crop enterprise selection developed, 5 farmer groups under FFS made operational. Growers (62.5%) trained in production and marketing of maize seed systems, 80% of farmers applied half-sib method at various isolation perspectives, and 108MT of pure maize seeds were produced. Presently growers have knowledge of seed production and access to pure quality seeds for use in production.

Keywords: *seeds-purity, smallholder, half-sib, farmer, school.*

Introduction

Maize (*Zea mays*) is one of the predominantly grown cash crops in Uganda with average yield of 2.7MT Ha^{-1} (Molnes, 2014) whilst ranked 2nd world wide to sugarcane, rice and wheat among produced crops (FAOSTAT, 2014). Uganda, like many sub Saharan countries, depends on agricultural products to finance the country development programs. The sources of income are predominantly from crop products to which maize output is very crucial and 4th in Uganda total value production ($387m) (Molnes, 2014). Maize productivity is low but can increase under intensive use of factors of production. Intensive use of pure quality seeds and availability to the smallholder farmers can help increase productivity per unit area. Maize production is mostly concentrated in West and Eastern low land regions. The far Eastern sub-region of Karamoja, maize output is low at 1.6MTha^{-1} below the average yield of 2.7MTha^{-1}, attributing the cause in particular to use food grains sourced from mobile food grain selling markets, neighbors and harvest from previous seasons than using adaptable maize seed grains of pure quality. Karamoja is endowed with vast cultivable land (27,000 Km^2) for which about 145,391 households are employed through farming to feed the increasing population estimated at 0.97million people (NPHC, 2014). The seed sector is majorly informal, with few

Seed Companies involved in producing, processing and marketing of seeds. The baseline survey on seed system in Africa found the formal use of improved seeds very low at 2.1% (AGRA, 2014) with majority using home saved maize grains than pure quality seeds. Hitherto growers needed a constant and reliable system of seed supply especially at planting time. The knowledge to understand the values and benefits of using pure quality seeds and or producing the seeds for sustainable sources during the cultivation time is very important. It's anticipated that when pure quality seeds are used with good crop husbandry practices, yield can potentially improve by over 50% (Farmers hand book on basic agriculture; 2016). Therefore with crop transformation into a health, and highly vigorous plant with minimal character variation in growth gives an indication of pure seeds being used in production. Such values when are paired with grower knowledge of the seed variety, seed rates, and viability then are ascertained that growers know, understand and can grow seeds. In Karamoja, growers had very limited access to pure quality seeds and also lacked knowledge about value and benefits of using pure quality seeds. The little seeds provided were in some cases found to be actually food grains with poor genetic quality and viability. The potential for cultivation is high, combined with fertile soils under semi-bimodal rains but with no actual, reliable and sustainable source of seed inputs especially at a time of planting hence justification for a pure seed production system. Therefore this intervention involved setting a strong framework for enabling the adoption of technologies that suits production of pure quality seeds through creation of a multi stakeholder innovation platform for commercial seed production, training and equipping farmers with practical grower knowledge, quality control and marketing of pure quality maize seeds in a sustainable venture, and increasing maize seed volumes through block farming.

Materials and methods

Area description

Karamoja comprises of seven districts situated in the Northeastern corner of Uganda between the limits of 1^0 and 4^0 North and 33^0 and 35^0 East, measuring 1000 sq. miles (27,200 Km^2), with ephemeral rivers that flow only periodically after heavy rains. A large area is dry but notably the Western and Southern margins, receive considerably higher rainfall (600-890mm). The area also has 7 green belts for cultivation in during the second season. Therefore technologies for production of pure quality maize seeds were conducted in the green belts as target foundation for increasing maize productivity.

Materials

Resources identified and used included farmer farmland, production inputs (foundation maize seeds, fertilizers: Urea 45.6%N and pesticides etc) and market for commercial product sales. Engaged stakeholders in the platform included: Research Scientists, private sector seed companies, Agro-seed dealers, NGO's operating in project scope areas, National Seed Certification Services (NSC's) and selected farmers. Maize commodity was chosen for farmer training in seed production due to its complexity in genetic purity maintenance, whereby if mastered then other cereal cross pollinate crops can be easier to produce using the same protocol. Foundation stock of open pollinated maize varieties used in seed production included MM3, Longe5 and Vpmax (Maize), sourced from National Crops Resources Research Institutes (NaCRRI), while waterproof pollination bags were used in pollen collection and transfer during selfing and cross pollination for genetic purity assurance. In popularization of seed production, fliers, posters, leaflets, signposts, banners and brochures were developed and used for reference in production.

Multi stakeholder innovation platform

The Approach of integrated Agricultural Research for Development (IAR4D) and constituency Innovation Platform identified by Adekunle *et.al.* (2014), were adopted in developing a multi-stakeholder innovation platform (MSIP) for maize seed production and genetic purity maintenance. The platform oriented problems involved in accessing, production of quality maize seeds using the hard and soft science to identify solutions for maize seed quality control. A number of key stakeholders identified to serve on the platform included: Breeders, Agronomists, Pathologists, Socio-economists, private seed companies, non governmental organizations (ACDI-VOCA, FAO) and the Ministry of Agriculture Animal Industry and Fisheries (MAAIF) and farmers. The platform was systemically engaged in sourcing production and marketing information for effective maize seed system operation, establishing a business venture through forecasting and identifying seeds on seed demand, analyzing seed business profitability and drawing a plan for actual production through contract agreements with outgrowing scheme.

Maize seed grower training

An approach of farmer field school (FFS) perspective as cogitated effective and efficient in extending proven technologies to farmers (Braun *et.al*., 2000) was adopted in imparting practical skills of quality maize seed production to growers. FFS is a practical approach involving training and implementation of gained knowledge (Elske *et al.,* 2000) during Farmer-Research interventions for application in improving agricultural productivity. Four farmer groups (≤ 25 grower) with 50% gender consideration were established on basis of FFS in 4 districts of Moroto, Nakapiripirit, Amudat, and Napak in Karamoja. The total numbers of farmers to be trained were summarized in the following model: fx (4 FGs*25 F/Grp) for initial training in the first cropping year with each participative farmer cultivating 2.0 acres of land for seed production. Different field plots (1.0 acres size) for practical studies were identified and for practical training of farmers and thereafter applies the gained technology on own individual field. Study fields involved the practice of learning production activities ranging from field identification, siting, preparation, seeding, crop husbandry practices, breeding and harvesting and concurrently implement what has been learnt at own farm under maize grower group supervision.

Maize genetic purity maintenance

A strategic application of *half-sib* method in production of pure maize seeds from varieties with pure genetic control (Maize Program, 1999) was adopted and isolation method as applied by MacRobert (2009). Under half sib method farmers grew maize and were able to collect and pollinate developed silks of selected plants. If each farmer was capable of selecting and pollinating at least 300 plants ensuring enough pure seed are achieved for source of seed use in the next cropping season. Different isolation methods of field under full sib were established within 400m distances apart to avoid foreign pollen grain reception, and time of planting either delayed or applied 2 weeks in advance to avoid same field flowering synchrony. Growers were also introduced to the National seed legislation through the Seed and Plant act 2007 regarding production, policy, processing registration, marketing and quality assurance.

Seed marketing approach

The strategy for maize seed marketing involved two adopted schemes the *voucher* and *Matrix* system. A Seed *voucher* is a credit scheme where a small holder farmer is offered a voucher specifying the seed quantity, type and cost, to obtain seeds from a central community seller and re-payable after harvest. Farmers receiving the voucher could be registered for easy follow-up. The essence was to enhance easy availability and ease of access to pure quality seeds especially at planting time. The *matrix* (Fig.1) system involved seed business commercialization with 3fold of research-farmer private sector (seed company). Research

obtains information on maize seed demand from Seed companies and in return provides the required maize variety for multiplication. Through credit scheme growers obtains, grow and sell maize seeds under contract agreement to the seed company, with backstopping knowledge of production from research.

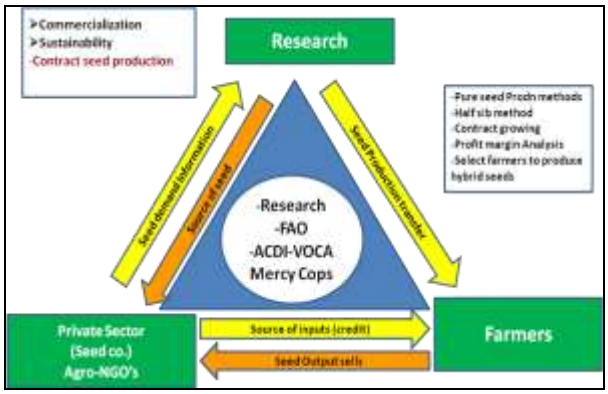

Figure 1: Showing matrix for seed business

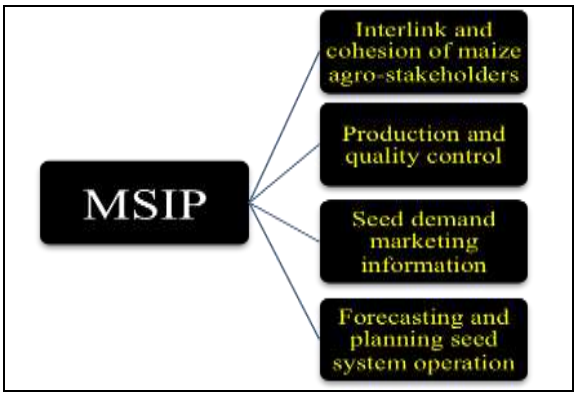

Figure 2: MSIP functional interaction

Block farming, popularization and promotion of maize seeds

Strategies for maize seed production and technology promotion were implemented through (i) *result* and *method* demonstration to enhance seed growers and other stakeholders an opportunity to observe, compare and evaluate the performance of the improved maize seed (ii) field day organization seed products exhibition and notion exchanges about venture success (iii) Awareness on radio talk shows (Karamoja 97.4FM) about the need for knowing maize seed production and accessibility through farmer production scheme (iv) development and availability of seed production reference materials such as fliers, poster and brochure. Maize fields in a homogenous cluster of seed growers under same variety were established in the community for production. This practice is relevant in avoiding foreign variety mixture from acting as source of contaminants thus increased productivity of good genetic purity.

Results and discussion

Using the integrated Agricultural Research for Development (IAR4D) approach, a strong Multi Stakeholder Innovation Platform (MSIP) was established with functional structures of interlink and cohesion of maize agro-stakeholders, production and quality control, marketing information, forecasting and planning seed system operations (Fig. 2). This structural function correlated positively with the stakeholder interaction in innovative platform identified by Adekunle *et.al.* (2012). The various portfolios on the MSIPs identified and placed include: Seed Companies, Farmers, Seed inspector (MAAIF) and Research and tutor in agricultural school. The platform identified lack of quality seeds of maize and production knowledge as cardinal problems in improving productivity of maize. Emphasis towards increasing productivity were geared to systematic cohesion and interlinks in sourcing production and marketing information for effective maize seed system operation, establishing a business venture through forecasting and identifying seeds on seed demand, analyzing seed business profitability and drawing a plan for actual production through contract agreements with outgrowing scheme.

Farmer training concentrated on grower practical learning of production field siting and preparation, seed sowing using dribble method, nutrient (Urea 46%N) application, variety descriptions and plant structure and weeding methods timing at respective crop growth stages for ensuring proper growth of pollinated plants. At least 8 farmer field schools (FFS) were formed and 62.5% (1148 farmers) of farmers trained to become maize seed growers (Tab. 1).

Table1. Showing number of trained farmers in production of pure quality maize seeds

Season	Farmers Trained	Cropping year 2017	2016	2015
A	206	104 (50.5%)	82 (39.8%)	20 (9.7%)

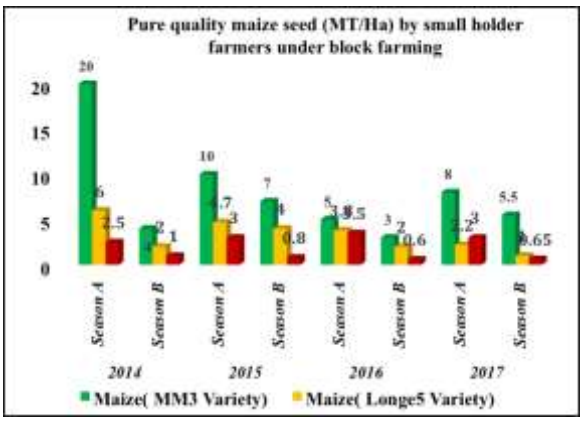

Figure3. Shows maize productivity under block farming

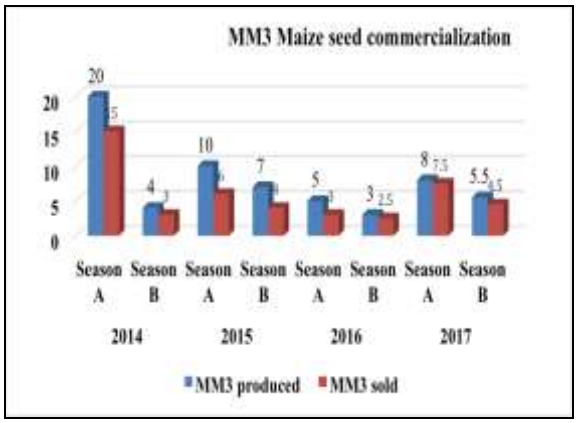

Figure 4. Maize (MM3) seed venture under nucleus farms

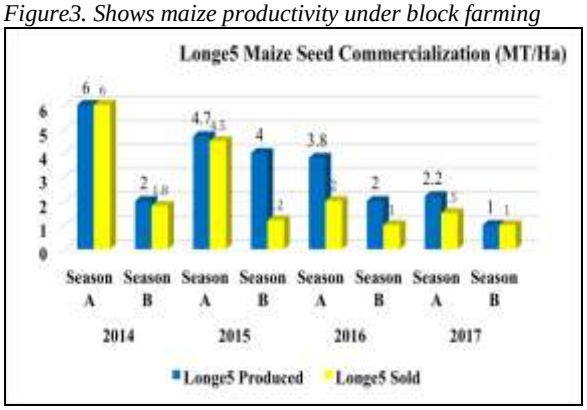

Figure 5. Maize (Longe5) seed venture under nucleus farms

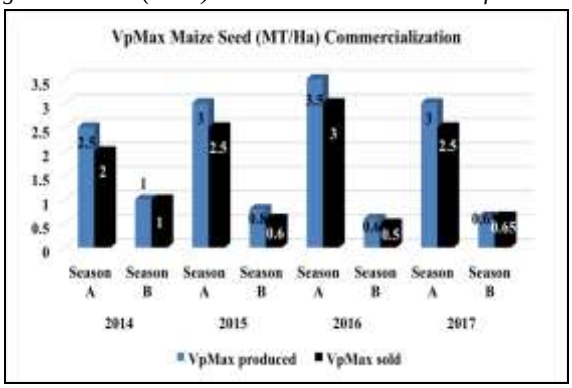

Figure 6. Maize (VpMax) seed venture under nucleus farms

In genetic purity maintenance, 60% of growers learnt and practiced the protocol of varietal purity control where maize tassels and silks were covered for pollen collection and protection of silks from foreign pollen grains respectively (Tab 1. and 2.). Growers used the same knowledge to identify off types prior to flowering, de-tassled and or rogued to maintain the genetic purity of same maize variety. The success of this technology enhanced growers to own implement the half sib technology where 98% of pollinated plants produced pure quality seeds hence preferred as quality declared seed (QDS). Similarly maize fields isolated at 400m from other maize plots were found uniform in tassel and silk structural appearance hence conformation of morphological plant purity, and harvested cobs appeared uniform hence purity assurance. The achieved results of genetic purity were in correlation with observation of MacRobert (2009) on maintaining and production of breeder seed of self-pollinated maize crops. Thus maize seeds produced under block farming system (Fig. 3) exhibited purity with 80% of MM3, longe5 and VpMax seed variety highly demanded by agro-stakeholders (Fig. 4-6) hence commercialization with cost benefit ratio of 0.55 under smallholder farmer management.

Conclusion

Equipping smallholder farmers with practical knowledge of production and genetic maintenance of pure quality maize seeds were and still remains one of the viable forms enhancing increased maize productivity within the confines of smallholder farmers under a commercialized seed system. Strengthening the venture with the MSIP platform helped to plan and implement with guided protocol for quality control assurance. 80% of smallholder farmer are in position to sustainably produce pure quality maize seeds and it's a stimuli for increase food production in Karamoja. Intensive seed system development is anticipated to stimulate more demand hence enhancing commercialization and ultimately leading to improved livelihood. However emphasis needs to be put on seed legislation for implementation under provided seed act.

Acknowledgement

Special thanks and appreciation are extended to National Agricultural Research organization for the financial support, farmers in Karamoja for enthusiasm and dedication to the project. Finally to all staff of Nabuin ZARDI, thanks for the scientific support in this study.

Abstract

In Lebanon, it has been shown that about 50% of table grapes productions are not exportable or marketable due to small berry size. Giberellic acid (GA3) is known as plant growth regulator used in vineyard in order to enhance berry quality, especially berry size. Therefore, investigating the effect of GA3 on berry quality of the seedless ARRA 15 table grapes variety was the objective of the study. The applied treatments were: T1: thinning treatment (1.5ppm GA3), T2: thinning treatment (1.5ppm GA3) + sizing treatment (20ppm GA3), T3: thinning treatment (1.5ppm GA3) + sizing treatment (40ppm GA3), T4: thinning treatment (1.5ppm GA3) + sizing treatment (40/20 ppm GA3), T5: thinning treatment (1.5ppm GA3) + sizing treatment (20/40/60ppm GA3), T6: thinning treatment (1.5ppm GA3) + sizing treatment (20ppm GA3 + 2ppm Synthetic Cytokinin), T7: control (without GA3 or Synthetic Cytokinin application). During growth cycle, the highest berry diameter and weight were obtained in T5 (19 mm, 5.3g), while at harvest berry diameter was the highest in T5 and T6 (≈6.5g). T6 gave the crispiest aspects with the lowest brix index (11.16°) while it reached 14° in T1 and in the control. T6 delayed the date of reaching brix 16° by 10 days compared to control. Finally, T6 was the best way to reach a better quality. But, in Lebanese conditions it is recommended to apply T5 because Synthetic Cytokinin should be used at low concentration to be effective without side effect on clusters which could be hard to some growers to regulate it and this products are almost unavailable in Lebanese market.

Keywords: *ARRA 15, Lebanon, Synthetic Cytokinin*

Introduction

The adaptation to the requirements of the markets is one of the basic characteristics of modern table grape production aiming to improve grape quality such as berry size. In, addition, the seedlessness represent an important attribute of the grape berry quality while seedless cultivars are characterized with small grains and required management for improvement of their size (Dimovska et al., 2014). The application of plant growth regulators represents a way to face this problem (Nampila, 2010). Giberellic acid (GA3) is one of plant growth regulators used extensively to increase berry size of seedless cultivars (Korkutal et al., 2007; Dimovska et al., 2011) as it stimulates parthenocarpic fruit development of grapes (Casanova *et al.*, 2009). Exogenous application of GA3 promotes cell division, stimulates the earlier flowering, increases the size and yield of fruits, and induce seedlessness in the seedless cultivars (Khan, 2009; Dimovska et al., 2006). It has been reported the GA3 was effective in improving berry size of table grapes such as Black Corinth, Red Malaga, and Thompson Seedless 51 (Christodolou et al. 1968, Singh et al. 1978, Weaver 1957, Weaver and McCune 1959).

In fact, Lebanese farmers are seeking to meet market demand for new seedless table grapes variety while it has been shown that about 50% of table grapes productions are not exportable or marketable in Lebanon due to small berry size. ARRA 15 variety is a new seedless variety introduced in Lebanon but it is still under experiment and not used for commercial aim yet. Without hormonal addition berry size did not required the need of local and exported market.

Consequently, the objective of this study was to investigate the effect of exogenous Giberellic acid on berry size, weight and Brix index of the seedless ARRA 15 table grapes variety.

Materials and methods

The variety used was ARRA 15 seedless table grapes and it was planted in normal conditions required for vine development. Seedlings were grafted on rootstock 1103P. Vines were trained by pergolas system, irrigated by drip irrigation and grown with a distance of 3 x 3 m. Several agricultural practices were also adopted (Pruning, thinning, fertilization…).

Seven treatments were applied: T1: thinning treatment (1.5ppm Giberllic acid (GA3)),T2: thinning treatment (1.5ppm GA3) + sizing treatment (20ppm GA3), T3: thinning treatment (1.5ppm GA3) + sizing treatment (40ppm GA3), T4: thinning treatment (1.5ppm GA3) + sizing treatment (40/20 ppm GA3), T5: thinning treatment (1.5ppm GA3) + sizing treatment (20/40/60ppm GA3), T6: thinning treatment (1.5ppm GA3) + sizing treatment (20ppm GA3 + 2ppm Synthetic Cytokinin (S.C)), T7: control (without GA3 or Synthetic Cytokinin application). The rates were chosen according to several references (Domingosa et al., 2016; Mohsen 2015; Abu Zahra, 2013 and Strydom 2013). The first application was at 120% bloom and the second one when the berry diameter reached 4-7mm. For T4, T5 and T6 the third application was done one week after the second application. The fourth application in T5 was also done one week after the third application. Spraying bunches was adopted for thinning application while bunch dipping was adopted for all other applications.

The experimental plot contains 126 vines of ARRA 15. The Complete Randomized Bloc Design was adopted with three blocks (repetitions). Seven treatments were applied in each block and each one is consisted on 6 plants. Preventive steps were also adopted to prevent contaminations between treatments.

In each block 6 berries were randomly collected from 3 clusters per treatment. Berry diameter and weight were measured during growth cycle and at harvest. Brix index was studied at 21th July and at 30th August using refractometer.

Results and Discussion

Berry diameter during growth cycle

Table 1 below showed that T5 increased berry diameter by around 5% compared to T2, T3, T4 and T6 and by around 10% and 15% compared to T1 and T7 (control) respectively.

Table 1: berry diameter during growth cycle

Treatments	Berry diameter during growth cycle (mm)
T1 (thinnhig)	17.0 c
T2 (20 ppm GA3)	18.0 bc
T3 (40 ppm GA3)	18.0 ab
T4 (40/20 ppm GA3)	18.0 bc
T5 (20/40/60 ppm GA3)	19.0 a
T6 (20 ppm GA3 + 2 ppm S.C)	18.5 ab
T7 (control)	16.0 d

In fact, during growth cycle, the application of GA3-S.C, single or double GA3 and thinning treatment increased slightly berry diameter while the triple application of GA3 as in T5 achieved a constant stimulation of cell size growth by a residual activity of GA3 resulting in highest berry diameter.

Berry diameter at harvest

Berry diameter results were changed at harvest. The highest berry diameter was recorded in T5 and T6 where it was higher by around 10% compared to all other treatments (Table 2).

Table 2: Berry diameter at harvest

Treatments	Berry diameter at harvest (mm)
T1 (thinnhig)	18.1 b
T2 (20 ppm GA3)	18.3 b
T3 (40 ppm GA3)	18.2 b
T4 (40/20 ppm GA3)	18.3 b
T5 (20/40/60 ppm GA3)	20.4 a
T6 (20 ppm GA3 + 2 ppm S.C)	20.2 a
T7 (control)	17.8 b

The only difference between T6 and T2 was the presence of S.C. in the first one. Consequently, the results observed in T6 could be due to the synergetic effects of GA3 and S.C. Those results confirm the finding of Dokoozlian (1995), Strydom (2013) and Mohsen (2015) on 'Sugraone' table grapes.

Berry weight

During growth cycle, T5 recorded the highest berry weight where it increased this parameter by around 39% and 19% compared to the control and to all other treatments respectively (Table 3).

Table 3: Berry weight during growth cycle

Treatments	Berry weight during growth cycle (g)
T1 (thinnhig)	3.8 bc
T2 (20 ppm GA3)	4.2 abc
T3 (40 ppm GA3)	4.4 ab
T4 (40/20 ppm GA3)	4.4 ab
T5 (20/40/60 ppm GA3)	5.3 a
T6 (20 ppm GA3 + 2 ppm S.C)	4.6 ab
T7 (control)	3.2 c

At harvest, as berry diameter, berry weight was the highest in both treatments T5 and T6 (around 6.5 g) while all other treatments were almost similar (around 4.5 g). The results obtained could be due to the fact that the application of GA3 in seedless table grapes compensates the low gibberellins berry concentrations (Pérez *et al*., 2000), which is correlated with seed number (Lavee and Nir, 1986). In fact, it is well established that GA3 promote cell expansion (Ubeda-Tomás *et al.*, 2008) and increase cell size by taking place to a higher accumulation of sugars and water (Casanova et al., 2009) leading to increase berry size and weight. In addition, Abu-Zahra (2010) had obtained an increase in berry weight after treating seedless table grapes with GA3 and S.C products.

Regarding berry diameter and evolution in time, it was remarkable that T5 and T6 had a similar constant growth during the growth stage until harvest. In addition, although T2, T3 and T4 had a higher berry size than T7, all had an immediate acceleration in growth but berries almost never grew at harvest. Moreover, T1 and T7 had a similar constant growth

during the growth cycle until harvest with superiority in berry diameter in T1 and this due to the fact that berry thinning means less berry number per cluster with a bigger size.
Even though the last T5 application was done 50 days before harvest and taking into consideration that the residual activity of GA3 after single application lasts up to 6 days, the increased dose of GA3 application (20-40-60 ppm) have managed to constantly stimulate cell size growth; hence, increasing the berry size and eventually it ranked the highest.

Brix index on July 21
T6 had the lowest Brix index (11.2°), while T1 and T7 recorded the highest one (14°) (Table 4).
Those results could be due to the fact that in general S.C delayed harvest date while GA3 delayed fruit maturity reducing berry color (Dokoozlian, 1998). On the other hand, the natural growth and therefore natural accumulation of sugar content led to the highest index brix recorded in T1 and T7. Actually, those results confirmed the findings of Reynolds et al. (1992) where they studied the effect of GA3 and S.C on harvest delay of Seedless table grapes.

Table 4: Brix index on July 21

Treatments	Brix index on July 21 (Brix°)
T1 (thinnhig)	14 a
T2 (20 ppm GA3)	12.7 b
T3 (40 ppm GA3)	13 ab
T4 (40/20 ppm GA3)	13 ab
T5 (20/40/60 ppm GA3)	13 ab
T6 (20 ppm GA3 + 2 ppm S.C)	11.2 c
T7 (control)	14 a

Brix 16° achievement in number of days

Table 5: Brix 16° achievement in number of days

Treatments	Days
T1 (thinnhig)	241 a
T2 (20 ppm GA3)	246 b
T3 (40 ppm GA3)	247 ab
T4 (40/20 ppm GA3)	246 ab
T5 (20/40/60 ppm GA3)	246 ab
T6 (20 ppm GA3 + 2 ppm S.C)	249 c
T7 (control)	239 a

The table 5 above showed that T6 had the highest number of days needed to reach Brix 16° where it need 10, 2, 8 and 4 days extra than the control, T3, T1 and the other treatments respectively. Those results also agree the findings of Reynolds et al. (1992).
Finally, berries of T6 have the crispiest aspects. As for control grapes, they had limp and a kind of dry aspect which confirm the results of Ben-Arie et al. (1997) and Dokoozlian (1998). The last author affirmed that in some cases S.C showed to increase firmness and reduce juiciness of fruits. In fact, the juiciness was not experimented in this study while no reduction in juiciness was remarked.

Conclusion

In conclusion, triple treatments of GA3 and the mixture of GA3-S.C where the most efficient was to reach the objective of this study where they almost have a similar effect on all parameters. On the other hand, the crispiest aspect provided by the mixture is mostly demand in markets. Consequently, it is recommended to use T6 if S.C is easily accessible which not the case in Lebanon. Therefore in Lebanon T5 is recommended especially for beginners or ignorant growers because S.C should be use carefully at low concentration to prevent cluster damage.

Abstract

Table grapes grown in Lebanese coast especially under greenhouse are faced by lack of enough chilling hours which affect negatively bud-break, some phenological stages and consequently yield. Few studies reported the beneficial effect of Gibberellic acid (GA) as plant growth regulator used in vineyard in order to regulate bud dormancy release in table grapes. Consequently, the objective of this study was to investigate the effect of gibberellic acid on budbreak, flowering and fruiting of three seedless table grapes varieties: ARRA 15, ARRA 18 and ARRA 19 grown under greenhouse and in open-field conditions in Lebanese coast. Therefore, Four treatments were the subject of this study: greenhouse/GA-, open-field/GA- (control), greenhouse/GA+ and open-field/GA+. Three parameters will be discussed in this paper: number of bursted bud per main shoot, number of flowers and number of clusters per vine. Giberellic acid did not have any effect in open-field conditions. However, under greenhouse, Giberellic acid induced full budburst compared to 35 % and 25 % in the control and the treatment greenhouse/GA- respectively. Number of flowers and clusters were higher in the treatment greenhouse/GA+ by around 67 and 80 % for ARRA 19 and ARRA 18 respectively compared to all other treatments. A full fruit set was observed in all treatments and regarding all varieties except on treated ARRA 15 under greenhouse where it was 54%. Thus, greenhouse cultivation created a suitable microclimate compared to open-field and could help Giberellic acid to be effective on resolving the disturbance of bud-break on vine in Lebanese conditions.

Keywords: *ARRA variety, bud-break, Dormex, Lebanon.*

Introduction

Cultivation of table grapes under greenhouse started arising Lebanese coast as experimental trials due to the need of local and exported markets for new seedless varieties and extra-seasonal products. In fact, this type of cultivation in the Lebanese coast was faced by the lack of enough chilling hours which affected negatively bud-break and consequently reduced yield. Recent study was conducted on the effect of Dormex application on the performance and productivity of three table grapes varieties grown under greenhouse and in open-field conditions in Lebanese coast (El Masri *et al.,* 2018). The results showed that the application of Dormex under greenhouse induced more uniform and full budburst, enhanced fruiting and flowering status and had a great effect on other parameters. However, this product was prohibited in many countries and recently in Lebanon. Therefore, finding an alternative was the main objective of this study. Actually, the alternative should be a plant growth regulator that could help vine to function normally. Several studies have reported an increased level of endogenous Giberllic acid (GA) in grapes, or an up-regulation of GA biosynthesis genes, following exposure of perennial endodormant buds to chilling, or fluctuations in the levels of GA during the natural bud endodormancy cycle (Zheng *et al.,* 2018). Larrouy *et al.* (2016) also reported that grapes require a cold period of several weeks to induce germination and the release from dormancy is associated with a quick increase in endogenous gibberellins. In

addition, the period of dormancy induction was accompanied by a gradual decrease in transcript levels of genes coding for GA biosynthetic enzymes, and the levels were lowest during deepest dormancy. Reduced GA biosynthesis capacity and the maintenance of stable GA inactivation ability during dormancy induction of grapevine mature buds correlate with the decrease in level of endogenous active GA1 following the period of dormancy induction, and its lower level during dormancy maintenance. Therefore, during the period of gradual dormancy release, expression levels of the GA biosynthesis genes generally increased (Zheng *et al.,* 2018). Few references indicated the role of exogenous GA on regulating bud dormancy in grapevine. In fact, both negative and positive effects of GA were reported on outgrowth of paradormant buds which are carried on actively growing shoots and are under the control of apical dominance (Zheng *et al.,* 2018) in various crops other than grapevines. For instance, in hybrid aspen, decreased bioactive GA levels in the apex and young tissues resulted in loss of apical dominance and increased branching of lateral buds (Mauriat *et al.*, 2011). GA has also been reported to induce lateral bud outgrowth in papaya. In addition, GA biosynthesis inhibitors inhibited cytokinin (CK)-mediated outgrowth of axillary buds of *Jatropha curcas*, whereas GA promoted it (Ni *et al.*, 2015). Consequently, the current study was conducted in order to investigate the effect of giberellic acid as Dormex alternative on bud, flower and fruits of three seedless varieties grown under greenhouse and in open-field conditions.

Materials and Methods

The experimental site was located at a village in Byblos (Jubeil) in the Lebanese coast. The lowest temperature recorded there was 5 degree and detected only in early January. Fluctuating temperature during the year and between days and nights were also detected there. Three seedless table grapes varieties: ARRA 15, ARRA 18 and ARRA 19 were planted under greenhouse and in open-field conditions. Each cultivation system occupied 0.3 hectares where each variety occupied 0.1 hectares. The seedlings were grafted on rootstock 1103P and cultivated with a space of 3 meters between plants as well as 3 meters between rows. The 4 years old plants were the target of the current study, were trained with pergolas system and were irrigated with drip irrigation. The work started in December by pruning the vine leaving 6 buds per main shoots (per cane). After Several trials, Giberellic acid (GA) was applied as follow: thinning treatment (1.5ppm GA) + sizing treatment (20/40/60ppm GA). At 120% bloom the canopy was sprayed with a 1.5ppm of GA as first application. The Second one was adopted when the berry diameter reached 4-7mm (20ppm). The last 2 applications were applied with an interval of 1 week. Bunch dipping for 2 seconds was adopted in the last three applications. Four treatments were the subject of this study: greenhouse/GA-, open-field/GA- (control), greenhouse/GA+ and open-field/GA+. And each sub-treatment consisted on 9 plant of each variety grown under the same experimental conditions. Statistical analysis was done using Spss program where ANOVA was applied. The three parameters discussed in this paper were taken by daily observation: number of bursted buds per main shoot, number of flowers per vine and number of fruits per vine.

Results and Discussion

Table 1 below showed that the non-interactive effects of factors cultivation system and Giberellic acid and the interactive effects of those factors had significant differences on all parameters. On the other hand, the non- interactive effects of the factor ARRA varieties and the interactive effects between this factor and the others had only significant differences on number of flowers and fruits per vine. It should be noted that Pvalue ≤ 0.05 was adopted for analysis of results.

Table 1: LSD table (parameters: yield, date of fruiting and date of harvest)

	Number of bursted/main shoot	Number of flowers/vine	Number of fruits/vine
ARRA varieties	.536	.000	.000
Cultivation system	.000	.000	.000
Giberellic acid (GA)	.000	.000	.000
ARRA*System	.298	.000	.005
System*GA	.000	.000	.000
ARRA*GA	.975	.000	.001
ARRA*System*GA	.975	.000	.001

In fact, GA did not have any effect in open-field conditions regarding the studied parameters. In addition number of bursted buds was almost similar among all varieties regarding all treatments (Figure 1). Under greenhouse, GA increased significantly the average of bursted buds from around 1.5 buds per main shoot to reach 6 buds which represent a full budburst. The number of bursted buds in the treatment greenhouse/GA- was slightly lower than in the control, this fact could be due to the higher air temperature under greenhouse which reduced chilling hours and affected negatively bud-break.

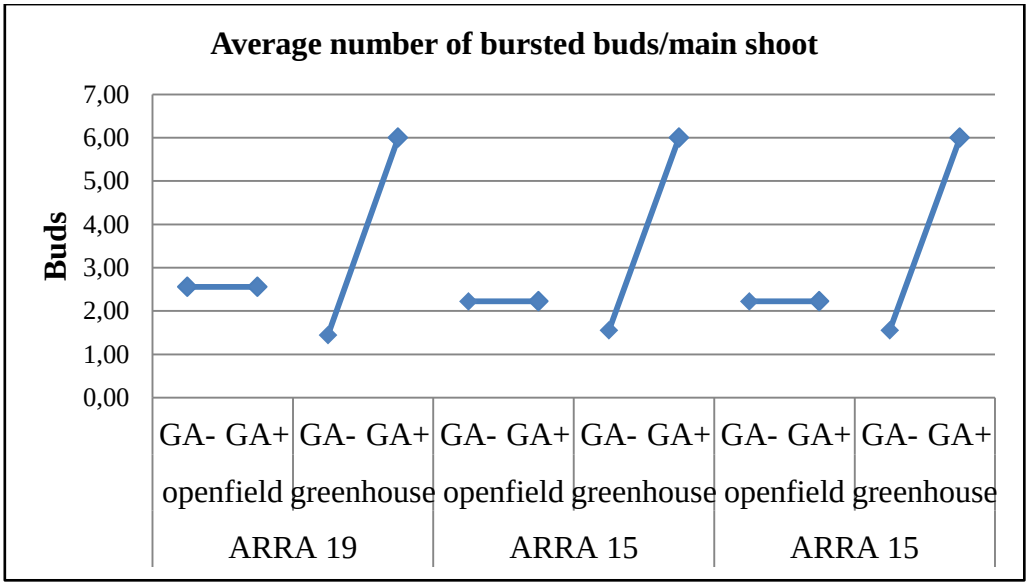

Figure 1: Average number of bursted buds/main shoot in each treatment.

When comparing all treatments and regarding all varieties, a full fruit set was observed. The only exception was observed for ARRA 15 where average number of flowers per vine was around 11 flowers and number of fruit was around 6 fruits per vine (54% fruit set) in the treatment greenhouse/GA+ (Figure 2 and Figure 3). This could be due to varietal effect were Giberellic acid effects is variety dependent (Khan, 2009; Dimovska *et al.*, 2006). In addition, this result confirmed the findings of Dokoozlian 2001. Moreover, number of flowers and fruits was almost similar (around 2 flowers or fruits/vine) in the three treatment open-field/GA-, open-field/GA+ and greenhouse/GA-. GA increased significantly those 2 parameters under greenhouse regarding all varieties reaching around 6 and 9 flowers or fruits per vine for ARRA 19 and ARRA 18 respectively.

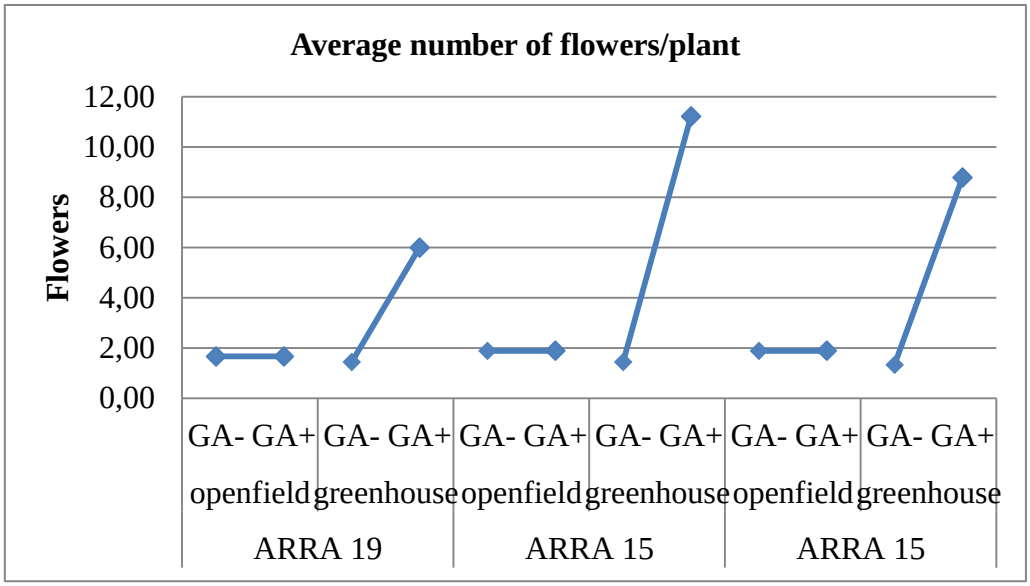

Figure 2: Average number of flowers per vine in each treatment.

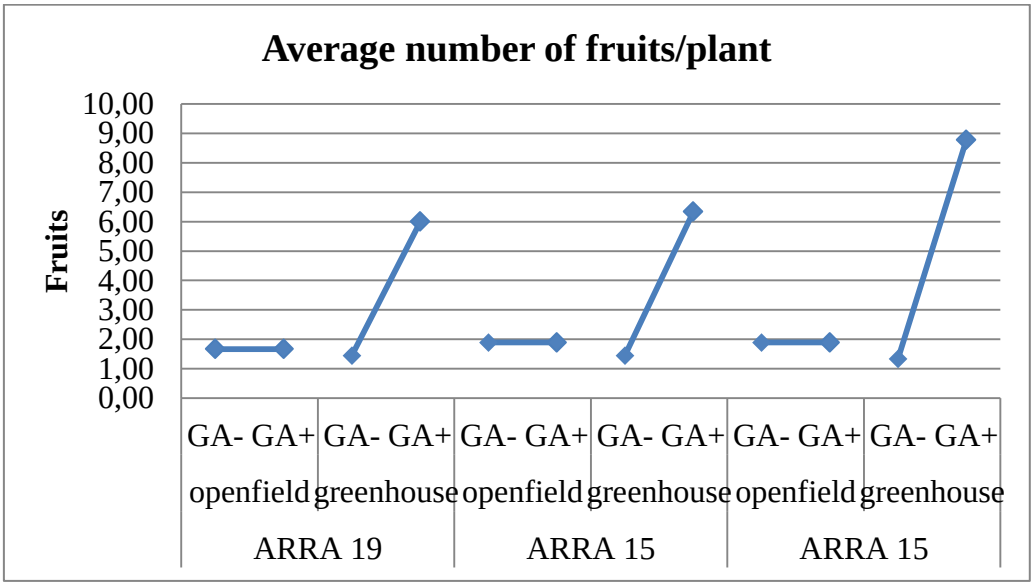

Figure 3: Average number of fruit per vine in each treatment.

In fact, it was mentioned by EL Masri *et al*., 2018 that greenhouse cultivation created more suitable microclimate with more stable conditions which could be a good reason to explain the beneficial effect of GA under greenhouse than outdoor where the climate is known by the fluctuating temperature especially between days and nights. On the other hand, those plant were in the last year treated by Dormex (3.5% Hydrogen Cyanamid) which also enhanced budburst, flowering and fruiting (El Masri *et al.,* 2018) and could be the reason behind the success of Giberellic acid effects where Dormex help vines to function normally as if the plant did not suffered from lack of enough chilling hours (El Masri *et al.,* 2018). Consequently, it is recommended to retry this experiment for more than one year to known the reality behind those behaviors where in fact treatment with GA improved embryo germination only when it was used in combination with sub-optimal cold treatments (Larrouy *et al.*, 2016).

Conclusion

Further studies should be carried out to ensure if Giberellic acid help vine to function normally in warm winter region as Dormex do. In addition, it is recommended to conducted studies that help knowing if Dormex had a residual effect on vine for several seasons.

Abstract

Passion fruit is a woody perennial vine that bears a delicious fruit which occurs in purple and yellow colors. Although in Lebanon passion fruit has not yet reached commercial volumes, however there is an increasing market demand for such fruit. In the current study, two cultivars of the purple passion fruit (*Passiflora edulis*) known as Perfecta and Black Knight were grown in Ghazir, Lebanon that is characterized by an altitude of 539 meters above sea level; latitude of 34°1'6 N and longitude of 35°39'58 E. This site was selected for being a suitable site that agrees with the minimum climatic requirements of purple passion fruit. The objective was to compare the behavior of both cultivars under local soil and climate conditions. Results indicated that the Perfecta was more adapted to clay soil and prevailing weather conditions than Black Knight. It showed a better vegetative growth that was expressed through greater averages of plant height (by 2.1 cm), leaf number (1 leaf), leaf nodes (by 11 nodes) and a higher accumulation of dry matter in leaves, shoots and roots. However, there was no significant difference at the level of leaf area, Specific Leaf Area (SLA), and Leaf Area Ratio (LAR) among both cultivars. Moreover, Perfecta plants flowered earlier and produced more flowers compared to Black Knight (94 and 4 flowers, respectively). Perfecta plants fruited while those of Black knight did not. Consequently, Perfecta cultivar showing a better adaptation is recommended for Lebanese growers seeking to diversify their income by growing alternative crops.

Keywords: *Passion fruit, adaptation, soil, climate.*

Introduction

Passion fruit belongs to the genus *Passiflora* (Pongpan *et al*., 2007). There are many varieties of passion fruit with clearly distinctive characteristics; however, the most-known two varieties are the bright yellow flavicarpa variety, also known as golden passion fruit (*P. edulis var.flavicarpa)* and the dark purple edulis variety (*P.edulis var.edulis*) (CRFG, 1996). Recent hybrids and cultivars of passion fruit are *P. edulis* 'Perfecta', and *P. edulis* 'Black Knight'. *P. edulis* 'Perfecta' offers large purple fruits that are eaten fresh (Chloé, 2014). Passion fruit is inhabitant of the tropical and semi-tropical zones of North, Central, and South America (Pongpan *et al*., 2007) where the climate is hot and humid (Joy, 2010) and could grows in warm to cool climates within altitudes ranging from 1200-2000 m above sea level (Mbora *et al*., 2008). The temperature range between 21 and 25°C is considered as the most favorable for the growth of the plant, being best between 23 and 25°C, but passion fruit is being successfully cultivated in temperatures between 18°C and 35°C (Joy, 2010). Cool temperatures are favorable for flower initiation and fruit set (18-23°C), while relatively high temperatures seem necessary for promoting juice production (23-33°C) and improvement in quality (Sema and Maiti, 2006). They are sensitive to severe frost (especially the purple granadilla). Additionally, Passion fruit vines are grown on many soil types but light to heavy sandy loams, of medium texture and at least 600 mm deep are most suitable. PH should optimally be from 5.5-6.5. Passion fruits are sensitive to excessively wet soil conditions, and

it is better to avoid clay soils (NDA, 1999). Such plant requires frequent application of balanced fertilizer during the growing season (Cooper *et al.*, 2011). In Lebanon, passion fruit has not yet reached commercial volumes. A limited number of trees are planted in private forests and gardens. Since the crop is still new, farmers are not familiar with its climatic requirements, as well as it cultivation techniques and the cultivars which are suitable for local climate conditions. Therefore, a research study was carried out in the field of the Ghazir research center, in the year 2015, which sought the comparison of the vegetative and reproductive development of two cultivars of purple passion fruit: "Perfecta" and "Black Knight" under the climate conditions of Ghazir, Mount Lebanon the assumption which of the purple passion fruit cultivars is the mostly adapted.

Materials and methods

Experiment

The experiment was conducted in Ghazir is a region located in Mount Lebanon mainly in Kesrouane with an altitude of 539 m above sea level; latitude of 34°1'6 N and longitude of 35°39'58 E. It was considered as a suitable site that agrees with the minimum climatic requirements of purple passion fruit. In fact, calculations has shown that in July the average temperature was 22.7 °C, beyond this month the temperature fluctuated between 24.2 °C - 20.06 °C and decreased to 15.2 °C in November. In addition, the average relative humidity was 72.5% in July, it fluctuated between 68.6 - 67.8% during August and September and was the highest during October 75%. The relative humidity became 69.3% in November. Precipitation was of 2.04 mm/day in October and then increased to 4.84 mm/day in November. Moreover, soil analysis has shown a clay soil that contained moderate amounts of phosphorus; it was poor in nitrogen, iron, and organic matter and rich in magnesium and potassium.

The two wire fence trellis and four shoots training methods were adopted.

Seedlings of 1.5 months old at the stage of four leaves were cultivated after being hardened in greenhouse with a distance of 170 cm between plants. Seedlings were irrigated twice per day and every 15 days, 6 g of the fertilizer N-P-K (12-11-18), 50 mL of iron (33.3g/L), and 50 mL of ammonium nitrate (166.6 g/L) were provided to each plant.

Data recording

Plant height, leaf number, number of leaf nodes, flower number, and fruit number were continuously recorded starting one week after the date of transplantation on the total number of plantsA destructive sampling was done where plant height, leaf area, fresh and dry weights of leaves, shoots, and roots were assessed. The Specific Leaf Area (SLA) and the Leaf Area Ratio (LAR) were calculated using the following formulas: SLA = LA/DML ($cm^2.g^{-1}$) and LAR = LA/DMP ($cm^2.g^{-1}$). LA is the total leaf area, DML is the total dry mass of leaves and DMP is the total dry mass of plant.

Statistical analysis

Two types of statistical analysis tests were adopted: the Independent-samples t test and the repeated measures ANOVA test. $P \leq 0.05$ was adopted for the statistical tests.

Results and discussion

Perfecta plants grew faster and reached an average height of 23.2 cm in October, while Black Knight reached an average height of 12.6 cm in the same month. This difference in growth behavior of plants was observed until the end of the experiment. Leaf nodes that produce both a flower and a vegetative lateral meristem (Chayut *et al.*, 2014) were observed starting from mid-September on plants of both cultivars simultaneously. In mid-September, Perfecta plants recorded a total of 24 leaf nodes while plants of Black Knight recorded a total value of 13 leaf nodes. Plants of the cultivar Perfecta produced the highest number of leaf nodes with the

quickest ramification where 129 leaf nodes in late-October was recorded compared to 46 leaf nodes in Black Knight plants. In July, leaf production by both cultivars was almost; it was about 6 leaves for Perfecta plants and 5 leaves for Black Knight plants. However, in the following months the average number of leaves started to differ; in late-September 40 leaves were registered for the first cultivar while 16 leaves were recorded as average for the second one. This tendency continued in the following months where leaf number of the first cultivar exceeded that of the second cultivar (63 leaves and 22 leaves respectively). Flowering was observed first on Perfecta plants which produced more flowers than those of Black Knight that started to flower later; on the 29th of September, the total number of flowers for the first cultivar was 42 while that of the second was only 1 flower. The total number of flowers for Perfecta cultivar increased largely where it reached 94 flowers in October while the total number of flowers of Black Knight cultivar reached only 4 flowers in the same month. In general, successful flower development of passion fruit requires certain environmental conditions; photoperiod influences flower induction and long days are necessary for intact flower development (Chayut *et al.*, 2014). In addition, the cold weather is not conducive to good flower production and fruit set and high levels of moisture can destroy the pollen (McCarthy and Dick, 1995). The average air temperature that was 24.1 °C in September in Ghazir decreased to reach an average of 20.1 °C in October. In addition, in September and October, days were becoming shorter. On the 20th of October, the total number of flowers recorded on Perfecta plants decreased to a total of 21 flowers while the one recorded Black knight plants which were 4 on the 13th of October reached only 7 flowers on the 20th of the same month. Thus, weather conditions at the field could have induced the drop in the total number of flowers on plants of the Perfecta cultivar. On the other hand, the lower flower number observed on plants of Black Knight may be due to the effect of photoperiod on the flower induction. In general, it seemed that flower induction of Perfecta cultivar was less affected by the photoperiod factor and the effect of temperature variation than Black Knight plants. An early fruiting was observed on plants of Perfecta (2 months after transplanting) in comparison to Dirou (2004) findings that had recorded fruit production at six months of age and Mbora *et al.* (2008) who indicated that plants of purple fruit bear fruits within 7 to 9 months after transplanting. In October, Perfecta cultivar started to give fruits; on the contrary, no fruits were produced by plants of the Black Knight during the whole duration of the experiment. In fact, the average fresh weight recorded for fruits of Perfecta was of 46.5 g while the average dry weight was of 6.64 g where the fresh weight was almost similar to Joy (2010) indications. Passion fruit plant yield is related to the growth of the branches because flowering starts in the axils of these parts of the plant (Gomes *et al.*, 2006). As it was observed plants of the cultivar Perfecta grew longer and prior to those of the cultivar Black Knight and produced a higher number of leaf nodes in the same period of time. Therefore, a general tendency for an earlier and heavier fruit production for plants of the cultivar Perfecta could be due to earlier and stronger vegetative development in comparison with plants of the cultivar Black Knight. Although both cultivars of passion fruit were grown in same soil conditions, the root system of Perfecta plants seemed heavier, thicker and more ramified as compared to the one of Black Knight plants. According to NDA (1999), growing granadillas requires the avoidance of clay soils, and soil test revealed that it was a clay one; therefore, the lower development of roots of Black Knight plants indicated that this cultivar may have a low tolerance to clay soils. On the contrary, Perfecta plants showed a higher tolerance to clay soils since root development was less affected, thus a greater root biomass was formed which was translated by a high fresh weight of roots (Figure 1a). In addition, plants of both cultivars were supplied by the same type and amounts of fertilizers that were provided simultaneously to all plants, however, they developed different fresh weight of roots, with a superiority for Perfecta cultivar which could explained by a higher absorption of nutrients from soil. Black

Knight cultivar may have not been able to absorb same amounts of nutrients from soil and consequently they developed a smaller, less ramified, and a lighter root system compared to the one developed by plants of the other cultivar. Dry matter accumulation in roots was significantly higher in Perfecta cultivars and this assumed the difference in nutrient absorption among plants of both cultivars and could explain the fact that Perfecta plants grew longer than Black Knight (Figure 1b). Furthermore, dry matter was more allocated to the upper parts of plants rather than to the root system.

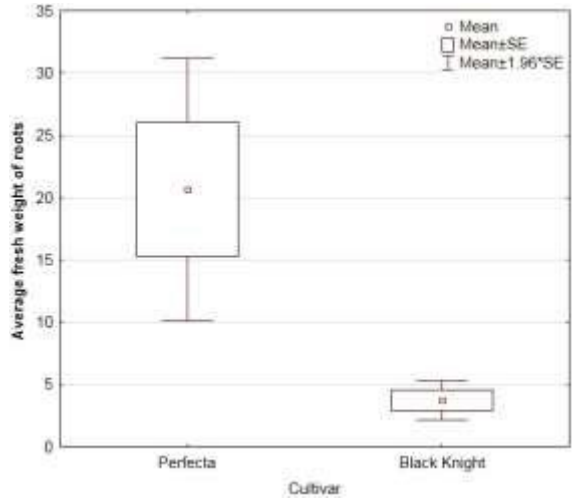

Figure 1a: Mean fresh weight (g) of roots.

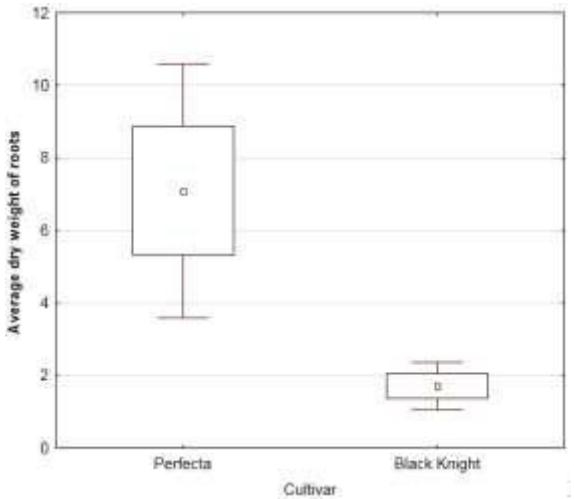

Figure 1b: Mean dry weight (g) of roots.

The higher nutrient absorption and translocation to the upper parts of plants that was observed on Perfecta cultivar resulted in longer plants and led to the development of a higher number of leaf nodes in Perfecta plant compared to Black Knight. Although the fresh biomass of shoots produced didn't significantly differ among plants, the high absorption of nutrients by plants of Perfecta cultivar has led to the accumulation of higher amounts of dry matter in their shoots compared to Black Knight plants (Figure 2a, b). Perfecta produced a significantly higher number of leaves than that of plants of Black Knight. Consequently, plants of the first cultivar showed a higher level of adaptation to the soil and climatic conditions of the experimental field as compared to the level of adaptation of Black Knight plants.

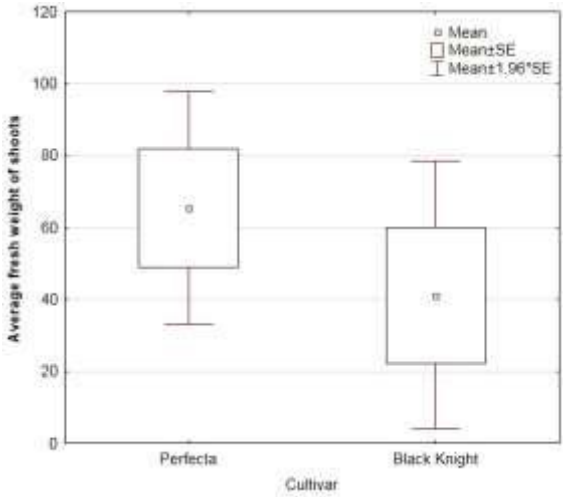

Figure 2a: Mean fresh weight (g) of shoots.

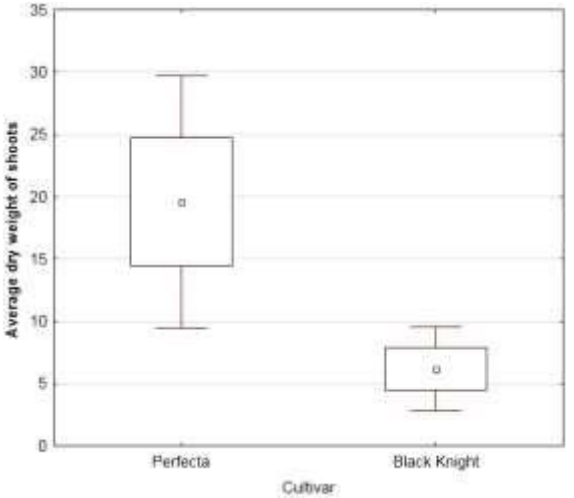

Figure 2b: Mean dry weight (g) of shoots.

During September and October, the weather at the orchard in Ghazir was cloudy sometimes and plants were shaded in a good part of the day. It seems that plants of both varieties of passion fruit had a similar behavior in compensating such deficiency in light by increasing the surface area of leaves (Gratani, 2014). The high number of leaves produced in Perfecta plants consequently the high photosynthetic activity may have allowed a high biomass accumulation in leaves that was sensed through a greater fresh weight and dry matter content in leaves compared to the one of Black Knight cultivar (Figure 3a,b). In fact, the difference of dry weight of leaves of both cultivars may have induced the difference of dry weight of roots (Bouteillé, 2011; Lizarazo, 2013). The high dry accumulation in leaves could also be due to the heavy fertilization that was adopted based on ammonium nitrate (46%) together with the complex fertilizer N-P-K (12-11-18) (Lizarazo *et al.*, 2013).

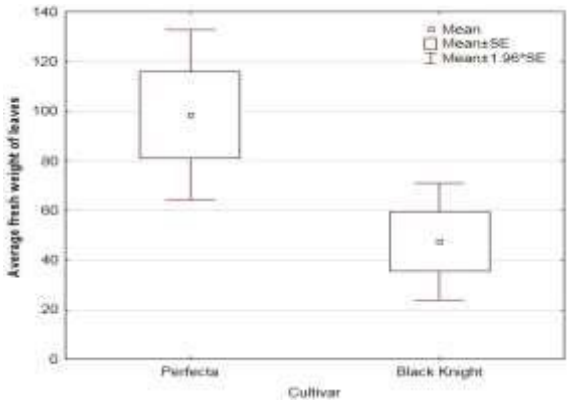

Figure 3a: Mean fresh weight (g) of leaves.

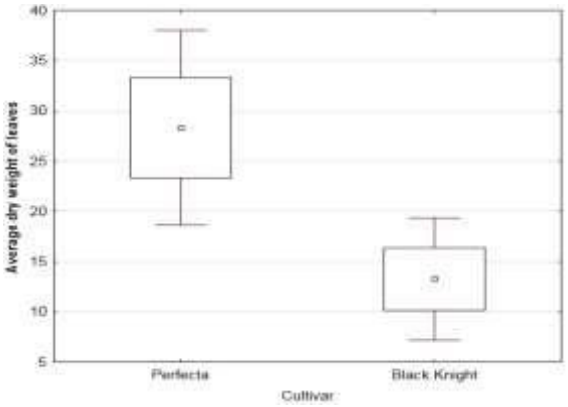

Figure 3b: Mean dry weight (g) of leaves.

Moreover, the high values of SLA (Figure 4a) and LAR (Figure 4b) could be attributed to the effect of cloudy weather t that has promoted an increase in leaf area and a decrease in dry matter accumulation in plants (Utsunomiya and Higuchi, 1996; Castro *et al.*, 2000). Regarding the cultivar Perfecta SLA (323.01cm^2/g) was higher than one of *Passiflora mucronata* (227cm^2/g) (Junior *et al.*, 2013). LAR values of both studied cultivars were higher by around 40%. However, the mean SLA and LAR values did not differ significantly among both cultivars.

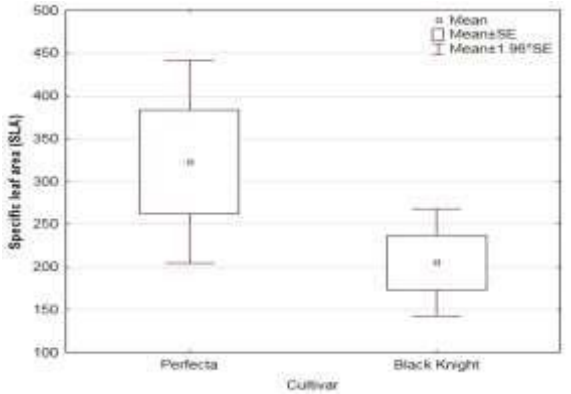

Figure 4a: Mean fresh weight (g) of leaves.

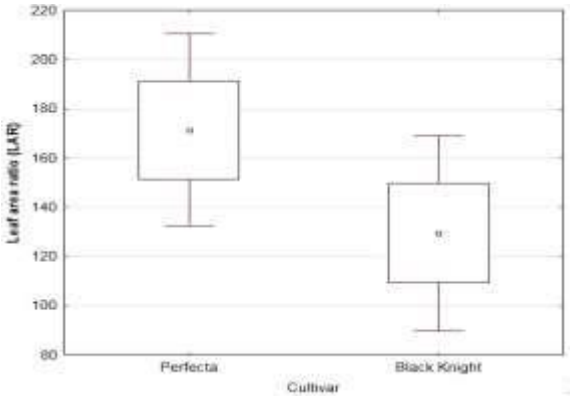

Figure 4b: Mean dry weight (g) of leaves.

Conclusion

Growing two cultivars of the purple passion fruit Perfecta and Black Knight and the comparison of their vegetative and reproductive development revealed a higher level of adaptation for the first cultivar to the climatic conditions of Ghazir. Therefore, the cultivar Perfecta can be considered as a promising cultivar at the agronomical level in Lebanon; it can be successfully cultivated.

Abstract

In order to meet local and export markets demand, seedless table grapes should require the visual and standard demands of those markets. Then several studies reported the beneficial effect of Giberellic acid (GA3) and Synthetic Cytokinin (S.C) on table grapes quality and yield. Consequently, the current study was conducted to investigate the effect of those plant growth regulators on cluster quality and yield of ARRA 15 seedless table grape variety in Lebanese cost. Seven treatments were applied: T1: thinning treatment (1.5ppm GA3), T2: thinning treatment (1.5ppm GA3) + sizing treatment (20ppm GA3), T3: thinning treatment (1.5ppm GA3) + sizing treatment (40ppm GA3), T4: thinning treatment (1.5ppm GA3) + sizing treatment (40/20 ppm GA3), T5: thinning treatment (1.5ppm GA3) + sizing treatment (20/40/60ppm GA3), T6: thinning treatment (1.5ppm GA3) + sizing treatment (20ppm GA3 + 2ppm S.C), T7: control (without GA3 or S.C application). T5 and T6 increased yield by around 38% where the highest cluster length (≈26 cm), the most compact cluster and some rotten berries were recorded compared to control. Cluster weight was the highest in T5 (780g) and the lowest one was in T7 (306g). Harvest was delayed in T5 and T6 by 3 and 7 days respectively compared to control. The control clusters were sold at 0.7$/kg compared to 1$/kg for clusters of T5 and T6. Since S.C is hard to obtain in Lebanon, the application of T5 is preferred which also has an acceptable delay in harvest date.

Keywords: *ARRA 15, Lebanon, market prices.*

Introduction

Table grape is an important agriculture product covering 15% of total Lebanese fruit production (MoA, 2012). Nowadays international table grapes varieties are being introduced and planted by Lebanese commercial farmers (USAID, 2014). It has been always known that local production of table grapes faces problems concerning marketability and exportation norms. In addition, the main challenge in the local production is the consistency of selling the product at valuable prices. This can be ensured if the production complies with the visual demands and standards of local markets and visual and sanitary standards of the importing country. In fact, big and homogenous clusters represent some of those characteristics. Farmers are overhauling and planting new vines of new variety especially seedless table grapes (USAID 2014) where ARRA varieties are newly introduced in Lebanon but they are under experimental trials. To meet market demand for new seedless varieties, plant growth regulators or plant hormones during the development cycle should be used to enhance ARRA grape quality in Lebanese conditions, since Dokoozlian (1998) reported that usage of plant growth regulators could increase berry size leading to better quality and therefore to high yield and expressed as a bigger part of quality production. Cytokinin is presented in plant as Kinetin and other forms and produced where cell division occurs. As exogenous application, it is also promoting cell division. In addition, Gibberellic acid (GA3) is also found in the plant where it promotes cell division and internodes elongation and enhances seed germination and flowering (Harms and Oplinger 1990). According to Durner (2013) Gibberellin and Cytokinin

induce a normal fruit growth in seedless fruits where in general seedless fruits tend to be smaller than seeded. Normal fruit set in table grapes is excessive, leading to high number of berries per clusters and thus to a potentially smaller size of berries (Di Lorenzo et al., 2011). Domingosa et al. (2016) succeeded in reducing the number of berries in seedless table grapes varieties via GA3 by spraying it on the vine canopy. Additionally, Williams and Roper (1989) were found that GA3 application increases berry size in table grapes where GA3 is commonly used for this purpose (Dimovska et al., 2011). In order to obtain optimal results from applying GA3, time of application, concentration and the part of vine must be carefully studied (Mullins et al., 1992) since GA3 effect is variety dependent (Khan, 2009). Moreover, Synthetic Cytokinin increases also berry size and weight (Dokoozlian, 1998).
Consequently, the objective of the current study was to investigate the effect of Giberellic acid and Synthetic Cytokinin on the yield and quality improvement of ARRA 15 seedless table grapes for better marketing and export.

Materials and methods

4 years old vines of the seedless table grapes ARRA 15 variety were studied. 126 vines were planted with a distance of 3 meters between rows as well as 3 meters between plants. The drip irrigation was adopted and training as pergolas system was applied. The Seedlings were grafted on rootstock 1103P. Giberellic acid (GA3) and Synthetic Cytokinin (S.C) were used at several doses and rates resulting in seven treatments represented in the table 1 below:

Table 1: Dose and rate of treatments

Treatments	Thinning application		Sizing application	
	Dose	Time	Dose	Time
T1			-	-
T2			20 ppm of GA3	4-7 mm berry diameter
T3			40 ppm of GA3	4-7 mm berry diameter
T4			20 ppm of GA3	4-7 mm berry diameter
			40 ppm of GA3	One week after the first sizing application
T5	1.5 ppm of GA3	120% bloom	20 ppm of GA3	4-7 mm berry diameter
			40 ppm of GA3	One week after the first sizing application
			60 ppm of GA3	One week after the second sizing application
T6			20 ppm of GA3	4-7 mm berry diameter
			2 ppm of S.C.	One week after the first sizing application
T7	-	-	-	-

The rates were chosen according to several references (Domingosa et al., 2016; Mohsen 2015 and Abu Zahra, 2013). Thinning application was applied by spraying the canopy (Domingosa et al., 2016) while sizing treatments was applied by bunch dipping for 2 second. The Complete Randomized Bloc Design was adopted with three repetitions. The seven treatments were studied in each repetition where 6 plants were selected randomly from each treatment. To avoid the contamination between treatments, preventive methods were used. 3 clusters per treatment were also randomly selected. At harvest, cluster weight and length were measured and cluster compactness was evaluated following international compactness grade scale:

grade1: rigid, unable to move berries on cluster; grade 2: some movement of berries; grade3: able to manually separate berries …. Finally, yield was calculated by multiplying the number of clusters in vine by the mean cluster weight in the same vine.

Results and Discussion

Length of cluster was similar between T5 and T6 (26 cm) and it was the highest. No significant difference was recorded between T2, T3 and T4 where length of clusters were higher than in T1 and T7 which had the lowest length (Figure 1). Considering T5 and T6 results, many studies obtained almost the same results (Dimovska *et al.* 2011).

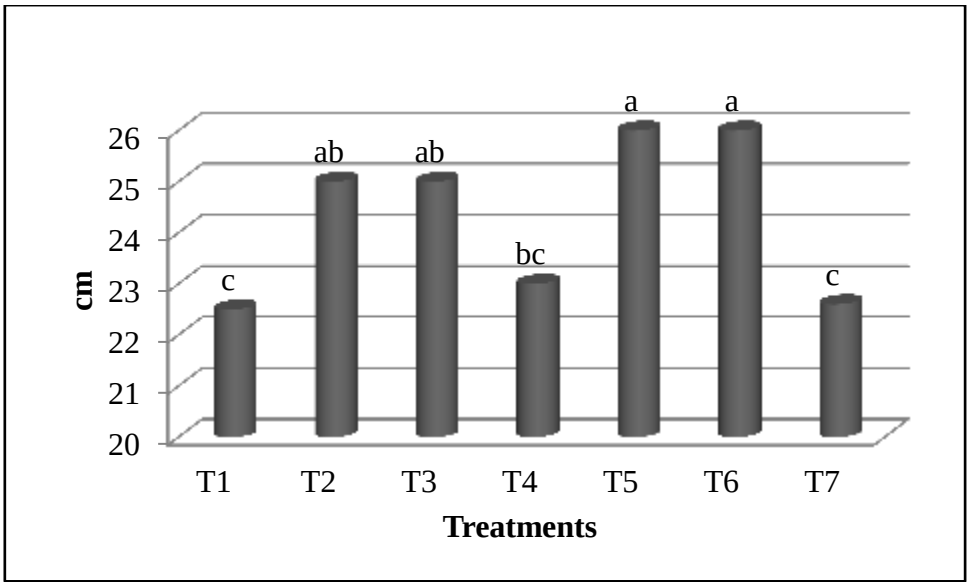

Figure 1: Cluster length at harvest

T5 increase significantly cluster weights compared to all other treatments (Figure 2). Whereas, cluster weight in the treatment T5 was higher by 46, 37, 34, 29, 12 and 60% than in the treatments T1, T2, T3, T4, T6 and T7 (control) respectively. In addition, Abu Zahra (2010) recorded an increase in cluster weight after applying those Plant growth regulators.

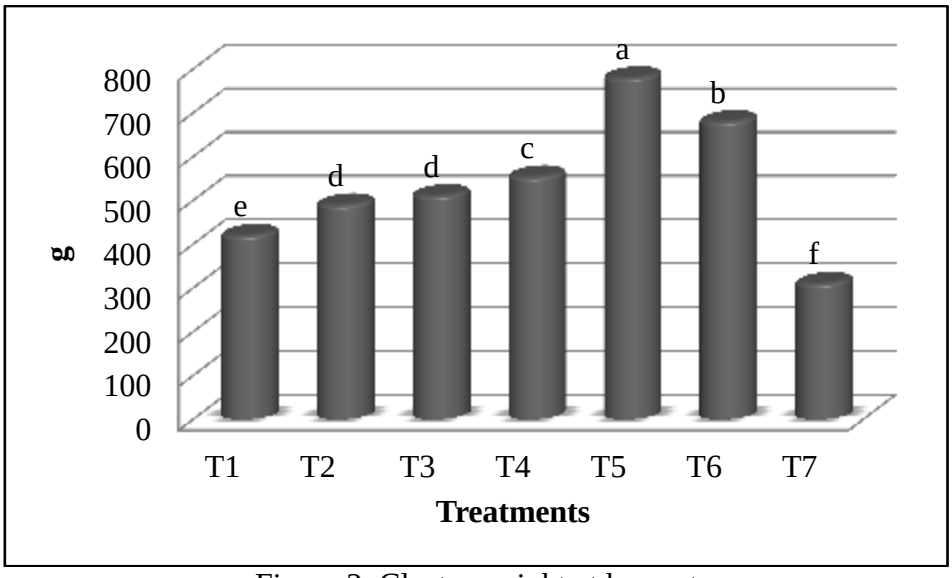

Figure 2: Cluster weight at harvest

The residual activity of GA3 after a single application lasts up to 6 days (Dokoozlian, 1998); thus for T5 the last 3 consecutive applications that were applied with an interval of one week between each one had led to achieve a constant stimulation of cell size growth resulting in a high cluster weight and length. In addition, the synergetic effect between GA3 and S.C. (Dokoozlian, 2001) could be the reason behind the increase of clusters length and weight in T6.

Moreover, the most compact clusters with grade 1 were obtained with T5 and T6, followed by T2, T3 and T4 with grade 2 and T1 and T7 with grade 3. Those findings were almost disagreeing with the results of Dokoozlian (1998). Although 1.5 ppm of GA3 was applied as thinning treatments, compact cluster were still obtained due to the sizing applications of plant growth regulators. Consequently, when certain sizing applications were applied, the dose of GA3 thinning application should be higher than 1.5 ppm to be effective avoiding the presence of rotten berries especially in the heavily compacted clusters as obtained in T5 and T6. Those results agreed with the findings of Domingos et al. (2016) while they reached the sufficient thinning doses. Furthermore, the yields obtained with T5 and T6 were significantly higher than all other treatments (Figure 3). They increased yield by around 15% compared to T1, T2 and T4 and by around 26% compared to T3 and the control. It is logical after obtaining the highest cluster weight in T5 and T6.

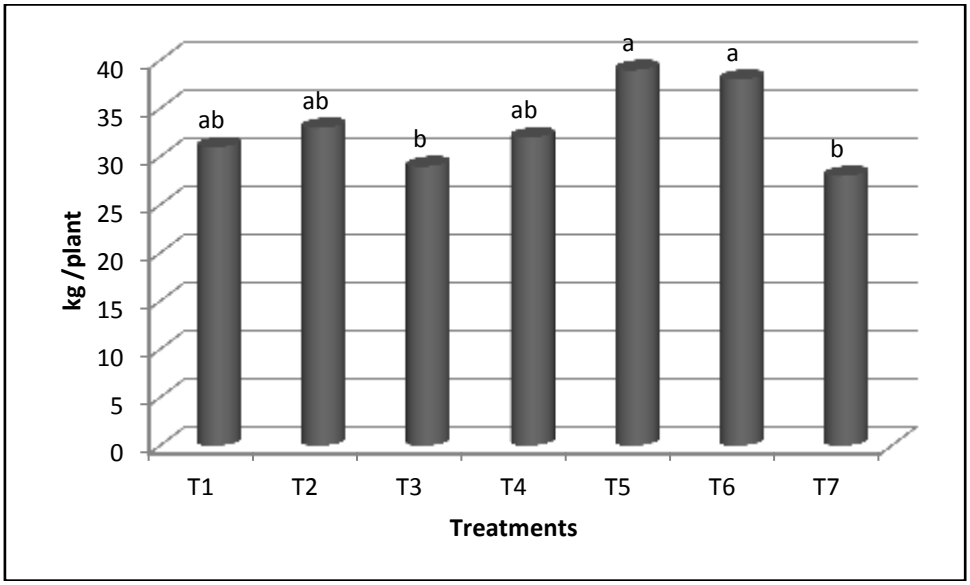

Figure 3: Total yield at harvest

As visual comparison, T7 developed small berries with poor uniformity overall as well as empty spaces within the cluster. On the other hand, T5 clusters exhibited big berry size with a good cluster symmetrical form. Additionally, T6 had decent oval berries with big dimensions as well as good berry uniformity; therefore the clusters had a big size with symmetrical shape. Finally, the clusters were sold by 0.7 and 1 $/kg for T7 (control) and T5 respectively. It should be noted that T5 delayed the date of harvest by 3 days compared to the control. Although T6 also delayed harvest by 1 week, its clusters prices were also 1 $/kg. Dokoozlian (1998) was found also that GA3 delayed fruit maturity and S.C delayed harvest date. A quick and mini feasibility study recorded that T6 cost less than T5 while it increased yield as much as T5 did. In fact, bunch dipping methods required a big amount of labors so a new technique should be tried in order to reduce the cost of production.

Conclusion

As conclusion, T5 and T6 increased yield and cluster length and weight with compact aspect, while the second one delayed harvest for 1 week which is not preferred by Lebanese farmers. It is recommended to apply T5 in Lebanese conditions since S.C. is less available in market. In addition, the dose of thinning should be adjusted to obtain a good berry quality.

Abstract

Sweet sorghum is used for the production of biofuels. The stalk and seed are used directly for biomass energy and lignocellulosic biofuel production. Sweet sorghum biomass is burned for getting energy. And also sweet sorghum biomass is burned by fast pyrolysis to produce syngas, bio-oil, and charcoal. One of the main products of sweet sorghum is its sweet juice which is obtained from stems of plant. The stalks are pressed and juice obtained. Sweet sorghum juice contains 15-20% sugar. High sugar content of juice allows to fermentation to make ethanol. The juice is fermented and distilled for the production of ethanol and biofuels. The residual fiber (bagasse) from sweet sorghum can be used to feed livestock or pelletized to burn for heat in buildings, produce electricity, paper, and cattle fodder. The objectives of the study were to determine yield and biofuel potential of some early sweet sorghum genotypes.
This research was carried out during the second crop growing season of 2016 in Sanliurfa, Turkey. The experiment was designed as complete randomized blocks design with four replicates, with 12 early sweet sorghum genotypes. In the study, flowering duration, plant height, stem yield, plant juice yield, water soluble dry matter ratio and ethanol yield properties were investigated. Significant differences were found between the genotypes for tested characteristics ($P \leq 0.01$). Flowering duration values ranged from 57.5 to 72.5 day, plant height from 252.25 to 340.75 cm, stem yield from 7440 to 13950 kg da^{-1}, plant juice yield from 3525 to 6225 L da^{-1}, water soluble dry matter ratio (brix) from %13.50 to %18.25 and ethanol yield from 214.3 to 464.5 L da^{-1}. It was determined that UNLY-hybrid-4, Blue Ribben, Rex and Colman sweet sorghum cultivars gave higher values than others in terms of stem yield, plant juice yield, water soluble dry matter ratio and ethanol yield.

Keywords: *Sweet sorghum, stem yield, plant juice yield, brix, ethanol.*

Introduction

Fossil energy resources are limited in the world and is depleting dramatically day by day to meet the ever-increasing energy demands globally. Also fossil fuels are causing environmental pollution. For this reason, it is necessary to focus on clean, environmentally friendly, renewable biofuels sources. Biofuels are sustainable and renewable source of energy derived from organic matter in the form of biomass. Biofuels can be derived from plant as well as animal biomass. Plants grown for biofuel purposes have potential to reduce the net greenhouse gas emissions. Crop plants are one of the best sources of renewable energy which can be used as feedstock for biofuel production. Sweet sorghum has a very good potential as an alternative feed stock for ethanol production.
Sorghum (*Sorghum bicolor* (L.) Moench) is a cereal grain. It is widely considered the most important cereal crop in the world. Sorghum ranks fifth among the most important cereal crops of the world, after wheat, rice, corn, and barley in both total area planted and production (Anonymous, 2018a). Sweet sorghum is well adapted to environmental conditions ranging from tropical to temperate conditions within 40°N and 40°S of the equator (Dogget, 1988). It tolerates drought and high-temperature stress better than many crops and has the capability of remaining dormant during the driest periods (Gnansounou et al. 2005). Its waxy leaves and

deep roots are better suited for dry and hot climates. It also has a high tolerance to salt, biotic and abiotic stresses (Bitzer, 2009). Sweet sorghum requires less fertilizer and water to produce significant biomass.

Sweet sorghum is a multipurpose crop providing food, feed, fiber and biofuel across a range of agroecosystems (Kilambya and Witwer, 2013). Sweet sorghum is also considered to be a significant crop for animal feeds used as animal feed (Maunder, 2018). The grain can be used as a gluten-free human food product. Sorghum is also used for human nutrition all over the world (Carter et al. 2018). Sorghum grain is higher in protein and lower in fat content. Grain sorghum is used for flours, porridges and side dishes, malted and distilled beverages, and specialty foods such as popped grain (Anonymous, 2018b). Sweet sorghum biomass is burned by fast pyrolysis to produce syngas, bio-oil, and charcoal. Also biomass can be used for lignocellulosic biofuel production.

The stalks of sweet sorghum has a high concentration of fermentable sugars. Sweet sorghum juice contains 15-20% sugar such as sucrose, fructose, and glucose which can easily be made into ethanol. The stalks are pressed, and the juice is fermented and distilled for the production of bioethanol. When the 10% bioethanol mixed to fuel, biofuels can be obtained. Sweet sorghum-based ethanol is sulfur-free and cleaner than molasses-based ethanol, when mixed with gasoline. The residual fiber (bagasse) from sweet sorghum can be used to feed livestock or pelletized to burn for heat in buildings, produce electricity, paper, and cattle fodder.

The objectives of the study were to determine yield and biofuel potential of some early sweet sorghum genotypes.

Materials and methods

This study was conducted as second crop conditions in 2016, Sanliurfa, Turkey. The experimental field is located in Harran Plain (36^o 42' N and 38^o 58' E) where the climate varies from arid to semi-arid. Table 1. provides the climatic data obtained from Sanliurfa City Meteorological Station. As can be seen from Table 1. that the weather is hot and dry in the months of June, July and August where maximum temperatures were all above 40 ^{o}C while the relative humidity was below 50%. Rainfall was very low from June to August in 2016.

Table 1. Monthly some climatic data during 2016 sweet sorghum growth period in Sanliurfa[†]

Meteorological observations	Months							
2016	May	June	July	August	September	October	November	December
Min. Temp. ^{0}C	9.30	13.1	15.4	16.2	14.0	9.2	1.7	- 0.8

[†]Data collected from the Sanliurfa Meteorological Station (Anonymous, 2016).

Table 2. Some physical and chemical properties of research soil

Deep (cm)	Organic Matter (%)	Total Salt (%)	pH	$CaCo_3$ (%)	P_2O_5 (kg da^{-1})	K_2O (kg da^{-1})	N (%)	Texture (%)		
								Sand	Clay	Silt
0-15	0.66	0.098	7.65	48.17	3.6	99.3	0.06	2.42	15.12	82.46
15-30	0.68	0.086	7.64	46.88	3.9	93.8	0.06	5.50	8.41	86.08

The soil of the research field was clay, slightly alkaline, high in lime and very low in salt contents. Field capacity of the soil was 33.8% on dry basis, permanent wilting point was 22.6% and bulk density was 1.41 g cm^3. Some physical and chemical properties of research

soil were given in Table 2. Twelve early sweet sorghum genotypes (*Sorghum bicolor* (L.) Moench *ssp. saccharatum*) were used as crop material.

Land was ploughed and cultivated then prepared for planting with a single pass of a disk-harrow. The experiment was laid out in a randomize block design with four replications. Each plot area was 14 m^2 (5 m x 2.8 m) and consisted of four rows of 5 m in length. The plants were grown 70 cm apart between the rows with 15 cm spacing in each row. The seeds were sown in second part of June at a 50-60 mm depth. At sowing, 50 kg ha^{-1} of pure N, P and K, as a 15-15-15 composed fertilizer, was applied to each plot; this was followed by 50 kg ha^{-1} of N as urea when the plants reached 30-40 cm in height.

Irrigation water was first applied to all the plots using a sprinkler irrigation system. After the emergence of plants, plots were irrigated equally by the furrow irrigation system. All tested characteristics were measured on randomly selected 10 plants in the center of each plot. An analysis-of-variance (ANOVA) was performed using Jump statistical package program to evaluate statistically differences between results. Means of the data obtained from research were compared using Duncan test at $P \leq 0.05$.

Results and discussion

Flowering duration (day)

According to variance analyses, flowering duration were significant ($P \leq 0.01$). As seen from table 3. that flowering duration values were ranged from 57.5 day to 72.5 day. The highest flowering duration value was found at Rex genotype whereas the lowest flowering duration value was seen at Simon genotype. It was found 15.0 day duration between the highest and the lowest flowering value. Some of the genotypes such as Rex, Colman, UNL-Hybrid-4, H.Sugarcane and Honey gave higher flowering duration value than other genotypes. Generally stem yield, plant juice yield and ethanol yield were lower at the early flowering genotypes.

While Rex, Colman and UNL-Hybrid-4 genotypes' flowering duration values were over 70 day, Rox, Orange, Norkan and Simon genotypes' flowering duration were below 60 day. Some researchers reported different flowering duration values such as 55-72 day (Gul et al., 1999) and 69-88 day (Reddy et al., 2005) in sorghum plant.

Plant height (cm)

Variance analyses results show that sweet sorghum genotypes were significant at plant height ($P \leq 0.01$). Plant height values varied between 252.25 and 340.75 cm. The longest plant height value was found at UNL-Hybrid-4 genotype whereas the shortest plant height was seen at Norkan genotype (Table 3). Average plant height value was found as 307.41 cm. Most of tested genotypes were over average plant height value. Plant height values of Blue Ribben, Colman, Honey, Early Folger, Rex, Rox Orange, UNL-Hybrid-4 and Waconia-L genotypes were over 300 cm whereas plant height values of H. Sugarcane, Mennonita, Norkan and Simon genotypes were below 300 cm.

Similar results were obtained by Clegg et al. (1986), Saglamtimur (1988) and Avcıoglu et al. (2009). These authors observed that plant height values were between 355, 370 and 394 cm, respectively. Some researchers reported lower plant height values such as 249 cm (Yılmaz and Hosaflioglu, 2000), 231 cm (Ozbilen, 1991), 226 cm (Acar and Akgun, 2009), 198.2 cm (Iptas, 1993) and 184.9 cm (Sevimay et al., 2001). It was found that early flowering genotypes gave lower plant height values.

Stem yield (kg da^{-1})

According to variance analyses, differences among genotypes were significant ($P \leq 0.01$) at stem yield. Stem yield values ranged from 7440.0 to 13950.0 kg da^{-1} (Table 3). The highest stem yield value was seen at UNL-Hybrid-4 genotype whereas the lowest stem diameter value was found at Norkan genotype. Stem yield values were dramatically different among tested

sweet sorghum genotypes. It was found 5385.0 kg da^{-1} differences between the highest and the lowest stem yield value. Stem yield values were over 10000 kg da^{-1} at UNL-Hybrid-4, Blue Ribben, Rox Orange, Colman and Mennonite genotypes. Some researchers reported lower stem yield values than our findings. Different stem yield values were stated by other researchers such as 4790-6593 kg da^{-1} (Tsuchihashi and Goto, 2004), 4100-5200 kg da^{-1} (Reddy et al., 2005), 2276-4485 kg da^{-1} (Chavan et al., 2009) and 2150-2660 kg da^{-1} (Geren et al., 2011).

†There is no statistical difference among values annotated with the same letter in a column according to Duncan test
** : denotes P≤0.01

Plant juice yield (L da^{-1})

According to variance analyses, sweet sorghum genotypes were significant for plant juice yield (P≤0.01). Plant juice yield values were varied from 3525.0 L da^{-1} to 6150.0 L da^{-1}. The highest plant juice yield value was obtained from Colman genotype whereas the lowest values were seen at Norkan genotype. There was a big differences at plant juice yield among tested sweet sorghum genotypes. Differences were 2625.0 L da^{-1} between the lowest and highest plant juice yield values. Blue Ribben, Colman, UNL-Hybrid-4, Waconia-L and Rox Orange genotypes gave higher plant juice yield than others. Rains et al. (1993) reported that plant juice yield ranged from 135.8 to 964.5 L da^{-1}.

Water soluble dry matter ratio (Brix) (%)

As seen from Table 3 that water soluble dry matter ratio (Brix) value were significant (P≤0.01). Brix values varied between 13.50% and 18.25%. The highest brix value was seen at Rex genotype whereas the lowest brix value was found at Norkan genotype. The highest brix values obtained from Rex, UNL-Hybrid-4 and Mennonite genotypes. It was seen 4.75% differences between the lowest and highest brix values. Our findings were in accord with other researchers' results. Similar brix values were reported as %8-17 (Maarouf and Moataz, 2009), % 6.2-20.7 (Subramanian, 2013) and %12.5-17 (Prasad et al., 2007).

Ethanol yield (L da^{-1})

Significant differences (P≤0.01) were seen among genotypes for ethanol yield. Ethanol yield values ranged from 214.3 to 464.5 L da^{-1} (Table 3). Similar founding reported by Grassi (2001). It was seen big differences about ethanol yield among tested sweet sorghum genotypes. There was 250.4 L da^{-1} between the lowest and highest ethanol yield.

The highest ethanol yield value was seen at Colman genotype whereas the lowest ethanol yield value was found at Norkan genotype. Some of the genotypes such as Colman, Blue

Ribben, UNL-Hybrid-4, Rox Orange and Waconia-L genotypes gave higher ethanol yield than other genotypes (Figure 1).

Different ethanol yield values were reported by some researchers. Smith and Buxton (1993) stated that 600 L da^{-1} ethanol yield was found in Iowa. Ethanol yield values reported as 125-562.5 L da^{-1} by Li (2003) and 81.16-345.85 L da^{-1} by Teetor et al. (2011).

As seen from Table 3 that ethanol yield values were higher at some genotypes which has long flowering duration. Dogget (1988) reported that late maturated genotypes were high yielding than earlier sweet sorghum genotypes.

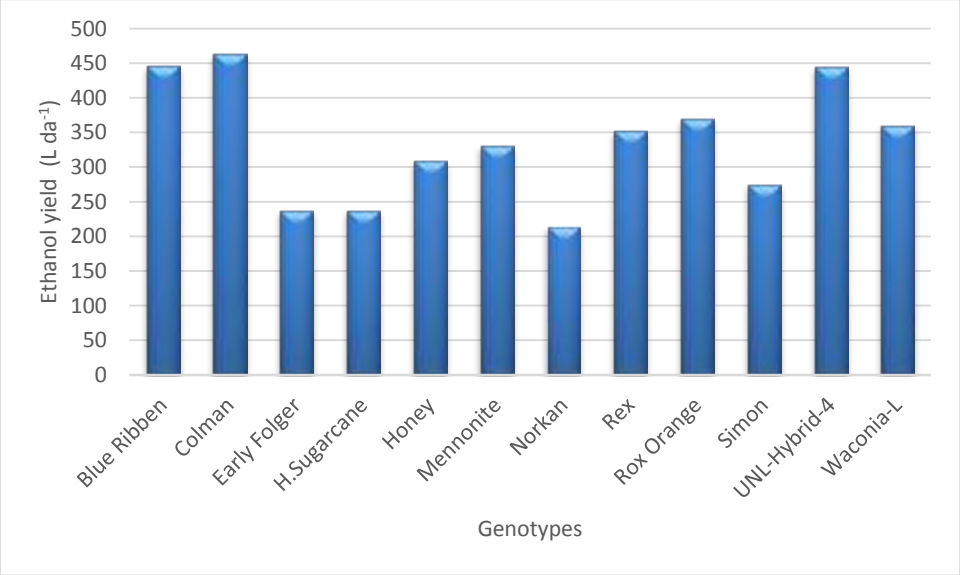

Figure 1. Ethanol yield values of sweet sorghum genotypes

Conclusion

As a result, it was determined that UNLY-hybrid-4, Blue Ribben, Rex and Colman sweet sorghum cultivars gave higher values than other ones in terms of stem yield, plant juice yield, water soluble dry matter ratio and ethanol yield. Ethanol yield values ranged from 214.3 to 464.5 L da^{-1}. Colman, Blue Ribben and UNL-Hybrid-4 genotypes gave higher ethanol yield than other genotypes.

Abstract

This study was conducted on the 4th and 5th leaf old Ferragnes, Ferraduel, Lauranne, Bertina and Felisia cultivars which are growing at the area of private sector at Bozova Province in Sanliurfa (Turkey). In the experiment, 9 fruiting trees were used as plant materials. Fruit samples were taken during harvesting time of the trees. Fruit set, yield and some quality traits were analyzed. According to two years results the highest (29,23 %) fruit set was determined Ferragnes cultivar while the lowest (11.57 %) was Bertina. According to yield per tree Ferragnes cultivar is the best average of two years. Pomological analyzes were done such as weight and dimensions of fruit and kernels. The obtained results show that the biggest fruit was Bertina cultivar. So the kernel and dimensions of fruit and kernel was higher than the others.

Introduction

Almond is one of the most important nut crops worldwide, whose fruits are widely used in food production. In the viewpoint of total production around 3 000 000 tons in the world. Main producer country is USA. Second is Spain, according to four years average of FAO records. Turkey's production is over 83 000 tons. The largest almond plantations in Spain but it was second country by means of production. There are suitable areas to grow almond trees (Ak, 2016). Spain, historically the second leading region, produced approximately 7% of World production but used a cultivated area of over 436,500 ha. Australian production has recently surpassed that of Spain, being slightly more than 7% of total. The remaining world production comes from about 20 countries including Morocco, Iran and Turkey (~4% each), Italy (3%), Tunisia (2%) and Chile (1%). The yield and income is not satisfactory for farmers (Socias y Company and Gradziel, 2017). The edible (sweet) varieties of almonds are consumed whole as a snack food. Apart from its snack value, almond kernels are limitedly used in the confectionary industry as a topping item placed on cakes, Turkish Delights, ice creams and other traditional Turkish sweets. Bitter varieties of almonds, however, are used as supplements and odor additives in the cosmetics industry (Ozudogru, 2003). There are wild named almond species i.g. *Amygdalus orientalis*, *A. turcomonica* etc. common in Turkey (Ak et.al., 2001). Almond culture is possible at South East Anatolia because: (i) there is enough high temperature and low relative humidity in summer time during maturation and harvesting time; (ii) winters are cold enough to provide chilling requirement; (iii) trees can be grown in soil with high lime content; and (iv) trees are resistant to dry or o reduced water conditions (Ak et al., 2005). South East Anatolia is mainly covered with pistachio trees. But almond is an alternative crop to pistachio (Kuden, 1998; Ak and Sakar 2012). Farmers prefer to grow almond instead of pistachio under irrigated areas (Kaska et al., 1999) because: (i) juvenile period is very short; (ii) there is no alternate bearing habit; (iii) harvesting is easy; and (iv) fruits can be stored easily. The main aim of this research is determination on yield and quality of some foreign almond cultivars which started to plant as new large plantations by farmers at Southeast Anatolian region.

Materials And Methods

This experiment was conducted on the four and five years old Ferragnes, Ferraduel, Lauranne, Bertina and Felisia cultivars, which are grown at the area of private sector at Bozova District of Sanliurfa. They were grafted on almond (*Amygdalus communis*) rootstocks. They are France and Spanish cultivars. In the experiment, nine fruiting trees were used as plant materials. Fruit samples were taken during harvesting time of the trees. The trees are irrigated subsurface irrigation methods from April to October (Ak, 2004). Some meterological data were given Table 1.

Table 1. Some metrological data for Bozova District

Pomological analyses were applied on nut and kernel. The traits analysed were weight (g), length (mm), width (mm), thickness (mm), double kernel rate (%) and shelling percentage (%).

Results and Discussion

The yield of different almond cultivars, which are grown in Sanliurfa-Turkey, were given Table 1. According to Table 1, the yield of per tree were changed of their ages and among the cultivars. But when it is considered as averagely, the highest (8.22 kg/tree) yield is obtained from Ferragnes cultivar while the lowest (4.53 kg/tree) yield from Felisia cultivar. The others also changed between this figures.

Table 2. Yield of different foreign almond cultivars (kg/ tree)

Cultivars	**4th leaf**	**5th leaf**	**AVERAGE**
Ferragnes	8.04	8.40	8.22
Ferraduel	8.16	7.60	7.88
Lauranne	4.56	9.85	7.20
Bertina	5.49	10.8	8.14
Felisia	2.79	6.27	4.53
AVERAGE	5.81	8.58	7.19

The yield efficiency that means of the yield per Cross Sectional Area were calculated as well. The results of this were given Table 2. The highest yield 136.21g/cm2 with Bertina cultivar.

Table 3. Yield efficiency in some almond cultivars (g/cm2)

Cultivars	**Yield Efficiency (g/cm2)**
Ferragnes	99.18
Ferraduel	99.11
Lauranne	99.44
Bertina	136.21
Felisia	57.65
AVERAGE	98.34

Fruit setting rate is given Table 3. As it is seen in the table, The highest (29.23 %) fruit set obtained from Ferragnes. The lowest (11.57 %) rate was obtained Bertina cultivar.

Table 4. Fruit set of different foreign almond cultivars (%)

Cultivars	**fruit set rate (%)**
Ferragnes	29.23
Ferraduel	13.05
Lauranne	22.47
Bertina	11.57
Felisia	26.04
AVERAGE	29.47

Some pomological analaysis were done such as fruit and kernel weights, dimensions, and shelling percentages were given Table 4. According to Table 4, Bertina is large and heavy nuts and kernels but shelling percentage is not same paralell. This means that the endocarp is thick and heavy. According to two years average, lenght, widith and thickness are very similar although statistically different.Nut weight is also heavy in Bertina cultivar when compared the others. But fruit set rate was low. Shelling percentages of the cultivars which used at the experiment is very important to determine of yieldness. Felisia cultivar is highest (38.09) when compared the other cultivars.

Conclusions

Almond husbandry in Turkey has not yet reached the point desired, because the infrastructure necessary to commercially maintain almond trees is not adequate. Being not capable of producing almonds in the desired quantity and quality makes our country a net almond importer although Turkey has the capacity to do better as far as almonds production are concerned. To break this vicious circle in the almond sector, efforts directed towards enhancing the area, yield, and production of almonds must be accelerated through preventing growers from using almond trees as bordering materials in orchards rather than using them in commercial production (Isgin and Ak, 2011). Some of the cultivars were obtained by breeding end of the long researches (Kester and Assay, 1975). Southeast Anatolian Region has started to be irrigated. These areas were covered by pistachio trees that are very highly resistant to

drought conditions. But new areas started to turn for almond orchards. Due to: (i) availability of high quality of irrigation water; (ii) existence of fertile and deep soils; (iii) productive late flowering and early bearing cvs; (iv) dry and hot summers with no rains at harvest times; (v) almost no frost damage; and (vi) high profits in comparison to field crops (cotton, corn,wheat, lentil, etc.), almond is going to be the major alternative nut to field crops in the GAP Region of Turkey. The obatined results showed that especially late flowering cultivars are suitable to establish as an economical orchards. If modern almond growing techniques such as pruning, harvesting, cracking, etc. are applied, Turkey can be at least self- sufficient in almond (Kaska, et al., 2005). It appeared that 'Ferragnès' and 'Ferraduel' are the most promising cvs for the region. It was determined many years before and these cultivars are commonly growing in nowadays.

Abstract

This research estimated changes in the number of stoma and types found on different types of olive and olive plant leaves. It also investigated different types of olives adaptation to low moisture levels in the hot and dry region of Sanliurfa (Turkey) from a stoma density point of view. Different cultivars were examined and no significant statistical differences were found on the three types of leaves found in the region. Stoma numbers varied from region to region in the same cultivar on the leaf. The changes are random, and for every cultivar the result varied. Negatif statistical results were found between stoma sizes and numbers. On the same type of leaves differences were noticed between different cultivars after examination on the middle, upper and lower part of the stem. Leaves ranging in size and length were examined from different regions for different olive types. Leaves found on the south regions were larger and longer in size.

Keywords: *Olive, Stoma, Density, Stoma Size, North, South.*

Introduction

A plant gives its water to the air as water steam by transpiration which is known to be carried out mostly by stomata in leaves. Pores on the epidermis of leaves which achieve the evaporation and the exchange the gases between outside and results from physiological activities of plant is named as stomata. When the stomata are open; oxygen, carbondioxide and water steam exchange between the intercellular cavities of the leaves and the atmosphere. This exchange is mostly prevented when stomata are closed (Sahin and Soylu, 1991; Olmez et al., 2001). Transpiration constant shows the amount of water necessary for the production of soluble solids and is an indicator how effective the plant uses the water (Secer 1988). Antitranspirant substances have been shown to increase the largeness of fruit and yield of tree in apricot (Ben-Porath, and Greenblat,1994). In addition, density and morphology of stomata in leaves are known to affect the amount of transpiration (Blanke,1987; Olmez, et al., 2001) . The mechanisms developed by plants as a response to water stress may be found in adaptations by roots, stems, leaves and fruits; the leaf modifications include the size and number of stomata (Kozlowski, 1976; Palasciano et al., 2005). Stomata are the morphological structures which control photosynthesis and transpiration. In general, there is an inverse relationship between the stomata number and size, characteristics which vary greatly among species and genotypes Moreover, the stomata frequency and size can be significant both in plant genetics and ecology (Fregoni and Roversi, 1968; Palasciano et al., 2005).

Requirements of the plant are provided by stomata (Karamanoglu, 1983; Resh, 1981). 90% of the water taken by plant is lost as water steam from the surface of the leaves. This phenomenon is called as transpiration and carried out mostly by stomata (Olmez et al., 2001).

Olmez et al., (2001) the variations of stomata numbers in leaves of apricots (*Prunus armeniaca*) related to the cultivars and regions and if these variations of stomata numbers are related with fruit characteristics (fruit and stone weight, acidity and soluble solid percentage) were investigated. They founded that a positive and statistically significant correlation between fruit weight and stomata numbers, the correlation coefficiency (r) was found as 0.295 meaning that the more stomata numbers are, the more fruit weight is. There was similar

correlation (r=0.194) between stone weight and stomata numbers, too. A negative but statistically non-significant correlation (r=0.127) was determined between stomata numbers and soluble solids percent. Available cultivars appropriate for drying process and fresh consumption were compared in three different region and interestingly, the stomata numbers of the cultivars appropriate for drying process were found less than that for fresh consumption. The results of this investigation demonstrated that stomata numbers in leaves of apricot cultivars appropriate for drying process were different from that for fresh consumption. In addition, we showed a relationship between stomata numbers and fruit weight.

The aim of this study was to investigate the variations of stomata numbers in olive leaves in related to the cultivars which are used as table and oil consumptions. Whether stomata numbers vary according to the part of the leaves (basal, middle and distal parts) and the leaves situation on the shoots in which the stomata were counted and evaluated.

Materials and Methods

The samples of leaves were taken from 9 or 10 years old olive trees which planted Akcakale Reasearch Institute. The samples were taken both north and south sides of the trees. Two annual shoots in each tree were used. Leaf samples were taken from tip, middle and basal of the shoots. Stomata counts were made on the tip, middle and base portion of leaves. For the counting of stomata, the epidermis layer was pulled out by nail polish from the abaxial side of leaves (Elci, 1994). Then, stomata were counted by using a microscope with a 10x40 magnification in 0.0625 mm^2 area(Gulcan and Mısırlı, 1990; Ozeker and Misirli, 2001). The obtained values were calculated as stomata numbers per mm^2. The countings were made 5 different leaves (6x5 = 30 replications) .Each leaf three part (30x3=90countings) and one shoot three part (tip, middle, basal leaves) (90 x 3= 270 countings) counted. So two sides (north and south) considered. That means 540 (270x2=540) countings were applied each cultivar (Figure 1).

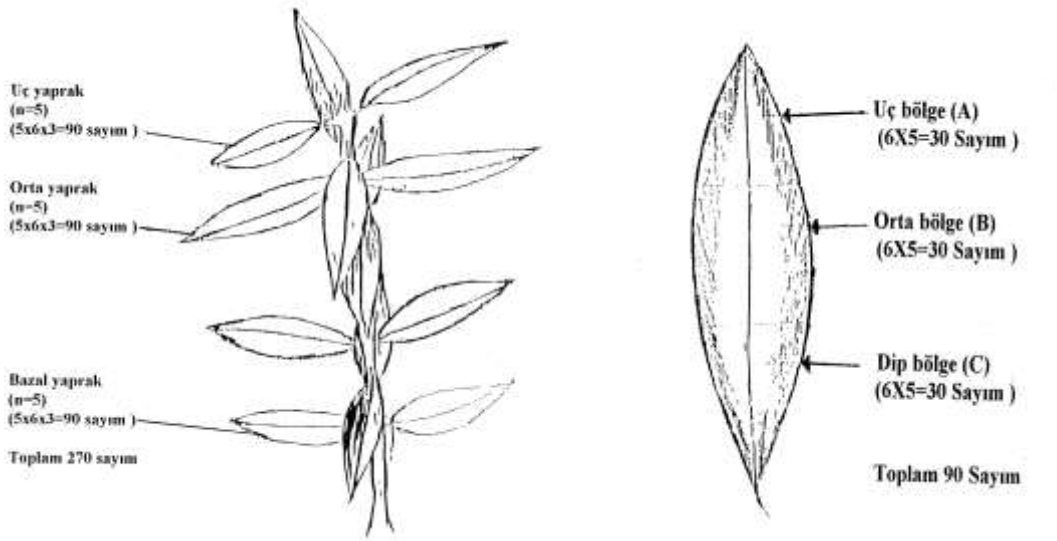

Figure 1. Leaf sampling and counting stomata on the shoot and each leaf.

Results and Discussions

Stomata numbers (per mm^2) were determined according to leaves positions (Table 1). The number of stomata were changed according to cultivars as well. According to average of stomata; the highest (464.467) in Nizip yaglik cultivar while the lowest one (388.242) Gemlik cultivar. Number of stomata were found less in the tip parts of the shoots (410.320) than the base (426.284) and middle (420.817) of the shoots.

Table 1. Stoma numbers of the different cultivars state of shoot (n/mm²)

CULTIVARS	SHOOT			AVERAGE
	TIP	MIDDLE	BASE	
Gemlik	369.381 c	416.200 b	379.144 c	388.242 b

$LSD_{0.01}$(Cultivar): 13,83 $LSD_{0.01}$(Shoot): 10,72
$LSD_{0.01}$ (Cultivar x Shoot):23,96

Stomata number also shows the drought resistancy. The *Quercus coccifera* (433 adet/mm²) more resistant to drought conditions than *Arbatus andrachne* (364 adet/mm²) (Olmez et al., 2001). The results of according to leaf states of the stomata numbers of leaves in different olive cultivars were given at Table 2.

Table 2. Stoma numbers of the different cultivars state of leaf (n/mm²)

CULTIVARS	LEAF			AVERAGE
	TIP	MIDDLE	BASE	
Gemlik	381.597 b	393.425 b	389.703 b	388.242 b
Manzanilla	464.468 a	465.027 a	454.981 a	461.492 a

$LSD_{0.01}$ (Cultivar): 15,20; $LSD_{0.01}$ (Shoot): NS
$LSD_{0.01}$ (Cultivar x Shoot):26,33

The highest stomatae number was found 469.391 with Nizip Yaglik at middle of the leaf. The lowest (381.597) in Gemlik cultivar. When it compared amond the tip' midlle and base of leaf' averagely the highest number (421.778) of stomata were obtained from middle of the leaf. The lowest number was obtained from tip of the leaf.
In this experiment the number of stomate side was compared(Table 3). Generally north side of leaf stomata number was found higher than south side of the taken leaves.

Table 3. Stoma numbers of the different cultivars state of the sides (n/mm²)

	South	11.0 ± 0.66	10.9	7.3 ± 1.49	6.95	0.663	0.637

Stomata bigness of the sampled cultivars were changed (Table 5). The bigger (78.25) was Gemlik cultivar, while the smallest (66.24) was Manzanilla. It can be seen in Figure 2 as well. This situation may affect to photosynthesis. Paul and Eagles (1988) reported a positive correlation between the stomata numbers of leaves and the rate of photosynthesis in four different Brassica varieties.

Table 5.The bigness of olive stomata rate according to side average.

CULTIVARS	WIDTH X LENGHT(µM²)
Gemlik	78.25

Manzanilla	66.24

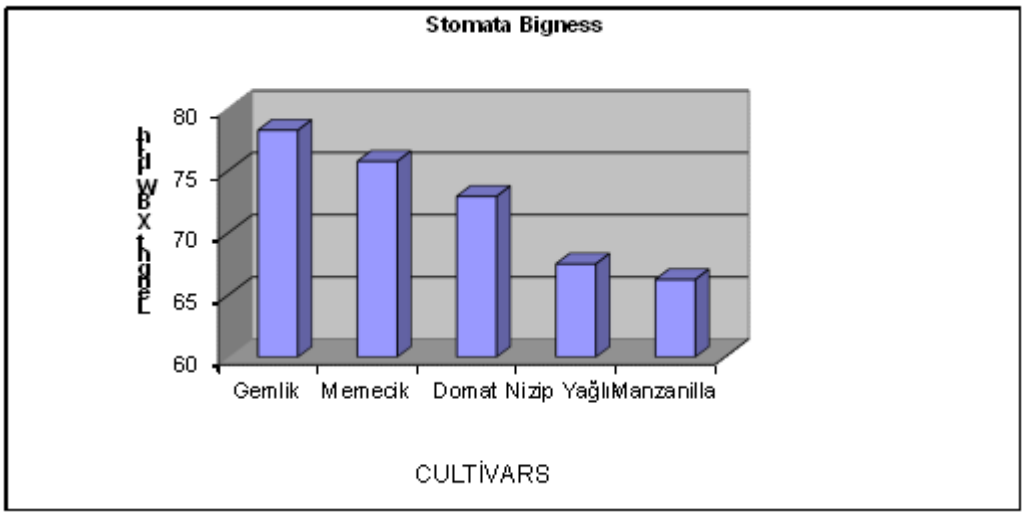

Figure 2. The changes of bigness (Lenght x Width)according to size of stomata in some olive cultivars.

Conclusions

The results of this study confirm significant differences among genotypes of olives cultivars about stomata numbers and sizes. It was understand that stomata number can be changed according to leaf position on the shoot, leaf part and side. But generally stomata number is changing according to olive oil contents. Because olives which is used to extract for oil' such as Nizip Yaglik the number of stomata is changing, that Gemlik cultivar which has been used for table consumption. In conclusion, it was demonstrated that stomata numbers in the leaves of olive cultivars maybe changed according to cultivars.

Abstract

Pistachio can be grown in only some part of the world due to special climatic requirements. The most important pistachio producer countries in the world are Iran, U.S.A., Turkey and Syria, respectively. Growing and processing techniques after harvest in Iran and U.S.A differ from those in other countries. Modern growing and processing techniques are performed in only U.S.A. In this presentation, the production values, growing problems and solutions, harvest and post-harvest processing techniques are compared that pistachio producer countries. In Turkey, growing of pistachio is intensified to the Southeast of Anatolia. After irrigation facilities start to be used in this area with GAP Project, it is expected to be important changes in new and old orchards. The farmers know the effect of water for pistachio trees. They are trying irrigation methods. An additional to this growing system, post harvest processing is start to be modernized during last decades.

Keywords: *Pistachio, production, yield, quality, irrigation.*

Introduction

Some of the species play an important role in vegatation at the Mediterranean and Asian regions and most of them have proved successful as rootstocks for top working the cultivated pistachio nut. Except *Pistacia vera* the other ones are not economical. They are called wild pistachio. In Afganistan, Iran, Pakistan, Turkey and all The Mediterranean countries there are millions of wild pistachio trees or bushes which belong to different *Pistacia* species. Pistachio is grown most intensively in Iran, Syria, Turkey and U.S.A. The other pistachio producing countries are in the Near East, North Africa and the Southern Europe. According to four years avarega (2013-2016), the production values in Iran is over 352 000 tons which is half of the world production (Table 1). The second country, USA, produces approximataly 300 000 tons covers 32 % and next one is Turkey with yield of 120 000 tons with 13.24 % of total world production.

Pistacia vera is grown 30-40 altitude and suited in microclimate areas in the world. The biggest (420 000 ha) production areas belong to Iran. Second country is Turkey. But its yield is very low when compared the production areas (Arpaci et al., 2005). This situation makes the scientist to think about the problems and solutions.

Pollination

Pollination occurs by the transport of pollens from male to female trees by wind. Pistachio flowers have no petals which attract insects. Therefore pistachio orchards must contain male trees and ratio of male to female should be 1/8 or 1/11 (Kaska, 1990, Ak,1992). It is necessary to have enough male trees to insure adequate pollination. Male and female flowers of pistachio are on separate trees. This situation has been recognized since 1697, (Whitehouse and Stone, 1941) that means pistachio trees (*Pistacia vera* L.) are dioecious. However male tree number can be enough in orchard. But, pollen shedding time should be with female flowering period. (Ak et al., 1998; Ak, 2001).

Rootstocks

In Turkey, there are four common *Pistacia* species (*P.vera, P.atlantica, P.khinjuk, P.terebinthus)* used as rootstocks. Except *P. vera* the others are not used commonly as seedling because of their low percentage of seed germination. According to observation, Siirt cultivar seeds have better growth and development than the other cultivars.

P.vera seedlings are stronger and more homogenous than the other rootstocks. Budded trees'on this rootstock grow slowly during the first year but growth becomes faster in the following years. There is no incompatibility in budding with cultivars of pistachio. In the budded trees the juvenility period lasts long; therefore, the trees bear fruit quite late. In arid zones the trees reach the bearing stage 15 to 20 years after planting. They can withstand drought, high lime content and salinity in the soil but are sensitive to high soil moisture. The trees of *P.terebinthus* are grown generally as bushes. The plant has a strong and deep root system. Therefore it can be grown in poor rocky and stony soils. It is a kind of dwarfing rootstock for *P.vera,* L. so the trees budded on this rootstock can be easily recognized. *P.terebinthus* is as hardy as *P.vera* but hardier than *P.atlantica.* Therefore it is preferred to *P.atlantica* in cold areas. In Turkey it can be grown successfully at elevations up to 1200 m. *P.terebinthus* is suitable for planting in calcareous soils along the Mediterranean coast. It grows very well in places where the annual precipitation is about 400 to 600 mm (Kaska, 1995).

Irrigation

James (1993) stated that between 60 and 95% of living plant biomass is water. Although plants need water primarily for transpiration, it also require water for other processes including photosynthesis, transport of minerals, structural support, and growthPistachio orchards were established in dry and unirrigated lands in Turkey besides the soils are very bad, unfertile and calcareous. The farmers believe in that pistachio should be grown without irrigation so far. This idea comes from their grandfathers. These old men have a bad experience about this matter. Because they were irrigated the result pistachio trees were died. And they teach this knowledge to their sons. But this situation had been occurred by wrong irrigation method. However last decades Research Institutes which are depend on Ministry of Agriculture, Universities start to make experiment on irrigation researches of Pistachio trees. Now, the positive effects of irrigation are told to farmers. The region where pistachio is

growing areas have not irrigation facilities until 1980's. Now in Southeast Anatolia project (GAP) provide to irrigation facility. The water is distributing by control. In the very near future new and irrigated pistachio nut orchards in the Southeast Anatolia Project (GAP) region will expand Turkey's pistachio nut areas. It is expected that when the project is completed the Turkish pistachio nut production will be at least doubled. As it is well known that irrigation is a very important factor in obtaining high yields on good quality.

In order to preserve the water from the winter and spring rains and snows, the soils are ploughed in Autumn. On the other hand in order to prevent evaporation, the soils are cultivated by chisel ploughs in whole spring and summer months. This type of soil workings destroy the weeds as well (Kaska, 1995).

As it is well known, some expected changes by irrigation, leaf size, number of current year's shoot and length of shoot will be increased. The result with irrigation increasing the yield, bigger nut size, high splitting percentage, low blank nut rate and lesser alternate bearing will be obtained. Arpaci et al., (1995) determined that in irrigated conditions with Siirt cultivar's yield 262 kg/da while 60-80 kg/da in dry conditions. This experiment shows that yield will be increased at least three or four times when pistachio orchards were irrigated.

As it is mentioned above pistachio orchards established under dry and very bad soil conditions. But, high yielding can be obtained irrigated and fertile soil conditions. According to Ak and Agackesen (2003) reported that pistachio trees should be established under irrigated and fertile or good soil conditions to get high yield and quality. The yield is compared. The yield of Kirmizi pistachio cultivar either fresh weight or dried weight in good conditions that means irrigated and fertile soil is higher than other conditions. As it is seen fertile soil without irrigation is better than poor soil with irrigation. The very important obtained results as below: (i) Fresh fruit weight was determined in arid soil irrigated conditions 21.80 kg, unirrigated conditions 15.50 kg. The yield were obtained fertile soil irrigated conditions 31.00 kg, unirrigated conditions 25.87 kg, respectively. 1 kg fresh fruit was determined 559.63 g after sun dried. According to this calculation, the highest dry weight was determined 17.043 kg per tree grown under fertile soil at irrigated conditions. (ii) The shell splitting rate was determined analyzing 300 fruits each tree. According to results of arid soil irrigated conditions 58.89 %, unirrigated conditions 37.45 %, at fertile soil 61.43 % obtained irrigated conditions, 61.10 % unirrigated conditions. The blank fruit rate was lowest, shell splitting and total filled fruit number rate increased with irrigation. (iii) 100 fruit weight determined the highest value under fertile soil irrigated conditions in splitted fruits. 100 fruit weight was determined statistically different from each others. Fruit weight and kernel weight were increased with irrigation. General average were obtained 86.64 g in nut, 44.37 g in kernel.

Blank or empty nut can be occurred by lack of pollination and fertilization. But mainly irrigation can effect to fill in. Irrigated condition blank fruit rate was 17 % when unirrigated trees were 30 % averagely. Likewise poor soil was 29.71 % while fertile soil 17.70 %.

Irrigation has been started but to apply suitable irrigation method is very important. Generally it should be drip irrigation system. This may be lying on soil surface or lying or buried sub soil sytem. There are advantages and disadvantages both systems. The amount of water is the key factor to prevent the trees from diseases.

Irrigation by underground drip systems are being used on olive plantations in Spain. This system has been started to be used for pistachio and almond orchards in Turkey. However farmers are not confident with this method. The advantages of underground drip irrigation system are mentioned as follows: lower water consumption, better water distribution, greater uniformity, waste water can be used, less evaporation, greater transpiration, location of fertilizer, less calcification, less diseases, possibility of tillage, The depth of the watering line is at approximately 20-25 cm deep, under the soil surface. This sytem is applying in Iran

because of lack or due to limited water. Exceesive water or weak dranage sytems or very high watertable kill the trees (Figure 1).

Figure 1. Excessive water killsthe pistachio trees.

Fertilization

The soil in area under pistachio plantation is mostly inadequate to N, P, K and organic matter. A survey conducted in 30 pistachio orchards in Southeast Anatolia, Tekin et al., (1985) revealed that in many orchards the trees were markedly deficient in phosphorus and zinc and slightly deficient in nitrogen, iron and manganese. The level of potassium was found adequate in many orchards though there were some districts where the trees showed slight deficiencies. In this region pH of the soils varies between 7.5 and 9.3 and the organic matter content is very low. Especially zinc deficiency effects on fruit set (Ak and Parlakci, 2006).

Crane and Maranto (1988) claimed that pistachio is not a luxury N consumer when it is abundantly available in the soil. Chemical form of nitrogenous fertilizers should be chosen depending on the soil pH. For instance, in the GAP (Southeast Anatolia Region) area only ammonium sulfate is recommended as a source of N because of the alkaline soils. Nitrogenous fertilizers should be given at the end of February or the beginning of March at the rate of 1.5 to 4 kg per tree (Kaska, 1995). In U.S.A. boron plays a unique role in pistachio. Responses to foliar B application include increased pollen viability and germination rate, increased fruit set and yield, decreased blanking percentage and increased leaf B concentration (Brown, 1995a). Generally nutrient statutes of pistachios should be critisize according to leaf analyzes. Leaf samples should be taken 16-31 July by Tekin et al. (1990).

Cultivars And Harvesting

The most important characteristics of the pistachio nuts desired by the markets are the should be; large size, high percentage of shell splitting, low percentage of blank nuts, high oil and protein content, .regular bearing, high percentage of green kernels. In pistachio green kernel is one of the most desired characteristics. Green kernel nuts are always at a premium. Though the green kernel is a varietal characteristic it is also related to altitude and harvest time. Generally the nuts of early harvested trees and plants grown on high plateaus produce greener kernels than those of late harvested and low land grown plants. On the other hand greenish is affected by pollen source. According to observation *Pistacia terebinthus* pollens causes metaxenia and xenia (Ak, 1992)

There are major cultivars each main producing countries. According to Sheibani (1995) there are 60 named cultivars in Iran. But main production cultivars are Ohady and Kaleh Ghochi. In Turkey, Kirmizi, Uzun, Halebi and Siirt are the major cultivars.

Alternate bearing is one of the important features of pistachio. Alternate bearer cultivars produce heavy crops in "on" years and little or no crop in the "off" years. In contrast to other fruit species such as olive, apple etc (Ak and kaska 1992). This situation can be change from

one cultivar to another one. For example Siirt variety is less alternating one (Ak, 1998). This means the tendency of alternate bearing of cultivars different. This can be decreasing by irrigation and fertilization.

Pistachio is harvested from late August to late October depending on cultivar maturation. During maturation the under colour of exocarp changes from a light green to pale straw or whitish, opaque appearance. The hulls can be removed from the fruits by being squeezed between the fingers. Another sign of maturity is splitting of shell. Decreasing in fruit removel force. Kernel dry weight and crude fat content are increase (Ak, 1998).

Conclusions

Pistachio nut culture is centuries old in Iran, Turkey and Syria. In this country the area under pistachio nut is the largest and the number of trees is the highest in the world. In spite of these facts the production is very low in Turkey and Syria. But the taste is good but the nuts are small and their splitting percentage is low. However, one should bear in mind that Turkey is the only country in the world that pistachio nuts are grown in such marginal lands with dry climate and poor, rocky and calcareous soils (Ak, 2002).

Turkey is full of other types of *Pistacia spp* called as wild pistachios. The topworking has done in 1980's. These trees are on the hill or mountains as irregular orchards. Some of them are very small, some of them not applied cultural practices. This situation makes the total yield very low. But These areas are not suitable for other agricultural crops. Because of this reason this type of areas gain as valuabled. Except this situation the regular orchards will be supported by government of Turkey and growing techniques will change to modern system. On the other hand, Turkey has very important advantage about aflatoxin. Because of low humidity and high temperature during growing and harvest season, the fruits are free from aflatoxin. It can be seen or contaminate during processing. Processing systems are also modernizing.That means Turkish pistachios has no aflatoxin and high quality about flavour and taste. Turkish cultivars are preferred in many European and U.S.A. markets due to their good taste and uniformly green kernels (Ak et al., 2016).

The researches had been showed that effects of irrigation 70 %, fertilization 50 %, variety 45 % and light pruning 17 % on yield of the pistachio trees . Pest and desiaese problems should be solved using chemicals wisely. The ecology of the tree is changing by irrigation so the pest which economically important types is chaning as well. Near future, when the problems are solved pistachio will gain big importance such as hazelnut in the world. Turkey's production will be increased three or four times when irrigation system established all the pistachio orhards either old trees or young new plantations.

DETERMINATION OF THE EFFECTS OF LESS AND EXCESSIVE LEAF REMOVAL ON CLUSTER CHARACTERISTICS IN "TRAKYA ILKEREN" GRAPE VARIETY

Bülent KÖSE*, Hüseyin ÇELİK, Damla ÇELİK

Ondokuz Mayis University, Agricultural Faculty, Department of Horticulture, Samsun, Turkey
*Corresponding author: bulentk@omu.edu.tr

Abstract

In Turkey, stuffed vine leaves is one of the main traditional Turkish foods. Because of this, consumption of vine leaves are quite high. The "Trakya Ilkeren" grape variety is an early ripening and high quality dark red colored table grape which is also use for brine. Leaf removal is made intensively for brine leaf production in Turkey. Also leaf removal is made for green pruning during the summer season in vineyards. This study was carried out at the research and application vineyard of Ondokuz Mayis University in 2017 growing season. The aim of the study was to determine the effects on the cluster properties of less and excessive leaf removal in "Trakya Ilkeren" variety. In the study no leaf removal, less and excessive leaf removal applications were carried out between May and June. Leaf removal application had significant positive effect on TSS, titratable acidity, bunch width, berry width and length. Less leaf removal had a positive effect on pH, berry weight, bunch weight and bunch length. Hue and Chroma values were found to be significantly high in the control, b (-) and *L* values were found to be considerably high in the less leaf removal. In the study, less leaf removal application had positive effect on cluster characteristics in "Trakya Ilkeren" grape variety.

Key words: *leaf removal, grape, brine leaf, cluster, berry.*

Introduction

The leaf is one of the important main organs of the plant body. The primary function of the leaf is to perform photosynthesis and respiration. Photosynthesis decrease by continuous (Caspari et al., 1998) or 90% leaf removal (Chaumont, 1995; Ollat, 1997). Since the photosynthesis products cannot be transported completely from the leaf throughout the day, they are also important as nutritive organ (Downton et al. 1987, During 1988, Roper and Williams 1989). Grape leaf consumption has a significant potential in Turkey. The composition of the grape leaf contains sugars, organic and amino acids, phenolic compounds and some vitamins (Ribereau and Reynold, 1971). On the other hand, crude cellulose, which is found in plant-based foods, was reported to reduce the formation of arterial stiffness, spinal disease and colon cancer (Gürses, 1980). However, an excessive removing of the leaves prevents the growth of the vines and the ripening of the fruits well. For this reason, it should be avoided excessive leaf removing during growth season. In order to produce brined leaves, it is necessary remove clusters to provide for leaf formation and development. Leaf removal provides better light penetration, good ventilation and disease control (Cangi and Yağcı, 2017).

In spring, vine leaves which is collected during periods when the shoots are still fresh, evaluated for making brined. Wrapping leaves is preferred with thin, hairless, fiber free, thin veined, small slices and having sour taste. The most important wrapping leaf in terms of these characteristics is "Sultani Seedless". For this reason, brine leaf production is an important income for the Aegean region. In this region, most of the grape fields are planted with dried seedless grapes. "Sultani Seedless" grapes are also regarded as brine leaves at the same time. This situation is the same for the Tokat region. In fact, "Narince" is the most important grape variety evaluated as wine and table grapes beside its leaves for brined for grape grower in

Tokat province and around. Beside these varietis, "Yapıncak" grape variety which is grown especially in Trakya region, is also widely evaluated for this purpose (Çelik et al. 2005). Ağaoğlu et al. (1988), stated that leaf picking begins on shoots when they reached to 15-20 cm length in Tokat region between mid-May to the beginning of August. In vineyards for planted brine leaf, about 600-700 kg of leaf is pickled from the acre without paying attention to the flower cluster. There are 45 brine companies registered in Turkey, about 30 company in the Aegean region and 15 company in Tokat province. The financial value of brined leaf in these companies is estimated; 40.000.000 Turkish Liras (Anonymous, 2014). Grape leaf picking for brine in the early vegetation period caused the vines weaken and the quality of the grape berry decreased in the late period (Göktürk et al., 1997). In particular, when the excess leaf picking done, grape bunches are not able to feed adequately and thus yield and quality are reduced. Some researchers have suggested that leaf picking should be done in the period when they take 1/3 to 2/3 of the full size of the leaves (Göktürk et al., 1997; Sat vd., 2002). The harvest of grape leaves for pickled are usually done in May and June, but leaves should not be taken after the veraison period so that grape yield and quality are not adversely affected. In viticulture for grape production, due to the leaf picking at different times cause decreased total assimilation and undesirable reductions may occur in yield and quality (Mullins ve ark., 1992). Grape cultivation for brine leaf; number of vine cluster negatively affect grape leaf area and vegetative development. For this reason, it is suggested that remove the clusters they are still in the flower stage and apply a regular fertilization in new establish vineyards for brine leaf production (Odabaş ve ark., 1995).

Flower abscission affected by solar radiation (Ferree et al., 2001) and leaf area (Coombe, 1962; Koblet, 1966; Caspari *et al.*, 1998). Reduction of leaf area during flower formation leads to a decrease of nutrient availability for developing organs and flower abscission (Candolfi-Vasconcelos and Koblet, 1991). However, when the leaf removal reaches 90%, plant photosynthesis is so much reduced (Caspari et al., 1998; Duchêne et al., 2003). Grape leaves are capable of storing solar energy by converting it into chemical energy by chlorophyll. With the removal of vine leaves, grape quality decrease and acidity increases (Ruckenbauer and Traxler, 1975). In order to obtain high quality grape leaves in vineyards which are established to produce brine leaves, regular and necessary fertilization should be done. In this regard, particular attention should be paid to nitrogen fertilization (Odabaş et al., 1992).

Uslu (1980) found that leaf picking reduce the total assimilation surface, but increase the photosynthetic activation of the leaves on the vines and increase carbon dioxide absorption. Uslu (1980) found that 4.51-7.12 cm^2 leaf area is sufficient for ripening of 1 g grape. Currle et al. (1983) calculated that the leaf area required for maturation of a cluster or 1 g of berry should have a 1.6-2.8 m^2 leaf area and it should be avoided excessive leaf picking. When this value falls below, insufficient photosynthesis cause delay ripening of grapes due to the lack of organic matter. Candolfi and Koblet (1990) reported that sugar accumulation in berry seems to depend on active leaf surface between veraison and harvest period. Leaf removal at the early stage of berry growth stages leads to both millerandage and decreased bud fertility in the following season. This critical period is limited from full bloom to 2-3 weeks after. The leaf area of the vine has a great influence on the bunch quality (Drissi et al., 2009). There is a positive relationship between leaf area per vine and fruit quantity per vine while a negative relationship between bunch number per vine is reported (Edson et al., 1995). Schultz (1995) found that young leaves have as high photosynthetic rate. Increasing leaf area per vine provides increase in photosynthesis and dry matter (Campo et al., 2002).

Materials and Methods

The research was conducted in the experimental vineyard of Ondokuz Mayıs University, Turkey in 2017. The vineyard located at 41°21'52 N latitude and 36°11'29 E longitude with an altitude of 195 m, and a distance of about 2.8 km from the Black Sea coast of Turkey. The research vineyard has 62.2% clay soil, pH 7.1 and 4.33% organic matter content. In the study; 10-year-old "Trakya Ilkeren" grape variety grafted on 5C rootstock was used. Spur pruned grapevines were trained onto double cordon with 3x1.5 m spacing. Grapevines were not irrigated, not fertilized and the only supplementary water received from rainfall. In the study, control, less and excessive leaf removal applications were carried out. Grape leaves removed when the size reach enough to wrapping.

Applications

1) Control (no leaf removal),

2) Less leaf removal: Between May 15, 2017 and July 15, 2017, at intervals of 10 days, 7 times per shoot were applied. Two mature leaves just above the flower cluster have been removed in each term. As long as the shoots are extended, 2 mature leaves in the middle of the shoot are removed. The secondary shoots are removed with the leaves.

3) Excessive leaf removal: From the flower cluster, all the leaves were picked except for the last two small leaves at the top of the shoot between May 15, 2017 and July 15, 2017, at intervals of 10 days with 7 times. The secondary shoots are removed with the leaves.

Leaf removal applied from 15 May 2017, 25 May 2017; 05 June 2017; 15 June 2017; 25 June 2017; 05 July 2017 and 15 July 2017 dates. In the vines, the veraison started in 15 July 2017 and leaves did not picking after this date.

The fruits were harvested on 22 August 2017. In clusters; TSS (Brix %), titratable acidity (%), pH, maturity index, cluster weight (g), berry weight (g), berry width (mm), berry length (mm), cluster width (cm) and cluster length (cm) were investigated. The berry skin color is measured with a Minolta CR-300 colorimeter. TSS (total soluble solid content) of the juice was measured with a digital refractometer (Atago PAL-1, McCormick Fruit Tech., Yakima, Wash.) and expressed as percentage. The pH of grapes was measured by pH meter (Hanna, model HI9321). Titratable acidity (%) was measured by titrimetric method. Skin color characteristics for all replication were measured in 10 grape berries using a colorimeter (Minolta, model CR–400, Tokyo, Japan). Chromatic analyses were conducted in accordance with the CIE (Commission Internationale de l'Eclairage) system of 1976. The L∗, a∗, and b∗ values explain a 3-dimensional color space. The L∗ value is the vertical axis and defines the lightness, and a∗ and b∗ values are perpendicular horizontal axes and define red-to-green and blue to-yellow, respectively. In addition, hue angle (H) and chroma (C∗) can be calculated from a∗ and b∗. H is distributed in the 4 quadrants of the a∗ and b∗ plane, and C∗ is higher the further it is from the origin of the coordinate (Bakker and others 1986). The color measurements of berry samples were computed as the means of each application. The hue angle (h°), calculated as $h^o = \tan^{-1} \times b^*/a^*$ formula. The chroma (C*), obtained as $C^* = (a^{*2}+b^{*2})^{1/2}$, is a measure of chromaticity, which defines the purity or saturation of the color (McGuire, 1992).

Statistical Analysis

The mean measurements were evaluated with complete randomized block design in the study. Cluster characteristics were measured in four vines and 3 replications per treatment. The data were analyzed by two-way analysis of variance (ANOVA) to test main effects and interactions between for treatments. Data analysis was performed using SPSS 16.0 for Windows. Results studied were presented as means and a pooled standard error of mean (SEM). Differences among means were detected using Duncan's multiple range tests at significance levels of ($p<0.05$).

Results and Discussion

The effects of less and excessive leaf removal on cluster characteristics of "Trakya Ilkeren" grape variety are given in Table 1. There were found statistically difference between applications in terms of cluster characteristics. Berry width, berry length, cluster length, cluster width, cluster weight and berry weight values was found significantly higher in less leaf removal. Excessive leaf removal application was decreased all cluster characteristics (Table 1).

Table 1. The effects of less and excessive leaf removal on cluster characteristics of "Trakya Ilkeren" grape variety

Leaf removal levels	Berry width (mm)	Berry length (mm)	Cluster width (cm)	Cluster length (cm)	Cluster weight (g)	Berry weight (g)
No- removal	19.07 b	18.20 b	14.13 ab	23.00	360.17 b	4.46
Less removal	19.46 a	18.54 a	15.20 a	23.00	431.32 a	4.59
Excessive removal	18.96 b	18.12 b	12.97 b	21.23	352.43 b	4.27
SEM	0.053	0.063	0.326	0.463	13.168	0.112

In the research, there were not statistically difference in cluster weight and berry weight in terms of cluster characteristics. Nevertheless, cluster length (23.0 cm) and berry weight (4.59 g) was found in less leaf removal application. The leaf area of the vine has a great influence on the bunch quality (Drissi et al., 2009). According to Winkler et al. (1974), there is no negative effect on the vine making green pruning when leaf picking done at on time and the adequate level. Palliotti et al. (2012) determined that the grapevine leaves removed before flowering were formed smaller berries and thin clusters than no leaf removed. Gomez del Campo et al. (2002) reported that dry matter production with increased leaf area in vines was in the same range as stressed and stress-free conditions.

Table 2. The effects of less and excessive leaf removal on berry characteristics of "Trakya Ilkeren" grape variety

Leaf removal leves	TSS (Brix %)	Titratable acidity (%)	Maturity index	pH
No-removal	15.8 b	0.61 a	26.5 b	3.38
Less removal	16.4 a	0.55 b	29.5 a	3.41
Excessive removal	15.2 b	0.57 b	27.2 ab	3.42
SEM	0.180	0.560	0.566	0.011

The effects of less and excessive leaf removal on berry characteristics of "Trakya Ilkeren" grape variety are given in Table 2. There were found statistically difference between applications in terms of berry characteristics. While total soluble solids and maturity index values was found higher in less leaf removal, titratable acidity (0.61 %) was determined high in no- leaf removal application. While TSS was obtained as 16.4%, maturity index was determined as 29.5 in less leaf removal. The least TSS (15.2%) was measure at excessive leaf removal vines. While pH is close together, the highest pH (3.42) was obtained in excessive leaf removal. Poni et al. (2009), determined that leaf removal application in pre-bloom stage increased berry set, and thus yield per vine. Unlike Alessandrini et al. (2018) stated that, leaf removal in pre- bloom stage is an effective practice for modifying canopy microclimate, vine yield, grape composition and wine quality. Pre- bloom leaf removal enhanced canopy porosity, total soluble solids and reduced bunch thickness. Similarly Pallliotti et al. (2012) in Ciliegiolo wines; found that wines obtained from leaf removal applications in the early period

were better in terms of aroma and taste than wines of non-leaf removal applications. They determined that because of the higher amount of polyphenols and anthocyanins, the structure of the wines were enhanced, resulting in better color intensity.

Table 3. The effects of less and excessive leaf removal on berry skin color of "Trakya Ilkeren" grape variety

Leaf removal leves	*L**	*a**	*b**	*C**	*h°*
No- removal	34.53a	2.06a	-3.70b	4.42a	298.54a
Less removal	33.55b	1.40b	-4.01a	4.40a	293.66b
Excessive removal	33.43b	1.38b	-3.77b	4.11b	290.23b
SEM	0.064	0.036	0.032	0.029	0.535

The effects of less and excessive leaf removal on berry skin color of "Trakya Ilkeren" grape variety are given in Table 3. It was determined that there are statistically difference between applications in terms of berry skin colour. *L**, *a** and *h°* values was highest in no-leaf removal vines (Table 3). *L**, *a**,*C** and *h°* values was measured in no-leaf removal vines as 34.53, 2.06, 4.42 and 298.54, respectively. In the present study, the highest *b** and *C** values was determined in less leaf removal as 4.01 and 4.40, respectively. In the study, less leaf removal was favorable in terms of b* and c* value. Berry skin coloration was found higher in less leaf removal application due to high sun light exposure.

Conclusion

Leaf picking is made intensively for brine leaf production in Turkey. In the present study, excessive leaf picking was led to reduction in cluster and berry weight. Less leaf picking was found more successful in terms of cluster and berry characteristics. However, brine leaf growers attach more importance to leaf production rather than grape. Therefore, they do not give much importance to grape yield. Also, it is necessary to apply leaf removal from fruit set to veraison more ventilation and to benefit from sunlight.

Abstract

World health Organization defined Hypertension (also known as high or raised blood pressure) as a condition in which the blood vessels have persistently raised pressure. Hypertension is an important public health problem worldwide due to the high prevalence and the increased risk of accompanying disease. Hypertension is prevalent all over the world and has many diseases. So, for centuries, there have been medical developments for the treatment of this disease, as well as the use of herbal products. Herbal products used vary from country to country. However, some herbal products in countries are more known and used in hypertension. The aim of this study is to investigate the herbal products used in hypertension in the world and studies on possible side effects.

Keywords: *Herbal medicine, hyperetension.*

Introductıon

Hypertension, also known as high or raised blood pressure, is a condition in which the blood vessels have persistently raised pressure (WHO, 2018). Hypertension is an important public health problem worldwide due to the high prevalence and the increased risk of accompanying disease (Kearney et al., 2004). The prevalence is rapidly increasing due to increased lifetime and increased prevalence of contributory factors such as unhealthy nutrition, obesity and physical inactivity (Cappuccio and Miller, 2016). Untreated hypertension has been shown to increase cardiac failure, coronary heart disease, hemorrhagic and thrombotic stroke, renal failure, peripheral arterial disease, aortic dissection and mortality (TEMD, 2018; Pierdomenico et al., 2009). Raised blood pressure affects 1.13 billion people worldwide (WHO, 2017). There are about 970 million people all over the world suffering from hypertension. The prevalence of hypertension is approximately 2/3 in developing countries and 1/3 in developed countries (WHF, 2012). Low-income countries have a higher prevalence of high blood pressure. In the WHO African region, it is estimated that in many countries more than 30% of adults have high blood pressure and this rate is increasing. Also, the average blood pressure levels in this area are much higher than the global average (WHO, 2015).

BLOOD PRESSURE CATEGORY	SYSTOLIC mm Hg (upper number)		DIASTOLIC mm Hg (lower number)
NORMAL	LESS THAN 120	and	LESS THAN 80
ELEVATED	120 – 129	and	LESS THAN 80
HIGH BLOOD PRESSURE (HYPERTENSION) STAGE 1	130 – 139	or	80 – 89
HIGH BLOOD PRESSURE (HYPERTENSION) STAGE 2	140 OR HIGHER	or	90 OR HIGHER
HYPERTENSIVE CRISIS (consult your doctor immediately)	HIGHER THAN 180	and/or	HIGHER THAN 120

Figure 1. Blood Pressure Categories according to the American Heart Association (AHA/ASA)

(AHA/ASA, 2017)

Hypertension treatment

Both dietary and lifestyle changes as well as medicines can improve BP control and decrease the risk of associated health complications (Tabassum and Ahmad, 2011).

To Make important changes in the treatment of hypertension: a balanced diet having a low salt rate, regular physical activity, limited alcohol, stress management, healthy weight management, quit smoking, regular drug use, act with the doctor in disease management (AHA/ASA, 2017). Also; The benefits of the DASH diet on blood pressure have been demonstrated in many studies (Moore et al., 2001; Craddick et al., 2003; Salehi-Abargouei et al., 2013; Fung et al., 2008).

Currently, there are various antihypertensive drugs with different mechanisms of action. Although these medicines are effective, many of them may have very annoying side effects. It is generally stated that the use of herbal medicine is high for such reasons. In addition to these studies, the antihypertensive therapeutic effects of local herbs on hypertension have been investigated and some of them have been proven to be effective and some need further investigation.

Herbal medicines in the treatment of hypertension

An herb is a plant or plant part that is used for its odor, flavor or therapeutic properties. Herbal remedies are a kind of food supplements. They are sold as tablets, capsules, powders, teas, extracts and fresh or dried plants. People can choose herbal remedies to protect and improve their health. Most people think that products with a "natural" label are always safe and good (OMICS, 2014). The use of herbal products is regulated by the Food and Drug Administration (FDA) as a special food category and classified as "food supplements" according to the 1994 Dietary Supplement Health and Education Act (DSHEA) (Sellami et al., 2018). Herbal medicines are often used for clinical purposes. Ayurveda is a medical system practiced in India, especially since 5000 years. It includes diet and herbal medicines, while emphasizing body, mind and spirit to prevent and treat the disease (OMICS, 2014).

Traditional herbal medicine use is high among adults in Subh Sahra Africa (38.5%-90%) (Eddouks et al., 2002; Oreagba et al., 2011). In a study conducted in Palestine, this rate was about 59%. In 2000s, 20% of the population over 16 years of age in Germany used "natural medicines", and they stated that they were the first choice for the treatment of minor diseases or disorders. 1.8% of respondents in a study conducted in Turkey reported using herbal medicine due to high blood pressure (Soner et al, 2013).

Herbal products used in the world vary according to the vegetation, cultures and beliefs of the living geography. The most commonly used herbal product in Ghana is bitter leaves grown in the tropical climate, while Tİan Ma Gou Teng Yin believed to be a healing effect in Taiwan, gamat in Malaysia, garlic in Nigeria and Palestine, while lemon and garlic in Turkey (Kes et al., 2016).

It is also noted that the herbal medicines used in some studies may cause adverse reactions (Mahomoodally et al., 2018; Olisa and Oyelola, 2009; Liperoti et al., 2017). Depending on the quality of the product or when used with other medicines, traditional medicines can cause harmful side effects (Soner et al., 2013).

Table 1. The Most Common Herbal Medicines And Possible Side Effects In Hypertension

Herbel Medicines	Yan etkileri
Citrus Limonum (Açıkgöz et al., 2014; Adıbelli et al., 2009; Toprak and Demir, 2007; Biçen et al., 2012; Bahar et al., 2013)	Any side effects haven't been specified.
Allium sativum L (Açıkgöz et al., 2014; James et al., 2018; Liperoti et al., 2017; Bahar et al., 2013; Biçen et al., 2012)	The most common side effects are breath and body odor, heartburn, nausea and vomiting. People treated with antiplatelet or anticoagulant medications should be cautious.
Petroselinum sp. root (Açıkgöz et al., 2014)	Any side effects haven't been specified.
Garcinia cola (Olisa ve Oyelola, 2009; James et al., 2018)	Palpitations and heartburn
A. vera (Olisa and Oyelola, 2009; James et al., 2018)	Skin reactions (contact dermatitis) Kan şekerini düşürebilir (Latif Ahmad at all., 2015)
Matricaria recutita (James at all, 2018)	
Crataegus sp. (Liperoti et al., 2017)	In clinical trials, side effects are rare and light. Nausea, dizziness, gastrointestinal complaints, headache, and palpitation can be observed.

Conclusıon

Although different crops are used in different societies, it is also seen that some herbal products are common. Most hypertensive patients using herbal products do not inform their doctors that they use herbal products (Biçen et al., 2012; Bahar et al., 2013; Mahomoodally et al., 2018). Having the antihypertensive effect of the plants and knowing their toxicity will be useful for safe use (Neamsuvan et al., 2018). Unconsciousness and frequent use of herbal products can lead to disruption of the patient's actual treatment and side effects on these products (Biçen et al., 2012). The Ministry of Health, doctors, herbalists, dietitians and the media have important duties to direct the society in the right direction.

Abstract

In the study, 7 triticale, 3 bread wheat, 2 barley, oats and 1 rye varieties were used as material. Experiments were established in four different locations in terms of soil properties as a randomized block design with three replications. Sowing was made by hand on a length of 6 m to 1 m wide (17 cm row spacing and 6 row) 500 seeds per square meter plots. In the study, grain yield and green grass yield and hay yield were investigated. According to the results of average grain yield, ITYN 818, TT 201 and ITYN 819 triticale varieties had the highest grain yield while Presto 2000 and Tatlıcak 97 triticale varieties had the lowest yield. According to the results of two year grain yield, TT 201 and ITYN 818 triticale varieties in Agriculture Faculty location, TT 201, ITYN 818 and TR 2201 triticale varieties in Ortaca location (water holding land), TT 201, ITYN 818 and ITYN 819 triticales in Kılavuzlu location (arid and slope land) and TT 201 and Tatlıcak 97 varieties of triticale in Selçuklu location gave the highest yield. According to average green grass yield, Tatlıcak 97 and Karma 2000 triticale varieties had the highest, while TT 201 and ITYN 819 triticale varieties the lowest yield values. In terms of the average hay yield, the ITYN 819, Karma 2000 and TR 2201 were found to have the highest value while the TT 201, Presto 2000 and Tatlıcak 97 triticale varieties gave the lowest values.

Key words : *triticale, line, different soil conditions, grain yield, forage yield and hay yield*

Introduction

Triticale (X*Triticosecale*Wittmack) is an annual C3 cool-season grass within the Poaceae (Graminae) family (Kavanagh and Hall 2015). Triticale is an amphiploid species stably baring the genomes of wheat (*Triticum* sp.) and rye (*Secale*sp.) (Ammar et al. 2004). Triticale is an established small grain cereal crop that combines the productivity of wheat with the hardiness of rye. Triticale may be octoploid (2N = 56; AABBDDRR) or hexaploid (2N = 42; AABBRR) depending on which wheat is crossed with rye (RR), i.e., common wheat (AABBDD) or durum wheat (AABB). The large genome of octoploid is less stable and with the exception of Asia cultivars; most cropping triticale is hexaploid type (Ammar et al. 2004). As triticale cultivation areas in the world are analyzed considering the last 10 years' data, it can be determined that while it is approximately 3.2 million ha in 2002, it has raised to 4.16 million ha in 2016 with 30% increase (FAOSTAT, 2017). 80% of the world's triticale cultivation area is used for winter, and 20% for summer. While Poland has the widest cultivation area among the countries producing triticale with 1.4 million ha, Germany follows it with 396 thousand ha, and France with 334 thousand ha (FAOSTAT, 2017). For the fact that the ecological conditions in our country are quite suitable for other crops and the alternative products are easily cultivated, triticale production could not reach to the desired level. In our country since 2017, triticale has been sown on 37.6 thousand ha area and 125 thousand tons of grain product has been obtained (FAOSTAT, 2017).

The average grain yield of triticale (332 kg/da) in our country is higher than the average grain yield of wheat (270 kg/da), rye (263 kg/da), barley (248 kg/da) and oat (226 kg/da). Trakya region has quite suitable characteristics considering the cool climate grain production. The average yield of the cool climate grains produced in the region is much higher than the

country average. Sowing, production and yields of cool climate grains cultivated in our country and Trakya region are presented (TÜİK, 2017).

When the average grain yield of cool climate grains cultivated in our country is examined, it is obvious that triticale has higher yield with 332 kg/da compared to other cool climate grains. Korkut et al. (2009) in their study which is conducted with 9 triticale genotypes, 3 bread wheat cultivars, 3 durum wheat cultivars, 3 barley cultivars and 1 rye in three years and 3 different locations of Trakya region, revealed that triticale genotypes have average grain yield 30 kg/da higher than bread wheat cultivars, 95 kg/da higher than barley cultivars, 63 kg/da higher than durum wheat and 121 kg/da higher than rye cultivar. They also found out that the fodder yield of triticale genotypes is 523 and 106 kg/da higher than bread wheat cultivars, 1183 and 381 kg/da higher than durum wheat, 1749 and 409 kg/da higher than barley cultivars. Triticale is the most important candidate plant against both biotic stress factors such as disease and pests, and abiotic stress factors such as drought, high temperature and cold. The study was conducted at four locations as Ortaca village (water holding), Klavuzlu village (sloped), Selcuklu village (productive land) and Agricultural Faculty experimental area. The aim of the study is to compare triticale with other cool climate cereals in terms of grain yield and grass yield in different soil structures.

Material and method

The study was conducted by using 7 triticale, 3 bread wheat, 2 barley, 2 oat and 1 rye type in 4 different locations in the first year considering the soil characteristics, and 3 different locations in the second year. Some agricultural features of 7 triticale (Karma 2000, Tatlıcak 97, Presto, ITYN 818, ITYN 819, TT 201 and TR 2201), 3 bread wheat (Flamura-85, Pehlivan and Yunak), 2 barley (Sladoran and Epona), 2 oat (Yeşilköy 330 and TT 301) and 1 rye (Aslım-95) cultivars are presented in the Table 1.

The study was conducted according to the randomized block experiment design with 3 replicates. Sowing was made manually by using marker to the parcels 6 m length and 1 m width (17 cm row distance and 6 rows) as 500 seeds in per square meter. Some visuals of the trial field are given in Figure 1. Four kg/da pure nitrogen (20-20-0) for per decare with sowing, compound fertilizer, 6,9 kg urea (46%) as pure nitrogen in tillering-bolting period, and 5 kg ammonium nitrate fertilizer (33%) as pure nitrogen before heading were given.

Thus, 15.90 kg nitrogen (N) and 4 kg (P2O5) were applied per decare during vegetation. Pesticides were applied against grass weeds in tillering period.

Picture 1. Some images from trial areas

Grain yield: 5 m^2 parcel field was obtained by disposing of the plants at 0.50 m from the beginning and the end as edge effect in the parcels planted as 6 rows, and the grain yield values gained from these parcels were found as kilograms by transforming them into the yield per decare. Fresh yield: Fresh yield was found as gram by reaping the plants in 1.0 square meter in each parcel from 8-10 cm height in their milk stage, and this value was transformed into kg/da later. Hay yield: The dry matter ratio was found as gram by drying fresh plant samples taken from each parcel at 105 C^o for 24 hours, and this value was transformed into kg/da later.

Results and Discussion

According to the results in 2008 and 2009 years, location and genotypes on grain yield is considered as significant statistically (Table 2). While the highest grain yield was obtained from Selçuklu location experiment field with 583.00 kg, the lowest values were observed in Kılavuzlu location which is inclined and infertile with 394.62 kg.

Table 2. Average grain yield and significance groups at 4 different locations during 2 years

Locations	Grain Yield	Locations	Grain Yield
Selçuklu	583.00 a	Faculty	522.933 a
Faculty	531.889 ab	Selçuklu	479.533 b
Ortaca	505.578 b	Klavuzlu	437.356 c
Klavuzlu	394.622 c		
HKO	3146.770		228.465

The highest grain yield in 2009-2010 growing period was gained from faculty location with 522.93 kg/da, and the lowest results were observed in Kılavuzlu location with 437.36 kg. The results reveal that the soil structure of the cultivation location is very effective in grain yield.

The grain yield of 15 genotypes in two cultivation years and significance groups are given in Table 3. The grain yield values of 15 genotypes in 2008-2009 cultivation period change between 646.08-255.00 kg. While the highest grain yield was obtained from TT 201 triticale genotype with 646.08 kg, it was followed by ITYN 818 with 644.167 kg, TR 2201 with 637.75 kg, ITYN 819 with 608.33 kg and standard Tatlıcak 97 with 608.00 kg. Bread wheat, barley, rye and oat are not in the same statistical group with triticale. The lowest grain yield was obtained from Yeşilköy oat cultivar with 255.00 kg, and it was followed by TT 301 with 275.417 kg and Aslım rye cultivar with 362.58 kg.

The lowest grain yield was obtained from Yelişköy oat cultivar as in the first year, and it was followed by Sladoran barley and Aslım rye. The average values and significances of location x genotype interaction are presented in Table 4.

In the first year, location x genotype interaction was found as significant statistically. In the first year, the highest grain yield was gained from TT 201, Tatlıcak 97, TR 2201 and ITYN 818 genotypes in the Faculty of Agriculture location, ITYN 818TTR 2201, TT 201, ITYN 819 and Tatlıcak 97 in Ortaca location, ITYN 819, TT 201, ITYN 818 and TT 2001 in Kılavuzlu location, Tatlıcak 97, TT 201, TR 2201, Karma, ITYN 818 in Selçuklu location.

The data reveal that the highest grain yield values were obtained from triticale genotypes in three locations. The lowest grain yield was observed in Yeşilköy and TT 301 oat in 4 locations. These genotypes were followed by Aslım 95 rye and other barley genotypes. The average values and significances of location x genotype interaction in 2009-2010 cultivation period are presented in Table 5. Location x genotype interaction in 2009-2010 growing year was found as significant statistically. The highest grain yield was obtained in ITYN 818, ITYN 819, Karma 2000 and TR 201 genotypes at Faculty location, ITYN 818, ITYN 819, and TT 201 genotypes at Kılavuzlu location, ITYN 819, ITYN 818, Tatlıcak 97, Yunak bread wheat and TT 201 genotypes at Selçuklu location. The lowest grain yield was observed in Yeşilköy cultivar at 3 three locations, and it was followed by rye and barley genotypes. In the second year, triticale genotypes gave the highest grain yield values in those three locations.

Green Grass and Hay Yield

Fresh and hay yields were examined in the obtained data in Selçuklu location in both two years. As the fresh yield was examined, it was observed that in the first year 3.88 ton of yield and in the second year 3.36 ton of yield were gained in Table 6.

Table 6. Fresh and hay yields in both years and significance groups

Year	Fresh yield
2008-2009 years	3.878 a
2009-2010 years	3.364 b
HKO	0.040

Fresh yields of the genotypes changed between 4.37-2.43 ton/da in Table 7. The highest fresh yield was obtained from TT 2201 genotype with 4.37 ton, and it was followed by Tatlıcak 97 and Karma triticale genotypes with 4.20 ton.

Table 7. Fresh yield obtained from fifteen genotypes and significance groups

The highest hay yield was gained from ITYN 819, Karma and TR 2201 triticale genotypes with 1.50, 1.43 and 1.40 ton. The lowest hay yield was observed in Flamura 85 bread wheat cultivar with 0.87 ton, and it was followed by TT 301 and TT 201 oat cultivars with 0.93 and 0.95 ton. When the data are examined, it is revealed that triticale genotypes have higher fresh and hay yield compared to other cool climate cereals.

Conclusion

According to the results of the study which was conducted in at 4 different locations in the first year and 3 different locations in the second year, triticale genotypes gave higher grain yield, fresh and hay yield values compared to other cool climate cereals. While triticale genotypes gave higher values in infertile soil conditions, they have higher values in fertile soil conditions as well compared to other cool climate cereals. These results reveal that triticale should be preferred in every kind of soil conditions especially in the regions in which culture animal husbandry is densely made.

Abstract

In the study, plant and productivities of six pomegranate varieties and types ('Kışnarı', 'Kirli Hanım', 'Nuz Ekşi', 'Çekirdeksiz', 'Hicaz' and 'Oğuzeli Çekirdeksiz'') were evaluated. The experiment was designed according to completely randomized design with five replications having single tree in each replication. In this study, the plant specifications such as tendency suckers from the base, branching condition, spiny situation, canopy width and height, and productivity such as yield per plant (kg/plant), yield per unit canopy volume(kg/m^3), yield per shoot length (kg/cm), yield per canopy geometric projection (kg/m_2) were determined for pomegranate varieties and types. Fifteen and more suckers from the base were observed for all varieties and types. Kışnarı and Kirli Hanım varieties had often branching while others had mid often branching. Hicaz and Kirli Hanım had medium spiny while the others had more spines. Canopy width and heights of Kışnarı and Kirli Hanım cultivars were higher than those of other genotypes. Kışnarı, Nuz Ekşi and Hicaz varieties had more yield per plant (14.8 kg,13.7 kg ve 13.3 kg, respectively) than the others. Oğuzeli çekirdeksiz and Nuz ekşi had higher yield per canopy volume (5.85 kg/m^3 and 4.81 kg/m^3 , respectively) than the others while Nuz Ekçi and Hicaz had higher value than the other types and varieties for yield per canopy geometric projection (4.74 kg/m2 and 4.49 kg/m^2, respectively).

Keywords: *Punica granatum, suckers, spiny situation, yield.*

Introduction

The pomegranate belongs to the *Punica* genus of the *Punicaceae* family, whose better known species is the *Punica granatum L*. The pomegranate is one of the oldest known species of fruit and its cultivation dates back to 3000 BC. It is native to the regions between the South Caucasus, Iran, Afghanistan, South Asia, Western Asia, Anatolia and the Mediterranean (Vardin and Abbasoğlu, 2004). The pomegranate is one of the fruits delivering the highest harvest per unit area. It is easy and cheap to produce its saplings and keep it maintained. It delivers produce shortly after being planted. Turkey lies within the pomegranate's native region. It has very favorable conditions enabling its cultivation. This explains the ever-increasing production of pomegranate (Özkan, 1993). The total production amounted to about 2.5 million metric tons, according to the USAID Report. The same data showed that India is the world's biggest pomegranate producer (1,773.66 million metric tons for 2015; Anonymous, 2017) followed by Iran (about 1,000.00 million metric tons for 2015; Anonymous, 2015a). Among other countries engaging in pomegranate production are Turkey (465,200 metric tons for 2016; TÜİK, 2018), the USA (the total production amounted to 282.532 metric tons from 2012-2013; Anonymous 2015b), Spain, Iraq, Afghanistan, Azerbaijan, Uzbekistan, Israel, Tunisia, Morocco, China, Cyprus, Egypt, Peru, Chile, Argentina and South Africa (Kahramanoğlu and Usanmaz, 2016). Turkey is home to eleven agricultural regions where pomegranate cultivation is carried out. An examination into pomegranate cultivation based on these areas shows that the highest amount of production is carried out in the Mediterranean, the Aegean, and Southeastern Anatolia.

This study aims to define the productive and botanical properties of some of the pomegranate types and varieties grown in Gaziantep, Turkey.

Materials and Methods

Material

The study was carried out at a pomegranate orchard containing six different types and varieties of pomegranates belonging to the Pistachio Research Institute (Gaziantep/Turkey) between 2011and 2012. The experiment orchard is 705 m above sea level and 38^{o} 57' north longitude. The Kış Narı, Kirli Hanım, Nuz Ekşi, Çekirdeksiz VI, Hicaznar and Oğuzeli Çekirdeksiz pomegranates in the experiment orchard were planted at intervals of 1x5 m in 2006. The plants were irrigated by drip irrigation since their transplantation. Pomegranate plants were formed as shrubs form with 3-4 trunks. The experiment was designed according to completely randomized design with five replications having single tree in each replication.

Fruit Productivity Elements of the Varieties

With the yield (kg) per tree in all varieties in mind along with productivity, the fruit count was calculated by counting every single fruit seen on the tree in July and considering the yield per crown unit volume (Westwood, 1988). The yield per canopy projection area was designated using the formula πr^2.

Plant Properties

Suckers springing from the root collar were assessed based on a scale of 1 to 5: (Mars, 1995).

Suckering tendency	Scale Value
Extremely low	1
Low	2
Medium	3
High	4
Extremely high	5

Level of branching is designated based on a scale of 1 to 3:

Level of Branching	Scale Value
Frequent	1
Mean	2
Rare	3

Thorniness is designated based on a scale of 1 to 5:

Thorniness	Scale Value
Without thorns	1
Few	2
Mean	3
Many	4
Too Many	5

Result and Discussion

The findings related to the yield elements of the pomegranate types and varieties are given in Table 1.

Table1. Fruit yield components of genotypes

Genotype	Yield per tree (kg/tree)	Yield per shoot length (kg/cm)	Yield per unit canopy volume (kg/m^3)	Yield per canopy geometric projection (kg/m^2)	No. of fruits/tree (piece/tree)	
					July Count	Harvest Count
Kış Narı	14.82 a[(x)]	2.01 ab	2.61 bc	4.04 a	66 a	69 a
Hicaznar	13.33 ab	3.12 a	3.20 bc	4.49 a	61 ab	39 ab
Çekirdeksiz VI	7.15 b	2.14 ab	3.50 abc	3.98 a	18 c	22 b
Oğuzeli Çekirdeksiz	6.66 b	1.08 b	5.85 a	3.17 a	32 abc	49 ab
Kirli Hanım	9.22 ab	1.15 b	1.53 c	2.74 a	48 abc	50 ab
Nuz Ekşi	13.69 ab	1.10 b	4.81 ab	4.74 a	29 bc	27 b
Significance	*	*	*	NS[(y)]	*	*

[(x)]Means within a column followed by different letter are significantly at the 5% level by Tukey's HSD test.

(y): No significant.

Yield

The Kış Narı provided the highest yield per tree (14.82 kg/tree). This was followed by the Hicaznar (13.33 kg/tree) and Nuz Ekşi (13.69 kg/tree) varieties. The lowest yield was delivered by the Oğuzeli Çekirdeksiz (6.66 kg/tree) and Çekirdeksiz VI (7.15 kg/tree) varieties. Difference between the yield of the types and varieties per tree was found to be statistically significant at %5 level. A selection study carried out to determine the pomegranate varieties appropriate for the Aegean region designated the average yield of 13 pomegranate types as 10-29 kg/tree (Ercan et al., 1991). Yılmaz (2005) determined the average yield values as being between 6.16 kg/tree and 10.6 kg/tree in a trial carried out on seven pomegranate varieties. Among the other determinations are Hernandez *et al*. (2012), 26.11kg/tree in Spain; Korkmaz (2013), 29.20 kg/tree in Muğla; El-Sayed *et al*. (2014), 21.83 - 40.50 kg/tree in Egypt; Parvizi *et al*. (2014), 73.6 kg in Iran; Ibrahim and El-Samed (2009), 23.35 kg/tree in Egypt; Bakeer (2016), 39.64 kg/tree in Egypt; Davarpanah *et al*. (2016), 16.00 kg/tree in Iran; Selahvarzi *et al*. (2017), 24.88 kg/tree in Iran. Our research findings are consistent with the literature values.

Hicaznar cultivar had the highest value (3.12 kg/cm) in terms of the yield per shoot length . This was followed by the Çekirdeksiz VI (2.14 kg/cm) and Kış Narı (2.01 kg/cm) varieties. Three other genotypes were obtained 1kg/cm yield. The yield per unit canopy volume of the types and varieties varied between the Oğuzeli Çekirdeksiz (5.85 kg/m^3) and Kirli Hanım (1.53 kg/m^3). In Egypt, Ibrahim and El-Samed (2009) found the Manfalouty pomegranate variety's yield per unit canopy volume to be 3.00 kg/m^3 and in Iran, Selahvarzi *et al*. (2017) found the Shahvar variety's yield per unit canopy volume to be 2.88 kg/m^3 as the average of various applications. Difference between the varieties in terms of both the yield per shoot length and the yield per unit canopy volume was found to be statistically significant at %5 level. The yield of the types and varieties per canopy geometric projection was found to be between 4.74 kg/m^2 for the Nuz Ekşi and 2.74 kg/m^2 for the Kirli Hanım. The difference between yield per canopy geometric projection was not found to be statistically significant. Onur and Tibet (1991) reported that yield per m^2 of canopy projection of the Hicaznar variety in Antalya conditions is 22.78 kg/m^2. Zhu *et al*. (2005) stated in a study carried out in China

that the Hongyushizi variety's yield per canopy geometric projection was 3.31 kg/cm^2. Our research study findings are consistent with the literature values.

Number of Fruits/ Tree

Fruit counting was carried out in two different periods for different types and varieties. The counting performed in July revealed that the Kış Narı produced the highest number of fruits (66 pcs/plant) and the Çekirdeksiz VI produced the lowest number of fruits (18 pcs/plant). The counting performed in the harvest season also revealed a similar result with the Kış Narı giving the highest value (69 pcs/plant) and the Çekirdeksiz VI giving the lowest (22 pcs/plant). Difference shown by the varieties in both of the counting periods was found to be statistically significant at 5% level. Hernandez et al. (2012) stated that the number of fruits per tree was 86.04 pcs/tree in their study carried out in Spain; Bakeer (2016) stated that the number of fruits per tree for a 13-year-old Manfalouty variety in Egypt was 100.85 pcs/tree; Davarpanah *et al*. (2016) stated that the number of fruits per tree for an 8-year-old Ardestani pomegranate variety in Iran was 57.4 pcs/tree; Marathe *et al*. (2017) gave the value of 18.9 pcs/tree for the Bhagwa variety in India; and Selahvarzi *et al*. (2017) provided the average value of 101.17 pcs/tree for the Shahvar variety in Iran. It can be stated that the average values we obtained are within the data ranges stated by our country's researchers.

Plant Properties

The findings related to the botanical properties of the genotypes can be found in Table 2.

Table 2. Tree properties of genotypes

Genotype	Tendency to sucker	Branching state	Thorn volume	Width of canopy (m)	Canopy height (m)
Kış Narı	Too many (5)	Frequent (1)	Many (4)	2.19 a$^{(x)}$	2.23 a
Hicaznar	Too many (5)	Mean (2)	Mean (3)	2.09 ab	2.19 a
Çekirdeksiz VI	Too many (5)	Mean (2)	Many (4)	1.51 c	1.53 c
Oğuzeli Çekirdeksiz	Too many (5)	Mean (2)	Many (4)	1.48 c	1.69 bc
Kirli Hanım	Too many (5)	Frequent (1)	Mean (3)	2.41 a	2.12 a
Nuz Ekşi	Too many (5)	Mean (2)	Many (4)	1.65 bc	2.05 ab

$^{(x)}$Means within a column followed by different letter are significantly at the 5% level by Tukey's HSD test.

It was determined that all of the genotypes have too many tendency to bottom branches (15 and above). It was observed that the Kirli Hanım and Kış Narı have a frequent branching structure, while the other varieties have a branching structure of medium frequency. It was also found that the Kış Narı, Çekirdeksiz VI, Oğuzeli Çekirdeksiz and Nuz Ekşi are too thorny while the Hicaznar and Kirli Hanım have medium thorniness. In a study on Hicaznarin tree properties in Antalya(Turkey) conditions; Onur and Tibet(1991) determined base shoot growth as being too high, level of branching as being medium, and thorniness as being of mid-frequent structure. Our study is also consistent with such data.

Canopy width and heights

The canopy height of the genotypes was determined as being between 2.41 m for the Kirli Hanım and 1.51 m for the Çekirdeksiz VI. The width of canopy values were measured between 2.23 m(for the Kış Narı) and 1.53 m(for the Çekirdeksiz VI). Difference shown by the varieties in terms of both the width of canopy width and height was found to be statistically significant at 5% level. Onur and Tibet (1991) determined the four-year average value of canopy height in Antalya as being 2.43 m and width of canopy as being 2.36 m; Abdelaty and Gamal (2009) determined the tree canopy height of the Manfalouty variety in Egypt as being 2.45 m; and Bakeer (2016) found the tree canopy height for the 13-year-old Manfalouty variety in Egypt to be 3.18 m. In Egypt, Ibrahim and El-Samed (2009) stated the Manfalouty pomegranate variety's width of canopy as being 2.45 m. Our study also generated similar results.

Abstract

This study was carried out at the pomegranate experimental orchard of Pistachio Research Institute in Gaziantep, Turkey. The objective of the study was to determine phenological and pomological characteristics of various pomegranate cultivars and types. Altitude of the experimental site was 705 m a.s.l. (38° 57' N). In the experiment, six pomegranate types and cultivars ('Kışnarı', 'KirliHanım', 'Nuzekşi', 'Çekirdeksiz', 'Hicaz', 'Oğuzeli Çekirdeksiz') were used. The experimental cultivars were planted on 1 x 5 m in 2006 as one-year-old plants. The plants were irrigated by drip irrigation since their transplantation. Pomegranate plants were formed as shrubs form with 3-4 trunks. The experiment was designed according to completely randomized design with five replications having single tree in each replication. In the study, some phenological observations (first flowering, full flowering and as well as fruit maturation date) fruit pomological analyses [such as fruit weight (g), fruit size (mm), seed weight (g), soluble solid (SS) (%), titratable acidity (%), pH, and fruit cracking ratio (%)] were determined. Fruits were harvested between 5 October and 11 November. The cultivars and types had a range of 168-453 g for fruit weight, 52-61% percent arils, 30-49% juice rate, 13.8-16.5% total soluble solids (TSS), 0.21-1.23% titratable acidity and 17-56% cracking rate.

Keywords: *Punica granatum, fruit characteristics, phenological stage.*

Introduction

The pomegranate is a tropical and sub-tropical plant grown in the Mediterranean, the Aegean and Southeastern Anatolia, up to 1000 m above sea level as a characteristic plant of the Mediterranean climate (Kurt and Şahin, 2013). Turkey had large swathes of land where pomegranates can be cultivated, adding that there was now an even greater capacity in Southeastern Anatolia with the completion of the GAP project and the increase of irrigation facilities. There is no precise data on pomegranate production areas and production quantities in the world. According to the USAID Report, total pomegranate production in 2008 equaled around 2.5 million metric tons (Kahramanoğlu and Usanmaz, 2016). Today, pomegranates are grown in the USA, Afghanistan, China, Morocco, Palestine, India, Iraq, Iran, Israel, Italy, Cyprus, Egypt, Syria, Saudi Arabia, Thailand, Tunisia, Turkey and some other countries. The global pomegranate trade is conducted on a small scale. Spain, Tunisia and Turkey are exporters of pomegranates. Pomegranate production in Turkey was 465,200 metric tons in 2016. Pomegranate cultivation is most widespread in the Mediterranean Region, followed by the Aegean and Southeastern Anatolia (TUİK, 2018). The aim of the study is to determine the phenological and pomological properties of the pomegranate varieties and types included in the experiment.

Materials and Methods

The study was carried out at a pomegranate orchard containing six different types and varieties of pomegranates belonging to the Pistachio Research Institute (Gaziantep/Turkey) between 2011 and 2012. The Kış Narı, Kirli Hanım, Nuz Ekşi, Çekirdeksiz VI, Hicaznar and Oğuzeli Çekirdeksiz pomegranate cultivars in the experiment orchard were planted at

intervals of 1x5 m in 2006. The plants were irrigated by drip irrigation since their transplantation. Pomegranate plants were formed as shrubs form with 3-4 trunks. The experiment was designed according to completely randomized design with five replications having single tree in each replication. In the study, some phenological observations (first flowering, full flowering and as well as fruit maturation date) fruit pomological analyses [such as fruit weight (g), fruit size (mm), seed weight (g), soluble solid (SS) (%), titratable acidity (%), pH, and fruit cracking ratio (%)] were determined. Flowering observations for varieties and types were made according to Özgüven (1997).

For the pomological analyzes, a total of 15 fruits were randomly selected from each variety at each maturity stage, and the analyzes were conducted according to completely randomized design with three replications having five fruits in each replication. The average fruit weight was determined by weighing the fruits one by one on a digital scale sensitive to 0.01g and classified into five categories [Very Small (<100g); Small (100-200g); Medium (200-300g); Large (300-400g); Very Large (> 400g)] (Mars, 1995). The fruit width, fruit length, and the skin thickness were measured using a Mitutoyo digital caliper sensitive to 0.01mm.

Total Soluble Solids (TSS %): The pomegranates were separated into four pieces with a steel knife and manually husked so as not to damage the texture of the arils. The juice from the arils was obtained by filtration through a cheesecloth. The total soluble solids was measured from this filtered juice using an Atago branded digital refractometer (NAR-1T, Atago, Japan). The results were expressed in percentages.

Titratable Acidity (%): Ten ml were taken from the above juice samples and 90 ml of distilled water was added to the 100 ml test tube. Acidity percentage was calculated in terms of citric acid type from the value determined by titration of this solution with 0.1N NaOH, according to Karacali (1990). Titration was determined with a Hanna branded pH meter (pH 211 RI, USA).

Aril Juice Content (%) and Skin Water Content (%): After the arils and skins of 10 cracked and uncracked fruits from each variety were separated after the harvest, they were dried in a drying oven until reaching their fixed weight and the obtained dry aril and skin weights were compared to the weights of the fresh arils and peels to determine the aril juice and peel water content (Yılmaz, 2005).

Results and Discussion

Phenological Observations

The phenological analysis results of the genotypes in the trial are given in Table 1. As seen in the Table 1, differences were observed between genotypes. Wood bud burst started between 21-23, March. Similarly, wood buds were observed to sprout between 28-30 March. The date of the first appearance of flower buds was between 25 April and 1 May. The first flowering was occurred between 19-30 May. Full blooming of the genotypes occurred between May 31 and June 7. When reviewed in general, both in terms of the appearance and sprouting dates of the buds, as well as the first flowering and the full flowering dates, the Hicaznar and Kirli Hanım were found to be early bloomers in comparison to other genotypes.

The sprouting of the Hicaznar buds was found to start on March 2, the first appearance of the flower buds on April 9, the first flowering on May 5, maximum flowering on May 24, fruit ripening on October 15, yellowing of the leaves on November 25 and the falling of the leaves on December 13, under Antalya ecological condition, Turkey (Onur and Tibet, 1991). The difference in timings is due to the different ecological characteristics of the regions.

Pomological Analyzes

The 2011 and 2012 results from the pomological analyzes of the varieties and types included in the experiment are are given in Table 2. The highest values of fruit weight (454.71g), fruit width (93.40 mm) and fruit length (80.31 mm) were obtained from the Nuz Ekşi variety,

followed by the Hicaznar and Çekirdeksiz VI. The lowest values in terms of all three properties were obtained from the Oğuzeli Çekirdeksiz variety. In terms of varieties and types, these properties were considered statistically significant at the level of 5%. Polat et al. (1999) determined the fruit weight of five different types of pomegranates grown in the region of Hatay/Kırıkhan to be 250.00-461.00g; Korkmaz (2013) found the average fruit weight of the pomegranate type Hicaznar grown in Muğla to be 454.32-557.51g according to different application results; El Sayed et al. (2014) found the average fruit weight of the Manfalouty pomegranate grown in Egypt to be 339-413g according to different application results; and Dandachi et al. (2017) found that fruit weights ranged between 43.15-358.60g in a study conducted in Lebanon. The average fruit weights of the varieties and types in this study had fruit weights ranging between 173.09-454.71g showing a large variation similar to the previous studies conducted in our country.

The highest value was obtained from the Hicaznar type (671.72 pieces/fruit) in terms of the number of fruit seeds, followed by the Nuz Ekşi (564.50 pcs/fruit) and Çekirdeksiz VI (531.49 pcs/fruit). The lowest value was obtained from the Kirli Hanım variety (374.00 pcs/fruit). Differences between the numbers of arils in the genotypes were found to be statistically significant at the level of 5%. In a trial conducted on seven types of pomegranates, Yılmaz (2005) found that the type containing the highest number of arils was the Hicaznar (594.6 pcs), and that the type containing the least number of arils was the İzmir 16 (295.2 pieces). Korkmaz (2013) found that the number of arils ranged between 606.807-713.002 pcs/fruit in different trials conducted on the Hicaznar in Muğla, while Tapia-Campos et al. (2016) found the least number of arils in the Manzanita (414.8 pcs), and the highest number of arils in the Chichona (823.9 pcs) in a trial conducted on 14 different types of genotypes in Mexico. In this study, the highest number of arils among all the varieties and types was obtained from the Hicaznar. The peel percentage of varieties and types ranged from 36.71%-39.41%; aril ratio from 55.68%-59.67%; while fruit juice yield ranged between 45.51%-48.8%. However, such differences between the types and varieties were not found to be statistically significant. Tehranifar et al. (2010) found that the average peel ratio of 20 types of pomegranates in Iran ranged between 32.28-59.82%, the aril ratios between 37.59-65.00% and the fruit juice yield between 26.95-46.55%. Korkmaz (2013) found that the Hicaznar had a peel ratio of 50.70% and a aril yield ranging between 45.41-51.82 % in the first year of the trial and 40.69-50.11% in the second year of the trial in Muğla, while she found that the fruit juice yield ranged between 35.20-40.83% in the first year and between 32.19-37.94% in the second year. Bakeer (2016) found that the Manfalouty had a peel ratio of 42.70% and aril yield ratio of 57.3% and Selahvarzi et al. (2017) found that the Shahvar had a fruit juice yield of 36.47% in Iran. It can be stated that the mean values we obtained are within the data ranges found by other researchers. The peel thickness was the highest (4.25 mm) in the Hicaznar and the lowest (2.87mm) in the Oğuzeli Çekirdeksiz. The peel thickness of the other types and varieties was found to lie between these two values. Differences found in the peel thickness of the types and varieties were found to be statistically significant at 5%. The total soluble solids (TSS) of the varieties and types varied between 16.48% (Hicaznar) and 14.03% (Nuz Ekşi) and the titratable acid amount varied between 1.31% (Nuz Ekşi) and 0.24% (Çekirdeksiz VI). The differences between the types and varieties in terms of total soluble solids and titratable acidity values were statistically significant. In a study covering six types of pomegranates in Morocco, Martínez et al. (2012) found that the total soluble solids ranged between 15.3-17.6% °Brix, and the acidity value between 2.1-4.7g/l; Korkmaz (2013) found that the total soluble solids in the Hicaznar ranged between 13.35-14.80% and the titration between 1.66-2.14% in different trials conducted in Muğla; Bakeer (2016) found that the Manfalouty had a total soluble solids of 16.29% and a titratable acidity rate of 1.34%; and Marathe et al. (2017) found that the Bhagwa had a total soluble solids of 15.21% and a

titration rate of 0.42% in India. Our research findings are consistent with the literature values. Tehranifar et al. (2010) reported peel thicknesses of 3.13-5.36 mm in Iran; El Sayed et al. (2014) found that the Manfalouty in Egypt had a peel thickness of 0.31-0.40 cm; and Dandachi et al. (2017) reported peel thickness as ranging between 0.10-0.34cm. Our research findings demonstrate a compliance with the values found in other studies.

While the aril juice content of varieties and types showed significant difference in physically uncracked fruits, they yielded similar values in cracked fruits. Yılmaz (2005) determined that there was no significant difference in aril juice content between cracked fruits and uncracked fruits when studying the average cracking ratio of pomegranate varieties. This study also showed similar results. On the other hand, the fruit peel juice content showed statistically significant differences in both types of uncracked and cracked fruits. Yılmaz (2005) reports that the cracking of pomegranate varieties and the average fruit peel juice differences between types of uncracked fruits are statistically significant and that the aril juice content amount of cracked fruits (65.87%) is lower when compared to uncracked fruits (69.04%). This study also showed similar results. The cracking rates of different varieties and types ranged from 57.05% (Kış narı) to 24.50% (Çekirdeksiz VI). Differences found in the cracking rates of the types and varieties were found to be statistically significant at 5%. In a study conducted in Izmir, Ercan et al. (1991) found that the cracking rates of types ranged between 1.41 and 26.64%; Özgüven et al. (1997) found that the cracking rates ranged between 0.9-24.7% in adaptation trials conducted between 1993-1997 for different types of pomegranates in Southeastern Anatolia; and Yılmaz (2005) found the rate of cracks to be 22.8% in the first year on average and 13.0% in the second year, tantamount to a decrease of almost half, and 5% in the third year in a study showing rates of cracks in fruits over the years.

Conclusion

The fact that the cracking ratios of varieties and types examined in this study are high compared to similar studies may be due to the fact that the day and night temperature difference of the region was high on the date of fruit ripening, that the upkeep of the orchard had been neglected for many years, that there was rainfall during harvest time, that the orchard was founded on rocky and stony terrain and that the plants were planted at close intervals.

THE EFFECTS OF DIFFERENT POTATO GENOTYPES YIELD CHARACTERISTICS OF DIFFERENT ALTITUDES

Gungor YILMAZ, Yasin Bedrettin KARAN*

Department of Crop Science, College of Agriculture, Gaziosmanpasa University, 60250, Tokat, Turkey
*Corresponding author: ybkaran@gmail.com

Abstract

This research was carried out in Tokat-Erbaa (230m), Tokat-Kazova (640m) and Tokat-Artova (1200m) in 2017 in Turkey. In different maturity groups 20 potato genotypes were used in the study. Fifteen (15) of these genotypes were advanced breeding clones and it was aimed to determine the responses of these clones to different altitudes. The experiment was established in the randomized complete block in a split plot design with three replications. According to the results of the research, Agria variety (4142.25 kg/da) and GOU-7/12 clone (4093.25 kg/da in Tokat Erbaa, Agata variety (3928.4 kg/da) and GOU6/28 clone (3927.7 kg/da) in Tokat Kazova and PAI-8.16 (4930.6 kg/da), PAI-8.8.57 (4695.7 kg/da) in Tokat Artova were determined as higher yielding other genotypes. It has been determined that the tuber yields per decare from the early season to the high altitude towards the late season increases from the low altitude to the late season.

Keywords: *Potato, tuber yield, altitude.*

Introduction

Potato, which is second main nutritional product of human nutrition after wheat, is orginated from high plateau of Ant mountain of South America Continent. It has been cultivated for 8000 years in the world. There are 2000 species of genus *Solanum* including potato and 160-180 species of them produced tuber. Eight species were used as food source in human nutrition. *S. tuberosum* is the most common species growen in the world (Rowe 1993). Potatoes are grown in a wide range of environments (Haverkort, 1990). The highest potential and actual tuber dry matter productions and yield are obtained in areas with temperate climates in North-western Europe and the North-west of the United States (Van der Zaag, 1984; Stol et al., 1991), thanks to long growing seasons combined with adequate cropping practices. The potential production and the ratio between actual and potential production are lower in tropical and subtropical climates. Part of this difference originates from the use of cultivars that are high yielding in temperate regions but are not adequately adapted to the high temperatures and short day length of tropical and subtropical climates. Another cause of the lower yields may be the shorter growth cycles due to unsuitable weather conditions in these climates. Some of the factors effecting high quality seed potato production are as follows; healthy beginning materials, altitute of production area and free of diseases and pests, experience level of growers, and production techniques (Yılmaz 2003). For healty seed tuber production, growing area should be free of pathogens or effective disease management programs should be performed (De Bokx and Mooi 1974; O'brien and Allen 1986) additionaly soil preparation, planting, cultivation, pest management, vine killing, harvest, and storage techniques also important for healthy seed tuber production(Sahtiyancı 1990; Tugay et al. 1995). The objective of this research was to test performance, yield and dry matter content of different potato genotypes and cultivars in various environments at different altitudes. A set of fifteen promising clones and five commercially available cultivars was tested in field trials at Tokat-Erbaa, Tokat-Kazova and Tokat-Artova conditions in 2017.

Material and Methods

This research was carried out in Tokat-Artova (1189 m), Tokat-Erbaa (276 m), Tokat-Kazova (571 m) and Tokat-Artova conditions in the 2017 vegetation periods. The material used in the experiment is composed of 16 promising clones and 5 commercial varieties (Agata, Alegria, Agria, Lady Claire, Lady Olimpia). The experiment was laid out in Randomized Complete Block Design, with three replications. The planting was carried out in Erbaa in the second half of April in Kazova in early March and in the first half of May in Artova. Potato tubers were planted at spacing of between rows and plants 70 cm and 30 cm respectively. The trials were fertilized 12kg/da 15:15:15 (N:P:K) at the time of planting in both locations. 8 kg/da N was applied 45 days after planting (Tugay et al., 1995). The plants were irrigated as required to maintain adequate moisture levels by drip irrigation. When cultural and chemical methods are needed to combat diseases and pests, necessary applications have been made.

Results and Discussion

Total Tuber Yield (kg/da): Total tuber yield were significantly affected by genotypes and various locations (Table 1). The Total tuber yield of genotypes were ranged between 908.1 kg/da and 4142.3 kg/da in Erbaa, between 1776.9 kg/da and 3772.4 kg/da in Kazova, and between 744.0 kg/da and 4930.6 kg/da in Artova (Table 1). The highest total tuber yield was obtained from Agria in Erbaa. The highest total tuber yield was obtained from Agata and GOU 6/28 in Kazova. The highest total tuber yield was obtained from PAİ-8-1-6 in Artova.

Mean comparison among tuber yield indicated that PAİ-8-8-57 and Algeria consisted of higher tuber yield than other genotypes. The highest total tuber yield was obtained of respectively Artova, Kazova and Erbaa. Results of total tuber yield showed that differences among different genotypes were significant (P<0.01). **Dry Matter Content (%):** In this study, the dry matter contents of the tubers were given in Table 2. Accordingly, the overall average of the tubers in terms of the dry matter content % 20,7 in Erbaa, %18.7 in Kazova, % 18.2 in Artova.

Conclusion

Dry matter contents of the 15 advanced clones and standard varieties differed from each other as well as from each other. In this study, the dry matter content of the genotypes ranged from 16.9 to 22.1 %. in all locations. The highest dry matter content was obtained from clone PAI-8-7-49. The dry matter content was determined significant in the all locations.

Abstract

This study was done as a part of the studies carried out on breeding potato varieties adaptable to central-north intersectional region. This study started in 2007, with about 20 thousand hybrid potato seedlings and as a result of clonal selection. Twenty clones, performing excellent characteristics in terms of yield and quality characteristics, were subjected to the analysis of stability in terms of genotype x environment interactions. The study was conducted under Tokat-Niksar, Tokat-Kazova (2012-2013) and Tokat-Artova (between 2011-2012 and 2012-2013) conditions as a randomized complete block design with 3 replications in 8 different environments, as the years and locations were accepted as an environment. In the study, four commercial varieties were tested as standards beside white, cream, light yellow and dark yellow clones. The data were subjected regression analysis. Based on the Finlay-Wilkinson regression coefficients, some of the clones (A7-12, T5-4, T11-10, T5-14, A3-15, A3-167, and T10-8) which had better yield and quality characteristics than commercial varieties, showed good adaptation to specific environments while the clones (T6-28 and A3-234) had good adaptation to all the environments (Tokat-Niksar, Tokat-Kazova, and Tokat-Artova). Also in terms of dry matter, A13-1 was identified as a clone with higher (28.4%) dry matter contents.

Keywords: *Potato, Clone Selection, Solanum tuberosum, Breeding, Stability Analysis.*

Introduction

Successful new varieties must show high performance in respect to yield and other essential agronomic traits. Moreover, their superiority should be reliable over a wide range of environmental conditions. The basic cause of differences between genotypes in their yield stability is the wide occurrence of genotype-environment interactions (GxEinteractions) i.e. the ranking of genotypes depends on the particular environmental conditions where they are grown. These interactions of genotypes with environments can be partly understood as a result of a differential reaction to environmental stress factors like drought or diseases, and consequently resistance breeding is of significance in improving yield stability (Becker and Leon, 1988). As a matter of fact, studies were carried out by different researchers in different agro ecological regions of the world have resulted in significant differences between genotypes in terms of yield and quality in the conditions of the region and it has been concluded that the most suitable genotypes should be determined for regional conditions [Caesar et al., 1978; Yılmaz and Tugay, 1999]. Potato is an important source of food which contains high levels of carbohydrate, protein, vitamins and minerals. It is also a source of income and employment opportunity in developing countries (FAO, 2016). In addition to high yields, the dry matter content of the tubers is considered an important quality criterion. This property is more important in terms of obtaining economically processed products and nutrient content of the industry. Potato tubers contain between 18 and 28% dry matter, depending on the variety and environment. The most important part of dry matter is starch. According to cultivars and growing conditions, 70-80% of dry matter is starch. On the other hand, 1.7-2.5% of protein is found in potato tubers and about 8% of dry matter is protein. Potato is the fourth most important plant used as a carbohydrate source in human nutrition. Varieties containing more than 16% starch are evaluated in the starch industry (Er and

Uranbey, 1998). The process of starch accumulation is expected to be profoundly dependent on the genotype and environmental conditions. Similar to other important agronomic traits, genotype (G), environment (E), and genotype by environment interaction (GEI) effects can be important to understanding the biochemistry and physiology behind starch development. GEI are common for multigene traits, such as starch content, and are important to understanding underlying sources of variation. Temperature, pH, and nutrient levels are important for maintaining plant health and subsequent starch accumulation (yield) throughout the growing season. The objective of this research was to test performance, stability of starch and dry matter content of different flesh color tubers in various environments. A set of 16 promising clones and four commercially available cultivars and one local genotype was tested in field trials at Tokat-Niksar, Tokat-Kazova (2012 - 2013) and Tokat-Artova (between 2010-2011 and 2012-2013) conditions. In order to determine genotypes with stable expression of traits and to examine possible differences in stability, analysis of yield, quality, and GEI was undertaken (Finlay and Wilkinson, 1963).

Material and Methods

This research was carried out in Tokat-Artova (1189 m) during the 2011 and 2012 vegetation periods and Tokat-Niksar (276 m), Tokat-Kazova (571 m) and Tokat-Artova conditions in the 2012 and 2013 vegetation periods. The soil reaction of the trial field is mildly alkaline. The material used in the experiment is composed of 16 promising clones and 4 standard varieties (Başçiftlik Beyazı, Slaney, Hermes and Agria) with different flesh colors selected as a result of the studies carried out within the scope of TUBITAK project 106 O 626 initiated in 2007 (Table 1). The experiment was laid out in Randomized Complete Block Design, with three replications. The planting was carried out in Niksar in the second half of April in Kazova in early March and in the first half of May in Artova. Potato tubers were planted at spacing of between rows and plants 70cm and 30 cm respectively. The trials were fertilized 12kg/da 15:15:15 (N:P:K) at the time of planting in both years and locations. 8 kg/da N was applied 45 days after planting (Tugay et al., 1995). The plants were irrigated as required to maintain adequate moisture levels by drip irrigation. When cultural and chemical methods are needed to combat diseases and pests, necessary applications have been made. After harvest, the tubers were stored for 8 weeks. Dry matter content was assessed as underwater weight (UWW), which can be converted into specific gravity (SG) by the formula: SG = 5000/(5000-UWW) (Meijers & Van Veldhuisen, 1972). Underwater weight was determined for each experimental unit, standardized to an underwater weight of 5 kg tubers in air.

It was determined the regression coefficient by regressing variety mean on the environmental mean, and plotting the obtained genotype regression coefficients against the genotype mean

yields [6]. According to Finlay and Wilkinson (1963), regression coefficients approximating to 1.0 indicate average stability. When the regression coefficients are approximating to 1.0 and are associated with high yield mean, genotypes are adapted to all environments. When associated with low mean yields, genotypes are poorly adapted to all environments.

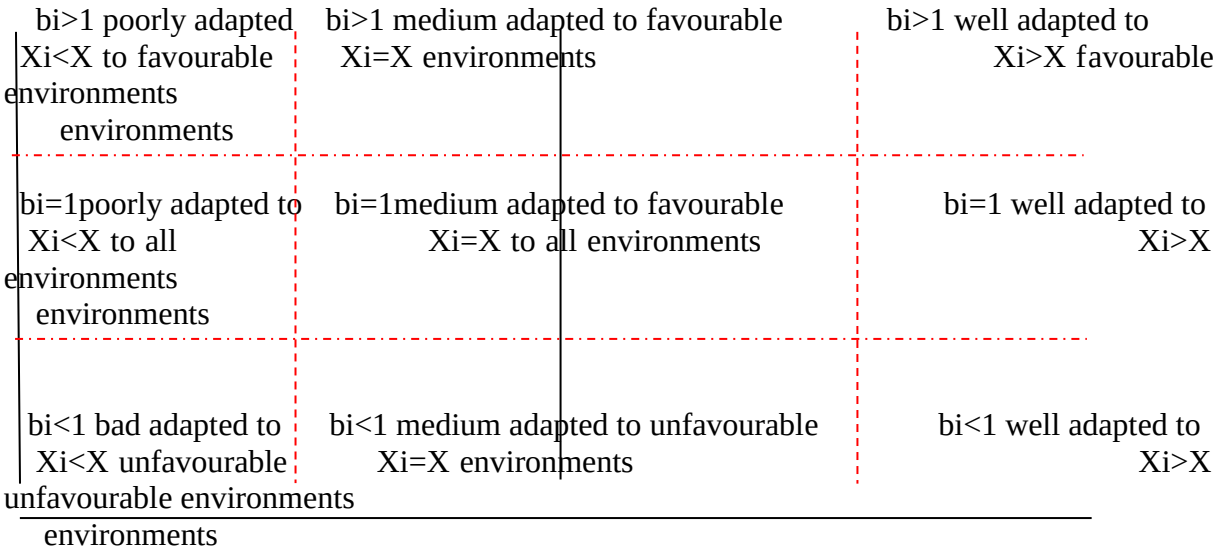

Figure 1. A generalized interpretation of the genotypic pattern obtained when genotypic regression coefficients are plotted against genotypic mean adapted from Finlay and Wilkinson, 1963.

Results and Discussion

Dry Matter Content (%)

In this study, the dry matter contents of the tubers were given in Table 2. Accordingly, the overall average of the tubers in terms of the dry matter content % 21,65, average of commercial cultivars were % 21,42 and average of advanced clones were % 22,03. Dry matter clones of the 16 advanced clones and standard varieties differed from each other as well as from each other. In this study, the dry matter content of the clones ranged from 17.2 to 28.4%. The highest dry matter content was obtained from clone A13-1(flesh color white).

According to flesh colors, the highest dry matter content was obtained from A13-1 clone (%28,4) in whites for all colors. Also the highest dry matter was obtained from A3-167 (% 24.50) in light yellows, the highest dry matter content was obtained from A3/368 (% 24.60) in the dark yellows. The dry matter content of the cream colors was lowest (17.2-20.2%) in all clones in this study. As for the locations, when ranking in terms of yield it was determined that Artova (22,86 %), Kazova (21,99 %) and Niksar (20,40%).

The highest dry matter content was determined from A13/1 in all locations and environments. It has been reported that the content of dry matter and starch varies not only with the genetic characteristics of the variety but also under the effect of environmental practices during production. It has been reported that late maturity varieties produce higher dry matter and starch content in cool climatic conditions and high altitude locations. In addition differences in quality of seed tubers affect the content of dry matter and starch (Yılmaz and Karan, 2011).

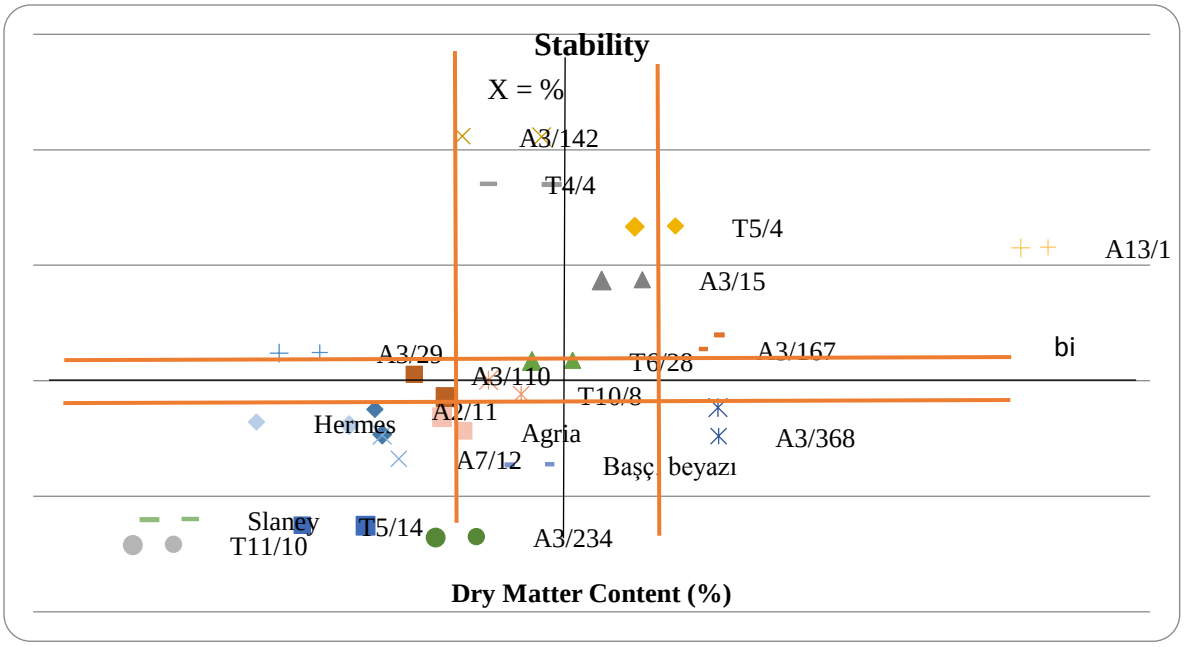

Figure 2. Adaptation classes of clones and varieties dry matter content (%)

Meanwhile, when all the environmental were examined separately, it was seen that some clones could have a dry matter content of over 23%. These clones have the potential to be evaluated as clones with high dry matter content. For example, These are A13-1, A3-368 (24,6%), A3-167 (24,5%), T5-4 (23,5%) and A3-15 (23,1%). All of the clones had higher dry matter content than standard commercial varieties in all environments (Table 3).

When the dry matter contents obtained from this study were examined in terms of genotype x environment interaction and stability, the regression coefficients ranged from bi = 0.29 to 2.06. T6-28 clone had better compatibility than other clones in terms of dry matter content. That is, as it was above the average dry matter content in different environmental conditions, it was the genotype that underwent minimal change. The average dry matter content of this clone (T6-28) in all environmental was above the general average and the regression coefficient was closest to bi = 1 (Table 2 and Figure 2). When the adaptation in terms of dry matter content was investigated, T5/4, A13/5 and A13/1 had high dry matter content in the favorable condition, A3/142 and T4/4 showed medium adaption in the favorable condition, A3/29 had low dry matter content in the all environmental. A2/11, A3/110, T10/8 and T6/28 were medium adapted in the all environmental. The A3/167 clone was a clone that can be regarded as a stable material, such as T6-28, in terms of dry matter content when confidence limits were taken into consideration. Slaney, Hermes varieties and T5/14 and T11/10 clones were bad adapted to unfavorable environmental. Agria, Basciftlik Beyazi cultivars and A7/12 and A3/234 clones showed medium adapted to unfavorable environmental. The A3/368 clone has been identified as a well clone that is it had high dry matter content even in unfavorable environmental.

Starch Content (%)

In this study, the dry matter contents of the tubers were given in Table 3. Accordingly, the overall average of the tubers in terms of the starch content % 15,88, average of commercial cultivars were % 14,38 and average of advanced clones were % 16,03. Starch content of the 16 advanced clones and standard varieties differed from each other as well as from each other. In this study, the starch content of the clones ranged from 11.7 to 22.6%. The highest starch content was obtained from clone A13-1(flesh color white).

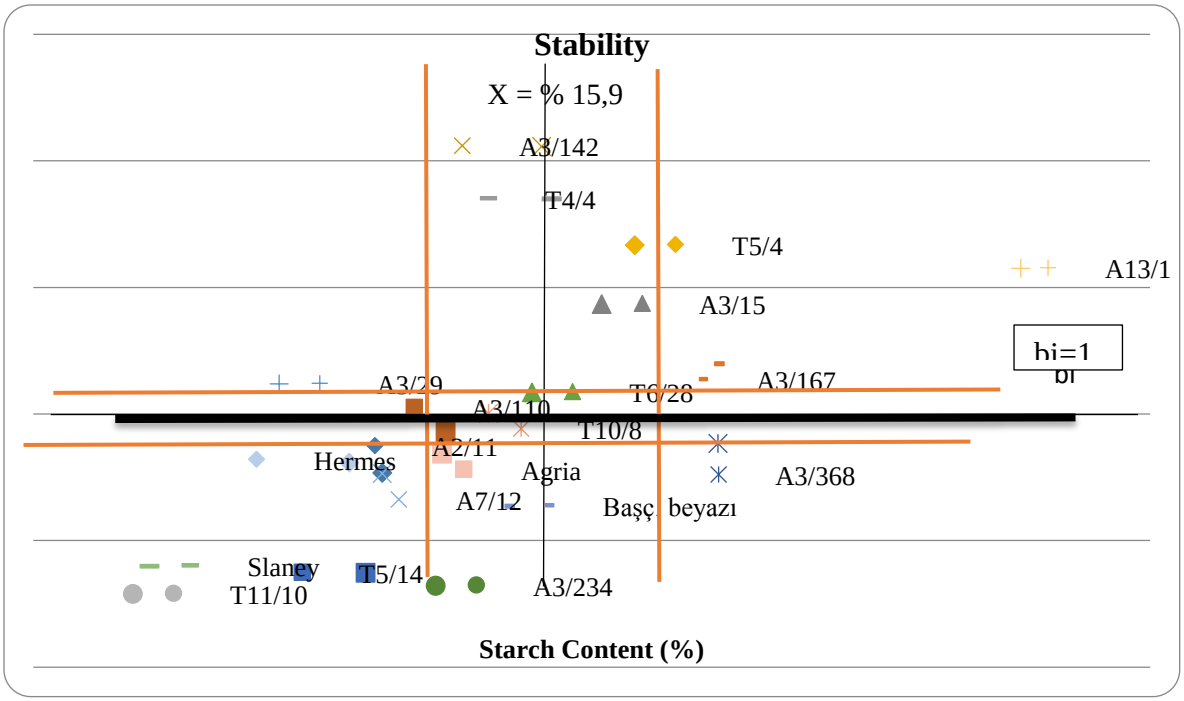

Figure 3. Adaptation classes of clones and varieties starch content (%)

The highest starch content was determined from A13/1 in all locations and environments. It has been reported that the content of dry matter and starch varies not only with the genetic characteristics of the variety but also under the effect of environmental practices during production. It has been reported that late maturity varieties produce higher dry matter and starch content in cool climatic conditions and high altitude locations. In addition differences in quality of seed tubers affect the content of dry matter and starch (Yılmaz and Karan, 2011). When the starch contents obtained from this study were examined in terms of genotype x environment interaction and stability, the regression coefficients ranged from bi = 0.70 to1.36. T6-28; T10/8; A7/12; A3/110 clones had better compatibility than other clones in terms of starch content. That is, as it was above the average starch content in different environmental conditions, it was the genotype that underwent minimal change. The average starch content of these clones in all environmental was above the general average and the regression coefficient was closest to bi = 1 (Table 3 and Figure 3).

PLANT PROTECTION AND FOOD SAFETY

MONITORING OF AFLATOXINS IN DIFFERENT PHASES OF CORN AND IN CONCENTRATED FOOD OF DAIRY COWS

Jani MAVROMATI[1*] Lulzim SHAQIRI[2],

Abstract

Some cereals and concentrated animal food are affected by mycotoxins which are produced from molds (genus of *Aspergillius, Fusarium, Penicillium*etc*)* in the different stages of grain growing and storage, being affected by atmospheric conditions such as humidity, temperature differences, drought and invasion of different insects.The purpose of this study was to determine the presence of aflatoxin in maize in the harvest phase, storage phase and in concentrated food for dairy cows. The determination of aflatoxins was carried out with rapid semi-quantitative methods and were confirmed by quantitative methods of ELISA's.The results of the study showed that 3 out of 10 samples of maize in the harvest phase and in storage were invaded by aflatoxins above the permissible norms for use in cows for milk production. Two samples obtained from concentrated food prepared with 50% from the above maize, resulted in permissible norms.From the above findings as well as from other authors, we can conclude that mycotoxins are a serious problem that can bring not only lower animal production but can also create disturbances in people. The monitoring of mycotoxin contamination in animal food, especially for dairy cows and using of various methods for preventing and absorbing mycotoxins if they are evident is a necessary and ongoing requirement. This monitoring and prevention process can be carried out in a cooperative way, where veterinarians, zoo techniciansagronomists and other scientists should be part of it.

Key words: *Mycotoxins, aflatoxins, cereals, animal food.*

Introduction

Many cereals and concentrated food of animals are affected by mycotoxins produced mainly by the molds of genus *Aspergillius, Fusarium, Penicillium* in the different stages of grain growing and storage, being affected by atmospheric conditions such as humidity, temperature differences, drought and invasion of different insects(Charmley et al, 1995; Ioannou-et al 1999;Creppy et al 2002; Biba and Mavromati 2014).

From the different authors are mention that the mycotoxins are a serious problem that can bring not only lower animal production and different pathologies (Helferich et al 1986; Diekman and Green 1992, Krogh et al 1992; Fernandez et al 1997), but can also create disturbances in people (Madsen et al 1982; Neal et al 1998; Biba 2007).

The purpose of this study was to determine the presence of aflatoxin in maize in the harvest phase, storage phase and in concentrated food for dairy cows. The determination of aflatoxins was carried out with rapid semi-quantitative methods and were confirmed by quantitative methods of ELISA's.

Material and Methods

The study was conducted based on the following methodology:

Sampling.

a . 10 samples of maize (1,5kg) during corn harvest. The farmer produced maize for their needs for the dairy farm

b. 10 samples of maize (1,5 kg) stored in their storage places for use in dairy farm.
c. 10 samples of 1.5 kg concentrated food for consumption of lactation cows of the farm. Concentrated food contained about 50% of the maize produced and stored by the farmer himself, as well as other protein elements (soy beans) or vitamins and microelements.

Rapid test sampling analyses.
The samples were analyzed by the rapid semi-quantitative test for the detection of total aflatoxins in corn and processed food.
TAFT-P Tests (Total Aflatoxin - Precise Rapid Test).

Instruction for use.
The rapid precision test is a competitive immunoassay for semi-quantitative detection of aflatoxin residues in cereals, livestock feed, and so on. Enables the detection of over 5ppb of aflatoxins in agricultural and livestock food. Time of proof: 5-10 min. Samples: Maize and concentrated food.

Results and discussion

The table below provides the TAF-P quick-release kit for samples taken during corn harvesting.

Table No. 1. The results of sample analysis are taken during corn harvesting.

Samples Nr	Dates of taking	Time	Parcel	Characteristics of plants of the parcels	Quantity of sampling	Dates of analysis	Results
01	25/9/2017	Dry	Nr 1	Healthy plants	1,5 kg maize	25.09.17	-
02	25.09.2017	Dry	Nr 1	Healthy plants	1,5 kg maize	25.09.17	-
03	25.09.2017	Dry	Nr 1	Healthy plants	1,5 kg maize	25.09.17	-
04	30.092017	Moisture	Nr 2	Not so healthy plants and invaded by insects	1,5 kg maize	30.09.17	+
05	30.092017	Moisture	Nr 2	Not so healthy plants and invaded by insects	1,5 kg maize	30.09.17	+
06	30.092017	Moisture	Nr 2	Not so healthy plants and invaded by insects	1,5 kg maize	30.09.17	+
07	30.092017	Moisture	Nr 2	Not so healthy plants and invaded by insects	1,5 kg maize	30.09.17	+
08	04.10.2017	Dry	Nr 3	Healthy plants	5 kg maize	04.10.17	-
09	04.10.2017	Dry	Nr 3	Healthy plants	5 kg maize	04.10.17	-
10	04.10.2017	Dry	Nr 3	Healthy plants	5 kg maize	04.10.17	-

Sampling took place on parcels during corn harvest. The corn was harvested on different dates. In parcel no.1, the harvest was done in dry weather. Plants in the parcels were uniform and with good performance. There was no invasion from different insects during the growing season and corn was clean.
The macroscopic examination for molds (by eyes) did not result infestation of corn. The results of the control for mycotoxin with the rapid test were negative.

In parcel No. 2 harvesting was carried out after a 3-day rainfall period. Plants in the parcels were not uniform and with low yields. There seemed to be invasion from different insects and the maize was not clean.
The macroscopic examination for molds (by eyes) of maize resulted with infestation of molds. The results of the rapid mycotoxin control test were positive.
In parcel No. 3 the harvest was done in dry weather. Plants in the parcels were uniform and above average. There was no visible invasion by different insects during the growing season and corn was relatively clean.
Eye examination for molds did not result in pronounced infestation of corn grain. The results of the control for mycotoxin with the rapid test were negative.

Table No. 2. The results of sample analysis are taken in storage.

Samples Nr	**Dates of taking**	**Time of storage**	**Origin of warehoused place of maize**	**The characteristics of storage place**	**Quantity of the samples**	**Date of analyses**	**results**
01	05.01.2018	3 months	Silos	Very good	1,5 kg maize	05.01.18	-
02	05.01.2018	3 months	Silos	Very good	1,5 kg maize	05.01.18	-
03	05.01.2018	3 months	Silos	Very good	1,5 kg maize	05.01.18	-
04	10.01.2018	3 months	Nr 1	Good	1,5 kg maize	10.01.18	-
05	10.01.2018	3 months	Nr 1	Good	1,5 kg maize	10.01.18	-
06	15.02.2018	4,5 months	Nr 2	Warehouse with humidity	1,5 kg maize	15.02.18	+
07	15.02.2018	4,5 months	Nr 2	Warehouse with humidity	1,5 kg maize	15.02.18	+
08	25.02.2018	5 months	Nr 3	Good	1,5 kg maize	25.02.18	-
09	25.02.2018	5 months	Nr 3	Good	1,5 kg maize	25.02.18	+
10	25.02.2018	5 months	Nr 3	Good	1,5 kg maize	25.02.18	-

From the data in Table 2, it turns out that maize storage is affected by the storage location, the quality of the storage environment and the length of the storage of maize in the werhouse.
In places with adequate ventilation, moist and dry places have the premise not to affect the quality of the product.
In storage No. 2 where storage conditions are not good, the level of mycotoxins in corn is above the permissible norms. 2 samples in this warehouse was positive in the TAF-P rapid analysis.
It draws attention to the three positive samples, which are 2 in warehouse no. 2 and one in warehouse no. 3.

Table no 3 The result of sample analyzes of concentrated food.

Smples Nr	Date of taking	Origin of warehoused place of maize	Quantity of concentrated food	Date of analyse	Results
01	15.01.2018	silos	1,5 kg	15.01.2018	-
02	15.01.2018	silos	1,5 kg	15.01.2018	-

09	28.02.2018	Nr 3	1,5 kg	28.02.2018	-
10	28.02.2018	Nr 3	1,5 kg	28.02.2018	-

In table no. 3 are presented the results of sample analyzes of concentrated foods.
Grinding and mixing of foods are done on the cattle farm. There was a simple evidence of supply of maize from the respective warehouses and food preparation.
From prepared mixer food from storage No. 2 we have 2 positive samples that pass the permissible limits of mycotoxins.
All other samples including samples of concentrated foods prepared with maize from magazine no. 3 (see sample No. 9 in table No. 2) are negative. The mixture of concentrate is made by placing 50% maize and adding other elements like soy beans, vitamin, macro and micro element. From this mixture the level of mycotoxins decreases and the samples are negative.
In the case of positive samples of concentrated food, it was used the physicochemical methods by using bentonite, sodium-calcium aluminosilicatefor mixing in the food (Patterson and Young et al 1993, Ioannou et al 1999).
The other new biological methods usin glactic acid bacteria to bind aflatoxins and other methods,which provides the possibility of absorbing mycotoxins and their level at permissible for animal consumption(El-Nezami et al 1998; Pierides et al 2000; Peltonen et al 2001; Diaz DE 2002).

Conclusions

From theoretical information and research through rapid tests, it turns out that mycotoxins are a real and serious problem that should be taken into account for the damage that can bring not only lower animal production but what is more important, can create disturbances in people. Their continuous control and careful monitoring of the feeding of animals that produce livestock products for public consumption is a necessary and continuous demand. This monitoring and prevention process can be carried out in a cooperation way, where veterinarians, zootechnicians agronomists and other scientists should be part of it.
Relying on the potential contamination of agricultural and livestock products consumed by the public, we recommend continuous control of them with quantitative methods to determine the amount of mycotoxins in different products.
We recommend the use of rapid tests as the first fast opportunity (5-10 min) and practical for field use. Rapid tests are semi-quantitative method and can oriented to performing other quantitative analyzes more accurate such as ELISA or HPLC methods.

Will be much better not using corn for concentrated foods if they have amounts of mycotoxins above the permissible limits.

In case of the detection of amounts above the permissible norms of mycotoxins in concentrated foods for livestock consumption, use absorbent substances with bentonite or other substances that absorb mycotoxins for reduction their levels without risking the animals, their products and public health.

Abstract

All species of plants, wild and cultivated, are subjected to diseases, although each species is susceptible to characteristic pathogens. Plant diseases cause a significant loss, it is 40% in industrialized countries and over 50% in developing countries. The occurrence and prevalence of plant diseases vary from season to season, depending on the presence of pathogens, environmental conditions, and crops varieties grown. The rhizosphere is rich in actinobacteria. This bacterial group has strong biocontrol capacity against plant diseases. In this study, isolation of plant pathogenic fungi was conducted on infested vegetable plants and cereal crops. The work was focused on the evaluation of antifungal capacity of actinobacteria against pathogenic fungi and their PGPR traits. Six strains of actinobacteria (*Streptomyces griseus* Lac1, *S. rochei* Lac3, *S. anulatus* Pru14, *S. champavati* Pru16, *Nocardiopsis dassonvillei* Vic8 and *N. alba* Pin10) isolated from rhizospheric soils of the semi-arid region in Northeast Algeria were used. These strains were tested for their ability to produce auxin (indole-3-acetic acid: IAA) in the presence of L-tryptophan (L-Trp) as a precursor, to hydrolyze phosphate and to produce siderophores. Thus, three phytopathogenic fungi were isolated and identified, namely: *Fusarium culmorum* TRI-1, *F. oxysporum* CIT-4, *Botrytis cinerea* SL-1. The *in vitro* antagonism of the actinobacteria strains against the phytopathogenic fungi showed that, except *N. alba* Pin10, the other actinobacteria inhibited the growth of all tested fungi, and *S. griseus* Lac1 presented the most significant activity. IAA was detected in all strains with L-Trp as a precursor and the quantities varying from 2.57 to 12.10 µg/mg DW. Four strains produced siderophores and only two hydrolyzed phosphate. This study revealed the antifungal activity and some PGPR traits of actinobacteria belonging to the genera *Streptomyces* and *Nocardiopsis*.

Key words: *Actinobacteria, Botrytis, Fusarium, IAA, phosphate, siderophores.*

Introduction

Phytopathogenic fungi significantly reduce crop productivity worldwide and cause significant economic losses (Prapagdee *et al.,* 2008). *Fusarium* wilt is one of the fungal diseases encountered in Algeria. It attacks several crops such as lentils (Belabid *et al.,* 2004), date palm (Sabaou *et al.,* 1983) and chickpeas (Larbi, 1991). Pathogens that are responsible for this disease belong to the genus *Fusarium*. Pesticides are broadly used to protect crops from plant diseases. Besides the emergence of pesticide-resistant insects and fungi, the agrochemical treatments may have a harmful effect on the environment, as well as human and animal health (Reddy *et al.,* 2016). Therefore, the biological control appears as a safe alternative method for replacing chemical treatments, has therefore attracted much interest and it is increasingly used (Tanaka and Omura, 1993; de Oliveira *et al.*, 2010). Among soil microorganisms, certain rhizobacteria are considered to be an effective biocontrol agents against plant pathogens (Mohandas *et al.*, 2013).

The current study aims to characterize six rhizospheric actinobacteria (*Streptomyces griseus* Lac1, *Streptomyces rochei* Lac3, *Streptomyces anulatus* Pru14, *Streptomyces champavati* Pru16, *Nocardiopsis dassonvillei* Vic8 and *Nocardiopsis alba* Pin10 for their antagonism against phytopathogenic fungi (*Fusarium culmorum* TRI-1, *Fusarium oxysporum* CIT-4, *Botrytis cinerea* SL-1). As the biocontrol agents also often promote plant growth, these strains were tested for traits typically found in PGPR: indole-3-acetic acid (IAA) production, phosphate solubilization and siderophore production.

Materials and methods

Collection of samples, and isolation of pathogenic fungi

Samples of durum wheat, tomato and watermelon which showed the wilt or rot disease symptoms were used for isolation of fungal pathogens. Durum wheat (*Triticum durum* Desf.) ears were collected from Ben Badis locality (Constantine). Infested tomato (*Solanum lycopersicum* L.) fruits were sampled in Biskra region, while infected seedlings of watermelon (*Citrullus lanatus* Thunb, Matsum & Nakai) were taken in the locality of Ben Badis (Constantine) (Figure 1). All samples were collected in sterile bags and transported directly to the laboratory for analysis.

Except the fungal colony collected from the tomato fruits, the other samples of grains, stems and roots (Table 1) were first washed with tap water then deceived in a 1% sodium hypochlorite solution for 10 minutes, then rinsed in sterile distilled water and dried on filter paper (Zehhar *et al.*, 2006). The culture of the different samples was carried out on potato dextrose agar medium (PDA) and Sabouraud amended with chloramphenicol. Plates were incubated for 7 days at 20°C (Rémi, 1997).

Figure 1: Collected plants (a) tomato fruit, (b) watermelon seedlings, (c) durum wheat ear

Table 1 : Origins and fungal diseases of collected plants

Localities	**Plants**	**Samples**	**Fungal disease**
Constantine (Ben badis)	Watermelon	Roots, stems	Fusariosis
Constantine (Ben badis)	Durum wheat	Ears (grains)	Fusariosis
Biskra	Tomato	Fruits	Grey rot

Identification of fungal isolates

The identification at the genus level was based on the fungi determination keys described by Botton *et al.* (1990), Messiaen (1991) and Rémi (1997). Species determination was carried out at the National Institute of Agricultural Research of Algeria (INRAA, Constantine, Algeria).

Antagonistic activity of actinobacteria against phytopathogenic fungi

Antagonistic actinobacteria used in this study are listed in Table 2. These strains were isolated from different rhizospheric soils collected in Algeria.

Table2: Origin of antagonistic actinobacteria

Strains	**Rhizospheric soil**	**Site**
Streptomyces griseus Lac1	*Lactuca sativa* L.	Cultivated plots, Batna
Streptomyces rochei Lac3		
Streptomyces anulatus Pru14	*Prunus domestica* L.	ITCMI, Oum el Bouaghi
Streptomyces champavati Pru16		
Nocardiopsis alba Pin 10	*Pinus halepensis* Mill.	Forest reserve, Khenchela
Nocardiopsis dassonvillei Vic8	*Vicia faba* L.	Cultivated plots, Batna

Antagonistic activity of actinobacteria against the fungal pathogens was evaluated according to Soares *et al.* (2006) with modifications. Each strain of actinobacteria was streaked as a straight line (7 mm wide) across the centre of PDA plates (145 mm diameter) and incubated at 28°C for 5 days. Two 7-mm diameter discs from an 8-day-old fungal culture were transferred at a distance of 1.5 cm from the edge of both halves of the plates. Plates were incubated at 28°C for 5 days and antagonistic activity was assessed by measuring fungal growth from the disk to the edge of the mycelium, perpendicularly to the bacterial line. Control treatments were prepared without actinobacteria.

Indole-3-acetic acid (IAA) production

The production of IAA by the six actinobacterial strains was assessed and quantified by spectrophotometric analysis. Flasks containing 50 mL of minimum starch medium (Legault *et al.*, 2011) supplemented with L-Tryptophan (10 mM, final concentration), were inoculated with 200 µL of bacterial inoculum from a 48h pre-culture. Cultures were incubated in the dark with shaking at 30°C for 6 days. Cells were then removed by centrifugation (3450 × g for 20 min) and dried to determine dry weight. One mL of the supernatant was mixed with 2 mL of Salkowski reagent (Gordon and Weber, 1951) in a test tube and kept at room temperature in the dark for 30 min. The development of a reddish to pinkish color in the solution indicated the IAA production which was measured at 530 nm (Tsavkelova *et al.*, 2007).

Siderophores production

Glassware was treated with 3 M HCl and rinsed with deionized water to remove iron contamination (Sridevi and Mallaiah, 2008). The six actinobacterial strains were grown for 48 h in ISP4 broth at 30°C with shaking (Lee *et al.*, 2012). The cells were harvested by centrifugation at (3450 × *g* for 10 min) and 1 mL of supernatant was mixed with 1 mL of chromo-azurol S (CAS) reagent prepared according to Schwyn and Neilands (1987). The color change from bluish to reddish-brown indicated the presence of siderophores. Un-inoculated ISP4 broth was used as a negative control and remained blue in the assay. This experiment was carried out three times in duplicate.

Microorganisms usually produce two types of siderophores: hydroxamate-type and catechol-type. Hydroxamate-type siderophores are detected by the ferric perchlorate assay (Atkin *et al.*, 1970). The isolates that tested positive with CAS were grown on medium composed (per liter) of 4.25 g Na_2HPO_4, 30 g KH_2PO_4, 0.95 g NH_4Cl, 0.35 g KCl, 0.65 g NaCl, 0.9 mL of trace elements solution, 1.3 mL of succinic acid solution (0.1 g L^{-1}), 1 mL of $MgSO_4$-$7H_2O$ (0.1 g mL^{-1}) and 3.7 mL of 1 M KOH (pH adjusted to 7.25). Cultures were incubated at 28°C with shaking (250 rpm) for 6 days. The colorimetric assay consisted of mixing 0.5 mL of culture

supernatant with 2.5 mL of ferric perchlorate reagent (5 mM Fe $(ClO_4)_3$, 0.1 M $HClO_4$) (Atkin *et al.*, 1970).The color change to purple was indicative of the presence of hydroxamate siderophores (Payne, 1994).
Detection of catechol-type siderophores was assayed by Arnow's reagent. Actinobacteria (200 µL of pre-culture) were grown in modified Fiss glucose medium (Barbhaiya and Rao, 1985). Fiss glucose medium was supplemented with 1% sucrose and 0.1% $(NH4)_2SO_4$ (Sridevi and Mallaiah, 2008). Cultures were incubated at 30°C for 6 days and cells were removed by centrifugation. One mL of sterilized supernatant was mixed with equal volumes of 0.5 M HCl, nitrite/molybdate reagent (10% $NaNO_2$ and 10% NaMo, wt/vol) and 1 M NaOH in a clear microcentrifuge tube, mixing vigorously between the addition of each reagent. The presence of catechol siderophores was indicated by a pink color change; the mixture remained clear if catechol siderophores were absent (Machuca *et al.*, 2001).

Screening for phosphate solubilization

The ability of the six actinobacterial strains to solubilize phosphate was determined on Pikovskaya's agar (Pikovskaya, 1948). After 5 days at 30°C, the presence of a clear zone around the colonies, revealed phosphate solubilization (Mohandas *et al.*, 2013).

Statistical analysis

The data were analyzed with analysis of variance (ANOVA), followed by the least significant difference (LSD) test using SAS 9.1 statistical software (SAS Institute Inc., Cary, NC).

Results and discussion

Isolation and identification of phytopathogenic fungi

Eight fungal isolates were obtained from samples. Durum wheat grains provided three fungal isolates belonging to *Fusarium*, *Alternaria* and *Penicillium* genera. Wilted roots and stems of watermelon provided four fungal isolates assigned to *Fusarium*, *Aspergillus*, *Rhizopus* and *Alternaria*. The grey rot tomato sample yielded a single isolate of the genus *Botrytis*. Considering their role in phytopathogenecity, three isolates that belong to genera *Fusarium* and *Botrytis* were selected and confirmed as pathogens. Their identification at the species level was carried out at National Institute of Agronomic Research of Algeria (INRAA). These isolates, that were obtained from watermelon, wheat and tomato were designated as follows: *F. oxysporum* CIT-4, *F. culmorum* TRI-1, and *Botrytis cinerea* SL-1, respectively (Figure 2, 3, 4).

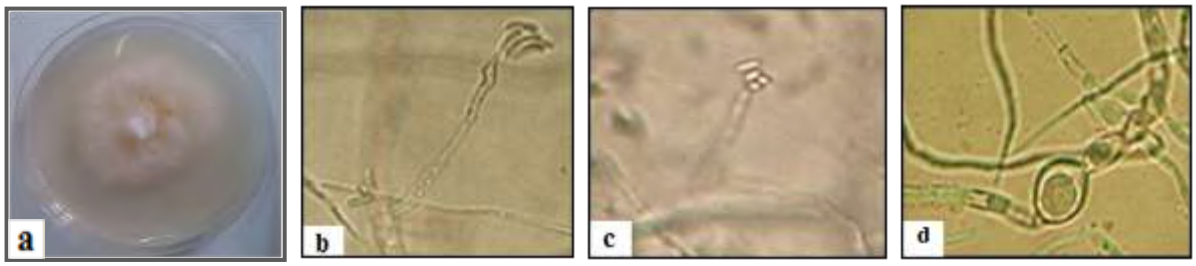

Figure 2: F. oxysporum CIT-4 (a) colony morphology on PDA (b) macroconidia; (c) microconidia; (d) chlamydospores.

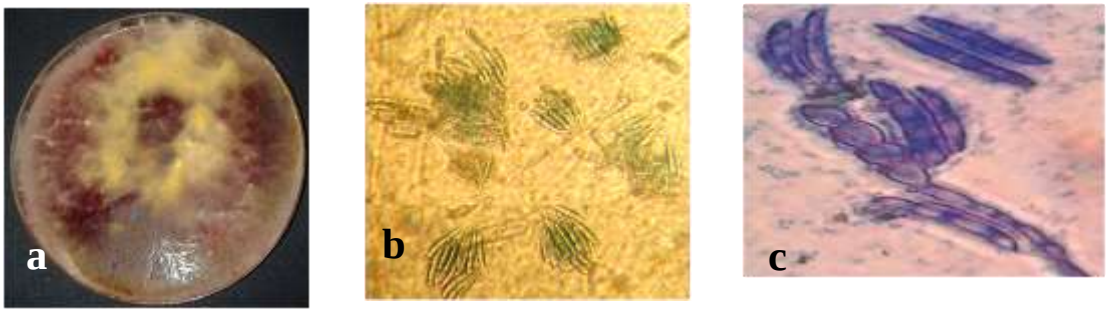

Figure 3 : *F. culmorum* TRI-1, (a) colony morphology; (b) sporodochia; (c) macroconidia

Figure 4 : *B. cinerea* SL-1, (a) colony morphology on PDA; (b) sclerotia (c) conidia

Screening of antagonistic actinobacteria against phytopathogenic fungi

All of the antagonistic actinobacteria reduced the *in vitro* growth of *Fusarium oxysporum* and *Fusarium culmorum*. The most significant antifungal activities were that of *S. griseus* Lac1, *S. anulatus* Pru14 and *S. champavati* Pru16 strains. Thus, *S. griseus* Lac1, *S. rochei* Lac3, *S. anulatus* Pru14, *N. dassonvillei* Vic8, and *S. champavati* Pru16 strains were found to be effective in reducing the growth of *Botrytis cinerea* mycelium rather than *N. alba* Pin 10 (Figure 5 C).

Production of indole-3-acetic acid (IAA)

The quantificative IAA assay was carried out with spectrophotometer at 530 nm according to the Salkowski reaction, a standard curve with commercial auxin was performed. The colorimetric assay revealed that in the presence of L-Trp, all strains of actinobacteria were able to produce IAA.

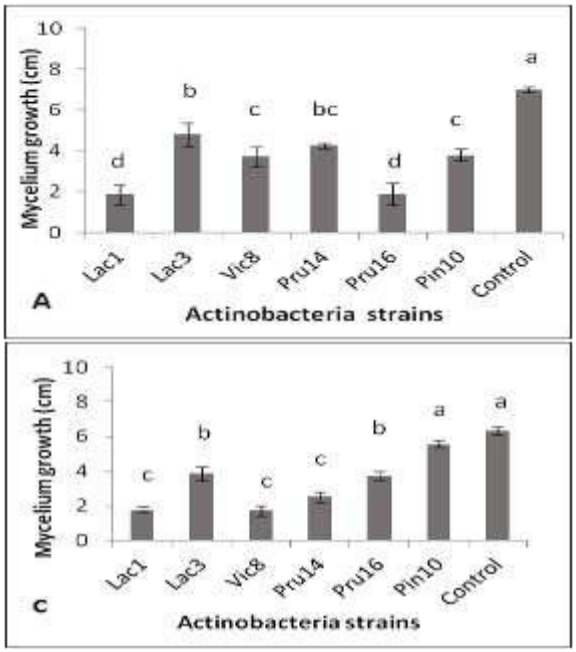

Figure 5: Effect of antagonistic actinobacterial strains on mycelium growth of phytopathogenic fungi. Results are the means of triplicates. Values with the same letter do not differ statistically (LSD). (A) *Fusarium culmorum* TRI-1, (B) *Fusarium oxysporum* CIT-4, (C) *Botrytis cinerea* SL-1.

However, there was no production of IAA when the growth medium was not supplemented with L-Trp (data not shown). The IAA amounts varied from 2.57 to 12.10 µg/mg bact. DW^{-1} (or 1.44 to 8.45 µg mL^{-1}). Strain *S. champavati* Pru16 was the highest IAA producer (Figure 6).

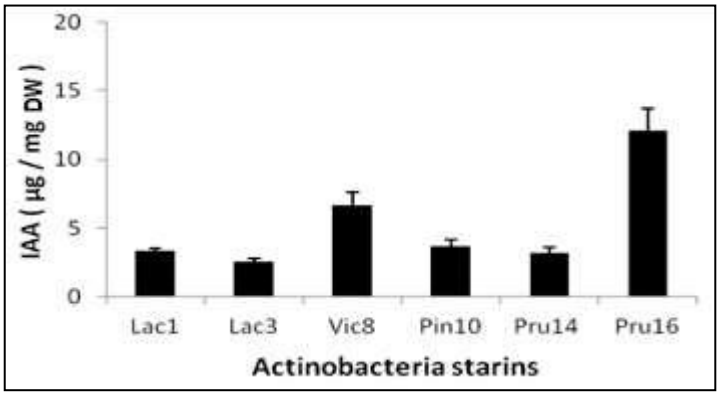

Figure 6: Indole-3-acetic acid production of actinobacterial strains

Solubilisation of phosphate and siderophores production

Among the six tested actinobacterial strains, two of them solubilized phosphate. After 5 days of incubation, diameter of clear zone was observed for two strains, *S. rochei* Lac3 (19.7 ± 0.6 mm) and *S. champavati* Pru16 (12.0 ± 1.0 mm). According to the CAS assays, four strains showed ability to produce siderophores. Specific detection revealed that three of them (*S. anulatus* Pru14, *S. champavati* Pru16 and *N. alba* Pin10) produced hydroxamate-type siderophores, while the strain *S.griseus* Lac1 produced catechol-type siderophores.

Among the eight isolated fungi, only three of them were retained since they are considered as pathogens. According to Breault *et al.* (2009), *Alternaria* and *Rhizopus* are saprophytic fungi which cause weakner diseases at the end of the growing season when the dried leaves are

covered with black pigmentation. Also, Patkowska (2002) reported that *Penicilium* sp. isolated from wheat, roots and necrotic stem bases are considered as saprophytes.

The results of this study coroborate with those obtained by Ajouz (2009) who isolated *Botrytis cinerea* from the tomato grown in France. The isolation of *F. culmorum* from lesions at the base of the stems of wheat seedlings has been already reported by Gindrat and Frei (2004). Patkowska (2002) analyzed the infected wheat samples and found that *Fusarium* species are the dominant phytopathogenic fungi, especially *F. culmorum* and *F. oxysporum*. *Fusarium culmorum* is the most phytopathogenic fungi, producing trichothecenes and it is the main agent of *Fusarium* wilt described in the world.

Fusarium oxysporum is found in soils all over the world, where it can behaves as a parasite or saprophyte. It attacks the vegetable crops (Messiaen *et al.* 1991). *Fusarium oxysporum* can be incriminated as the pathogen because *Rhizopus*, *Aspergillus* and *Alternaria* also isolated from watermelon roots do not cause dwarfism. The latter is due to vascular fusariosis. According to Larkin *et al.* (1996), *F. oxysporum* var. *niveum* is known to be a watermelon pathogen that causes vascular fusariosis which results in dwarfism. Corresponding to Rémi (1997), this pathogen has many specialized forms that attack several plants (peas, tomatoes, watermelons, melons, etc.). In this study, the percentage of actinobacterial strains active against *F. oxysporum* was also higher than what was obtained by Kitouni *et al*. (2005) with non-rhizospheric soil samples from a semi arid region in North-Eastern Algeria.

Actinobacteria are well known to produce secondary metabolites and extracellular enzymes (Khamna *el al.,* 2009). It has been reported that nearly 5% of rhizobacteria can promote growth of plants and protect them against pathogens such as bacteria and fungi (Suslow, 1982). According to Beauchamp (1993), PGPR stimulate indirectly plant growth by their antagonistic effect on detrimental microorganisms (antibiosis). PGPR are also beneficial to plants directly by increasing plant nutrients uptake via siderophores production and phosphate solubilization, producing plant growth regulators or triggering plant resistance mechanisms.

The production of IAA is a characteristic commonly found in PGPR. In the presence of L-Trp, the six actinobacterial strains tested produced appreciable amounts of IAA (from 2.57 to 12.10 µg/mg bact. DW), comparable to those found in the literature (Khamna *et al.*, 2009 ; Chaiharn and Lumyong, 2011). However, IAA amounts are significantly higher than those found by Mohandas *et al.* (2013). IAA production was higher for *S. champavati* Pru16 compared to the other strains.

Among the six actinobacterial strains explored in this study, three of them produced hydroxamate-type siderophores, while one produced catechol-type. In a study on siderophore-type production by *Streptomyces* strains, Lee et *al.* (2012) found that only 20% of isolates produced catechol, while all produced hydroxamates. Our study revealed catechol production by *S. griseus* Lac1, which is newly reported in *S. griseus* strains, previously shown to produce only hydroxamate-types siderophores (Yamanaka *et al.*, 2005 ; Macagnan *et al.*, 2008).

Phosphorus (P) is one of the most essential nutrient requirements in plants. In the soil, P is mainly found in insoluble forms that are not accessible to plants. The ability to solubilize phosphate is therefore an important trait of PGPR for increasing plant yields. In the present paper, only two strains (*S. rochei* Lac3 and *S. champavati* Pru16) were found able to solubilize phosphate, while strain *S griseus* Lac1 with the highest biocontrol potential, showed no abilities to solubilize phosphate. Franco-Correra *et al.* (2010) have isolated thirty rhizospheric actinobacteria, they found that twenty one of them exhibited phosphate solubilization ability. Among the several potential mechanisms for phosphate solubilization those involving the production of chelating compounds, like organic acids or by means of a modification of pH of the medium by the secretion of organic acids or protons are the more often described in the literature (Pikovskaya, 1948; Richardson *et al.*, 2009).

Conclusion

In the present study, the isolation of three phytopathogenic fungi was reported. Six antagonitic actinobacteria were tested against these fungi. These actinobacteria are of interest for the biocontrol of fungal plant pathogens since they were not only produced antifungal molecules, but they also showed PGPR traits. Interestingly, the present results showed that *Nocardiopsis* species possess the ability to produce IAA and siderophores *in vitro*. However, none of the two *Nocardiopsis* strains solubilized phosphate. There is scarce information in the literature on phosphate solubilization, IAA and siderophore production by non-*Streptomyces* genera and, to our knowledge, this is the first study focused on the *Nocardiopsis* species to evaluate their potential PGPR abilities. However, the apparently efficient biocontrol abilities of actinobacteria strains need to be examined under field conditions.

CONTENT OF Pb, Fe, Cu AND Zn IN THE FIG AND HIP FRUIT ON DIFFERENT AREAS

Alma MIČIJEVIĆ*, Aida ŠUKALIĆ

Agromediterranean Faculty, University of Džemal Bijedić in Mostar, University Campus 88104 Mostar, Bosnia and Herzegovina
*Corresponding author: alma.micijevic@unmo.ba

Abstract

In everyday diet, fruits and vegetables are used more and more because of their well known beneficial effects on human health. Population is mostly oriented on consummation of greater amounts of fruits that are planted in their surroundings. The Herzegovinian area is well known after figs and hips, during the history. These kinds of fruits are common for this area, and they are available for all population layers such as poor ones and rich ones as well. Both cultivations are available during the whole year and they can be consumed both as fresh ones and processed as well. This research had an aim to establish, on the science base, the way that metal went from the ground to the fig and hip fruit and their accumulation in these fruit cultivation. We chose different locations all around Mostar city area and its suburb. Our research showed that certain fig fruits, with or without peel, had different contents of researched elements, but content in all fruits was under permissible level. It was very interesting that all fig samples with peel showed higher level of iron presence, when we compared them with samples without peel. The presence of iron, copper and zinc was shown in the hip fruit, with or without mesocarp, and the levels were under permitted ones. Generally, we could say for the hip fruit that zinc, iron and copper were mostly accumulated in samples of grain with mesocarp instead of pure grain.

Keywords: *fig, hip, ground, heavy metals*

Introduction

The fig and the hip are plants and they are not demanding of land quality, therefore they are planted in barren soil, soil degraded from nutrients, they are also very persistent when they do not have enough water (Džubur, 1999). Nutrients from the soil influence on plant (Greaf, 2001). Plants cannot recognize nutrients they need and those that are not important for them, and that is the reason they take all of them (Blagojević *et al*., 2009). The intensity of accumulation depends on nutrient, its influence on biochemical reaction, its content in outdoor area and so on (Ćatović, 2007). Heavy metals are the most polluted elements, they pollute both environment and plant as well, and they cause oxidation stress. It is very important to find out mechanisms of their harmful influence, and tolerance of plants on presence of heavy metals in environments (Goyer *et al*., 1995). The accumulation of heavy metals is in the parts of plants, it is mostly accumulated in fruits and it is mostly taken from the root and from leaves (Borić-Šaćiragić, 2010). High content of heavy metals in the soil causes also high accumulation of heavy metals in plants (Yanyu *et al*., 1996).

Material and Methods

Through chemical analysis of adult plants, fig plant and hip plant, researched the quality of soil, presence of metals and their influence on development of plant that take all components from the soil. Transport of harmful matters is possible if they are present in larger quantities.
Researched locations were in the city of Mostar (Entity of Federation of Bosnia and Herzegovina), the center of the town and suburb area. Chose three locations: the area of Dubravska plateu, located 40 km away from the city of Mostar, on the south, private property,

at about 200m air distance from the highway. Small place called Blagaj, in the suburb of Mostar, at about 10 km away from the city centre. This location is 3km air distance away from highway, it is close to the place called „Zalik" on the north of Mostar city area. This place has large content of researched metals. Researched areas are far away from each other, and they can give us relevant data about presence of researched metals. We supposed that these locations had different quality of soil.

We passed through following phases of our research: choosing location, taking samples of the soil, taking samples of fruits (fig and hip), preparing of samples for analysis, lab analysis of soil and fruits. We used standard methods with chromed probe we took 5 individual samples by the diagonal of the parcel. We collected all of those samples into one average sample, it weights at about 2 kg. We had two different depths of the soil, one of them was from 0 to 30 cm and the other was from 30 to 60 cm. We prepared six samples of the soil, and they would be researched in order to show the quality of the soil, especially the content of following metals: Pb, Fe, Cu, Zn. We did this during vegetation period, but before the fruit ripening, during September and October in 2012.

Figs were ripe earlier, because of hot weather during the summer in 2012, so we started our research from 2nd to 4th of September. We took at about 1 kg of healthy fruit from all trees, from the average branches in all three locations, and we formed one sample. Fresh figs from all locations are separated in two different groups: one group was figs with skin and the other group was peeled figs. This is a period when the figs are dried in order to consume them during the whole year. We collected **six** different samples. Our samples were put into plastic boxes and they were frozen at -20^{o}C, in that way we protected our samples till analysis.

Hip was taken from 15th to 25th of October in 2012, hip fruits were ripe at that time, and its consummation was intensive at that time. We picked hips up for few different trees in different areas, and we took at about 30 healthy fruits, and after that we prepared one sample. From every picking fruits we prepared two samples: one sample was just grain of the hip and another was grain of the hip with mesocarp, because while we prepare the juice of the hip we also use one part of mesocarp. We prepared **six** samples. We put our samples into plastic boxes and we froze them at -20^{o}C, and we kept them at that temperature till our analysis.

Results and Discussion

Results of physical- chemical analysis are shown in the following table 1.

Table 1. Physical - chemical parameters of the soil

Location	Depth (cm)	pH values (±0,01)		% The content of nitrogene	% The content of phosphorus/ 100g of the soil	% The content of potassium/ 100g of the soil	% The content of humus	% Higroscopic humidity
		in H_2O	in n-KCl					
Dubrave	0-30	7.50	6.70	0.21	6.50	10.4	1.24	2.38
	30-60	8.12	7.20	0.23	9.15	14.8	1.20	2.21
Blagaj	0-30	7.70	6.90	0.25	9.45	12.1	3.18	2.37
	30-60	7.96	7.10	0.26	7.80	11.5	1.46	2.01
Zalik	0-30	8.06	7.15	0.18	6.40	12.5	3.62	3.33
	30-60	7.70	6.80	0.24	8.45	15.8	2.49	4.24

From the table, we can see that according to Ph values in the water, we can realize that it is slightly alcaline soil, and pH values are normal from 7.50 to 8.12. pH values in n-KCl-u are also neutral from 6,70 to 7,20, and all three researched locations are neutral. The result of

nitrgene in all three researched areas is balanced and it is at about 0,2 mg/100 g of the soil, and we can conclude that all three researched areas are rich in this element. The content of phosphorus is poor, because the content of this element is under 15 mg/100g of the soil. The content of potassium is very low from 10.4 to 14.8 mg/100g of the soil. All three researched soil are categorised as average as far as quality of soil is concerned. According to nutrients in the soil, all three researched soil can be categorised as barren soil. In the table 2, there are results of chemical analysis of the content of metal in the samples of researched locations.

Table 2 The content of researched metals in the soil

Location	Depth (cm)	Pb (mg/kg) MDK 50,00	Fe (mg/kg) MDK 30.000,00	Cu (mg/kg) MDK 50,00	Zn (mg/kg) MDK 100,00
Dubrave	0-30	16.36	13.774,85	32.56	90.20
	30-60	16.82	19.529,71	25.97	78.71
Blagaj	0-30	23.42	13.068,13	22.87	64.35
	30-60	17.18	13.999,21	21.74	54.31
Zalik	0-30	94.93	29.717,17	51.42	140.33
	30-60	76.29	35.346,06	53.07	191.40

The content of researched metals in the samples of the soil is very different in different locations. Values of permitted concentration go over maximal values. The presence of lead in the location of Zalik is high, and its value is 94,93 mg/kg (in the depth from 0 to 30 cm) and 76,29 mg/kg (in the depth from 30 to 60 cm), that is 89,86 %, or 52,58 % higher when we compare it with MDK. The lowest values were in the area of Dubrave, in the depth from 0 to 30 cm it is 16,36 mg/kg. In this area we expected low content of Pb, because it is far away from all potential pollutant. The content of iron in the location of Dubrave and Blagaj,in both depth, and in the location of Zalik in the first depth is under permitted values, while the concentration of this element is higher than permitted values in the second depth in the location of Zalik. The presence of copper is in permitted values in the location of Dubrave and Blagaj, while its presence in the location of Zalik is above permitted values. Higher values of copper are in other depth of the same location. In the location Dubrave and Blagaj, the content of present zinc is under MDK, while in the location of Zalik, this element is above permitted values. In the first depth, in the location of Zalik its presence is higher for 40,3%, while it value is higher for 91,4% than permitted value.

Table 3 shows data about content of the most relevant values that show the quality of fig fruit.

Table 3 Physical-chemical analysis of fig fruit

Location	Shape	pH-of fruit (±0,01)	% Dry matter	The level of acidity g/100ml	% total sugars
Dubrave	With the skin	5.16	35.95	0.21	23.40
	Without the skin	5.11	30.99	0.21	24.00
Blagaj	With the skin	4.79	34.69	0.18	23.00
	Without the skin	4.72	32.20	0.19	18.40
Zalik	With the skin	4.95	39.13	0.56	29.40
	Without the skin	4.86	30.21	0.42	17.00

The results of pH-values show that the fig fruit is acid taste. From the table we can see that the samples of fig fruit without of skin had lower pH-value. The percent of dry matter is between 23.54 and 39.13. The level of acidity shows that all researched samples have acidity very close to lower value, and we can explain that with dry climate conditions during the time of ripening the fruit. The level of acidity had an example from the location of Blagaj, and it was the fig with the skin ant its value was 0.18, while the highest level of acidity was in the fig with skin from the area of Zalik and it was 0.56. According to the content of total sugars, the sample of peeled fig from the location of Zalik had the lowest value, it was just 17.00, and the highest content of total sugars, in the fig with the skin, was in the location of Zalik, and it was 29.40.
In the table 4, there are data about the content of researched metals in the fig fruit.

Table 4 The content of researched elements in the samples of fig

Location	Depth (cm)	Pb (mg/kg) MDK 0.10	Fe (mg/kg) MDK 30.00	Cu (mg/kg) MDK 10.00	Zn (mg/kg) MDK 150.00
Dubrave	With the skin	It was not found	2.39	0.30	1.06
	Without the skin	It was not found	1.62	0.26	0.97
Blagaj	With the skin	0.004	2.78	0.59	1.14
	Without the skin	0.002	2.48	0.67	1.45
Zalik	With the skin	0.012	3.44	0.40	1.32
	Without the skin	It was not found	1.78	0.31	1.15

The presence of all researched elements in the samples of fig fruit, both peeled and unpeeled, was in the permitted values.
The content of lead was not found in 50% of samples, while in the rest of samples it was found under MDK. Amounts of present iron were also under permitted values, and the highest values were found in the sample of fig with skin in the area of Zalik. The content of copper and zinc were very low.
Parameters of basic values of the hip samples are shown in the table 5.

Table 5. Physical-chemical analysis of hip sample

Location	Shape	pH-fruit (±0.01)	% Dry matter	The level of acidity g/100ml	% Total sugars	The content of vitamin C mg/100gr
Dubrave	Grain	4.01	24.00	1.00	12.00	7.55
	With mesocarp	3.88	23.68	1.50	11.60	7.80
Blagaj	Grain	3.04	27.47	2.02	9.60	8.20
	With mesocarp	3.13	25.96	2.11	9.20	10.20
Zalik	Grain	3.18	26.29	2.42	10.60	10.50
	With mesocarp	3.06	26.33	2.64	8.20	5.60

According to pH-values, hip belongs to acid fruit, because the values of acidity are between 3.04 and 4.01. The content of dry matter is between 23.68 in the sample with mesocarp in the

location Dubrave, it is up to 27.47 in the location of Blagaj and in the sample of pure grain. The level of acidity is pretty low, the same as the level of total sugars.
This is acid fruit, and the proof for that is the content of vitamin C, and its content had the highest values in the area of Zalik, Those values were 10.50 mg.
The presence of researched metals in the samples of hip is shown in the table 6.

Table 6. The content of researched elements in the sample of hip

Location	Depth (cm)	Pb (mg/kg) MDK 0.10	Fe (mg/kg) MDK 30.00	Cu (mg/kg) MDK 10.00	Zn (mg/kg) MDK 150.00
Dubrave	Grain	Wasn't found	1.532	1.163	0.548
	With mezocarp	Wasn't found	2.180	1.293	0.573
Blagaj	Grain	Wasn't found	2.738	1.186	1.638
	With mezocarp	Wasn't found	1.856	0.765	0.641
Zalik	Grain	Wasn't found	2.735	1.111	1.207
	With mezocarp	Wasn't found	2.850	1.398	1.607

The results of chemical analysis of the hip sample showed presence of iron, copper and zinc and their values were under permitted. The content of lead was not found in the samples. In the areas of Dubrave and Zalik values of iron were higher in the samples with mesocarp, while in the area of Blagaj its presence was higher in the sample with pure grains. The presence of copper was found in all samples. The lowest values were found in the area of Blagaj in the sample with mesocarp, and highest value was found in the sample with mesocarp from the area of Zalik. The content of present zinc was pretty lower, when we compared it with permitted content. The lowest values were found in the area of Dubrave, and highest values were found in the sample with pure grain in the area of Blagaj.

Conclusions

In the area of Zalik in the samples of the ground, we found increased content of all four researched elements, when we compared them with MDK. The content of zinc was above normal values for 91,1%, the content of lead for 89,86%, iron for 16,7% and copper 3,1%. According to results of our research we can see that this area is the most polluted. Other two locations did not contain higher concentration of these elements.
Individual fruits of fig, with skin or peeled one, had different contents of researched elements. It is important to mention that all values in whole samples were under permitted values. All samples of figs with skin had higher value of iron, when we compared them with peeled ones. The content of zinc and copper in two samples with skin was higher when we compared them with peeled samples. In general, we can conclude that presence of researched metals is higher in samples with skin. The highest level of lead (0.012 mg/kg) was found in the sample of fig with skin in the area of Zalik, at the same place, there was the highest level of lead (94.93 mg/kg). The presence of iron, copper and zinc was found in all samples of hip fruit, with or without mesocarp, and values were under permitted values. Lead was not found, not even in one sample therefore we can conclude that hip is a plant that does not accumulate this element from the ground. The higher value of zinc and iron in the samples of hip with mesocarp was found in two samples, and only one sample of pure grain had increased content of these two elements, and this was in the area of Blagaj. The values of copper were higher in the samples with mesocarp in two locations, while it was vice versa in the area of Blagaj. For the hip fruit we can also conclude that iron, zinc and copper are more accumulated in the samples grain with mesocarp when we compared it with pure grain.

Abstract

In Entity of Republic of Srpska (Bosnia and Herzegovina), average annual production of potatoes is produced on an area of about 15.000 ha, and the average yield is 11.9 t ha^{-1}, while the seed potato production represents about 80 ha, which is only about 8% of the total needs for Republic of Srpska. The largest part of seed production is located in the municipality of Rogatica, about 54 ha. This is influenced by agroecological conditions, but also by the tradition of potato production in this area. The analysis of seed potato production was conducted in the association of farmers „Solanum produkt", where the seed potatoes were grown on 30 hectares, and mercantile potatoes on about 8 hectares. A two-year study (2014 and 2015) was performed on 5 varieties (Agria, Faluka, Kennebec, Kurada and Desiree) which were grown on the larger areas on "Solanum produkt." In the two-year study the highest yield was found in Desiree variety with an average yield of 18.6 t ha^{-1}, while Kurada variety had the lowest average yield of 14.05 t ha^{-1}. In 2014, the average potato yield was 21.4 t ha^{-1} and in 2015 average potato yield was 27.9 t ha^{-1}. For all varieties we noticed a large variation in yield due to agro-ecological conditions, and lack of moisture in the embryo phase and in the filing of tubers. Since this is a seed potato production, it is necessary to take care of the size of tubers because the large tubers are not desirable. In 2014, there was a higher percentage of seed tubers because of the influence of weather conditions and the timely interruption of vegetation, while percentage of small tubers increased in 2015. In the case of seed production, it is necessary to stop the vegetation earlier, in order to obtain a greater percentage of seed tubers.

Keywords: *seed potatoes, variety, yield, tuber yield structure.*

Introduction

According to RZS data, the average perennial production of mercantile potato takes place on the surface of about 15,000 ha, and the average yield is 11,9 t ha^{-1} (*Milic and Bogdanovic*, 2009; *Govedarica et al*, 2016), while the seed production of potatoes is represented on about 80 ha, which is only about 8% of the total needs for the Republic of Srpska (http://www.rzs.rs.ba). The largest part of seed production was organized in the area of Rogatica municipality, about 54 ha. This was influenced by agroecological conditions, but also the tradition of potato production in this area. In the association of farmers "Solanum produkt" seed potatoes are grown on 30 hectares and mercantile on about 8 hectares.

Potatoes have high economic significance for the mountainous region of Republika Srpska. This significance arises from the surfaces on which it is grown, the wide use and the nutritional and physiological values *(Djordjevic*, 2000a and b; *Cota*, 2000; *Milic et al*., 2012; *Milic et al*., 2006a; *Milic et al*., 2000a, *Milic et al*., 2000b, *Milic et al*., 2006b). In addition to favorable agroecological conditions for the production of potatoes, the yields per unit area are still small and fluctuating by age (*Milic et al*., 2000c, *Milic et al*., 2016). Small average yields are the result of extensive production, which is reflected in the use of poor planting material, inadequate sorting and inadequate agro-technology.

Although in the Republic of Srpska there are constant needs for pre-basic and basic seed potatoes, as well as the center for its production, the basic planting material (elite) is imported from the Netherlands and other countries of Western Europe. The need for pre-basic or basic planting material (elite) is much higher than the current consumption. In the eighties of the last century a modern center was established in Sokolac with the aim of producing pre-basic seed potatoes, i.e. elite and certified planting material. Although well equipped, the production of a virus-free potato was suspended. Today, the production of seed potatoes in the Republic of Srpska deals with the private sector, and one of the most important domestic producers is "Solanum produkt" from Rogatica.

The aim of this paper is to analyze the seed production of potatoes in the "Solanum produkt" of Rogatica in two years of research.

Material and methods

A two-factorial experiment was placed on a random block system in four repetitions. Basic soil cultivation was carried out in autumn by destroying natural meadows at a depth of 30 centimeters. 450 kg ha^{-1} NPK 8:16:24 and 200 kg ha^{-1} NPK 9:18:27 were entered into the land. Planting was carried out at an interval of 70 cm and 24 cm in length, giving a set of 59.523 plants per hectare. Planting material was used in the category of elites purchased in the Netherlands. Planting was carried out in the period from May 15 to May 25. During the experiment, care measures were taken (hoeing, 300 kg ha^{-1} 27% cannabis and dressing), as well as protection (fight against weeds, insects and causative agents) according to needs. The interruption of vegetation was carried out at the end of August with Reglon in the amount of 5 l ha^{-1}.

Factor A - variety (experiment included 5 varieties): Agria (a_1), Faluka (a_2), Kenebek (a_3), Kuroda (a_4), Desire (a_5). The experiment was set in 2014 (b_1) and 2015 (b_2).

The experiment was set up at Mountain Borika, at an altitude of 980 meters, 43 ° 53'16 "SGS; 19 ° 06'34" IGD. Borika Mountains have a mountain climate with large snow, which lasts for a long time, until late spring. Maximum temperatures reach 30 °C, minimum -28 °C, and medium 15 °C. The annual rainfall reaches 1500 mm, while the amount of atmospheric precipitation (distributed over the seasons) is even the most accurate in Europe. Data on temperatures and precipitation in the biennial experiment were monitored at the registered meteorological station (Sokolac).

To determine the average weight and number of tubers, we took samples with twenty fruits in each basic parcel, while yield was obtained by weighting the yield of each plot and calculating the yield per hectare.

All data was statistically processed using Sigma Plot Windows 2000 (*Jandel Scientific, Erkhart, Germany*) and Statistica for Window. The obtained differences for each tested parameter were tested with the LSD test.

The average daily temperatures in 2014 and 2015 were higher compared to the perennial average (Table 1). During vegetation of potatoes (May-September), the average daily temperatures were 14.38 °C, which is more than 0.38 °C compared to the perennial average (May-September). In 2014 the amount of precipitation was significantly higher (1218.9 mm) than the perennial average. In the vegetation period, potatoes fell to 765.9 mm, which is sufficient to obtain higher yields of the tin of the corresponding fractional structure. Frequent shifts in sunny and rainy days affected the development of the disease, which often led to the protection of fungicides.

Table 1. Meteorological conditions for 2014-2015 and perennial averages for Sokolac (Sokolac Weather Station)

Month		I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII
Average (1961 1990)	Temp. (°C)	-4.2	-2.6	2.2	5.7	11.5	14.6	16	15.7	12.2	7.7	2.8	-1.8
	Precipi. (mm)	51	45	63	71	81	96	67	76	75	86	80	57
2014	Temp. (°C)	2	4.7	4.8	7.6	10.7	15.2	17	16.8	12.2	9.1	6	-0.5
	Precipi. (mm)	37	11	63.6	153.9	260.1	170	76.2	112.6	147	42.9	56.6	88
2015	Temp. (°C)	-2.5	-1.3	2.1	6.2	13.4	15.3	19.8	18.9	14.5	8.4	3.2	-1.6
	Precipi. (mm)	89.9	56.1	74.7	53.2	75.4	113.3	25.2	85.7	84.3	106.9	71.2	0.3

In 2015, higher daily temperatures were recorded compared to perennial averages and temperatures in 2014. In 2015 there were 836.2 mm of precipitation, and during the vegetation it fell 383.9 mm of rain. The lack of precipitation in July (25.2 mm) did not compensate for the precipitation in August, which significantly influenced the yield reduction and the formation of minor troughs that are of no more significance. Potatoes are best grown in deep, fertile and loose soil. In such a root environment, the plant system can be developed more rapidly at greater depths and, if necessary, from these layers, the moisture necessary for normal growth and development. Potatoes do not tolerate heavy, wet and water-impermeable soils because they do not provide the aeration needed for breathing of the root of the plant. Potatoes are well grown on poorly acidic soils (pH/H_2O 5.5 to 6.5) (*Jakovljevic*, 1994). However, on extremely acid and alkaline soils (pH 4.5 and 7.5), poor yields are produced and the product is of poorer quality (*Maksimovic*, 1996). An increase in c. above-ground parts of the plant, it is best at a pH value of 7.40 to 8.27. (*Jakovljevic*, 1994; *Lazic et al.*, 1998). Table 2 gives the chemical characteristics of the land on which the tour was carried out.

Table 2. Chemical characteristics of the soil in the test field (Borike)

Depth (cm)	pH/H_2O	pH/KCl	Humus	N	Soluble mg/100g	
			%	%	P_2O_5	K_2O
0-30	5,02	3,85	2,55	0,16	8,98	25,38

The experiment was set on sour-brown soil (distric cambisol). After the chemical analysis of the soil sample, we determined that this is a highly acidic soil (pH/KCl analysis), i.e. a poorly acidic reaction (pH/H2O). The land is humus, provided with nitrogen, poorly secured with phosphorus and well secured with potassium. Potatoes are poorly developed in heavy, humid and cold soils, they are late to trowle, grow old and remain small and irregular. In such soil conditions, potatoes often also form air tusks in the lower leaves. They are best grown on mountainous blackberries, forest shrubs, alluvial soils, which are slightly acidic, so that the optimum value of the soil solution pH is from 5.2 to 6.

Results and discussion

The average number of tubers for all the tested varieties and years was 6.01 (Table 3). In the Agria variety (8.17) we determined the highest number of tubers per herb and it was statistically significantly higher compared to other investigated varieties. The smallest number of formed tubers per plant (6.19) had the varieties Kurad and compared to the variety Kenebek (6.55) was significantly lower, as well as the variety Desire (6.62), while compared to Faluk (6.99) this difference was highly significant. The variety Faluka compared to the variety Desire and the Kenebek variety had a significantly higher number of tubers. The highest number of tubers per plant in all tested varieties was achieved in the year when the highest number of PNI per plant was determined, which agrees with the results (*Momirovic et al*., 2000; *Bussan et al*., 2007; *Postic et al*., 2012a).

Table 3. Number of tubers per plant

Year / Variety	2014	2015	Average for the variety
Agria (a_1)	9.05	7.30	8.17
Faluka (a_2)	7.27	6.72	6.99
Kenebek (a_3)	6.70	6.40	6.55
Kurada (a_4)	6.67	5.72	6.19
Dezire (a_5)	6.88	6.36	6.62
Average for the year	7.31	6.50	6.91

LSD	A	B	AxB
0,05	0.304	0.216	0.423
0,01	0.517	0.368	0.728

The number of formed tubers, as well as the equalization of their size, depends on the hereditary characteristics of the variety, but also on the external influences. According to *Kopetya & Steinek* (1958), in years with normal climatic conditions, tart forming begins 4-5 weeks after sprouting. If there is enough moisture on all the columns during this period, the tubers will be formed. In the absence of moisture during this period, the plant reduces the number of tables and forms a smaller number of tubers. *Van dam et al*. (1996) and *Barkley* (2005) in their researches received a higher number of tubers per plant per lower than at higher air temperatures. These results are in line with our results. In 2014, the average temperatures were worse than temperatures in 2015. In 2014, the average number of tubers was 7.31, which is statistically significantly higher compared to 2015 (6.50). *Barcak et al.* (2003) found that genetic factors determine the possibility of the formation of columns, the number of tubers and their morphological properties. However, meteorological conditions in combination with soil properties determine the extent to which these characteristics will manifest themselves. The average mass of the tuber for all the tested varieties and the research year is 49.9 grams (Table 4). In 2014, the average mass of the tuber (61.3 grams) was statistically significantly higher, compared with the average mass of the tuber (38.4 grams) in 2015. The air temperatures that were optimal for the production of potatoes in June and July at the stage of table formation, the taper of the tuber and the beginning of the filling of tubers, followed by evenly distributed precipitation, played a key role in the formation of seed tubers in 2014, which is in line with results (*Van Dam et al*., 1996; *Jovovic*, 2011; *Postic et al*., 2012a).

Table 4. The average weight of tubers (g)

Year / Variety	2014	2015	Average for the variety
Agria (a_1)	42.2	35.4	38.8
Faluka (a_2)	73.9	26.6	50.3
Kenebek (a_3)	64.9	43.1	54.0
Kurada (a_4)	55.5	39.6	47.5
Dezire (a_5)	70.0	47.5	58.8
Average for the year	61.3	38.4	49.9

LSD	A	B	AxB
0,05	4.448	3.148	6.296
0,01	7.604	5.384	10.752

By increasing the number of pellets and calls per tuber, the number of primary trees per plant also increases, the number of planted tubers per plant is growing, but not their average mass, and vice versa, which is in agreement with the results (*Djokic*, 1988; *Bussan et al*., 2007; *Postic et al.*, 2011). The Desire variety had the highest mass of tubers in the years of research, and it did not have the largest number of PNIs formed, nor the largest number of formed tubers.

Statistical analysis of the yield (Table 5) showed very significant differences in the variety Desire (18.06 t ha^{-1}), and in comparison with the varieties Kurad (14.05 t ha^{-1}) and significant differences compared to the Agria variety and the Faluka variety, while the differences in the yield of tubers between the variety Kenebek and Kudar varieties were significant. In addition to climatic conditions and the quality of planting material, the yield of tubers is influenced by the genetic potency of varieties (*Ilin et al*., 2000; *Djukic et al*., 2000). Differences in yields of potatoes by varieties in the same year result from the genetic potential of the yield of the variety under given conditions, which is in accordance with our results. *Djordjevic* (2000) believes that the proper selection of potato varieties for the given production conditions would best exploit their genetic potential. Varieties that shrink a smaller number of tubers and form short and medium long stolons are suitable for cultivation especially in years with precipitation deficiency (*Bugarcic*, 1991), which is in line with our results.

Table 5. The yield of tubers (t ha-1)

Year / Variety	2014	2015	Average for the variety
Agria (a_1)	18.3	12.1	15.20
Faluka (a_2)	19.7	11.1	15.40
Kenebek (a_3)	20.8	13.1	16.95
Kurada (a_4)	17.3	10.8	14.05
Dezire (a_5)	22.6	14.6	18.60
Average for the year	19.74	12.34	16.04

LSD	A	B	AxB
0,05	2.26	1.15	3.19
0,01	3.86	2.24	5.47

In 2014 the average yield of tubers (19.74 t ha^{-1}) was statistically significantly higher, and compared to 2015, when the average yield of tubers was 12.34 t ha^{-1}. The layout and amount of precipitation during the vegetation period in 2014 largely met the needs of water potatoes, which largely reflected that the total yield of tubers was significantly higher compared to 2015, when a large deficit was recorded, especially in July, which influenced the watering of the tuber. Such results are in line with the research of many authors (*Tadesse et al*., 2001; *Tomasevic et al*., 2003; *Daric & Dimitrijevic*, 2009; Milic et al., 2010; *Momirovic et al*, 2010; *Jovovic et al*., 2011; 2011; *Postic et al*., 2012ab), which state that the conditions of production affect the total yield of potato tubers.

The farmers' association "Solanum produkt" currently produces seed potatoes at about 30 hectares. Table 6 shows the total production of seed potatoes in "Solanum produkt" in Rogatica. The areas on which seed potatoes have grown in recent years, and on the demand of seed potatoes on the domestic market, it was significantly influenced by the creation of optimal conditions for the storage and processing of seed potatoes.

Table 6. Total tuber yield (t ha-1)

Year / Variety	2014			2015		
	Yield (t ha^{-1})	Land area (ha)	Total yield (t)	Yield (t ha^{-1})	Land area (ha)	Total yield (t)
Agria (a_1)	18.3	9	164.7	12.1	12	145.2
Faluka (a_2)	19.7	6	118.2	11.1	7	77.7
Kenebek (a_3)	20.8	4	83.2	13.1	4	52.4
Kurada (a_4)	17.3	3	51.9	10.8	3	32.4

Tables 7 and 8 depict the fractional structure of tubers in years 2014. and 2015. In 2014. The small tubers widespread was 1, 33%, seed tubers 88, 91% (fractions 28-35 mm and 35-55 mm) and large fraction 9, 76%. in 2015. The ratio of fractional structure was unfavorable because there was 0, 88% of large, 50, 12% seed and 49, 18 % of small tubers. in 2015. The percentage of small tubers in fractional structure was between 31.7 to 57.5% which is undesirable in seed production. High percentage of small fraction like this is affected by favorable conditions during tuber setting, and then there was dry period (month of July) which had negative effects on tuber filling. In average for all varieties and years the achieved yield of small fraction was 3,104 t ha^{-1}, seed fraction 11,925 t ha^{-1}, and large tubers 1,019 t ha^{-1}. The Agria variety had the biggest yield of small tubers, the biggest yield of the seed fraction had the Dezire variety, and of the large fraction, the Kenebek variety. In 2014. The average yield of small fraction was 0,258 t ha^{-1}, seed fraction 17,553t ha^{-1}, and large fraction 1,927 t ha^{-1}. The Kurada variety had the biggest small fraction yield, the biggest yield of the seed fraction had the Dezire variety, and the biggest yield of large fraction had the Kenebek variety. The smallest small fraction yield had the Faluka variety, varieties Agria and Kurada had the smallest yield of seed fraction, and varieties Faluka and Kurada had the smallest yield of large fraction. In 2015. The yield of small fraction was 5,954 t ha^{-1}, the yield of seed fraction 6,295 t ha^{-1}, and the yield of large fraction was 0,111 t $ha^{-1.}$ The Dezire variety had the biggest yield of large and seed fraction, and Agria the biggest yield of small fraction. The smallest yield of small fraction had the Dezire variety, and the smallest yield of seed and large tubers, the Kurada variety.

Conclusion

Providing sufficient quantities of quality seed material is one of the prerequisites for achieving high and high yields. In the Republic of Srpska there is seed production, but it is insufficient and can not meet the needs of the domestic market. Mountain-hilly areas are suitable for seed potato production. In the Rogatica municipality there are several associations of agricultural producers, as well as individual agricultural producers engaged in the production of seed potatoes. Tackling the problems of seed potato production we have come to certain conclusions:

- In the Republic of Srpska, the production of seed potatoes is organized on 80 hectares;
- In the area of Rogatica municipality, seed potato is cultivated on about 54 hectares, of which in the association of farmers "Solanum produkt" is grown on about 30 hectares;
- Agroecological conditions partially favored potato production. In both years of research, higher average temperatures were found, compared to the perennial average. In 2014, there were higher precipitation years than average, but with regular protection of crops, it was preserved from the causative agent of the disease, and significantly higher yields were achieved, compared with 2015, when a large deficit of moisture was recorded in July.
- Average number of tubers varied between 6, 50 and 7, 31. The number of formed tubers per plant was affected by the number of PNI , as well as large amount of rainfall during the forming of stolon and tuber setting;
- Average tubers mass in 2014. was 61.3 grams, and in 2015. 38.4 grams. The size of tubers was affected by their number, weather conditions and the application of agro technical measures;
- Tubers yield is affected by their number and mass, genetic potential of the variety and agro ecological conditions. The yield varied between 19.74 t ha^{-1} (in 2014.) and 12.34 t ha^{-1} (in 2015.). The biggest yield had the Dezire variety, and the smallest Kurada variety. Big fluctuation of yield was registered through the years, which was the result of lack of moisture during the tuber filling phase.
- The production of seed tubers requires a proper fractional structure of the tubers. In 2015. There was bigger widespread of small tubers, which is unfavorable in potato seed production.

ENTOMOPATHOGENIC FUNGAL ENDOPHYTES: CAN THEY COLONIZE CUCUMBER PLANTS?

Roshan SHAALAN*, Lioudmilla IBRAHIM

Lebanese University, Faculty of Agricultural Engineering and Veterinary Medicine, Lebanon
*Corresponding author: roshan.shaalan23@hotmail.com

Abstract

Entomopathogenic fungi (EPF) are considered as insect pathogens and, thus, attention is mostly focused on developing them as inundative biopesticides. Lebanese local strains of *Beauveria bassiana* and *Metarhizium anisopliae* isolated from soil have previously shown effectiveness in controlling a wide range of pests. There were no studies reporting their endophytic ability in cucumber plants. Therefore, the present study investigated the abilities of these fungal species to colonize cucumber seeds through artificial seed inoculation and to determine the endophytic activity of these fungi in resulted cucumber seedlings. The results of the germination test showed that treating seeds with EPFs and incubating at 25^{o}C for 2 days would significantly improve germination rate by more than 26% if compared to untreated seeds. Greater enhancement of germination was also observed in seeds treated with *B. bassiana* (72.5%) or *M. anisopliae* (47.5%) when grown under outdoor conditions. In addition, seedling's roots developed from treated seeds grew faster than untreated reaching 15 cm in length compared to 10 cm long control roots after 10 days of incubation. Moreover, seedlings from seeds treated with *B. bassiana* produced a significantly higher number of roots. However, seed treatments with fungal conidia had no effect on stem elongation. Ten days post-inoculation resulted seedlings were assessed for endophytic recovery from their tissues. Results show that both, *B. bassiana* and *M. anisopliae* have colonized cucumber seedlings. Significantly higher percentage recovery (100%) was observed in the cucumber plant tissues colonized by *M. anisopliae* as compared to 58.3% (cotyledon and stem) and 50 % (roots) of *B. bassiana* endophyte. No fungal growth was recorded in control. This is the first study to report a significant data on the interaction between *B. bassiana, M. anisopliae* and cucumber seedlings. However, there is a need for further research to find out if the colonized tissue with EPF can be used as an effective strategy against pests of cucumber crops.

Keywords: *Metarhizium anisopliae, Beauveria bassiana,* cucumber, colonization, plant growth promoter.

Introduction

Agriculture is the third most important sector in the Lebanon. Beside main crops including cereals, fruits, vegetables, olives, grapes, tobacco that are cultivated in the country, cucumber (*Cucumis sativus*) is represented as a very popular salad vegetable. Entomopathogenic fungi (EPF) has been documented in a variety of herbaceous and woody plants, especially *Beauveria bassiana* and *Metarhizium anisopliae* have been shown to colonize certain plant tissues endophytically. Lebanese local strains of these entomopathogenic fungi have been isolated from the soil and identified as potential candidates for future commercial products. The term "endophyte" refers to a phenomenon by which certain fungi or bacteria occur inside plant tissues without causing any apparent symptoms or harm to the host (Aly *et al*., 2011). Although, the ecological function of endophytic EPFs remains largely unknown, some studies have implicated them in plant growth as probiotics (Dora, 2013), herbivore and plant disease resistance (Vega *et al.*, 2008), increased stress tolerance of plants to abiotic factors (Rodriguez *et al*., 2009) and bioremediation of heavy metals (Bajan *et al.,* 1998). Some of the

fungi have been reported as naturally occurring endophytes while others have been introduced into plants using different techniques. The most recent findings show that EPFs are just beginning to be explored as endophytes, with interesting experimental results for the management of insect pests (Vidal and Jaber, 2015). To the best of our knowledge, there is no information in the literature of endophytic colonization of *M. anisopliae* and *B. bassiana* in cucumber plants. Therefore, the overall objective of this study was to demonstrate that EPFs could be used as probiotic (endophytes) of cucumber seeds through internal colonization of externally inoculated seeds with *M. anisopliae* and *B. bassiana* and by re-isolating the fungi from internal tissues of tested plants.

Materials and methods

This preliminary study was conducted in October 2017- April 2018 at the Lebanese University, Faculty of Agricultural Engineering and Veterinary Medicine in the laboratory of Crop Protection Department.

Fungal isolates and maintenance

Lebanese strains of *Beauveria bassiana* (L1B1) and *Metarhezium anisolpiae* (L1M1) isolated from fallow soil (Ibrahim *et al.,* 2011) were used in this study. Long term storage of the isolates was achieved by freezing conidia in 10% w/w Glycerol at -20^{o}C. When required, frozen conidia were re-hydrated by suspending in a small volume of sterile 0.03% (v/v) Tween 20 solution, placed on Potato Dextrose Agar (PDA) and incubated at 23 ±2^{o}C in the dark for 14 days. Spores from these cultures were used for subsequent experiments.

Sterilization of cucumber seeds

There are various cucumber varieties cultured in Lebanon, but Beit Alpha hybrid cucumber seeds were used in this experiment. Prior to inoculation with tested entomopathogenic fungi, seeds were soaked in sterile distilled water (dH_2O) for 15 min and then surface-sterilized by immersion in 3% sodium hypochlorite for 2 min with subsequent rinsing with sterile dH_2O and additional immersion in 70% ethanol for 2 min followed by 3 rinses with sterile dH_2O. The axenically treated seeds were stored overnight at 5 ^{0}C for synchronization of seed germination and growth. To assess the effectiveness of the sterilization method, 20 randomly selected seeds from the seeds used in the screening test were placed onto PDA media plates, incubated at 25 ^{0}C in darkness and then examined over 3, 5 and 10 days. The disinfection was considered successful when no fungal growth was observed on the PDA plate.

Preparation of fungal inoculum

Conidia from 14-days-old cultures grown on PDA were suspended in 0.03% Tween 20, shaken on a rotary shaker at 354 rpm for 30 min. Resultant suspension was filtered through sterile cheesecloth under sterile conditions to remove any hyphal fragments. Conidial concentration was determined using light microscope and hemocytometer (Fuches-Rosenthal) and later adjusted to 1 x 10^{6} conidia/ml.

Seeds inoculation

Axenic seeds were immersed into the fungal conidial suspension for 2 h and placed onto sterile moist filter paper inside Petri dishes. For the control group, seeds were immersed in sterile 0.03% Tween 20 only.

Effect of EPFs on seed germination

To determine the effects of external seed inoculation with fungal suspension on seed germination, the following experiment was conducted. Inoculated seeds were incubated at 25

^{0}C under fluorescent lighting (16h Light / 8h Dark). Germination and occurrence of cotyledons were recorded over period of 10 days (every 2 days). Sterile dH_2O was periodically added to each plate to keep the filter paper moistened. Each test was replicated 6 times with 10 seeds in each replicate and the experiment was repeated 6 times. At the same time, inoculated seeds of each treatment were cultured outside in 3 blocks with 40 replications for each treatment.

Effect of EPFs on seedling's growth

To determine the effects of external seed inoculation with fungal suspension on seedling growth, root and stem lengths and number of roots of the resulting seedlings of each treatment were measured after the completion of seed germination test.

Endophytes re-isolation

After germination test, randomly selected seedlings were surface-sterilized: seedlings were first immersed in 0.5% sodium hypochlorite for 1 min, and then in 70% ethanol for 30 sec, followed by 3 rinses in sterile dH_2O. Disinfected seedlings then were allowed to air-dry in the laminar flow hood for a few min, cut into root, stem and cotyledon parts using sterile scalpel. Obtained plant materials were placed onto PDA selective media amended with antibiotics (20 mg L^{-1} Amoxicilline), incubated at 25^{0}C for 4 weeks and inspected regularly to observe fungal outgrowth, recordings were taken one-week post-inoculation. The success of this disinfection process was assessed by plating on PDA 1 ml of residual rinse water. Percent colonization/recovery of different seedling's parts by the respective inoculated fungus was calculated following the Petrini and Fisher (1987) formula: % colonization = number of sampled plant tissue showing fungal outgrowth divided by the total number of plated plant tissue samples ×100. The test was repeated 3 times.

Statistical Analysis

The statistical analysis in this study was made using the function one way ANOVA and the means of treatments were compared using DUNCAN test, using the statistical package SPSS (2011).

Results and discussion

In the current study, seed treatment with *B. bassiana* and *M. anisopliae* did not reduce seed germination or seedling growth and did not result in the development of root disease. On the contrary, the results of the germination test showed that treating seeds with EPFs and incubating at 25 ^{0}C for 2 days would significantly improve germination rate by more than 26% if compared to untreated seeds. After this date, the rate of germination showed no significant difference between the treatments (Table 1 and Fig.1). Greater enhancement of germination was also observed in seeds treated with *B. bassiana* (72.5%) or *M. anisopliae* (47.5%) when grown under outdoor conditions (Table 1 and Fig.2). In addition, seedling's roots developed from treated seeds grew faster than untreated reaching 15 cm in length compared to 10 cm long control roots after 10 days of incubation. Moreover, seedlings from seeds treated with *B. bassiana* produced significantly higher number of roots, whereas seedlings treated with *M. anisopliae* produced the lowest number of roots per seedling. However, seed treatments with fungal conidia had no effect on stem elongation (Figs.3 and 4).

Table 1. Germination mean (%) of treated and untreated cucumber seeds (in an incubator, 2 days post treatment and under outdoor conditions seven days post treatment).

Treatment	**Germination of cucumber seeds** % ±SE˜	
	Germination (25 ^{0}C)	Germination (outdoor)
Control	^{a} 40.0 ± 0.856	^{a} 32.5 ± 0.11
M. anisopliae	^{b} 66.7 ± 0.422	^{b} 47.5 ± 0.05
B. bassiana	^{b} 68.3 ± 0.654	^{c} 72.5 ± 0.11

˜ Mean percentages (±Standard Error, SE) within a column followed by the same letter not significantly different according to Duncan test (P≤0.05).

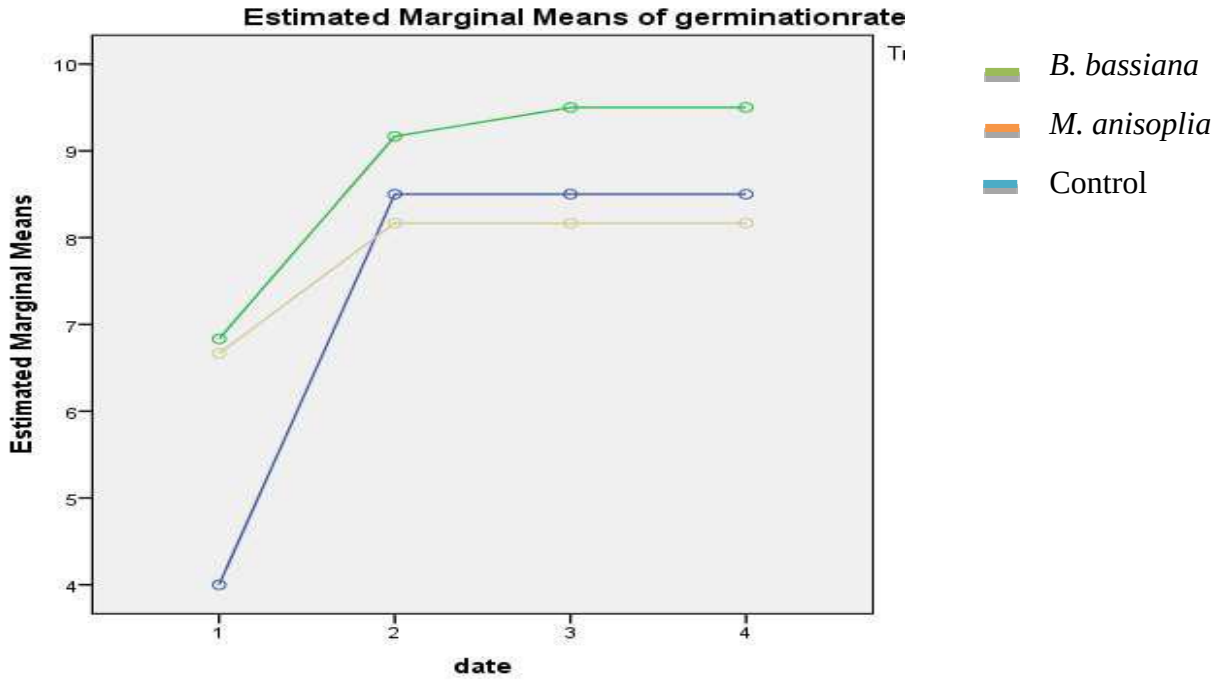

Figure 1. Germination rate of treated and untreated cucumber seeds at 25^{0}C 2 days post-treatment.

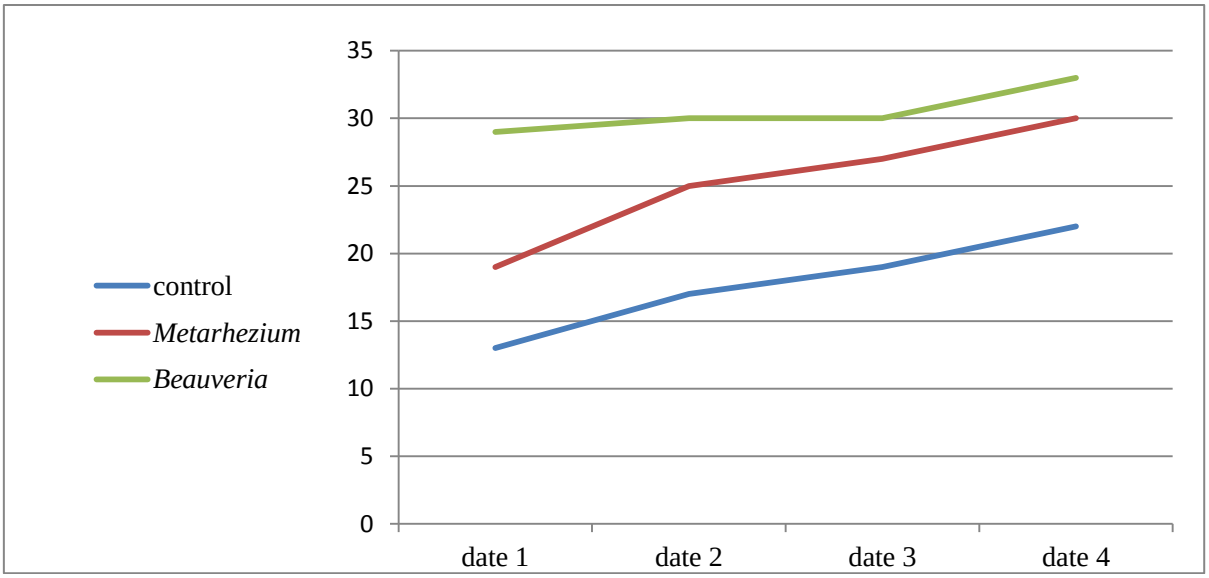

Figure 2. Germination rate of treated and untreated cucumber seeds seven days post-treatment, under outdoor conditions.

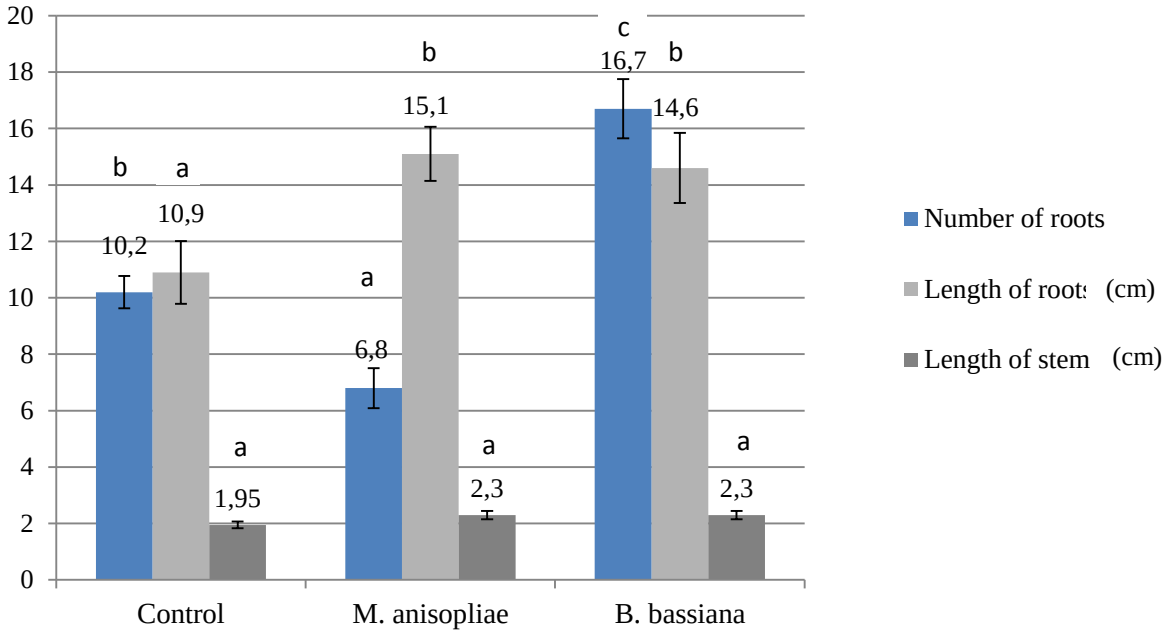

Figure 3. Physiological characteristics of roots and stems of cucumber seedlings after 10 days of incubation of treated and untreated cucumber seeds. Same letters for each parameter indicate non-significant difference according to Duncan test (P≤0.05).

Figure 4. Development and growth of cucumber seedlings untreated and treated with EPFs.

Artificial inoculation of cucumber seeds carried out by their direct submersion into conidial suspensions provided successful colonization of plant parts with tested *B. bassiana* and *M. anisopliae* isolates. Presence of the fungi in the internal tissues was confirmed by their recovery from roots, stems and cotyledon/leaf pieces on Potato Dextrose Agar (PDA) selective medium 10 days post-inoculation. Results in Table 2 and Figure 5 show that both, *B. bassiana* and *M. anisopliae*, isolates 10 days post-inoculation have colonized cucumber seedlings. Significantly higher percentage recovery (100%) was observed in the cucumber plant tissues (roots, hypocotyls and cotyledons) colonized by *M. anisopliae* as compared to 58.3% (cotyledon and stem) and 50 % (roots) of *B. bassiana* endophyte. No fungal growth was recorded in control seedlings (Table 2 and Fig.5).

Table 2. Effect of conidial seed treatments on percentage recovery of B. bassiana and M. anisopliae from different parts of cucumber seedlings.

Treatment	**Cotyledons (% ±SE)**	**Stem (% ±SE)**	**Roots (% ±SE)**
Control	0.0 ± 0.00 a˜	0.0 ± 0.00 a	0.0 ± 0.00 a
B. bassiana	58.3 ± 0.15 b	58.3 ± 0.15 b	50.0 ± 0.15 b
M. anisopliae	100.0 ± 0.00 c	100.0 ± 0.00 c	100.0 ± 0.00 c

˜ Means within a column followed by the same letter are not significantly different according to Duncan test (P≤0.05).

Figure 5. Re-isolation of EPFs from cucumber seedlings

The procedure of artificial inoculation by *Beauveria* and *Metarhizium* caused no visible defects on the germinated seeds and colonized plants did not present any physical symptoms

of damage. No fungal growth was ever observed in PDA plates with last rinse water indicating a high efficacy of surface sterilization procedure and confirming that the fungi growing from surface-sterilized plant materials onto culture media were endophytes that originated from within internal plant tissues. No *Beauveria* and *Metarhizium* were detected from control tissues, which confirms the absence of natural colonization and cross-contamination in control plants.

To our best knowledge, the artificial introduction of *M. anisopliae* and *B. bassiana* into the seed tissue followed by its successful establishment as an endophyte in other parts of resultant cucumber plant is demonstrated for the first time in present study. Interestingly, 79% of studies reported very variable results in the efficacy of artificial introduction of EPF into plants. There are works indicating that a leaf is a poor route of entry for EPF to colonize plants, as was demonstrated for *B. bassiana* on coffee seedlings (Posada *et al.*, 2007) or on tomato plants (Qayyum *et al.*, 2015). It is hypothesized that specific cuticular components might have a detrimental effect on conidium germination, but their effects have not been tested (Posada *et al.*, 2007). This study proves that seed inoculation method is a very successful approach to introduction of EPF into all parts of cucumber plants since recovery of 100% for *M. anisopliae* and 58 % for *B. bassiana* was registered in seedlings and plant parts after 10 days of cucumber seed inoculation.

Current data presented evidence that entomopathogenic fungi, not only had endophytic capacity, but could also act as plant growth promoters in cucumber. Entomopathogenic fungi could significantly increase the germination rate and seedling emergence of inoculated cucumber seeds under laboratory and outdoor conditions. Furthermore, seed-inoculated cucumber plants show significantly higher number and larger length of roots when compared to control plants. These observations prove the potential of entomopathogenic fungi in promoting plant growth and development by a symbiotic relationship that serve as extended root system possibly improving the absorption of nutrients and moisture (Sasan and Bidochka, 2012).

Conclusions

This is the first study to report a significant data on the interaction between *B. bassiana, M. anisopliae* and cucumber seedlings, and thus extends previous reports on the ability of entomopathogenic fungi to act as endophytes. However, there is a need for further research to find out if the colonized tissue with EPF can be used as an effective strategy against pests of cucumber crops.

Abstract

This paper presents information from the first phase of Bulgarian and international *in situ* conservation of grain legumes CWR projects. An expedition investigation has been carried out in regions indicated in the flora of Bulgaria as well as other preliminary studies. Description of several species localities has been carried out in Strandzha Mountain and Kaliakra Natural Reserve - North Black Sea region, which during the past years of species, belonging to the group of rare species in Bulgaria: *Pisum elatius L., Cicer monbretii, Lupinus albus* and *Vicia incisa*. The number of population sand concomitant species have been defined. Seed material for *ex situ* collection has also been collected. It has been found, that the main limiting factors for disturbing condition of natural habitat sare the invasive plant species and some socio-economic reasons. We consider it is necessary to undertake a profound analysis for the situation of preserving the CWR in Bulgaria and to coordinate this activity with all scientific centers and institutions. It is imperative to prepare an action plan and monitoring.

Keywords: *Grain legumes, CWR, in situ conservation, ex situ collection, Action plan, Monitoring.*

Introduction

Crops wild relatives are of particular importance to ensure food security, human health and to preserve the biodiversity in Bulgarian flora. They are impeccable source of diverse genetic material for the breeding process. The wild relatives utilization is especially important today. Due to the introduction of modern and monoculture varieties the diversity of wild relatives decreased considerably. The *in situ* conservation has an important role for the preservation of natural resources common policy. The *in situ* method completes *ex situ* preservation system. This method is effective for all species in their natural habitats.

The lack of capacity, including the absence of effective operational framework and national plan to deal specifically with the conservation of crop wild relatives has been identified as a significant obstacle for their conservation and use.

The purpose of this paper is to develop action plan for *in situ* conservation of grain legumes- *Cicer monbretii, Pisum elatius, L. albus.*

Routes based on the flora in Bulgaria and preliminary studies carried out by Bulgarian scientists were developed *(Mihov et. al., 2001)* with the goal to confirm and establish natural habitats of several species grain legumes wild relatives *(The Bulgarian flora, The Red Book of Bulgaria*). The altitude of localities, size of the population and concomitant species is registered. This research is result from the implementation of national and international projects. A number of botanic expeditions are undertaken to the following routes:

Cicer monbretii– Strandzha Nature Park
- Kosti village
- Road to Gramatikovo village– Malko Turnovo– Ahtopol– Brodilovo village
- Malko Turnovo– Mishkova niva and Indipaskha localitie
- Along Veleka River

Lupinus albus– Strandzha Natural Park

Golyam Pazvlak locality situated in Varvara village
Pisum elatius– Northern Black sea coast
Kaliakra Archaeological Reserve
Yaylata Archaeological Reserve

Materials and methods

The research to the above mentioned areas has been conducted in 2006 -2016.
An expedition investigation has been carried out in regions indicated in the flora of Bulgaria as well as other preliminary studies. Description of several species localities has been carried out in Strandzha Mountain and Kaliakra Natural Reserve - North Black Sea region, which during the past years of species, belonging to the group of rare species in Bulgaria: *Pisum elatius L., Cicer monbretii, Lupinus albus* and *Vicia incisa*. The number of population sand concomitant species have been defined. Seed material for *ex situ* collection has also been collected.

Results and Discussion

1. *Cicer monbretii* is growing in localities in Strandzha Natural Park in an altitude up to 300 m

Important morphological features**:** A perennial, herbaceous plant with up right stem up to 80 cm high. Compound and non-pinnate leaves. The leaves are broad, elliptical, ovate, sharp toothed. The flowers are from 2 to 5, rarely single, in a loose grape-like in florescences in the axil. The banner is ovate, white. Wings are ovoid elliptic a land white. The keelis white with a purple spot. The pod is smooth, broad, oblong, brown, three-fourseminal. The seeds are round, brown or black. Depending on climatic factors the wild chickpea blossoms in the third ten days of May and ripens at the end of June / early July.
The first confirmed habitat of *Cicer monbretii* is on the road to Gramatikovo village– Malko Turnovo and has been registered by Miho Mihov in 2001.Our team discovered and marked habitats on the road to Ahtopol– Brodilovo village in 2010. The two habitats represent a group of plants or a single plant, situated not far from one another, close to the highway. Larger habitats of wild chickpea have been identified in Mishkova niva and Indipaskha localities during joint expeditions with Belgian colleagues held in 2012 and 2014. The habitats grow in proximity to oak forest on cinnamon forest soil. We observed a bigger plant groups occupying an area of 15 – 20 m^2. Although the density is not great, the plant condition is good. Predominant are the species of the families *Poacea* and *Vicia ssp.* The species growing along the streets are vulnerable to road reconstruction and expansion, while these situated in proximity to the forests by sanitation cut, timber industry, excessive tourist impact

are less vulnerable. Seeds from *Cicer monbretii* are collected and multiple growing field trials *(ex situ*) are carried out. All of them failed.

2. *Lupinus albus.* According to preliminary data of Strandzha Nature Park. Management Plan, the species is determined in Golyam Pazvlak locality at an altitude of 70 m-80 m. The locality is rocky with a slight slope.

Important morphological features: The stem is high, stright, branched, covered with white hairs. The leaves are palmated. The petals are pointed, back ovoid et the top, blunted. The stipules are long, soft, partially grown with the handle. The flowers are consistently located, with white color. The pods are oblong, fibrous, pinched with 4-6 seeds. The seeds are flattened, white or lightye llow, smooth, matt.

During the several investigations carried out by our team was discovered that the condition of *white lupin* population is good and it is not threatened by human activity. Natural disasters and erosion are considered as hazards. *Lupinus albus* is represented by single and small group of plants occupying an area of 1000 m^2 at distance varying from 10 m. to 15 m. As concomitant species is determined only *Aegilops*, because the research period coincided with the ripening phase of *white lupin*, while the other species have completed this phase. The habitat of *Lupinus albus* is markedfor *in situ* conservationand is a subject to deeper study to include it in *ex situ* collection.

3 Pisum elatius. During participation in within a project for Development of Management Plan for Kaliakra cape (situated in an altitude of 56 m.) the team has identified the species in 2000 – 2002. A joint expedition with French scientists and our registered organization for conservation of crop wild relatives and old indigenous varieties in 2016 confirmed that *Pisum elatius* grow in Kaliakra cape and is identified in Yaylata Archaeological Reserve (at altitude of 25 m).

Important morphological features: The stems are semi-upright or semi-lodged, slightly branchy, nude. The stipules are ovate and elliptical. Compound leaf with three double leaves, elliptic terminal flower with tendrils. The inflorescence has one –two petals. The small glass is nude. The corolla is purple, elliptic prolong. Wings are elliptic, round. The pod is wide, linear, yellow or brown. The seeds are round, black or dark brown.

The habitat of wild pea growing in Kaliakra cape consists of single plants spread on several areas, while the one on Yaylata Archaeological Reserve the wild pea population is bigger, situated on an area with a length of 210 m. - 215 m and grown on larger areas. The condition of the populations is good. Concomitant species are from the family of *Poacea, Vicia ssp, Lathyrus ssp.* There is nearby large habitat of red *Paeonia peregrina*. We consider as danger of species destruction the climate, erosion as well as incorrect mowing forecast against invasive plants in the Reserve. We collected seeds and conducted multiple growing field experiments (*ex situ*). All of them failed. The long term conservation of crop wild relatives should be national policy supported by the European Union institutions.

Conclusion

The conservation of grain legumes CWR has largely been neglected, due to the exclusion of the agencies responsible for the conservation of plant genetic resources for food and agriculture and those responsible for the conservation of wild plant populations in general or the habitats they grow. The annual monitoring performed at suitable vegetation periods and as well as the support from national bodies will allow long-term *in situ* conservation.

Abstract

The present study was designed to investigate the effect of spray-drying as microencapsulation technique on the stability of roselle calyces (R.C.) anthocyanins. Different extraction conditions were evaluated to identify the best extraction presider for extracting roselle anthocyanins. The results showed that using 2% citric acid solution by 1: 10 solids: solvent ratio with a crushed flower at 85°C for 20min. was the best condition for extraction of the red pigments from roselle calyces and recorded the highest anthocyanin yield of 1229mg/100g R.C. Total phenolic contents (TPC) and antioxidant activity was determined and the results showed that roselle calyces had TPC ranged from 12.16 to 14.45mg. gallic acid equivalent /g. depending on the extraction solvent. Methanol: water (80:20 V/V) recorded the highest TPC. Results also reflected that R.C had a strong antiradical efficiency of 0.727 and EC_{50} of 1.37μg roselle extract/μg DPPH. Thermal stability of roselle anthocyanins was investigated and the results showed that roselle extract heated at 95°C for 30 min. recorded retention value of 80.017%. The effect of three different encapsulating agents i.e. maltodextrin D.E. 18.7, gum Arabic and whey protein isolate on pigments stability was investigated. Maltodextrin DE 18.7 was found as the most effective carrier in stabilizing the pigments under the storage conditions examined with a half-life of 577.62days. The application results proved that the addition of encapsulated roselle anthocyanins as a natural color with the level of 0.3 % in a strawberry drink model system and 0.5% to jelly formulation was acceptable and can replace the synthetic color.

Key words: Roselle (Hibiscus subdariffa L), Anthocyanins, Encapsulation, whey protein, shelf-life, jelly.

Introduction

Today the food industries have an extensive range of both natural and synthetic colors. In line with the generally observed trend from synthetic dyes towards natural colorants (Pedro et al., 2016). However, because of the problems of the synthetic pigments that cause toxicity and carcinogenicity in the human body, the use of them is gradually has decreased. Therefore interest in natural pigments, that can replace synthetic ones, which caused many side effects, is increasing (Limbri et al., 2015). Recently in response to this trend, tend to use natural pigments as adding natural materials in the natural dyeing, healthy functional foods, cosmetic products for human health and safety have been gradually expanded (Kim et al., 2011). Currently, pigments of various kinds and forms have been used as additives or supplements in the food industry, cosmetics, pharmaceuticals, livestock feed and other applications. Roselle (*Hibiscus subdariffa* L.) is a tropical plant belongs to the family *Malvaceae* and is known by Egyptian consumers as Karkadah. Water extract of the Roselle calyces produces a brilliant red color and a pleasant acid test, rich in anthocyanins, and ideal for producing brilliant red colorings in many foods. Roselle anthocyanins as with most natural food colorants, suffer from inherent instability. Color stability of anthocyanins was found to be depending on a combination of various factors including: structure of anthocyanins, pH, temperature, oxygen, light, and water activity. Enzymatic degradation and interactions with food components such

as ascorbic acid, sugars, metal ions, sulfur dioxide and copigments are no less important (Duangmal et al., 2004).

Microencapsulation can be used for many different products such as encapsulation of liquid flavors, enzymes, artificial sweeteners, coloring agents, vitamins and minerals (Mahdavi et al., 2014). Various techniques have been developed for encapsulation of both food ingredients and nutraceuticals, including spray drying, spray cooling/chilling, freeze drying, extrusion, fluidized bed coating, coacervation, liposome entrapment, inclusion complexation, centrifugal suspension separation, co-crystallization and emulsions (Desai and Park, 2005).Spray-drying is the most commonly used technique, on account of it being a continuous, low cost process that produces dry particles of good quality, and for which the machinery required is readily available (Arueya et al., 2014 and Mahdavi et al., 2016).

The main targets of the present work are: First, to investigate the effect of different extraction conditions (solvents type, solvent-to-solid ratio, temperature, extraction time, and particle size) on extraction efficiency of anthocyanins from roselle calyces. Second: to produce dry red powder of roselle pigments by using spray-drying technique and three different encapsulating agents (maltodextrin 18.7, arabic gum and whey protein) and study the stability of the encapsulated pigments during storage. Finally: utilization of the encapsulated roselle extract as food colorants in a model drink and jelly.

Materials and methods

Materials

The Roselle calyces were obtained in a dried form (sun-dried) in summer 2013. The dried calyces were divided into two parts: The first part was kept as it is while the second part was crushed for 5 seconds using a blender (Braun type 4249, CombiMax (Germany). Both of the two parts were immediately packed in polyethylene bags kept away from light at low temperature (4°C) and till used. All chemicals used were purchased from Merck (Darmstadt, Germany).

Methods

Determination of total phenolic content

The Folin–Ciocalteu method was used to determine total phenolic compounds according to the methods described by Singleton, *et al.*,(1999). The total phenolic content was determined by comparing with a standard curve prepared using gallic acid (10–200 µg/ml; $Y = 0.025X + 0.2347$; $R^2 = 0.9986$). The mean of at least three readings was calculated and expressed as mg of gallic acid equivalents (mg GAE)/100 g of roselle calyces.

Determination of radical scavenging activity

The free radical scavenging activity of the anthocyanins was analyzed by using the 1,1-dipheny-2-picrylhydrazyl (DPPH) assay according to Abba Pacôme *et al.*, (2014). The scavenging or inhibition percentage was calculated according to the following equation:

$$\text{Scavenging (\%)} = \frac{(\text{abs. control} - \text{abs. sample}) \times 100}{\text{abs. control}}$$

Where: abs. is absorbance at 515nm

The measurement was performed at least in triplicate. Inhibition of coloration was expressed as a percentage, and the effective concentration 50 % (EC_{50}) was obtained from the inhibition curve.

Extraction of anthocyanins

To investigate the efficiency of extracting condition in the yield of anthocyanince from roselle calyces two different solid-to-solvent ratios (1:10 & 1:20), two temperature values (4°C &

85°C), and two extraction time 20 min & 24h.) were studied. Distilled water & citric acid 2% was used as solvents and the extraction of pigments was carried out according to the procedures described by Cissé *at al.*, (2012) with some modification as described in Table (1).

Table (1): Conditions for extracting of pigments from roselle calyces

Sample	Roselle Calyces	Solvent	Solvent: sample ratio	Temperature	Extraction time
Treatment1	Crushed flowers	Hot water	1:10	85 °C	20 min
Treatment 2	Crushed flowers	Hot water	1:20	85 °C	20 min
Treatment 3	Whole Flowers	Hot water	1:10	85 °C	20 min
Treatment 4	Whole Flowers	Hot water	1:20	85 °C	20 min
Treatment 5	Crushed flowers	Cold water	1:10	5 °C	Overnight
Treatment 6	Crushed flowers	Cold water	1:20	5 °C	Overnight
Treatment 7	Whole Flowers	Cold water	1:10	5 °C	Overnight
Treatment 8	Whole Flowers	Cold water	1:20	5 °C	Overnight
Treatment 9	Crushed flowers	2 % citric acid	1:10	85°C	20 min
Treatment 10	Crushed flowers	2 % citric acid	1:20	85°C	20 min
Treatment11	Whole Flowers	2 % citric acid	1:10	85°C	20 min
Treatment12	Whole Flowers	2 % citric acid	1:20	85°C	20 min

Total pigment content:

Total anthocyanins content of roselle extracts were determined calorimetrically according to the procedure described by Abou-Arab *et al.*, (2011).

Color diminution of roselle calyces extract (L*, a*, and b*)

The color of different samples was determined using a Chroma Meter CR-400 optical sensor (Konica Minolta Sensing, Inc., Osaka, Japan) according to the CIE Lab scale (CIE Colorimetric Committee 1974).

Microencapsulation processes

For encapsulation purposes, maltodextrin 18, whey protein concentrate and gum arabic were evaluated as wall materials the process was cured out according to Idham, et al., (2012) with some modification. Twenty grams of each carrier were dispersed in 150 ml of the pigment extract (5°Brix) and the pH was maintained at the range 2.6. Then, the mixtures were vigorously homogenized at 10,000 rpm for 15min at room temperature. The resulting mixtures were subsequently were fed into the pilot plant spray dryer (Mini Spray Dryer B-290, BÜCHI Labortechnik, Switzerland) with a nozzle atomization system with 1.5 mm diameter nozzle and main spray chamber of 500 x 215 mm. at feed flow rate of 5 cm3/min. The prepared microcapsules were collected in a cyclone and packaged to prevent light incidence and stored at room temperature for further experiments.

Degradation kinetics of the encapsulated pigments:

The degradation of roselle anthocyanins was followed periodically by measuring the coloring power of the stored samples. 0.5 gram of each encapsulated sample was dissolved in 20 mls. of distilled water on 50ml. beaker and magnetically stirred for 10 mins. The pH was adjusted to 2.6 and the volume was made up to the mark with distilled water. After filtration, absorbance was measured at 520 nm using a Spectronic 2000, Spectrophotometer, Busch and Lomb, (USA) and the coloring strength of the extract was expressed using the following formula:

$$E_{cm}^{1\%} = A_{\lambda} / CL$$

Where: $E_{cm}^{1\%}$: Extinction coefficient (55.9), A_λ : Absorbance measured at a particular wavelength, λ; C: Concentration of the anthocyanin, (g./ 100 ml of the solution) and L: Length of the cell, in cm

Degradation parameters including degradation rate constants (k) were obtained from slope of a plot of the natural log of anthocyanins retention and half-life value (T1/2) for the encapsulated roselle anthocyanins were calculated by applying a first-order reaction model.

Applications of encapsulated pigments:

Addition of encapsulated Roselle extracts to a model system of drink

A model system of a drink were prepared according to Duangmal, et al., (2004) with added roselle extract at three different concentrations (0.1, 0.2, and 0.3 % w/v, 0.1% w/v, carmine and 0.05% w/v Carmoisine) was studied.. The anthocyanins content and color were measured at zero time. The bottles were divided into two groups: the first group was stored in the refrigerator at 4-5ºC, the second was stored at room temperature (40 ±2 ºC). For each sample group, one bottle was randomly selected for analysis every week for a period of 10 weeks.

Addition of encapsulated Roselle extracts to strawberry jelly formulation

Jelly powders were prepared according to Egyptian Standard ES: 800/ 2007. Three treatments of jelly with different adding reoselle extract, were prepared with added roselle extract at concentrations of 0.167, 0.33 and 0.50%, while carmine treatments was colored with carmin at concentration of 0.167%. Control treatment was a commercial jelly powder including synthetic color (carmoisine). Jelly samples have been sensory evaluated for jelly attributes such as color, flavor, texture, Transparency, and overall acceptability.

Statistical analysis

Data were expressed as the mean± SD for five rats in each group. The data were analyzed using SPSS software package version 20.0 and values were analyzed using one-way analysis of variance (ANOVA). Duncan's multiple range tests at 5% level of significance were used to compare between means.

Results and dissection

Total phenolic and antioxidant activity of Roselle extract

The results showed that the highest phenolic compounds were found when methanol: water (80:20) was used as extracting solvent (14.245mg /g roselle calyces) followed by citric acid solution and ethanol: water (50:50) which gave 13.71mg/g and 12.83mg/g roselle calyces) respectively. On the other hand, distilled water extracted the lowest quantity of phenolic compounds. This finding could attribute to the polar character of the phenolic compounds which makes them soluble in the polar solvents such as methanol, ethanol, and water (Chinedu et al., 2011). Also, the presence of acid solvent extraction of anthocyanins is the initial step in the determination of total and individual anthocyanins prior to quantification, purification, separation, and characterization (Abba Pacôme et al., 2014 and Jafarian et al., 014).

DPPH radical-scavenging activity of the Roselle calyces extract

The results of the antioxidant activity of different concentrations of the roselle extract are shown in figure (1). The results indicated that the DPPH radical-scavenging activity of roselle calyces was occurred in a dose-dependent manner. With increasing the concentrations of roselle extract the inhibitory activity against the DPPH radical increased. The lower EC_{50} value reflects better protection action against oxidation. The concentration required to inhibit 50 % radical-scavenging effect (EC_{50}) was determined from the results of a series of concentrations tested. A lower EC_{50} value corresponds to a larger scavenging activity. The EC_{50} values of the roselle extract were EC_{50}= 1.375µg roselle extract /µg DPPH and antiradical efficiency AE (0.7272). These results reflated that when roselle extract used with a

concentration of 0.31μg roselle extract /μg of DPPH the inhibition ratio was 20.22% while the concentration of 6.94μg roselle extract /μg of DPPH recorded inhibition ratio of 90.69%.
These results indicated that there are abundant antioxidative phytochemicals present in the clyces extracts of roselle. Our results are similar to that reported by Abba Pacôme et al., 2014; Tsai et al., 2012 and Sirag et al., 2014)**.**
The strong antioxidant activity of roselle extract could be due to the presence of polyphenol compounds. Abou-Arab et al., (2011) Investigated antioxidant activity of roselle plant extracted by different solvents and indicated that the ethanol acidified with 1% citric acid extracts exhibited higher value in total antioxidant activity and recorded (EC_{50}) of 42.77 (μg/ml).

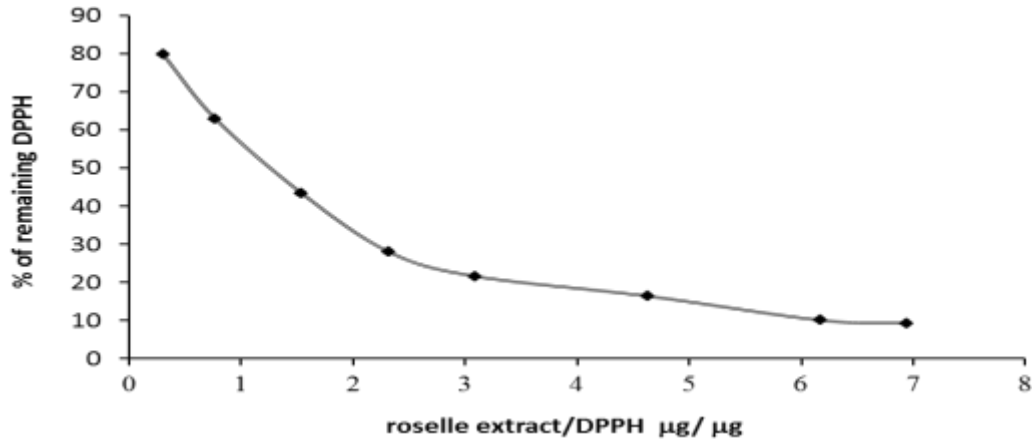

Fig. (1). Percent of remaining DPPH as function of μg of roselle extract per μg DPPH

Effect of extraction conditions on the extraction efficiency of roselle anthocyanins
The effect of extraction condition on the yield of pigments recovered, the total soluble solids and the pH of the extracts are showed in table (2). By reducing the particle size, the yield of anthocyanins was increased in all the extraction conditions examined. The crushed flower gave total anthocyanins of 0.994.18mg./100g. dry weight while the whole flower gave 912.96mg/100 dry weight under the same conditions. It could be also noted that adding citric acid to the extraction medium had a great effect in stabilizing anthocyanins, thus the extraction efficiency increased. When 2% citric acid solution was used as extraction solvent with crushed flower and 1:10 solid: solvent ratio, total anthocyanins recorded 1229.62 mg. /100g dry weight. These observations reveal that the pH value is a very important factor affecting the extraction of anthocyanins. It was reported that the extracting solution should be slightly acidic to maintain the flavylium cation form, which is red and stable in highly acidic medium Andersen and Markham, 2006 and Abou-Arab *et al.*, (2011). Likewise, Chandrasekhar et al., (2012) reported that and the mixture of 50% (v/v) ethanol and acidified water resulted in maximum anthocyanin content (390.6 mg/L). Similar results were reported by (Cisse et al., (2012) and Oancea et al., (2012) and Lambri et al., (2015). Extracting the anthocyanins at 85°C for 20min recorded higher anthocyanin content than extracting at 5°C for overnight in all condition investigated (Pedro et al., 2016).

Table (2): Extraction efficiency of different extraction conditions and color diminution of the extracts

Sample	T.S.S	pH	Total anthocyanins Mg./ 100 g/ D.W.	L*	a*	b*

Degradation kinetics and storage stability of encapsulated Roselle anthocyanins.

Kinetic studies on the degradation of roselle anthocyanins encapsulated in Maltodextrin DE 18.7, Whey protein isolate (90 %) and Gum Arabic, were carried out in dark at30ºC and control sample without carrier. changes in color strength for the different encapsulated roselle anthocyanin powders were followed by periodical measurements of absorbance to define the order of anthocyanins degradation reaction. As illustrated in Fig. (2). Plotting color strength values (Ln E_{520}) vs storage time (days) gave straight lines for the different encapsulating agents and control. Linear regression analysis showed that the degradation of roselle anthocyanins encapsulated in the three evaluated coating materials followed first-order reaction kinetics. Similar kinetic responses were reported by Martynenko, et al., (2016) and Gradinaru et al., (2003) for the degradation of pelargonidin based anthocyanins at different water activity conditions.

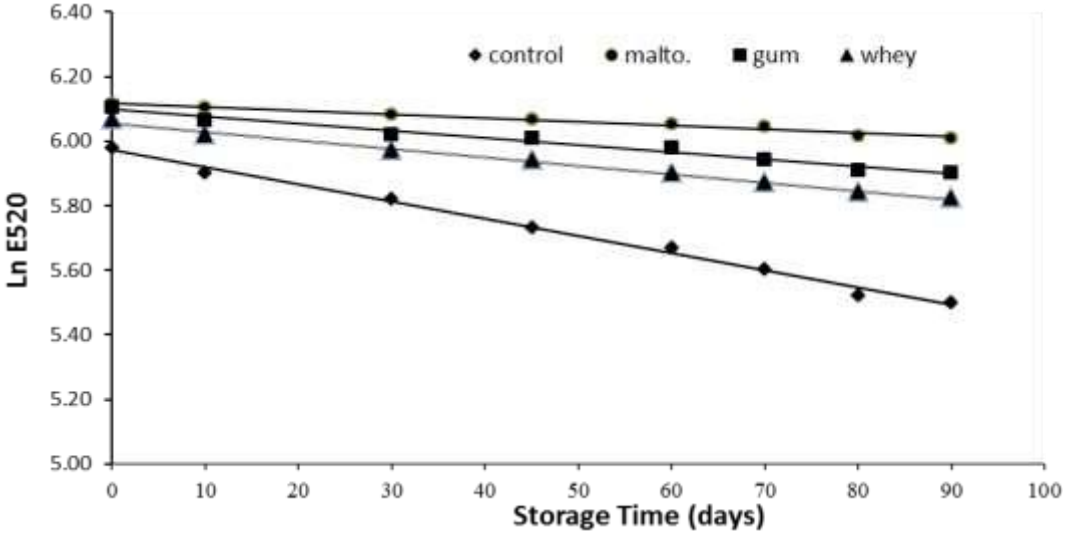

Fig. (2): First-order degradation plots for spray-dried roselle anthocyanins with different encapsulating agents during storage at 30°C in dark containers.

Degradation rate constants for anthocyanins encapsulated in the different matrices were calculated with the correlation coefficients and half-life period and the data is presented in table (3). The obtained results showed that degradation rate constant values were 5.3, 1.2; 2.2 and 2.6 X 10^3 for the control, Maltodextrin DE 18.7; Gum Arabic Whey protein isolate respectively. The highest value of the rate constants for anthocyanins degradation was

observed at for the control sample while the lowest rate constant was recorded for Maltodextrin DE 18.7. Among the polymeric matrices, which largely elongated the half-life of roselle anthocyanins, maltodextrin DE 18.7 was found as the most effective carrier in stabilizing the pigments during storage.

Table (3): Degradation rate constants for roselle anthocyanins encapsulated in different encapsulating agents during storage at 30 °C in the dark

Encapsulating agent	Rate constant ($days^{-1}$)	Correlation coefficient R^2	Half - life period (days)
Control	5.3×10^3	0.99	130.78
Whey protein	2.6×10^3	0.99	266.60
Gum arabic	2.2×10^3	0.98	315.07
Maltodextrin	1.2×10^3	0.97	577.62

The half-life period of the encapsulated roselle anthocyanins were increased feom130.78 for the control sample to; 266.60; 315.07and 577.62 days for Whey protein isolate; Gum Arabic and Maltodextrin DE 18.7 respectively. Similar kinetic responses were reported by Gradinaru et al., (2003 and Sipahii et al., 2017**)**. The could be due to the open porous structure obtained in the freeze died final product, which makes it exposed to air if the encapsulated product is not packed under vacuum or inert atmospheric condition (Gómez-Carracedo et al., 2007).

Roselle anthocyanin stability in a drink model of system.

One of the most key factors affects the applications and usage of natural colorants in the food industry is the stability during storage and handling. Roselle anthocyanin stability in a drink model system has been investigated during storage of the drink model at 40 °C & 5 °C. Three different concentration of roselle anthocyanin (0.1, 0.2 and 0.3%) were used; Carmine E 120 dosage 0.1% and Carmoisine E124 dosage 0.05% were used for comparison as the most common used red colors; Natural and synthetic respectively. The color retention was measured periodically by 10 days; the results are shown in Figure (3). When the samples were stored at 40 °C, the drink model samples were colored by the roselle anthocyanin extract lost their color faster than the drink model samples colored with Carmoisine and Carmine.

During storage at 40°C, the sample colored with roselle anthocyanin 0.1% was recorded the highest color losses and recorded a retention ratio of 26% after 70 days storage. The results reflected that the storage temperature had a very important effect on the roselle anthocyanin stability.

When the drink samples stored at 5°C, the degradation rates for the five treatments were lower than the degradation when stored at 40 °C. After 70 days storage at 5°C, the drink model samples colored with roselle anthocyanin retained 42.16, 45.37 and 68.65 % of anthocyanin content, while drink model samples with Carmine and Carmoisine retained 78.05 and 87.01 of the color content respectively.

It could be noted that with increasing roselle anthocyanin concentrations, the stability of color was increased. Therefore, colored sample with 0.1% roselle anthocyanin extract retained only 41.03 % while the sample colored with 0.3 % roselle anthocyanin extract retained 60.35 % of its color after 70 days storage at 5 °C. This is could be due to the copigmentation reaction which enhanced the stability of roselle anthocyanin. Similar findings were reported by Gris et al. (2007); González-Manzano et al., (2008).

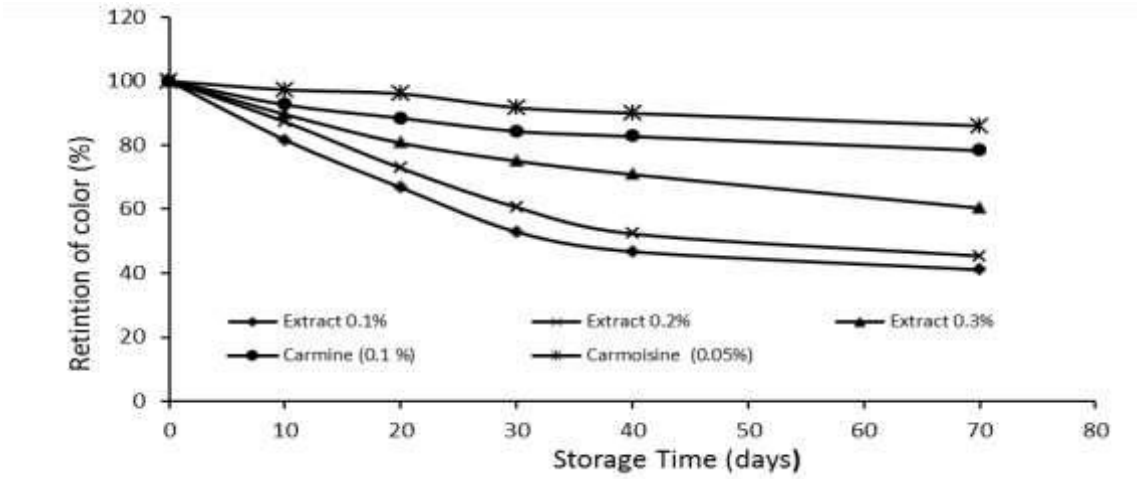

Fig. (3). Stability of roselle anthocyanin in a drink model of system stored at 5°C.compared with carmine and carmoisine.

Application of encapsulated roselle extract in jelly formulation.

The prepared jelly samples were sensory evaluated and means scores were statistically analyzed and the results are presented in fig. (4). The results indicated that no significant differences ($p > 0.05$) found between sample colored with carmoisine; carmine and sample colored with roselle anthocyanins at a level of 0.5% as coloring agent. On the other hand, there were significant differences between samples colored with roselle anthocyanins at low level 0.16 and 0.33 and the other samples. It could be notes that jelly sample colored carmoisine scored the highest value for color of (9.67) while the sample with 0.167roselle anthocyanins recorded the lowest value for color of 7.50.

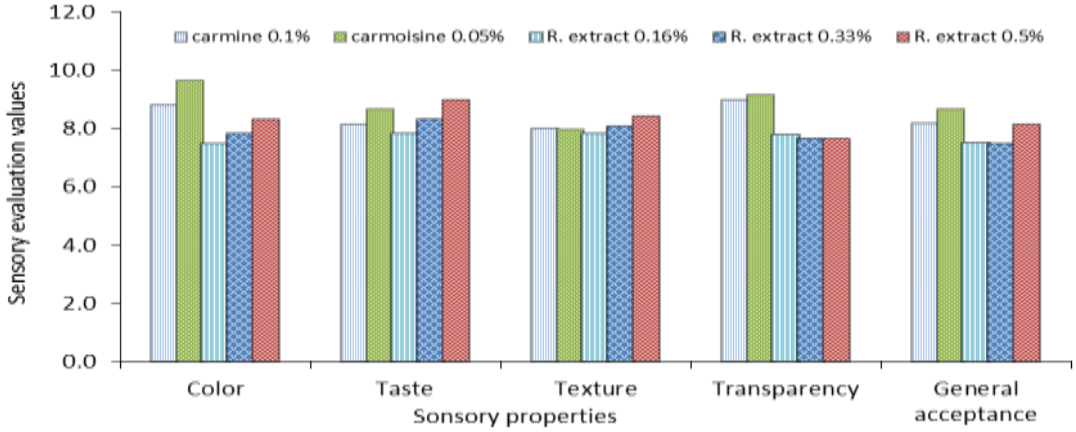

Fig. (4). Sensory evaluation of jelly samples containing encapsulated roselle extracts, carmine and carmoisine.

Regarding to the samples taste sample with roselle extract at a level of 0.5% recorded the highest taste value of 9.00. The results reflected that there were no significant differences ($p > 0.05$) between all samples except the sample colored with roselle extract at a level of 0.16% which scored the lowest value for taste (7.83). The results showed that no significant differences ($p > 0.05$) found in sample colored with carmoisine and carmine in transparency while those colored with different concentrations of roselle anthocyanins i. e. 0.16, 0.3 and 0.5% were not significantly different. Sensory data showed there were no significant differences based on texture of all samples. Concerning the overall acceptability, most of the panelists preferred the samples colored with carmoisine and carmine and samples produced with 0.5% roselle anthocyanin. Based on data collected from sensory evaluation in the

studies, adding 0.5% of roselle anthocyanins to the jelly formula gave close scores to carmoisine and carmine samples thus, indicates that the addition of the natural color with level of 0.5% to the jelly formulation was acceptable and can replace the synthetic color. Similar results were reported by Mahdavi et al., 2016.

Conclusion

Using 2% citric acid solution by 1: 10 solids: solvent ratio with a crushed flower at 85˚C for 20min. was the best condition for the red pigments from Roselle calyces. Encapsulation of anthocyanins with polysaccharides enhanced the stability of anthocyanins for efficient utilization in food systems. The storage stability result supported that maltodextrin as wall material gave the longest shelf life and the smallest change in the pigment color. Storage period significantly affect the color changes of the spray dried powder. Hence, this study signifies that the encapsulation process could stabilize and extend the shelf life of anthocyanins content. The results indicate that the addition of roselle anthocyanins as a natural color with the level of 0.3 % in the drink model system and 0.5% to the jelly formulation was acceptable and can replace the synthetic color.

Abstract

Potato is one of the most important food crops in Georgia. Average yield of potato in Georgia is still low (8-11 tons/ha). Potato diseases are the main reason for yield losses. Potato wart (causal agent *Synchytrium endobioticum*) is a very harmful quarantine disease distributed in nearly 60 countries of the world including Georgia. According to official results of the observations of potato plantations and depositaries undertaken in 2009-2012 in Khulo mountainous region (western Georgia) potato wart was detected for the first time and identified in samples collected in several villages (Ghorjomi, Tkhilvana, Danisparauli, Diakonidzeebi) of Khulo municipality which was the economically important place for potato production (Gorgiladze et. al., 2014). However, the potato growers from villages Tabakhmela and Didajara observed wart symptoms earlier, in 2006 on potato cv. 'Agria', which was widely grown there for home consumption. According to the disease survey results obtained in the frame of the PhD work the incidence area of potato wart was extended. Namely, in 2016-2017 the disease was also found in 13 villages of Khulo municipality on varieties Briz, Impala, Finka, Picasso and Marfona, Saturna and in one Mestia village of the highland Zemo Svaneti region (northwest Georgia). The disease symptoms were observed on the tubers, stolons and root neck. All samples obtained were identified as *S. endobioticum* based on the morphological descriptions (OEPP/EPPO, 2004) and a specific PCR test using primers F49 and R502 (van den Boogert *et al*., 2005). The research has been continued under PhD grant of Shota Rustaveli National Science Foundation.

Keywords: *Potato wart, Georgia, Incidence area*

Introduction

Potato, which was first introduced in Georgia in 1820s, is one of Georgia's major staple and cash crops nowadays. Because of the wide range of environmental conditions in Georgia and the ability of potatoes to adapt to different conditions, potatoes grow two times a year. The area under potato cultivation varies between 30.000 and 37.000 ha per year, but the productivity still remains very low (Table 1) (GeoStat, 2017).

Table 1. Production and average yield of potato by regions

Region	Production of potato (ths. Tons)				Average yield of potato (t/ha)			
	2014	**2015**	**2016**	**2017**	**2014**	**2015**	**2016**	**2017**
Adjara AR	16.5	11.5	14.2	15.3	11.6	7.3	12.3	13.0
Kakheti	…	…	4.5	4.6	…	…	5.3	4.7
Mtskheta-Mtianeti	…	…	3.2	2.4	…	…	5.7	5.6
Samtskhe-Javakheti	99.7	101.2	160.5	103.4	13.4	10.1	14.9	9.6

Kvemo Kartli	70.6	49.8	44.1	38.0	12.3	8.2	10.5	9.3
Shida Kartli	…	…	16.0	10.5	…	…	7.9	5.8
The remaining regions	28.5	24.0	6.5	5.8	7.2	4.7	8.0	7.8

Source: National Statistics Office of Georgia (2017)

According to the data of GeoStat (2017), the average yield of potato ranges from 8 to 11 t/ha. Specifically, 57% of the total volume of potato production is produced in Samtskhe-Javakheti region, 21% - in Kvemo Kartli, 9% - in Adjara, 6% -in Shida Kartli, 3 % - in Kakheti, 1% -in Mthkheta mtianeti, and 3% - in other regions (Fig. 1), which confirms the lowest productivity of potatoes.

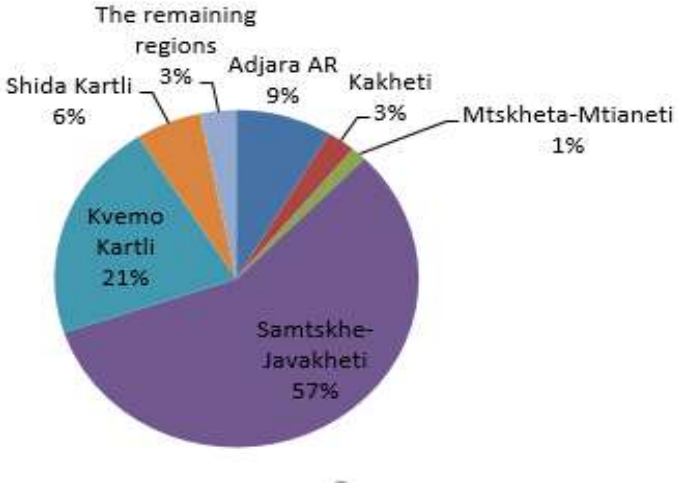

Figure 1. The percentage index of potato production per regions

In Georgia, the reduction in the potato production is due to various reasons. Namely, due to the growth of unadapted varieties, the substandard potato seeds, low level of the agrotechnical system, the lack of primary seed-growing system, and so on. Among them, pests and diseases are major constraint contributors. The most important disease affecting potato crops is the potato wart disease (PWD) which is caused by soil-borne fungus *Synchytrium endobioticum (Schilberszky)* Percival. The pathogen is an obligate parasite causing the proliferation of warts on potato tubers, stolons, the aerial buds at the stem bases, which may vary markedly in form. Deformation of leaves may also occur, with the exception of roots (OEPP/EPPO, 2017).

Potato wart disease contributes to yield losses in the range of 50-100% (Hampson, 1993; Melnik, 1998). The major agricultural problem is not only the yield losses, but also the contamination of soil with persistent resting spores of *S. endobioticum* remaining infectious for more than 20 years (Obidiegwu *et al*., 2014), that requires the long-term official control, quarantine, the prohibition of the growth of potatoes on it and legal sanctions (Hampson 1993; OEPP/EPPO, 1999, 2017). Subsequently the fungus is currently considered the most important quarantine pathogen of cultivated potato (Smith et al. 1997). It is included in the A2 list of quarantine of EPPO (OEPP/EPPO, 2004), and is also the limited distributed quarantine organism in Georgia (Order of Minister of Georgia, 2006).

S. endobioticum originates in the Andean zone of South America, from where it was introduced into Europe through the movement of infected or contaminated tubers in the

1880s. It spread widely in Europe, Asia, Africa, America and Oceania including 47 countries (EPPO/CABI, 1997). The disease has been occurring in Georgia since 2009. It was first found in two villages of Khulo Municipality. However, according to stories of growers from this region wart symptom was noted in 2006 on potato variety Agria. As the result of the survey conducted in 2012-2013 in the frame of GNSF grant, potato wart was also found in other villages of Khulo municipality (Gorgiladze et al., 2014).

Despite the studies conducted in Georgia in 2009-2013, precise details on records of the distribution of potato wart incidence for the demarcation of infested areas have not been known.

This paper presents the results of the disease survey conducted within the framework of the Ph.D. work, namely, of potato wart monitoring in producing regions of Georgia and determining the boundaries of its foci to prevent the spread of disease.

Materials and Methods

To detect the potato wart loci, determine quarantine and disease incidence area in accordance with pre-determined plan and route, the observation of the potato plantation in the fields and potato tubers in the depositories in the different potato producing regions of Georgia were conducted by expeditions depending on potato planting and harvesting time.

The infected potato tubers and other parts of plants, and soil samples were collected from fields according to standard protocols recommended by EPPO (PM 7/28 (2)) in 2016-2017. Identification of *S. endobioticum* was mainly based on microscopic observations of summer sporangia and winter (resting) sporangia (OEPP/EPPO, 2017). The specific polymerase chain reaction (PCR) was conducted for accurate detection and quantification of *Synchytrium endobioticum i*n soil samples and in plant parts (van den Boogert et al., 2005)

Results and Discussion

According to the results of the survey, the potato wart was found in 17 villages of Khulo municipality by inspection of tubers at harvest on potato varieties Dezire, Briz, Impala, Finka, Picasso, Marfona, etc, and the pathogen was also detected from the soil samples (Fig.2).

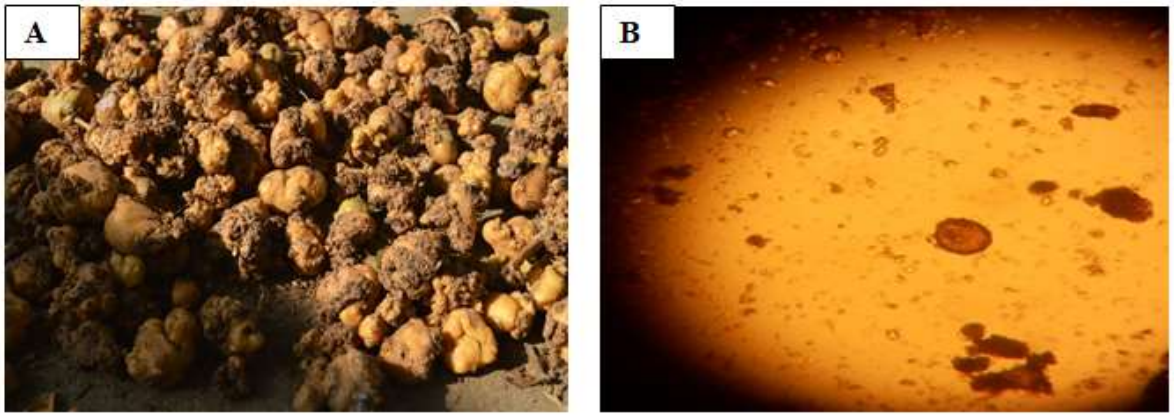

Fig. 2. A figure shows infected tubers of potato collected in the village Skvana: B figure shows the winter sporangia detected from the soil sample

As for Mestia, municipality (the highland Samegrelo-Zemo Svaneti zone of northwest Georgia), the pathogen was only detected in the soil samples in four villages of Ushguli settlement. The infested areas in Adjara AR and Zemo Svaneti are very separated (Fig.3).

Figure 3. Geographical distribution of the main places of surveys of *Synchytrium endobioticum* in Georgia

The infested areas are indicated in Table 2. Disease incidence was very high and the fields were heavily infested in the private plots of villages of Khulo municipality. Soil analyses performed in Khulo infested plots have been shown existence 5-30 sporangia per 1g of soils. Presumably, the pathogen was introduced in Georgia through infected seeding material of potato from Armenia and Turkey where the disease occurred. Areas of disease have increased because quarantine measures to prevent the spread of disease have been begun very late in Georgia.

Table 2. Areas infested by *Synchytrium endobioticum* in Georgia

Potato growing regions	**Villages**

	Zhibiani
	Latali

Disease surveys are continued in Georgia under PhD work and in accordance with the Order of Government of Georgia #305, 25th June, 2015 on the Rule of Potato Wart Control.

Conclusions

A survey showed that potato wart *(Synchytrium endobioticum*) is limited distributed and occurred in two regions: Khulo and Zemo Svaneti with different severity.

THE ECONOMIC PARTNERSHIP AGREEMENT BETWEEN THE EUROPEAN UNION AND JAPAN: A COMPARATIVE ANALYSIS WITH FOCUS ON THE QUALITY STANDARDS IN THE AGRI-FOOD SECTOR

Katja PIETRZYCK[1]*, Annette REXROTH[2], Brigitte PETERSEN[1]

[1]International Food Net Center, University of Bonn, Germany

Abstract

In 2013, the European Union (EU) initiated negotiations for an Economic Partnership Agreement (EPA) with Japan, one of the largest economies in the world and a key trading partner. After 18 rounds of negotiations, both partners agreed on the principles and implementation of this Free Trade Agreement (FTA) on 6 July 2017. The final EU-Japan agreement is expected to enter into force at the beginning of 2019 and will give both economies a major boost, lowering tariffs and trade barriers as well. Primarily, it will open new markets for agri-food export. Moreover, it is another strong example of the global supply chain matters and the sharing of values and interests. This study outlines the current situation of quality standards used in the EU and Japan. Japan, as well as the EU, have their own regulatory schemes applied to labeling, certification and trade in the agri-food sector. The purpose of this study is to investigate the differences between their standards and gain more insight into their similarities. The research has three major objectives. Firstly, the food safety regulations of the EU and Japan will be discussed more detailed. Secondly, the primary investigation of this paper is to compare those food safety standards and focus on their equivalency issues. Finally, the study insists on the necessity of understanding the importance of the emerging issues from food safety equivalency in relation to trade between the EU and Japan. Thus, the main research question, namely, till what extent are the food safety standards between the EU and Japan equivalent, will be answered and analyzed in this paper.

Keywords: *agri-food industry, food safety, quality standards, EU-Japan Economic Partnership Agreement (EPA), Free Trade Agreement (FTA).*

Introduction

The economic ties between countries are characterized by globalization. The European Union (EU) applies an open trade and investment policy with respect to the rest of the world. In that sense, the EU promotes free and fair world trade, agreeing to progressive international trade treaties as well as tearing down trade barriers at the same time as to ensure human health. Japan and the EU have been working together bilaterally for decades. They agreed on a joint Economic Partnership Agreement (EPA) in 2017, which has been signed on 17.07.2018. This Free Trade Agreement (FTA) aims to strengthen trade relations and set a strong signal in the world [EC, 2018a; EC, 2018b]. In their negotiations for EPA between 2013 and 2017, the EU and Japan aimed not only to reduce tariffs but also to establish regulatory coherence. Japan is considered a country with very high product standards in the agri-food sector and exemplary consumer protection. Nevertheless, disturbances which endangered human health occurred in the past. Cases of food poisoning, bovine spongiform encephalopathy (BSE), avian influenza and fake labeling have arisen a strong interest and awareness of food safety within the Japanese population [Morishita, 2012]. This study is motivated by the importance for both European food producers and exporters to understand Japanese food safety measures in the light of the EPA. In order to gain a comprehension of the legal framework for food safety and the quality standards of the agri-food sector of the two cooperating parties, the authors have

explained, compared and discussed these aspects in detail, focusing on Japan. The relevance of the EPA in the context of the food safety regulations and quality standards has not been appropriately analyzed yet. Moreover, this study should be useful for policymakers and exporters.

Materials and methods

An intensive desktop analysis was conducted to analyze food safety measures and to compare food safety systems in Japan and the EU under the EPA, including a literature review of available documents and reports on the outcome of the FTA negotiations and food safety regulations in Japan and the EU.

Results and Discussion

Overview of the EU-Japan Economic Partnership Agreement (EPA)

Cooperation between the EU and Japan already has a long history. In the past, several significant agreements were negotiated and adopted between the two partners. In the 1970s, the EU Commission supported European companies in their export efforts and the market entry activities in Japan by special promotional programs. In 1999, the EU-Japan Business Round Table has been established [Felbermayr et al, 2017]. In January 2002, the Mutual Recognition Agreement came into force. Later, in June 2003, the Agreement on Cooperation on Anticompetitive Activities was approved by the EU Council. In the following, the Agreement on Cooperation and Mutual Administrative Assistance came into effect on 01.02.2008. The Science and Technology Agreement between the EU and Japan was signed on 30.11.2009. Following many bilateral discussions and a constructive dialog at the EU-Japan Summit in 2011, the negotiations for an Economic Partnership Agreement, which constitutes a bilateral Free Trade Agreement (FTA), were finally officially launched on 25.03.2013. After 18 rounds of negotiations, the partners reached a basic agreement on 07.07.2017. Afterward, a few technical details were clarified and the fine adjustment has been made so that the EPA could be signed on 17.07.2018 by both partners. Ultimately, formal consent by all EU Member States and the European Parliament must be granted (ratification). In Japan, representatives from two parliaments, the Lower and Upper House, must approve the agreement. The entry into force of the EPA is expected in 2019 [EC, 2018a; Deloitte, 2018; EC, 2018b]. The aim of both partners is to engage in free and fair trade and to counteract isolationism. An important intention of the EPA is to send a strong signal to the world and counteract protectionism. The primary objective is also to strengthen international standards and reduce tariff and non-tariff barriers between the EU and Japan [EC, 2018a]. The EPA consists of 23 chapters, whereby the Agri-Food sector is directly or indirectly affected in many chapters. Chapter 2 (Trade in goods) stipulates the liberalization of Japanese agricultural imports. Nearly 99% of bilateral trade goods have been liberalized, with the exception of rice and seaweed. 91% of all import tariffs will be gradually phased out. A distinction is made between a full tariff elimination and a progressive elimination of customs duties, with product-specific annual installments beginning on the date of entry into force of the FTA. Imports of wine and other alcoholic beverages will be duty-free immediately with the entry into force of the EPA (previously 15%). Customs duties on pork meat shall be eliminated, from 4.3% to duty-free, in six equal annual installments as well as the complicated import regulations shall be reduced. For processed pork, the tariff rate will be diminished from 8.5% to 0%. Moreover, the tariff for beef will be reduced from 38.5% to 9% in 15 annual installments. Due to the FTA, a gradually reducing of import tariffs for hard cheeses from 28.9% to duty-free within the next 15 years is specified. For soft cheese and cream cheese, a duty-free quota has been implemented. Generally, the quotas for dairy products have been increased [EC, 2018a]. Other important chapters of the EPA are Chapter 3 (Rules of

origin and origin Procedures), Chapter 7 (Technical barriers to trade), Chapter 16 (Trade and sustainable development), Chapter 18 (Good regulatory practices and regulatory cooperation) and Chapter 19 (Cooperation in the field of agriculture). By virtue of chapter 6 (Sanitary and phytosanitary measures (SPS)), the two partners reaffirm their rights and obligations under the WTO. The SPS standards and regionalization in disease control have been mutually recognized. Noteworthy is Chapter 14 (Intellectual property), with which Japan recognizes 205 geographical indications (GIs) of the EU and provides trademark protection [EC, 2018b]. Significant studies which analyze the most important assumptions, objectives and scope of EPA regarding the effects on the EU economy are "On the economics of an EU-Japan Free Trade Agreement" [Felbermayr et al., 2017], "Market opportunities for EU agribusiness in the context of the EU-Japan EPA" [Fournel, 2017], "Trade Sustainability Impact Assessment of the Free Trade Agreement between the European Union and Japan" [EU, 2016] and "Assessment of Barriers to trade and investment between the EU and Japan. Copenhagen Economics" [Sunesen et al., 2009]. The EU predicts that the EPA will increase bilateral trade in goods and services by 24% [EC, 2018b].

Food Safety regulations and policy measures in the EU and Japan

This section presents the legal framework, food security policies, state and private quality standards of the EU and Japan and compares them, if possible.

Food Safety in the EU

In response to the BSE scandals, food law in the EU has been revised and restructured. As a result, the legal basis of EU food law is the General Food Law (EU-GFL) (Regulation (EC) No 178/2002) of 28 January 2002, which lays down the general principles and requirements of food law, it establishes the European Food Safety Authority (EFSA) and lays down procedures in matters of food safety. Furthermore, the Rapid Alert System for Feed and Food (RASFF) has been introduced. This law is mandatory for all EU Member States and covers the entire agri-food value chain from production until the point of consumption. The three main objectives of EU food law are settled in Article 5 of the EU-GFL. The three main objectives of EU food law are settled in Article 5 of the EU-GFL and are intended to protect public health, plant health, animal health with respect for animal welfare, prevention of fraud and deception by providing appropriate information. In April 2004, the EU adopted three further important regulations, the so-called hygiene package, which are directly linked to EU-GFL: Regulation (EC) No 852/2004 on the hygiene of foodstuffs, Regulation (EC) No 853/2004 laying down specific hygiene rules for food of animal origin and Regulation (EC) No 854/2004 laying down specific rules for the organization of official controls on products of animal origin intended for human consumption. From all the legal bases mentioned above result the seven basic principles of EU food safety: (1) Principle of the agri-food chain with defined responsibilities, (2) Principle of corporate responsibility, (3) Principle of traceability of the origin of all products „From farm to fork", (4) Risk analysis with independent scientific risk assessment, (5) Separation of risk assessment and risk management, (6) Precautionary Principle and (7) Transparent and efficient risk communication. Furthermore, the application of the concept of Hazard Analysis and Critical Control Point (HACCP) is mandatory in the EU.

In addition to the governmental regulations valid throughout the EU, European food manufacturers also apply the international DIN EN ISO standards and private standards, for instance, IFS Food (International Featured Standard), BRC (British Retail Consortium), QS Standard (Quality and Security GmbH), GlobalGAP and GMP+. At the retail level, many supermarket chains have set their own standards that manufacturers must comply with. These standards are often stricter than EU law and a number of quality labels have emerged.

Food Safety in Japan

The Japanese administrative system is similarly structured to that in the EU and pursues the same goals. The legal framework is the Food Sanitation Law (FSL), the Food Safety Basic Law (FSBL) and the Japanese Agricultural Standard Law (JASL).

The FSL first came into force in 1947 and has been partially modified several times over the years. This law ensures the safety and hygiene of food an in May 1996, the voluntary application of HACCP has been included. In 2002, regulations on import and sale bans were added. Another milestone was the introduction of a "positive list" for agricultural chemical residues in foods in May 2003. At the same time, the Monitoring and Guidance Plan was implemented. In addition, the FSL prohibits to put foods containing harmful substances on the market and lays down guidelines for food standards, additives and packaging. Comparable with the EU basic principles is, inter alia, Article 3 of the FSL which establishes the entrepreneurial responsibility for the entire production chain of food. The law also defines the operating principles of the Ministry of Health, Labor and Welfare (MHLW), which is the food authority at the national level.

The second most important food safety basis in Japan is the FSBL, which came into force in May 2003 and builds/is based on the FSL. It sets the principles for developing a food safety regime and describes the role of the Food Safety Commission (FSC) and Justification of the Prime Minister's Office. Basically, this law is comparable to the EU-GFL.

The Law Concerning Standardization, etc. of Agricultural and Forestry Products, known as JASL, lays down the operating principles of the Ministry of Agriculture, Forestry and Fisheries (MAFF) and specifies the mandatory and voluntary labeling regulations. Also, it is linked to the Food Labeling Act, which is used in the consumer agency division. This law has been in force since 1950 and has been amended several times. It aims to improve quality, increase productivity, enhance fairness and simplicity of transactions, rationalize the consumption and utilization of agricultural and forestry products, as well as the protection of consumer interests. Due to this law, a standardized certification system (JAS system) has been established, which provides the voluntary use of the JAS label. On the one hand, an examination of the products by MAFF is required, on the other hand, the certification must be carried out by authorized certification bodies. The certification ensures a certain quality of agri-food products, which were produced by specific methods. For organic food products the use of the JAS standard is mandatory. The JAS is a consumer protection standard, so labels have been established for consumers visibility. The different JAS labels are shown in figures 1-5.

Figure 1: Logo for General JAS *Source: MAFF, 2018*	Figure 2: Logo for Specific JAS *Source: MAFF, 2018*	Figure 3: Logo for Organic JAS *Source: MAFF, 2018*	Figure 4: Logo for Production Information JAS *Source: MAFF, 2018*	Figure 5: Logo for distribution under fixed temperature control JAS *Source: MAFF, 2018*

The general JAS (figure 1) has been applied to all foods and forestry products. It confirms quality, such as grade, composition and performance. The second logo (figure 2) is awarded to certified products that conform to specific processing procedures or manufacturing methods and that have distinctive characteristics of quality, thus standing out from ordinary products. The organic label (figure 3) is not voluntary, so if an organic product is not certified according to Organic-JAS, it is not allowed to be called "organic". The JAS Production Information logo (figure 4) identifies those products that have declared their ingredients and that comply with JAS production information. For instance, in the case of beef and pork meat, the feed and veterinary medicinal products used must be disclosed. For plant products, the use of pesticides and fertilizers must be expounded. Figure 5 shows the JAS logo, which is used exclusively for Bento (lunchbox) made of rice. The essential prerequisite is, that the Bento Box be transported within the supply chain under constant fixed temperature control [MAFF, 2018].
As in the EU, in addition to governmental standards, private food safety standards also apply. Japan also distinguishes the food quality standards set by the Japanese government and the standards set by Japanese companies. For example, some supermarket chains and retailers have developed their own specific rules, which are even more stringent than government regulations. Particularly, supermarket chains are focusing on compliance with HACCP and ISO standards [Jonkert et al., 2005]. Exemplary the private standards for Good Agricultural Practices (GAP) are presented and compared below. One of the widely known private standard is GLOBALGAP, which is internationally recognized. This is a worldwide voluntary standard for Good Agricultural Practice with the aim of ensuring safe and sustainable food production around the world. The global organization defines itself as a standard provider with a certification system. Every certified company gets the possibility to use the logo (figure 6) [GlobalGAP, 2018]. Also, in Japan, a private standard was created for certification of Good Agricultural Practices, the JapanGAP (JGAP). This is the only international standard in Japan and is managed by the Japan GAP Foundation. The non-profit organization was founded in 2006 and the certification system persists since 2007. Since then, 4,113 farms have been certified (as of 03/2017). The focus is on fruits and vegetables, tea, cereals and legumes as well as animal products and livestock. Equally GlobalGAP, JGAP is a consumer protection and industry standard that aims to contribute to production safety, environmental protection and sustainable agriculture, as well as transparency along the entire value chain. The JGAP labels (figures 7 and 8) attest to the compliance with the required standards of food safety, environmental protection and occupational safety and certification schemes [JGAP, 2018].

Comparison of three important basic principles of food safety

The following section highlights and compares only the basic principles of food safety, which are often controversial issues in the negotiations of free trade agreements. It should be noted, that there are only a few fundamental differences between the EU and Japan. In the case of EPA, the different approaches have been mutually recognized by the EU and Japan.

Risk Analysis

According to the Codex Alimentarius Standard (Codex), which is recognized worldwide, risk analysis is executed using the three inter-related components of risk analysis: Risk

Assessment, Risk Management and Risk Communication. This international framework is implemented in the EU due to the Article 6 of the EU GFL, with the food law based on risk analysis. One basic principle is that Risk Assessment and Risk Management are operating separately. The risk assessment has to be carried out by an independent scientific institution. In the EU, the scientific responsibility pertains solely to the European Food Safety Authority (EFSA), based in Parma (Italy). The described separation of roles in Risk Analysis is also implemented in Japan (figure 9) and is consistent with the Codex. The Risk Assessment is ensured by the Food Safety Commission (FSC), which works separately from Risk Management. FSC was established in July 2003 after the adoption of the FSBL. The risk management is under the responsibility of the MHLW on the one hand and MAFF and the Consumer Agency on the other. For hygiene issues, MHLW is also advised by the Pharmaceutical Affairs and Food Sanitation Council. Similar to the EU, Risk Communication takes place, by all institutions and is coordinated by the Consumer Agency. This agency was founded in September 2009. The public warning of the population is ensured by the MHLW.

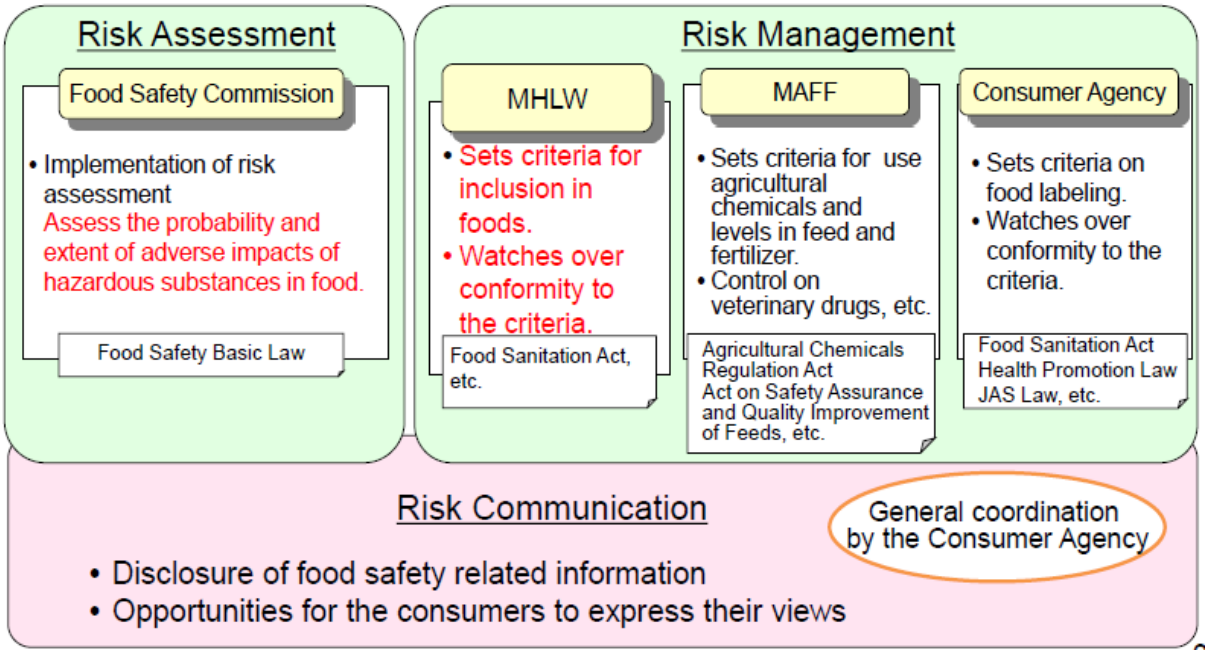

Figure 9: Risk Analysis in Japan. *Source: Sumi, 2014*

Application of the Hazard Analysis and Critical Control Point (HACCP) concept

As a quality management system, HACCP is a globally recognized system to reduce risks in the production of food. It obliges companies to analyze, control and document the entire food processing flow, from the raw material to the final product. Regulation (EC) No 852/2004 of 29 April 2004 legally required European food producers to apply the HACCP principles in conjunction with good hygiene practices. Therefore, all food manufacturers in the EU shall act according to the seven principles of the HACCP concept.

Since 1996, following the Escherichia coli O157: H7 outbreak in Sakai, the Japanese government has been recognized a need to introduce HACCP [WHO, 2006; Sumi, 2014]. So far, HACCP does not necessarily have to be applied in Japan because it is not required by national laws and regulations. As part of the FSL, only a voluntary HACCP approval system was introduced in 1996, which concerns to the production of milk and milk products, meat products, surimi-based products, low-acid canned foods and soft drinks [WHO, 2006]. In Japan, a differentiation is made between HACCP standard A and HACCP standard B. The HACCP standard A is based on the seven HACCP principles and respects the size of the companies. Imported goods, slaughterhouses and poultry processing companies belong to this category. The HACCP standard B allows more flexibility for small-sized businesses and

caterers [MHLW, 2016]. At the 7th Global Food Safety Initiative Focus Day in Tokyo on September 4, 2017, Hideshi Michino, head of department at the MHLW, announced an amendment to the FSL for 2018, which makes systematic implementation of the HACCP mandatory. The aim is to optimize the self-management of hygiene in production, raw materials and the production environment, as well as to eliminate the discrepancy between national and global standards of food safety management. This is justified by the increasing aging of the Japanese population, which raises the risk of food poisoning, the expanding globalization in food trade and the hosting of the Olympic and Paralympic Games 2020 in Tokyo [CGF, 2017].

Precautionary principle and scientific principle

Differences of risk perception pre-exist in the different doctrines. In most countries, including Japan, the *scientific principle* is the preferred approach. In the EU, the *precautionary principle* became legally binding due to Article 168 (1), Article 169 (1) and (2) and Article 191 of the Treaty on European Union and the Treaty on the Functioning of the EU. Internationally, the *precautionary principle* is recognized by the WTO, since it has been integrated into article 5 (7) of the WTO Agreement on Sanitary and Phytosanitary Measures (SPS Agreement) in 1995. In Japan, the precautionary principle is not explicitly embedded in the FSL, but there are regulations, which go along the same lines, for instance, Article 7 of the FSL. For example, the MHLW, in coordination with the FSC, may also prohibit the distribution of high-risk foods as a precautionary measure until evidence has been provided that they pose no risk to health. The precautionary principle was also determined in the EPA, namely in the following chapters: SPS-Chapter, which deals with food safety, animal health and plant health, and the chapter on technical barriers to trade, which governs technical product requirements and regulatory law [EC, 2018b].

Conclusion

This study analyzed the food safety measures and compared food safety systems in Japan and the EU under the EPA. Effective food safety regulations and policy measures play a key role in reducing potential threats to the health of humans and animals. It is well known worldwide, that both the EU and Japan have very high product standards and exemplary consumer protection. This has been verified by the results of this study. In many areas, both EPA partners have created standards that are in some cases higher than the international standards. In Japan, food is a massive political issue, reflected in the state's diverse and complex food security policy.

STUDY ON THE ALLELOPATHIC EFFECT OF *AMARANTHUS RETROFLEXUS, DATURA STRAMONIUM* AND *PANICUM MILIACEUM* ON THE GERMINATION OF MAIZE

Rita SZABÓ*, György PÁSZTOR

University of Pannonia, Georgikon Faculty, Institute of Plant Protection, Keszthely, Hungary
*Corresponding author: szabo-r@georgikon.hu

Abstract

The plant extract of *Amaranthus retroflexus* showed an inhibitory effect on the development of both cotyledons and rootlets in the Petri dish trials. In the pot experiments, among the three examined weeds, dry plant residues of *A. retroflexus* hindered the germination of maize to the greatest extent. Also in the pot experiments, it showed a negative effect on the shoot length and weight, while a positive effect on the root length and weight.

A 2.5% concentration of *Datura stramonium* plant extracts showed a stimulative effect, but the 5% and 7.5% extracts inhibited the shoot and root development of germinating maize. In spite of the 60% germination rate, the incorporation of dry plant residues into the soil did not show any significant effect on the development of shoots, but a stimulative effect on root development was observed. However, the dry weight of roots exceeded the control values only at a concentration of 7.5%.

The plant extract of *Panicum miliaceum* had a stimulative effect on the shoot and root development of maize. The dry plant parts in the soil of the pots hindered the germination of maize, but significant effect on the shoot and root lengths could not be proven. At the 7.5% ratio the dry weight of shoots was higher than the control values, but all the other soil-plant part rations caused lower values.

Keywords: *dry weight, germination, weed extract, root, shoot*

Introduction

One of the solid bases of today's agricultural production is the effective control of weeds. Weeds are responsible for about 34% of yield losses globally; moreover, resistant species can be revealed increasingly (Khawar *et al.*, 2015). Improperly timed weed control measures, repetitive use of similar herbicides and spraying at an inappropriate phenological stage under unfavourable meteorological conditions can accelerate this process (Solymosi, 1990). There are about 6700 weed species having effects on the plant production worldwide, 200 of them can be considered important, which may cause serious damage on every side where agricultural production is taking place (Holm *et al.*, 1977). Modern weed control has to be performed in the spirit of integrated plant protection, which means that efforts should be made to ensure properly timed mechanical weed control, profound knowledge of the weed flora and the prediction of the expected weed coverage of the given field.

Based on these, the number of treatments with herbicides should be reduced as far as possible and combination of differently acting herbicides should be used to avoid the appearance of resistant or tolerant biotypes of weeds. The headway of herbicide resistance requires more active ingredients, but their number is finite, and in addition to it, currently used herbicides are not allowed in biological production (Soltys *et al.*, 2013). To eliminate this factor, it is important to have as many tools and technologies as possible to reduce the damage to weeds.

Understanding allelopathy helps to explain the interaction between cultivated plants and the weed flora and it may open up new opportunities for integrated and biological plant protection. The key compounds of allelopathy are the so-called allelochemicals that are synthesized by plants having allelopathic effects. These biologically active compounds

influence development of other plants in the surrounding of the emitting plant. Most of these compounds have negative effects, but they may have positive effects as well. These compounds can cause disturbance of germination or growth by upsetting photosynthesis, respiration, water balance and hormonal equilibrium, which processes are typically based on enzyme inhibitions (Rice, 1974, 1979, 1984; Putnam and Tang, 1986; Szabó, 1994; Solymosi, 1996; Szabó, 1997; Inderjit and Keating, 1999). By studying allelochemicals, exploring their mode of action, based on allelopathic processes, even new active ingredients can be produced, which can be used later in weed control. All these help to avoid the resistance of weeds and reduce the load of the environment with herbicides.

The use of allelopathic compounds can be an important component of future integrated and environmentally sound weed management, as increasing emphasis is placed on the research, development and application of environmentally friendly plant protection methods and devices.

In addition to the traditional chemical protection, integrated plant protection is preferred and the research of natural substances that can be used in organic and biological farming is also emerging.

Material and Methods

Petri dish germination trials

Green samples of the given weed plants were collected in the summer of 2015. The samples of red-root amaranth and jimsonweed derived from sunflower and maize fields of August at Bajót (Komárom-Esztergom county, Hungary), the samples of proso millet were collected in a stubble field in the vicinity of Keszthely (Zala county, Hungary).

The collected plant material, purified from soil residues, has been dried for 6 weeks under air-dry condition. At the end of the drying process, a predetermined portion of the samples was selected for the Petri dish trials, and the rest was kept for the second stage of the experiment series for pot experiments. The dried plant parts (stalk, leaf) were cut into 1-2 cm pieces with secateurs and later homogenized with a coffee grinder.

The purpose of this experiment was to prove the allelopathic effect of the donor species.

The experiment was designed with triple dilution line (2.5%, 5% and 7.5%) of plant extracts; therefore dry plant material was measured in required quantities for 200 ml of liquid, in this case distilled water, to obtain the desired solution. Plant samples had been left in the water within measuring cups for 24 hours at room temperature to allow the allelochemicals to dissolve.

At the end of the dissolution, Petri dishes were prepared. The seeds were placed on double-layer filter paper, and then were poured with 15 ml of extract (distilled water for control). For each concentration, eight replications were used, so for each of the three concentrations eight Petri dishes were ordered.

The germination experiment was performed with the seeds of 'MV Koppány' maize variety, placing 25 pieces in each cup, in four replications. As a control, only water was used.

Subsequently, the Petri dishes had been kept for 7 days at 20°C in a germinating incubator. The moisture content lost during the incubation was retrieved with water spray. As an evaluation of the experiment, the germinating seeds were individually examined on the 7^{th} day. Each concentration consisted of eight replications, each with 25 pieces of germinating seeds per repetition.

By measuring the length of the cotyledons and rootlets, 200-200 length data for each concentration were received and the average was considered as the result of the certain concentration. The same method was used in the case of control Petri dishes, where the average length of 100 cotyledons and rootlets were calculated. The data were recorded in a Microsoft® Excel spreadsheet.

This process was carried out in the same way for all the three weed species. The evaluation of seedlings treated with the extract of *Amaranthus retroflexus* was carried out on 04.11.2015, with the extract of *Datura stramonium* on 11.11.2015 and with the extract of *Panicum miliaceum* on 18.11.2015.

Pot experiment

In the second part of the experiment, the remainder part of the weed samples collected for the previous experiment were used, so their collection time and place were the same. In this case, however, 1-2 cm of dried plant pieces were break into a smaller size range of 1-6 mm by an electric coffee grinder.

Two liters of common black mould were placed in the pots, which served as a nutrient medium. To the given medium, the 2.5%, 5% and 7.5% dilution line was used, adding the plant debris required for the desired concentration. The shredded plant parts were incorporated into the soil within the upper 6 cm layer.

For each concentration, four replications were planned, so for each mixture of 2.5% and 5% and 7.5% soil-plant parts, four pots were assigned with five corn kernels per pot. The kernels were sowed in a depth of 3 cm. Four replications were designed for control; there were only black mould and corn kernels in the control pots.

The 4-4 pots, belonging to the certain concentrations, with seeds and weed residues after being injected with 200-200 ml of water were placed into a BINDER-type rearing chamber at 20°C for 30 days. The constant moisture was kept by irrigation throughout the germination period.

The evaluation took place after 30 days. The germination percentage according to certain concentrations was calculated and the dry weight and the length of roots and shoots were measured per plant. The data were recorded in Microsoft® Excel spreadsheets. The average of the repetitions of the same plant residues / soil ratio was taken to the end result of the experiment. The data were processed by single-factor analysis of variance.

All these steps were performed separately for each of the three weed species tested. The evaluation of maize treated with *Amaranthus retroflexus* samples was carried out on 19.10.2016, with *Datura stramonium* samples on 27.01.2017 and with *Panicum miliaceum* samples on 28.02.2017.

Results and Discussion

Petri dish germination trials

In the case of all the three plant extracts, the germination percentage ranged from 99% to 100% in every replication and in all concentrations, so detrimental effect of the extracts on the germination of maize could not revealed. Each seed brought a cotyledon and rootlet. The length of these cotyledons and rootlets was compared with the results of the control group to ascertain whether the extracts of weeds have an allelopathic effect on the germination.

During the evaluation, it was observed from the measured data that *Amaranthus retroflexus* extracts caused shorter lengths in the case of both the cotyledons and rootlets.

On the effect of the 2.5% dilution, the cotyledons reached 67% of the control average size, which was 25% in the case of the 5% dilution while it was 45.6% in the case of the 7.5% dilution. Thus, the strongest inhibition of shoot development was induced by the 5% solution (Doffkay, 2018).

Rootlets were also less developed in comparison to the control ones; in this case, the detrimental effect was proportional to the concentrations so the strength of inhibitory activity ranged from the smallest concentration to the highest. On the effect of the 2.5% plant extract, the rootlets reached 97% of the control size, which was 83.2% in the case of the 5% and 74.7% in the case of the 7.5% extracts.

Datura stramonium extracts also had an inhibitory effect. The average size of the cotyledons decreased proportionately with the concentration of the plant extracts, reaching 52.1% of the control size in the case of the 7.5% dilution. Rootlets showed a transient stimulatory effect at a concentration of 2.5% with more developed root components than the control ones, but in the case of 5% and 7.5% extracts growth inhibitory effect was manifested (Gerlinger, 2012).
In the case of *Panicum miliaceum*, a stimulative effect was observed, similarly to the previous results of Prutenskaya (1974) and Bellán (2017). The 5% concentration had the highest positive effect on the growth of cotyledons, in this case the average length of them was 56.9% higher than the mean values of the control. The same positive effect was observed on root growth, where the average root size was 29.8% higher than the average root size. By comparing data using single-factor analysis of variance, it can be established that there was a difference at 5% significance level between the effect of each weed extract on rootlets and cotyledons compared to controls and concentrations. These were potent inhibitory effects in the case of *Amaranthus retroflexus* and *Datura stramonium* while stimulative effect in the case of *Panicum miliaceum* (Bellán, 2017).
It can be seen that the inhibitory or stimulative effect does not necessarily follow the dilution line. The 2.5% solution of *Datura stramonium* had a stimulative effect, only the more concentrated solutions showed inhibitory effect. In the case of the *Panicum miliaceum* extracts, the 5% concentration showed the strongest stimulative effect. The reason of this may be that allelochemicals are able to quench the effect of excessive nutrients in the solution at a given concentration. In addition, consideration should be given to the inhibitory effects derived from the potential differences of solutions, which are independent from the allelopathic effects.
The more concentrated solutions are more difficult to absorb into the seeds, so they can absorb less water for germination. Additionally, plant residues contain spare nutrients besides allelochemicals, which may be released and become available for germinating seeds as germination supporting agents. These effects make it difficult to study allelochemicals.

Results of the pot experiment

Germination percentage

In the pot experiment, on the effect of the weed stalk and leaf fragments detrimental effect on germination has been appeared compared to the control group. In the control pots, all corn seeds germinated successfully, resulting in 100% germination.
During the experiment, it was revealed that the germination of maize was reduced in the case of all weeds in all concentrations compared to the control. In the greatest extent, *Amaranthus retroflexus* plant parts hindered the germination, but reversely to the proportion of plant debris, so the smallest concentration inhibited mostly the germination of corn (Doffkay, 2018). This meant a 35% germination rate.
Datura stramonium also decreased the germination, but soil-plant residue ratios did not show any significant difference in this extent (Gerlinger, 2012). In all three concentrations, the germination ratio was about 60%.
Panicum miliaceum plant parts also had a hindering effect on the germination compared to the control group. In this case, the 5% soil-residue ratio resulted in the highest plant number, similarly to the Petri dish experiment, where the 5% solution had the highest stimulative effect.

Length of roots and shoots on the effect of weed plant residues

In this experiment, stalk and leaf residues had been decomposed during germination, so besides the allelopathic effect, the nitrogen and water removal effect of the microbial bacteria involved in the decomposition had to be taken into account as well. The absence of

germination and differences in cotyledon and rootlet lengths may be attributed to this effect, apart from the effects of any allelochemicals.

During the evaluation, the length of shoots and roots were measured separately with centimetre accuracy. Their lengths were compared to the results of the control group in order to determine whether any inhibitory or stimulative allelopathic effect on germinating maize's shoot and root lengths manifested on the effect of weed stalk and leaf residues incorporated into the medium. After comparing the results, it has been found that *Amaranthus retroflexus* caused the smallest germination percentage, but the greater the amount of its plant residues in the pots, the greater the length of roots and shoots developed on the maize. Both the shoot (SD5% = 7.2%) and the root growth (SD5% = 8.8%) showed significant differences compared to the values in the control group.

In the case of *Datura stramonium*, although the average length of maize shoots decreased proportionally with concentration, it did not show significant difference. The root length averages (SD5% = 9.8) however, differed significantly. The root mass of all the concentrations exceeded its control group, so a kind of stimulative effect occurred.

In the case of *Panicum miliaceum*, there was not found any significant difference between the shoot (SD5% = 9) and the root lengths (SD5% = 9) compared to the control group.

On the effect of *Amaranthus retroflexus* plant debris, the dry weight of maize plants lagged behind the control group. The lowest dry weight value was measured at a ratio of 2.5%. The inhibitory effect was inversely affected by the increase in concentration, and at 7.5%, the dry weight almost reached the control value (Doffkay, 2018). The dry weight of roots at all three concentrations far exceeded the control group's values. Therefore, *Amaranthus retroflexus*, of which plant residues had been added to the soil, had a positive impact on the growth of the roots.

On the effect of *Datura stramonium* plant residues, with the exception of the 5% ratio, both groups showed a stimulative effect on the dry weight of the stalk. The root weight remained below the control values at 2.5% and 5%, but exceeded them in the 7.5% group.

Panicum miliaceum had a negative effect on both the root and shoot weight. Only 7.5% concentration resulted in a higher shoot weight ratio than the control group.

Conclusions

Amaranthus retroflexus plant extracts exhibit a negative allelopathic effect on maize. The *Amaranthus retroflexus* extract showed growth inhibitory effect on both the maize cotyledons and rootlets and the highest concentration caused the strongest inhibition.

In the case of *Datura stramonium* extracts, the smallest 2.5% concentration caused a stimulative effect on both cotyledons and rootlets, but the 5% to 7.5% solutions have inhibitory effects. In the case of *Panicum miliaceum*, a stimulative effect was observed for the growth of both cotyledons and rootlets in each of the three concentrations. The 5% solution exerted a stimulative effect to the greatest extent.

All weed extracts showed significantly different influence on cotyledon and rootlet development of maize.

Pot experiments

When incorporating *Amaranthus retroflexus* stalk and leaf residues into the soil, the average shoot and root lengths of germinating maize differed from the control group. The 2.5% and 5% plant-soil ratio had a negative effect on the germination of maize. In the case of root length, the 5% and 7.5% ratios showed a stimulative effect. For each of the three concentrations, the dry mass of root per plant was higher than that in the control group, however, the dry weight of shoots per plant was below the control values.

The *Datura stramonium* plant parts had a stimulative effect on the root development of maize, all three ratios showed similar effect, with the 5% group being most prominent. The effect of

residues of *Datura stramonium* on the shoot and root length could not be statistically proven, there was no significant difference among groups.
The groups treated with the residues of *Panicum miliaceum* did not show any significant difference the stimulative or inhibitory effects in this experiment were not statistically proven.
The dry plant parts of all three weeds resulted in a decrease in germination percentage in all tested concentrations compared to the control.

THE ROLE OF SOLANUM NIGRUM IN THE SPREAD OF POTATO VIRUSES

András TAKÁCS, Melinda CSERPES, György PÁSZTOR*

Plant Protection Institute, University of Pannonia, Georgikon Faculty, Keszthely, Hungary
*Corresponding author: pasztor018@gmail.com

Abstract

Solanum nigrum is a common, high-spread weed throughout the country. It occurs commonly in arable lands and agricultural areas, and likes high nitrogenous soils. It can spread anywhere, where the right living conditions are met. The biggest problem is caused by cultures belonging to the same genus, especially in potatoes. In many ways, this relationship is unfavorable: it makes difficult to use herbicides, the weed can easily absorb many important nutrients from the crop and greatly promotes the spread of viruses from infected weeds. The aim of the experiment was to determine the virological examination of *Solanum nigrum*, and to determine the viruses appearing on the collected samples. The examined plant samples were collected in the autumn, from the potato peaks around Keszthely, Central Transdanubia, Hungary. A total of 55 *Solanum nigrum* plant samples were tested. More developed individuals with viral symptoms were collected. In order to detect viral infections, DAS ELISA serological method was used. Of 55 samples, we could diagnose viral infections in 30 cases. Epidemiological studies showed *Potato virus A* (PVA) and *Potato virus Y* (PVY) in most of the cases: PVA in 24 cases, PVY in 21 cases. In 10 samples *Tobacco mosaic virus* (TMV). *Potato virus X* (PVX) 3 samples, *Tomato mosaic virus* (ToMV) 2 samples were identified. *Tomato spotted wilt virus* (TSWV) was not detected in the collected samples. In most cases, complex viral infections were observed. Six types of virus complexes were diagnosed from 20 multiply infected plants. 12 samples showed PVY, PVA complex, PVY, PVA, TMV complex on 4 samples, PVX, PVY, PVA, TMV, ToMV complex, PVX, PVY, PVA TMV complex, PVX, PVY, PVA complex and TMV, ToMV complex appeared only at 1 plant. Our results point to the huge role played by weeds in spreading viruses. In our study, it has been shown that *Solanum nigrum* can not only carry a pathogen in most cases, but it can also carry more than one. Therefore, weed control is of particular importance.

Keywords: *Solanum nigrum, PVX, PVY, PVA, TMV, ToMV.*

Introduction

In our country, the biggest field of cultivated vegetables are from the *Solanaceae* family. This includes tomatoes, peppers, potatoes and eggplant. Plant protection is a complicated task and requires great expertise as it is advisable to apply complex protection against pathogens, animal pests and weeds. The main problem with the protection against viruses is, that it can only be prevented against them. Most importantly, it is the production and use of resistant varieties, but it can also be used to protect them against the use of virus-free propagation material, the removal of diseased plants, and the destruction of weeds and viral vectors.

Solanum nigrum is a weed belonging to the family Solanaceae. It is native to the Carpathian Basin as an Eurasian flora element. Very common, tough plant, spread throughout the country. Due to its aggressive expansion and nutritional abilities, it is also dangerous for cultivated potatoes, but also because of its viral carrier and transferring role. There are several pathogens in a single weed that can increase the chance of complex viral infection.

Our goal was the virological examination of the *Solanum nigrum* one of the most important weeds of potato. Our investigation was carried out in the spring of 2018 on samples from potato fields around Keszthely, Central Transdanubia, Hungary.

During the cultivation of potatoes, the aim is to cleanse the area from sowing to harvest. It is essential that weed has to be removed as soon as possible and this condition is maintained until the harvest. After the plant closure, potatoes can suppress the weeds until the end of the growing season. At this point a new weeding wave starts, as the foliage of the plant begins to clink and collapse for this period. The longer the ripening time, the weeding process lasts longer. (Mészáros *et al*., 2007).

PVX is almost everywhere in the world, especially where potato production is taking place. It has been shown in a variety of plant families, but mostly Solanaus species in the *Solanaceae* family are susceptible to the virus. (Horváth, 1978). PVY is the most potent and most serious damaging viral disease in potatoes. It is spread all over the world and occurs in all potato-producing countries. Its host plant circle is very extensive, especially the plants of *Solanaceae, Amaranthaceae, Chenopodiaceae* are susceptible (Edwardson, 1974, Horváth, 1983). PVA economically belongs to smaller viruses. Its significance is mainly when it comes along with PVY and PVX. It often appears in combination with PVY (Smith, 1972). It has a narrow host plant where the families of the *Solanaceae* family and two other families: *Trigonella* and *Melilotus* (Spaar *et* Hamann, 1977). TMV occurs everywhere in the world, both found in lower and higher order plants (Gibbs *et* Harrison, 1976; Horváth, 1977b). It has the most extensive host plant circle, the number is over 1000 (Horváth, 1976). Among the natural host plants it can infect economically important tobacco species (*Nicotiana* spp.), pepper (*Capsicum annuum*), tomato (*Lycopersicon esculentum*) and potato (*Solanum tuberosum*). ToMV can be found worldwide. Its main host is tomato (*Lycopersicon esculentum*), but it also infects other plants, including ornamental plants (marigolds). In addition to the plants of the family Solanaceae, it can infect some of the black currant, apple, barley, weeds, and some of the family of *Asteraceae, Chenopodiaceae, Malvaceae, Passifloraceae, Tetragoniaceae, Plantaginaceae, Cucurbitaceae, Fabaceae* (Rod *et al*., 2005; Moreira *et al*., 2003). TSWV is responsible for a number of epidemics in various regions of the world, especially in horticultural and floral plants, which often cause destructive and severe economic losses. It has a broad host plant, with the latest data currently being 1090 plant species.

Material and methods

The examined plant samples were collected in the autumn, near Keszthely, Central Transdanubia, Hungary, from potato fields. 55 samples of *Solanum nigrum* plant specimens were tested. The plants were placed individually in a polyethylene container and then frozen until the time of the laboratory test. When trying to take samples, It was tried to collect the individuals with more developed viral symptoms. The DAS ELISA (Double Antibody Sadwich-Enzyme-linked Immunosorbent Assay) method was used for the detection of viral infection, which was written by Clark and Adams in 1977. This is the most commonly used laboratory procedure for the diagnosis of plant viruses. The test does not detect the pathogen, but determines the activity of the enzyme related to the antigen or antibody, thus giving the starting point for the amount of antibodies it produces.

Results and discussion

Based on the results of the DAS ELISA serological test, the infection of the examined plant samples is shown in Table 1. by highlighting the number of samples in red.

Table 1.: Viral infection according to the DAS ELISA-method (red:infected

Solanum nigrum	1	2	3	4	5	6	7	8	9	10	11	12
A	**X***	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**

E	**48**	**49**	**50**	**51**	**52**	**53**	**54**	**55**				

The first diagram shows that the number of virus-infected plants shows a changing tendency. Based on the virus epidemiological studies *Potato virus A* (PVA) and *Potato virus Y* (PVY) were detected in the highest levels. Of the 55 plant samples, 24 PVA infected platns were diagnosed, and 21 in PVY were diagnosed. In 10 samples we identified *Tobacco mosaic virus* (TMV). *Potato virus X* (PVX) 3 samples, 2 *Tomato mosaic virus* (ToMV) infected samples were observed in serological tests. The presence of *Tomato spotted wilt virus* (TSWV) was not detected in the collected samples (Figure 1).

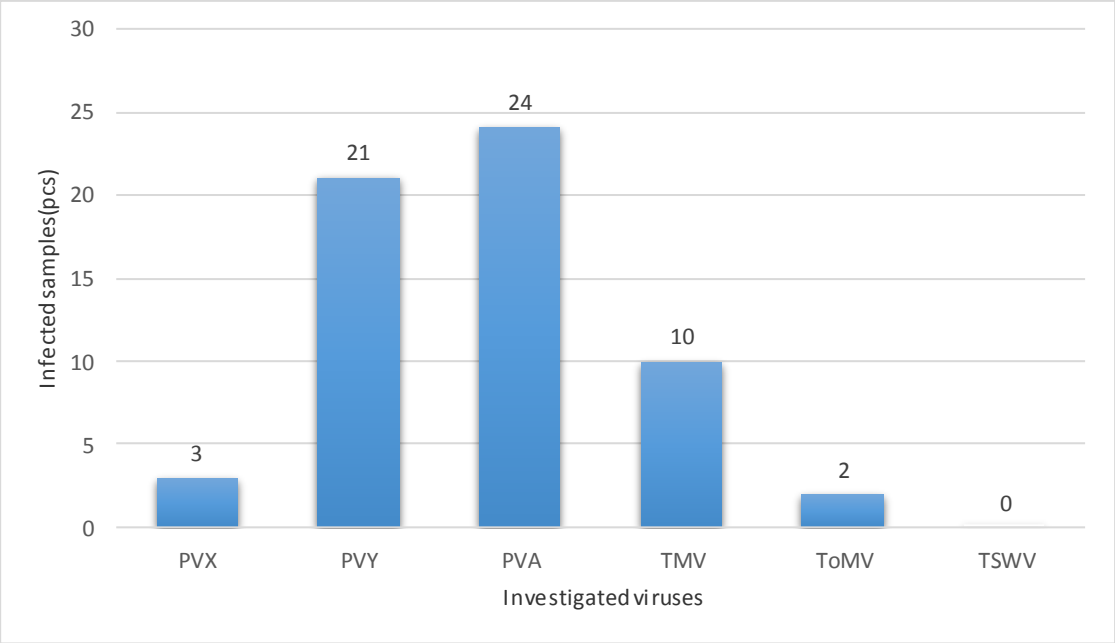

Figure 1.: Number of the infected plants

In most cases, complex viral infections can be observed. According to the number, 6 types of virus compositions were diagnosed from 20 multiply infected plants. 12 samples showed PVY, PVA complex, PVY, PVA, TMV complex on 4 samples, PVX, PVY, PVA, TMV, ToMV complex, PVX, PVY, PVA TMV complex, PVX, PVY, PVA complex and TMV, ToMV complex appeared only at 1 plant. The evolution of multi-infected plant samples is illustrated in the following diagram (Figure 2).

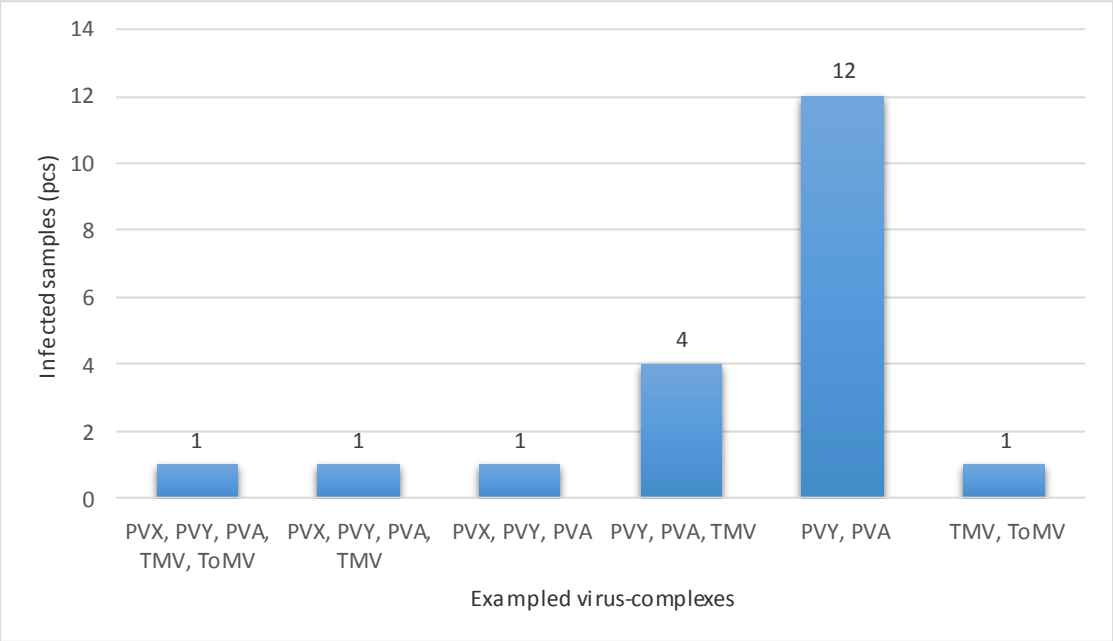

Figure 2.: The complex infections

There were simple viral infections in 9 plant samples. PVA for 5 plants, TMV for 3 and PVY for 1 (Figure 3).

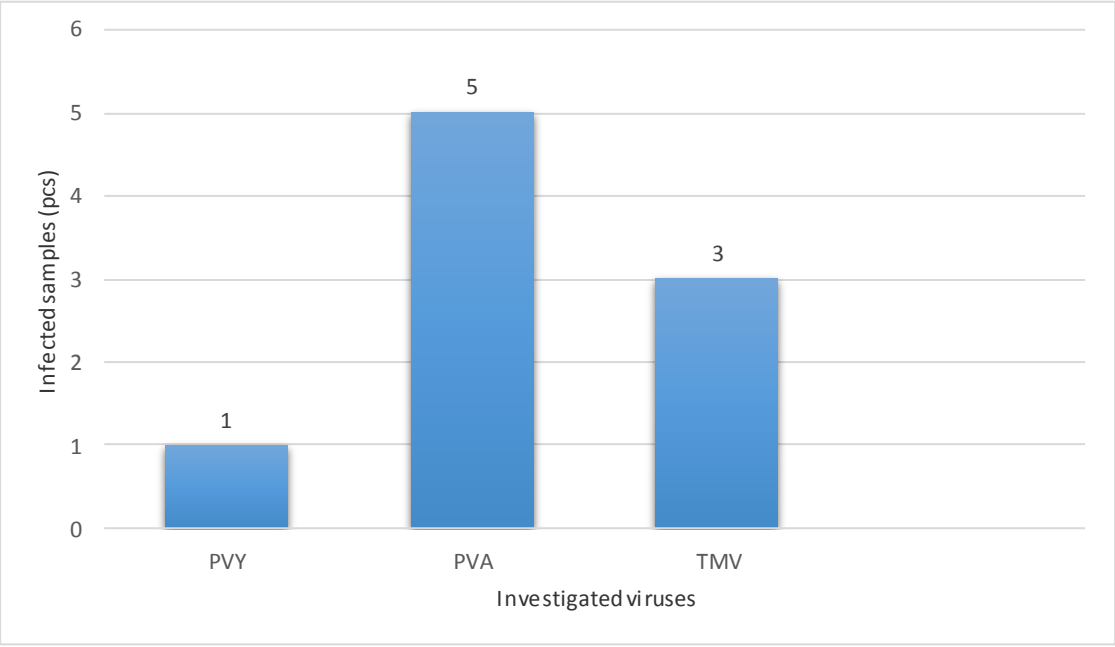

Figure 3.: The simple virus infections

Conclusions

The results of the experiment show that the weeds of cultivated potato species, especially *Solanum nigrum*, can play a significant role in the distribution of potato viruses, apart from their direct competitive effect. For this reason, it is of great importance in our cultivated crops to prevent weed control, to prevent the spread of wild *Solanum* species.

Potato virus A (PVA), *Potato virus Y* (PVY), *Tobacco mosaic virus* (TMV), *Potato virus X* (PVX) and *Tomato mosaic virus* (ToMV) occurred during the experiment. The presence of *Tomato spotted wilt virus* (TSWV) was not proven in any case.

PVA is the largest amount of pathogen detected. It is not a significant virus unless it is combined with PVY or PVX. It often appears with PVY, this is also apparent from the experiment since a total of 19 infected samples were found where these two viruses were present together. PVY is the most potent and most serious damaging viral disease in potatoes. Based on our investigations, the virus in the second most frequent samples was also present in all the viral combinations. TMV is a virus all over the world occurring in plants. During the study, it appeared on 10 infected samples alone and in combination. Its significance is mainly due to the decrease in yield, quality and dry matter content. PVX is mainly found in potato-producing areas worldwide. Of the examined plant samples, it was released in combination with only a few other viruses. The virus is mechanically easy to transfer and it is also excellent to spread with insects. ToMV is also found worldwide, most of which threatens tomatoes, but it also infects other plants. Of the collected *Solanum nigrum* samples only two showed and only in combinations where TMV was present. TSWV is responsible for many epidemics in the world, especially in horticultural and floral plants.

The results of the studies revealed that this virus was not present in any of the samples. This may also be justified by the fact that the plants under study come from arable potato culture. Protection against viruses is based on preventing and preventing infection. At present, it is not possible to treat infected plants. Most efficiently using virus-free propagating material, using biotechnological methods (resistant varieties), heat and chemotherapy, digestive cultivation, appropriate agrotechnical techniques such as stubble and other soil operations, control of vectors and virus reservoirs and, last but not least, weed control of the infectious source. In addition, due to the fact that many viruses can spread mechanically well, it is important to pay greater attention to compliance with hygiene rules in general phytosanitary regulations. Their transmission through the disinfection of tools and work clothes, frequent hand washing, and destruction of diseased plants

INVESTIGATION OF THE IN VITRO REGENERATION OF *ASCLEPIAS SYRIACA* AND *SORGHUM HALEPENSE*

György PÁSZTOR*, Márton OCZOT, Erzsébet NÁDASY

Plant Protection Institute, University of Pannonia, Georgikon Faculty, Keszthely, Hungary
*Corresponding author: pasztor018@gmail.com

Abstract

According to the Hungarian weed surveys, the significance of the *Sorghum halapense* and the *Asclepias syriaca* is growing significantly. Today, Johnsongrass is the most important weed of maize, and their field coverage in Hungary is over 1%. It is ranked on the 11th place on maize fields, which shows its significance. The northeastern part of the country is the most infected. The common milkweed is spreading in more and more places. In 2002 there were more than 200,000 hectares infected. Its proliferation continued both on wheat and maize fields. It is spreading predominantly in the northeastern part of the country, but its appearance can be expected anywhere. The aim of our study was to observe the regeneration of two perennial weeds, using the vegetative reproductive organs of common milkweed and johnsongrass, under controlled in vitro conditions. For this purpose, a climate chamber experiment was set up at Keszthely with different lengths of root segments (1, 3, 5 nodes and 1, 5, 10 cm), at the Plant Protection Institute, University of Pannonia. The different sized vegetative organs were regularly measured, and the renewal capabilities of the two weeds were concluded. According to our experience, the initial size of the segments had an effect on the shoots generated by them. By increasing the size of the roots the number of buds increased. The buds in the direction of the apex formed the longest shoots, because of the abolition of apical dominance. However, the larger initial size did not mean clearly higher values in the average length of the shoots. For the defense against perennials, we need to combine our capabilities, think towards an integrated approach, and if it is required, we need to use herbicides against the perennial weeds. This is the only way now, which can be used for a long period of time to suppress the foes of our crops.

Keywords: *Hungary, regeneration ability, apical dominance, Sorghum halepense, Asclepias syriaca.*

Introduction

With the advancement of cultivation technology and methods, the composition of arable weed comunities (Pinke - Pál, 2005) has also changed. A number of European researchers have been working on the follow-up of changes in weed patterns.

The significance of Hungarian perennial weeds is well illustrated by the results obtained from the National Field Weed Surveys, the principles of which were defined by Miklós Ujvárosi (1973). Records were made for plant protection purposes and found which are the most dangerous weeds and recorded their cover data and spread.

Effective regeneration of perennial weeds is served by modified underground shoots (rhizome, propagation root etc.). In the modified lifeform system of Ujvárosi (1957), the G1 group includes the *Sorghum halapense* (L.) Pers. The rhizome is a modified underground stem. Their regeneration is efficient, all rhizome segments are capable of forming a new plant after breaking up, with at least one intact axillary bud. The distance between axillary buds is 1-1.5 cm on rhizomes.

Propagation roots for reproduction are mostly run horizontally in the soil. The roots originating from them, however, penetrate deep into the ground in a vertical direction. In the

life-cycle of Ujvárosi (1957), G3 the species was named as weed with propagation roots. Propagation roots are a modified root in which adventive buds are reproduced.
Generally, a 5 cm long root segment is capable of forming a new shoot. As a result of the cultivation of the soil, the fragmented rhizomes will be regenerated according to the principle of apical dominance. Due to correlative inhibition, in most of the time, only one or two shoots will grow, while the rest will remain calm. The axillary buds that are closer to the peak groove always grow longer than the other rhizome segments, so they are polarized.
According to American researchers Johnson and Bucholtz (1962), the activity of vegetative organs has a periodicity similar to seeds. The effectiveness of herbicides is greatly influenced by the extent to which they are able to translocate in the weed plant. This process is related to the metabolism of organs (floemtransport), so we need to know the activity of regeneration functional organs (rhizomes, propagation roots).
Research by Holm (1978) and his colleagues highlighted that the johnsongrass are present in the tropical and Mediterranean countries as the world's sixth most important weed. In Romania it was declared a quarantine-weed in the 1950s. It has been grown in Hungary due to its good nutrient content and apiculture (because of its intensive nectar production).
The johnsongrass became more and more adaptive to the unfavorable, cooler climate of its initial development, so it was able to conquer new areas, the neighboring states of Slovenia, Croatia, Serbia, Bulgaria and Romania.
Thanks to the photosynthesis of C4, it has a great competitive potential against the majority of crop plants (usually C3s). They play a major role in reducing crop yields because they compete for the same resources (water, nutrients, air, sunlight, etc.). With its presence, it directly and indirectly damages our crops.
The later spread of the common milkweed, *Asclepias syriaca* L., species in Hungary has greatly contributed to the high potentials as a decorative plant in different applications. Field cultivation later has been abandoned, but the remains of the cultivated and run wild plants formed invasive centers, and the plants spread from them later caused significant damage (Botta-Dukát and Mihály, 2004). The construction of railways and roads contributed greatly to the spread of silkworm, as the competing plants were extinguished in these areas.
The potential causes of the explosive spread of common milkweed in recent years include the dry weather of the past 10 years, the increase in the number of frost-free days, the lack of stubble and plowing, soil erosion, reduced tillage, (lack of competition) or rarely targeted weed control (Kőrösmezei, 2000). It can cause natural problems as it prevents the regeneration of close-knit associations in occupied territories.
The common milkweed invasion is significant in areas degraded by anthropogenic activity. Its appearance can be combined with the planetary surface (trampling, plowing, overgrazing, erosion) or nutrient enrichment (fertilization, forest fires).

Material and methods

The aim of the study was to observe the regeneration of two perennial weeds, using the vegetative reproductive organs of johnsongrass and common milkweed, under controlled in vitro conditions.
The rhizomes of the johnsongrass and the propagation roots of the common milkweed were collected at Keszthely, Central Transdanubia, Hungary. The samples were collected on 2017.11.16 on the corner of a field plate.
The rhizomes and propagation roots were taken directly from the top 25 cm layer of the soil. Axillary buds were removed during their preparation, which allowed the control of the integrity of the buds, and thus the length of the axillary buds evolved in the early stages of regeneration. Prior to the measurements, the vegetative parts were disinfected with chlorogen and then sliced into 1, 3 and 5 nodular units for *Sorghum halapense* and 1, 5, and 10 cm

propagation root segments for *Asclepias syriaca*. From the vegetative formulas of different lengths, 10 pieces were placed in a Petri-dish lined with filter paper and 15 ml of distilled water in a 3 repetition.
To test the regeneration ability, the Petri-dishes labeled by the initial length and repetition number were placed in a thermostat. The climate chamber was kept at 20 ° C for the duration of our observations. Measurement of the shoots and roots continued until the condition of the plant parts allowed it. During the experiment, for each species we measured the total number of roots and shoots. When studying the johnsongrass, we associate the position of the buds with the length of the shoots, i.e. how many nodes develop. Knowing the situation of buds allowed us to observe the legitimacy of apical dominance.
We used Microsoft Excel and SPSS to evaluate and analyze the data. We have repeatedly applied single-factor analysis of variance considering distributions and deviations.

Results and Discussion

Sorghum halepense

In the case of 5 nodular rhizomes, the number of shoots was significantly higher than in the other two cases. The number of buds in the 3 node rhizomes was not significantly higher, but it is clear from Figure 1. that the number of nodes 3 developed more than the 1 nodus rhizome segments.
Comparing the length of shoots from various nodomous segments and evaluating our data, the following results were obtained:
On the first day of measurement, we found that the 5 nodular rhizomes had the significantly longest shoots, and in some cases reached 30 mm.
The longest shoot was 161 mm, which was placed on a 3 nodular rhizome with the other 3 shoot with over 100 mm. In the 5 nodal segments, we counted 10 shoots above 100 mm (including one 160 mm) and one over 100 mm.
Our measurements show that the starting length of the rhizomes (1, 3, 5 nodus) and thus probably the nutrient quantity did not significantly influence the length of the axillary buds developing in our present experiment.
Apart from the first measurement time, we could significantly show the dominance of the first nodes in both 3 nodus and 5 nodous segments.
From Figure 1. it can be seen that there are no significant differences between the different days of measurement in the average of the shoot lengths of the 1, 3 and 5 nodular rhizomes. The line diagram fitted to the graph illustrates that the 5 Node pieces had significantly more buds of the total time intervals of the measurements. The bar graphs show the length of the shoots on the node, while the line diagram shows the number of buds out.

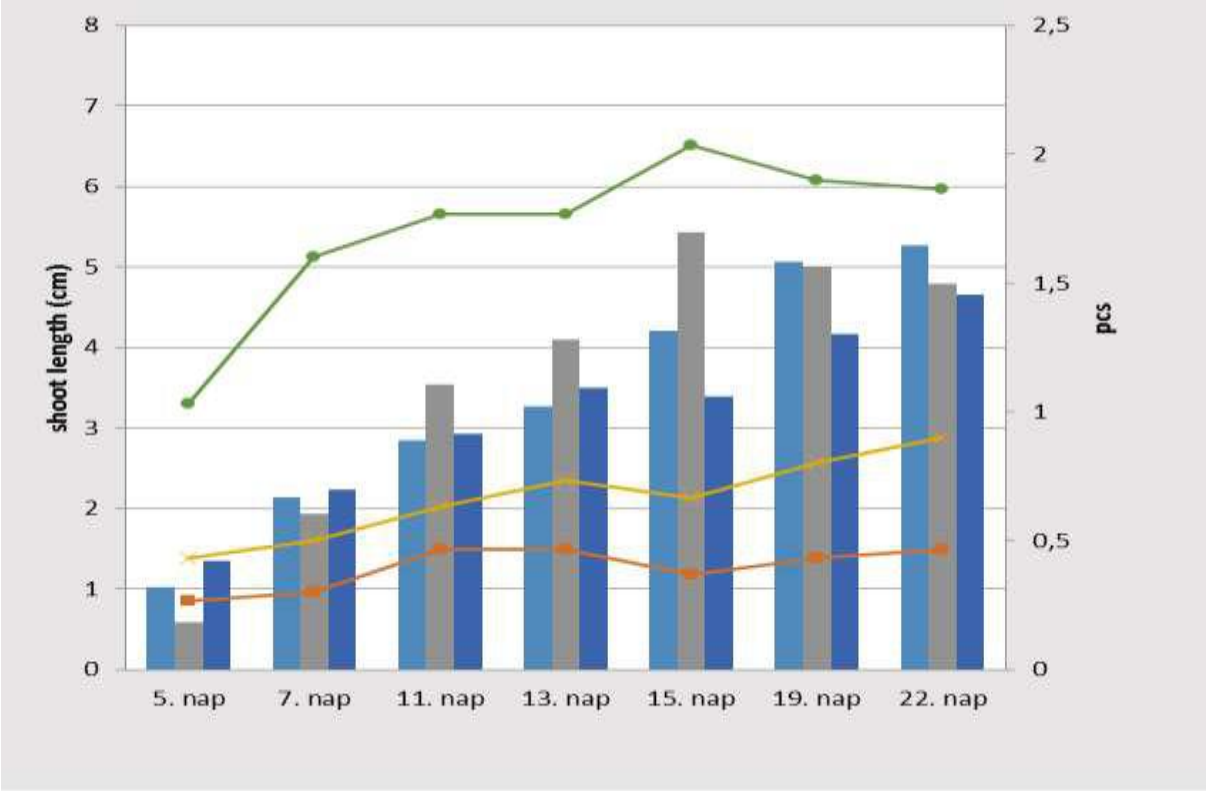

Figure 1.: Average number of sprouted buds (line diagram), average length of shoots (bar graph), depending on the days elapsed

Asclepias syriaca

The 10 cm root segments produced higher values from the start to the end of the experiment than the 5 or 1 cm counterparts. The lengths of 1 cm and 5 cm did not reach the average of 2 outbound buds on a single day of the measurements, while the 10 cm propagation roots generated an average 3-3.5 fold per segment.

There was no significant difference between the lengths of the shoots of different lengths of ripening root pieces until the 13th day. From the 13th day on, however, the difference was significant. From day 13 to day 33, the lengths of the 1 cm pieces were smaller than the other two groups, but there was no significant difference between them. From the 33rd day all three groups were significantly different. The common milkweeds propagation root, unlike the underground rhizomes of the johnsongrass, is not divided into nodes, so the position of the buds could not be fixed. But we were still curious about the relationship between the buds and the length of the shoots. For this purpose, the two data groups are displayed in a diagram, each of the measurement dates separately for the representation. At the beginning of our measurements, on the 5th day of the experiment, the number of spilled buds was 1 cm, and the 5 and 10 cm pieces had almost the same amount of bud. It can also be seen that longer propagation roots have been developed for longer shoots. However, these findings do not stop at the beginning of development. Looking at data from other days of the experiment, we see that 1cm pieces still have the smallest amount of buds and the size is the shortest. However, Figure 2. also shows that the number of buds on the 5 cm growth roots decreases by 10 cm, but the average length of shoot buds is higher, showing higher values even over the average lengths of 10 cm pieces. Thus, under the same conditions, the 5cm propagation roots sought to create longer shoots while the 10 cm segment increased the number of buds. This is probably due to the fact that 10 cm pieces had more nutrients. The bar graphs show the length of the shoots on the node, while the line diagram shows the number of buds out.

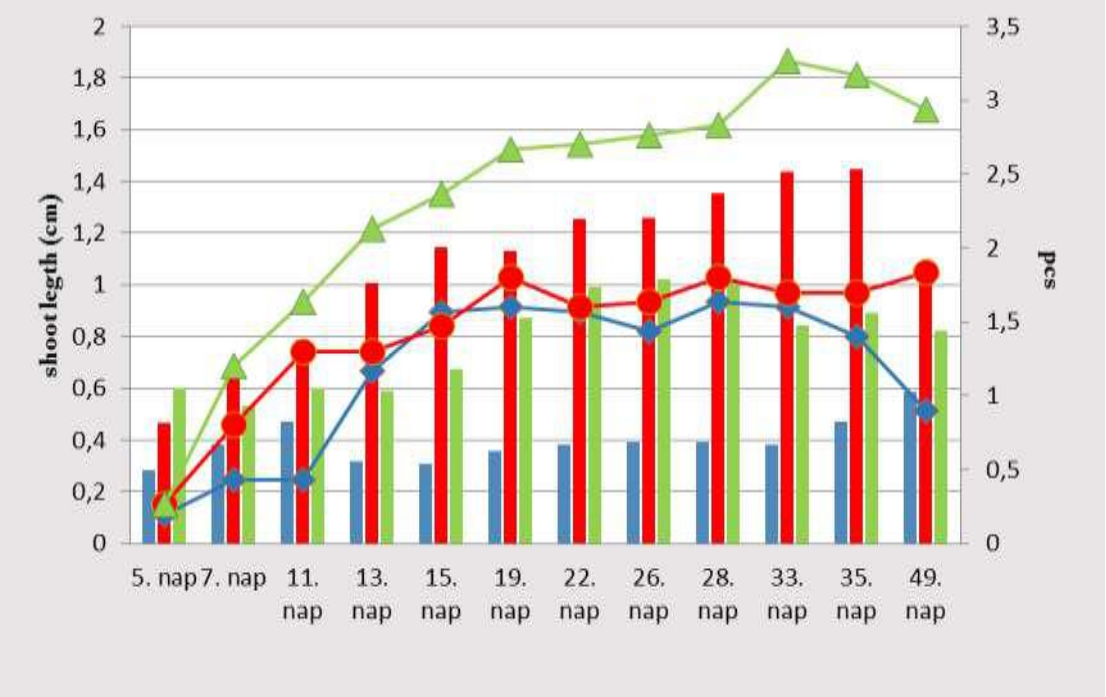

Figure 2.: The average number of sprouted buds of the common milkweed (line diagram), the average length of the shoots (bar graph), depending on the days elapsed

It was found that the number of shoots produced was also clearly influenced by the size of the fragmented vegetative reproductive organs in *Sorghum halepense* and *Asclepias syriaca*. The longer the length, the more spinning buds resulted in the experiment. We have clearly experienced the phenomenon of apical dominance, which, by regulating the tranquility of the axillary buds, plays a prominent role in the plant's species maintenance. As a result of the fragmentation, partial axillary bud activation resulted in partial dissolution of the correlative inhibition. During the experiment, the axillary buds closest to the originally apex were producing the longest shoots.

Based on our experiment, it was concluded that increasing the length of the rhizome segments does not result in significant differences in the average length of axillary buds in the case of johnsongrass. Multinodular rhizomes are presumably contain more nutrients, but due to the partial dissolution of apical dominance mentioned above, they are not concentrated in a single shoot. The case of common milkweed it eas not proved, that the longer propagation root piece would produce longer shoots, as the 5 cm root segments formed longer shoots rather than 10 cm pieces.

It is not possible to completely uproot the weeds we have tested, but we must strive to reduce their presence under integrated protection to the level of economic damage.

Conclusions

The preventive (precursor, stubble), agrotechnical, mechanical and chemical elements of our defense must be applied complexly in crop rotation. We must take care of the cleanliness of our machines, thus preventing the weeds and vegetative propagation patterns from entering our territories. The rhizomes and propagation roots are rotated by rolling into the deeper layers of the soil by deep plowing, causing anaerobic conditions into the soil. However, too deep autumn plowing can increase the chance of overlapping if vegetative formulas are already under the freezing zone. When cultivating, roots are split into smaller pieces, we can deliberately activate the formation of quiescent axillary buds and then we can defend

mechanically or with total herbicide after spraying. Good results can be achieved with soil cultivation, but in case of incorrect application, we can promote the growth of perennials. The axillary buds of the vegetative propagation staves torn together by conventional soil and sprouting tools are activated, thus increasing the perennial weeds in the area.

Abstract

This study wasconducted to detect the pathogenic fungi associated with bean stem base and root rot disease and evaluate the activity of Salicylic acid (SA) and Phylax to induce resistance in the plants against the main causal agent under field conditions. Nine species belongs to 7 genera of fungi were found associated with infected plants collected from three locations in Baghdad area at different frequency levels. *Rhizoctoniasolani* was the more dominant followed by *Fusarium solani* and *Macrophomina phaseolina*. Seven isolates belongs to *F. oxysporum, F.semitectum, F. solani, M. phaseolina* and *R.solani* have caused reduction in seed germination and increase in disease severity in contaminated soil compared with control.Amongthe tested isolates, *R.solani*isolates,RS1 and RS3, were found to bemore aggressive with totally inhibition of seed germination. It was found that seeds socking, soil application or foliage application with SA and Phylax at 2500 ppm, separately or in combination induced resistance in bean plants characterized by are striction of *R.solani*and a suppressionofdiseasesymptomsdevelopmentassociatedwithincreaseinplantfresh and dry weights. Soaking seeds in water and soil application of SA+ Phylax was found the more effective in reduction of disease incidence and severity compared with control.

Key words: *Root rot, Rhizoctonia solani, Salicylic acid.*

Introduction

The bean (*Phaseolus vulgaris* L.) is considered among the most nutritive crop in Fabaceae, where the dry seeds contain high percentage of protein,vitamins, and nutritive fibers (Buruchara, 2006; Nicolai et al, 2015). Bean crop is cultivated in the middle and southern areas in Iraq at 249 .75 Hectarewith annual yield up to 1249 ton (Statistic group, 2016).

Bean plants are subjected to infection with many soil borne pathogens including *Fusarium oxysporum,F.solani, Macrophomina phaseolina, Pythium* spp., *Rhizoctonia solani* causal agents of seed rot, seedling damping off, root and stem base rot(Matlob,2012; Binagwa et al. 2016; Marcenaro and Volkanen,2016, Maina et al. 2017). Several means were adopted to control these pathogens, mainly fungicides, but the excessive applications of fungicide have created enormous problems to ecosystem and human health (Choi and Hwang, 2011). Therefore, the research was oriented toward natural,effective and innocuous, means alternative to artificial chemicals to manage plant disease. Many compounds including Benzoic acid, Salicylic acid, Ascorbic acid and Phylax were used as foliage application, soil treatment, seed soaking, showing high inhibition activity against several fungal pathogens *in vitro* and reduced infection with root rot disease under field conditions (Katay et al. 2011; Adghough et al. 2013; Al-Juboory, 2016). The study was carried out to evaluate the efficiency of seed treatment, foliage application, or soil treatment with Salicylic acid and Phylax in controlling stem base and root rot caused by *Rhizoctoniasolani* in beans.

Materials and methods

Fungi isolation and identification

Bean plants showing stem base and root rot symptoms were collected from Al-Madaen, Al-Dora and Al-Rathwania regions in Baghdad governance. Pieces of 0.5-1 cm from rotten stem and root were surface sterilized with 2% Sodium hypochlorite for 2min, rinsed with sterilized distilled water, dried on filter papers and cultivated on potato dextrose agar(PDA) in Petri plates (ø9 cm), 4 pieces/plate. The plates were maintained at 25 ±2ºCfor 4 days. The fungi colonieswere purified and identified based on the morphological characteristics (Parameter and Whitney,1970; Barnett and Hunter,1972). Fusarium species were identified according to Leslie and Summerell (2006).The frequency percentage of fungi was calculated by the following equation:

$$\%\text{fungus frequency} = \frac{\text{No of pieces containing the fungus}}{\text{Total number of pieces}} \times 100$$

Pathogenicity test

The fungalisolates were grown on millet (*Panicummiliaceum*L.) seeds in 250 ml flasks. Millet seeds were distributed in Hu flasks, 50g/ flask, and autoclaved at 121ºCand 1.5 kg/cm^2 for 20 min. The seeds were inoculated with discs (~0.5 cm) taken from the margin of fresh fungal colonies on PDA, 5 discs/flask, and incubated at 25± 2ºCfor 15 days, with agitation every 3 days (Dewan, 1989). The inoculum was mixed with sterile soil and peat moss(2:1) at 1% in pots (10 cm dim). Sterilized millet seeds were added to other potsas control. The pots were watering and covered with polyethylene bags for 3 days and sown with surface sterilized bean seeds (5 seeds/pot). The pots were distributed in completely randomized design (CRD) with 4 replication,under greenhouse conditions. Seed germination was calculated after 10 days and the disease severity was estimated after 30 days of sowing, according to disease scale described by Matloob (2012).

0= healthy plants; 1= rolling of secondary roots; 2= discoloration of secondary roots and part of main root; 3= rotting of main root; 4= rotting and disruption of main root.

$$\%\text{ disease severity} = \frac{\text{Number of plants from 0 degree} \times 0 + .. + \text{No. of plants from 4} \times 4}{\text{Total No. of plants} \times 5} \times 100$$

Effect of Salicylic acid and Phylax application on disease development

The experiment was carried out in a field of Collage of agriculture, University of Baghdad. Bean seeds were separately soaked in water, Salicylic acid and Phylax for 24 h and sown in the field in wells (3 seeds/well) at 25 cm inter space on lines of 3 m length, 1m inter spaces, with the following treatments:

1. Seeds soaked in water and foliage application of SA+ RS3.
2. Seeds soaked in water and foliage application of Phylax + RS3.
3. Seeds soaked in water and foliage application of SA+Phylax + RS3.
4. Seeds soaked in water + RS3/ control.
5. Seeds in soil treated with SA+ RS3.
6. Seeds in soil treated with Phylax + RS3.
7. Seeds in soil treated with SA+ Phylax +RS3.
8. Seeds soaked in SA + RS3.
9. Seeds soaked in Phylax + RS3.
10. Seeds soaked in water/control.

SA and Phylax were used at 2500mg/l for foliage application and at 50ml/well for soil treatments. *R.solani* inoculum grown on millet seeds was added in groove along the lines under the wells at 50 g/m. Disease incidence, disease severity, plant fresh and dry weight were assessed after 90 days of cultivation.

Results and Discussion

Fungi isolation and identification

Results of isolation and identification showed presence nine species belong to seven genus associated to the root rot and stem bases (Table-1-) which had rot and lesion symptoms disease and the *R.solani* fungus had the priority with variance presence percentage between the regions ranged between 75 -100% followed by *F.solani*with percentage ranged between 40.5- 65.2%, while the *M.phaseolina* presented between 9.5-35.5% . These results were inagreement with Mwang-ombe*et al* ,(2007) of the spread of a soil borne fungal pathogen in the bean fields of the fungal *F.solani, M. Phaseolina*and *R. solani* by surveying the root rot of bean for ten fields in Kenya, they found that the main cause of root rot disease of beans is *R.solani* followed by the Fusarium with an appearance ranging from 5.6-65.2%. Roots rot disease spreads in many region in Babel governance and *F.solani*is the more spread fungus and it was founded in most of the tested samples with different percentage ranged between 14- 65% followed by *R.solani*and *M.phaseolina*at presence ratio 28.1 and 22.6% respectively(Matloob, 2012). Timothy *et al*, (2013) mentioned that the most important causes of root rot disease are *M.phaseolina*and *Fusariumspp* and they appeared in most samples which were collected from Latin America, Middle America and Carbine sea fields, *F.oxysporum*and*F.semitectum*appearance in Al-Maden, AL- Dora and Al- Rathwania regions samples ranged between 22.65-35.5% and 20.6-30.7 % respectively. These results agreed with many studies that explained that species of *Fusariumspp* such as *F.oxysporum, F.proliferatum ,F.semitectum*and*F.solani*were from the main causes of root rot in some field of vegetables crops(Salari*et al*,2012; Zakaria and Sasetharan, 2014). These results agreed with Al-Juboory*et al.* (2016) that isolates of *M.phaseolina*, which were isolated from watermelon plants grown with root rot disease, significantly reduced the germination rate of the seeds on the WA plant ranging from 0 to 65%.

These results agreed with finding of each of Al- Juboory(2002), Matloob (2012), Al-Mosawe (2012), that the *F.oxysporum, F.semitectum* and *F.solani* species were caused that caused root rot disease in some plants of different plant families . The results of microscopic examination revealed a number of fungi associated with the roots and bases of bean stalks such as *Alternariaalternata, Drechsleraaustraliensis* and *UlocladiumAtrum,* with ratios of less than 10.63, 5.10 and 1.7% respectively. Presence of these fungi may be attributed to their high ability in productive unit's production and to tolerance of the inconvenient condition and to their ability to stay live with host presence and their family range is wide and their large competition ability against the other soil organisms. There are some factors that contribute in rising the infection ratio of roots rot disease such as continuation on using inconvenient agricultural systems, soil fertility levels decline , use seeds collected for the same previously cultivated farms , repeating crop cultivation yearly and use sensitive species to roots rot disease infection . The incidence and severity of the disease varies according to environmental conditions and soil conditions, such as the number and type of pathogens present under certain conditions (Morris. 2017).

Table 1: Fungi accompanying to the infected roots of bean plants and ratios and regions of them.

Fungi	Frequency*%			
	Al-Maden	AL-Dora	Al-Rathwania	Average
Alternariaalternata	6.8	14.5	10.6	10.63
Drechsleraaustraliensis	6.5	3.8	5.00	5.10
Fusarium oxysporum	25.4	35.50	22.65	27.85
F. semitectum	30.7	20.6	25.5	25.60
Fusarium solani	55.0	40.5	65.2	53.56
Macrophominaphaseolina	25.7	35.5	9.5	23.56
Rhizoctoniasolani	75.0	90.8	100.0	88.6
Trichoderma harzianum	3.2	2.61	4.11	3.30
Ulocladiumatrum	2.1	3.00	0.00	1.70

$$\text{*Frequency (\%)} = \frac{\text{Number of pieces containing thefungus}}{\text{Total number. of pieces}} \times 100.$$

The result showed that *F.oxysporum* (**Fig.1** A) colony differed from white to pink to purple and it produced three kinds of Microconidia spores lifted by short tripods of kind Monophialides and Macroconidia and they were short to medium length and were divided by three barriers , Chlamidio spores is as single or pairs and it may be as groups or short chains on PDA media(Leslie and Summerel, 2006) .*F.semitectum* colony(**Fig.1** B) characterized by its brown or light brown color changes to light orange color and it forms three kinds of spores, the Macroconidia divided by 3-5 barriers , while Microconidia is rare and it is difficult to find it and Chlamidio spores is single or as chains form. *F.solani* colony characterized by its white to creamy color on the PDA media (**Fig.1** -C) and the microscopic test showed three kind of spores , they were Macroconidia, spindle to cylindrical shape , 5-7 barriers , Microconidia colony had oval to elliptical shape and 1-2 barriers resulted from monophilides kind of long tripods and Chlamidio spores was single or in pairs and sometimes as short chains (Leslie and Summerel, 2006).

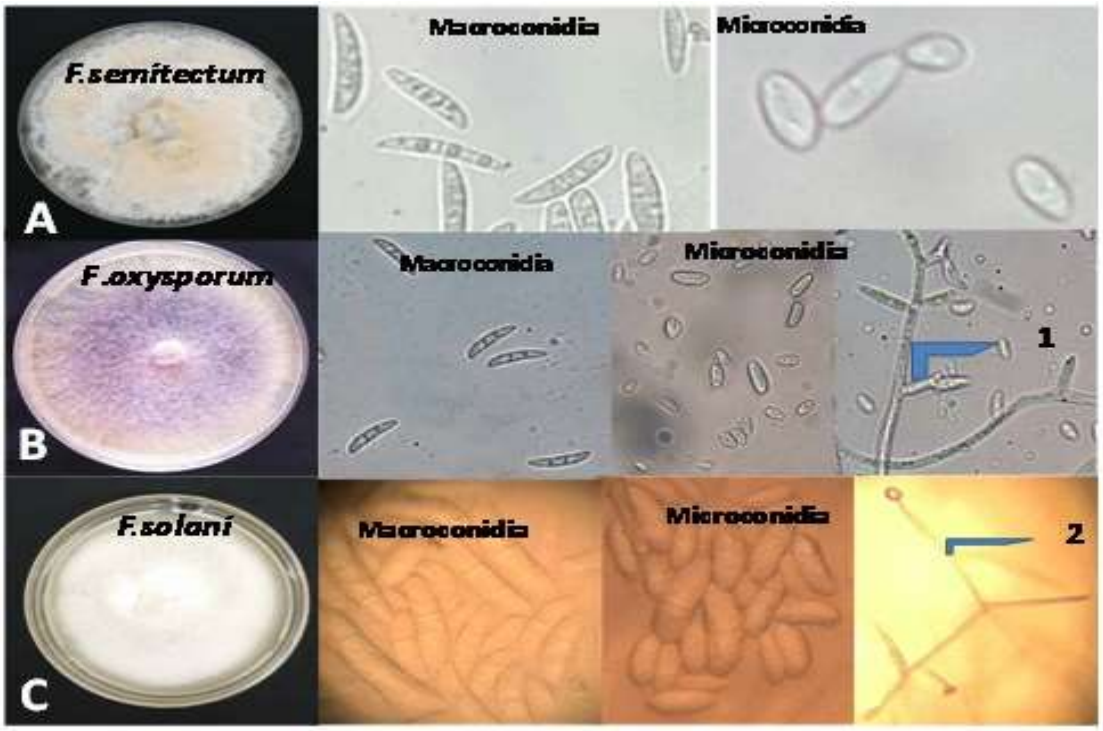

Fig.1 - Cultural and microscopic characteristics of the F species A- colony growth on PDA of *F. semitectum* , 1- short condia tripods, B- colony growth on PDA of *F.oxysporum* nature and shape of growth and Microconidia and Macroconidia , condia spores of Microconidia and Macroconidia,c- colony growth on PDA *F.solani* - long condia tripods type Mono which is classification property of fungus.

M.phaseolina isolations characterized by their fast growth on PDA compared with other fungi and by their while color that may change to dark color and then to black color(**Fig.** 2 -A) due to Microsclerotia formation and have irregular shape on surface of PDA Media(Picture 2 - B) . Disease intensity is correlated with Microsclerotia numbers in soil(Khan, 2007).

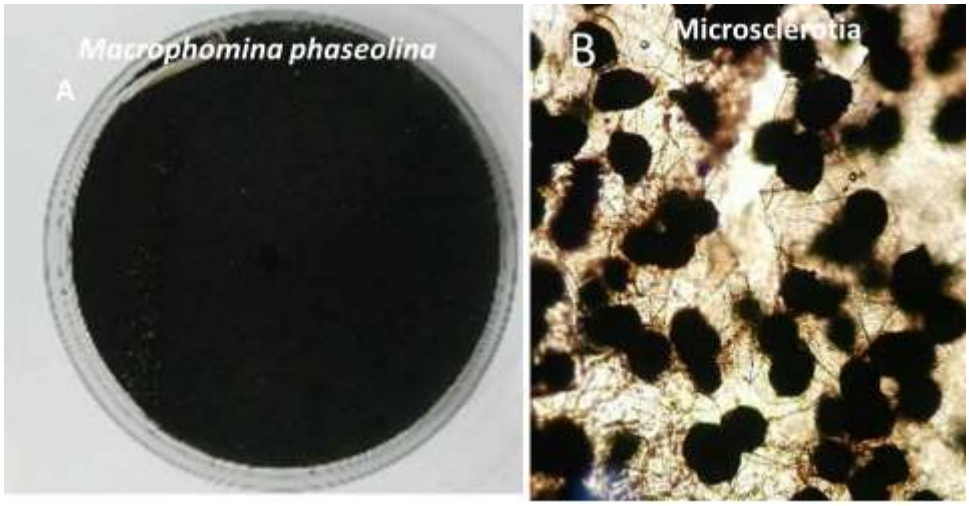

Fig 2 – Cultural and microscopic characteristics of M. phaseolina. A=M. phaseolina colony growth on PDA B= Microsclerotia x40

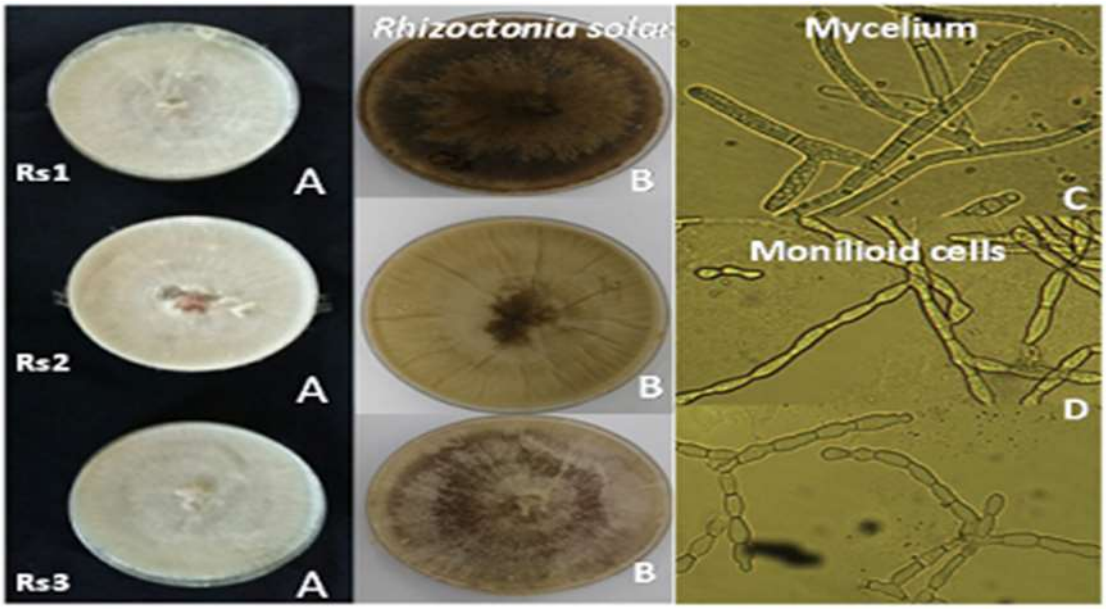
R.solani fungus isolation characterized showed clear variance in spinning fungus shapes and its density . Fungus colony color and size of Microsclerotia (Picture 3) colonies color characterized in the beginning of fungus threads by a white to light brown color(Picture 3-A)

and turned gradually to dark brown color with advance of colony age with variance degrees(Picture 3-B) Microsclerotia formed brown and round colony and the microscopic test showed that the fungus spinning was divided and had many standing tillers with the main fungus spinning angle and presence tears near place of branch emergence and presence of barrel cells aggregated as chains in places of chamber bodies formation(Picture 3-C) , these properties agreed with those properties which were mentioned by Parmeter and Whitney, 1970; Andersen and Stalpers, 1996).



Pathogenicity test

All the isolates obtained from plants showing rot symptom on bean stem base and root have caused significant reduction in seed germination compared with control. Variations in Virulence between the isolates were observed. The most aggressive isolates were of those belong to *R.solani*, where Rs1and Rs3 have totally inhibited seeds germination compared to 5, 10, 15, 20 and 25% germination with the isolates Rs2 , Fso2, Mp1, Fox2, Fse1,respectively. All the isolates caused significant increase in disease severity compared with control. *R.solani* isolates were found the more pathogenic with disease severity 100% for Rs1, Rs2, Rs3, compared to 79.45, 65.71, 60.31 and 54.28% withFso2, Mp1, Fox2, Fse1 respectively (Table 1).

Table 1. Effect of pathogenic fungi isolates on bean seeds germination and disease severity.

Treatments	%seeds germination	%disease severity
Fusarium oxysporum (Fox2)	20.0	60.31
F. semitectum (Fse1)	25.0	54.28
F.solani (Fso2)	10.0	79.45
Macrophominaphaseolina (Mp1)	15.0	65.71
Rhizoctoniasolani(Rs1)	0.00	100.00
R. solani (Rs2)	5.0	100.00
R.solani(Rs3)	0.00	100.00
Control	100	0.00
LSD 0.05	5.95	1.25

Each number in the table represent the mean of 4 replications

Some previous studies reported that causal agents of root rot fungi belongs to *R.solani, M.phaseolina*and *F.solani*caused reduction in seed germination up to 70% with disease severity between 40- 100% compared with control.

The pathogenicity variations between isolates may attribute to genetic and ecological variations led to differences in isolates ability to produce lytic enzymes and toxinsIt was reported that *F.solani* produce many lytic enzymes including cutinase, cellulase, polygalacturonase and protease that hydrolyze plant cell wall and penetrate into the cell. It was found that the aggressiveness of *M. phaseolina* depend on its capacity to produce toxins and lytic enzymes including, Amylase, Cellulase, Hemicellulase, Lipase and Pectinase that hydrolyze cell wall (Kaur, 2012; Kumar and Sharma, 2013). The fungus also reported to produce secondary metabolism compounds, Fusaric acid, Javanicin, polypeptides and toxins that effects cell membrane permeability and inhibits many cell enzymes(Vidhyasekaran, 1997; Azliza et al. 2014).

Effect of Salicylic acid and Phylax application on disease development

The treatment of bean seed with SA and Phylax in the presence of *R.solani* induced high reduction in disease incidence and severity compared with control. Soaking seed in water and addition SA with Phylax into the soil induced the higher reduction in disease development with disease incidence and severity 6.66% and 3.75% compared to 100% and 77.08% in control, respectively. This treatment was followed by soaking seeds in water and addition SA and Phylax separately into the soil with disease incidence and severity, 20.00% and 12.50% and 26.67% and 16.67%, respectively compared to 46.66%, 32.14%,66.67%, 41.66%, 33.33%, 12.15%in soaking seeds in water with foliage application of SA and Phylax separately and in combination respectively (Table 2).

Table 2.Activity of Salicylic acid and Phylax on bean stem base and crown rot disease development and growth parameters

Treatment	%disease incidence	% disease severity	Fresh weight kg	Dry weight g
Soaking seeds in water and SA foliage application + RS3	46.66	32.14	1.29	425.34
Soaking seeds in water and Phylax foliage application + RS3	66.67	41.06	1.26	390.65
Soaking seeds in water and SA +Phylax foliage application + RS3	33.33	12.15	1.31	430.86
Soaking seeds in water and soil application of SA + RS3	20.00	12.50	1.47	563.13

Soaking seeds in water + RS3 /control	100.00	77.08	0.83	452.34
LSD 0.05	2.56	2.64	0.18	9.72

The activity of SA and Phylax in restriction of *R.solani* growth and suppression of disease symptoms development may attribute to induction of several compounds in plants mainly

phenolic compounds and phytoalexins that enhance strengthening of cell wall and prevent fungus penetration in to the cell. The restriction of disease development by SA and Phylax may be also through activation of specific set ofgenes to the plant encoding for pathogenesis related proteins(PRP) some of which possess antifungal activity. It was reported that treatment of plants with SA or one of its functional analogues, Acibenzolar-s-methyl (ASM) induce systemic resistance and activate pathogenesis – related protein (Hammer Schmidt, 1999). Meenakshi and Baldev (2013) found that soaking seed in SA induced activation of some enzymes correlated with plant defense mechanisms and accumulation of phenolic compounds that inhibit the fungal penetration into the cells (Meenakshi and Baldev, 2013). Shehata (2015) reported that soaking seeds in SA has restricted the development of root rot caused by *R.solani* associated with activation ofPRP genes. The restriction of bean stem base and root rot development by SA and Phylax was found associated with promotion of plant.

The fresh and dry weights of plants emerged from water soaked seeds in soil,1.46kgand 540.20g, 1.48kg and 574.13g respectively, 1.29 kg and 425.34g, 1.26 kg and 390.65 g, 1.31 kg and 430.86 g of plant emerged from water soaked seeds and foliage application with SA, Phylax and SA + Phylax respectively, 1.29 kg and 431.11g, 1.26 kg and 382.00g of plants emerged from seeds soaked in SA and Phylaxrespectively compared with 0.83 kg and 252.34g in control respectively (Table 2).

The promotion of plant growth may result mainly from the suppression of disease causal agent as well as considered as plant hormone can enhance plant promotion. It was reported that spraying citrus seedlings with SA at 100 mg/l induced increase in plant height, branches number, fresh and dry weights, leaves contend inchlorophyll and carbohydrate through activation many enzymes and photosynthesis(Abd-El Wahed et al. 2011).

Conclusion

Bean plants are subjected to infection with many soil borne pathogens including *Fusarium oxysporum*,*F.solani*,*Macrophomina phaseolina*, *Rhizoctonia solani* causal agents of, root and stem base rot .they found that the main cause of root rot disease of beans is *R.solani* . Many compounds including Salicylic acid, and Phylax were used as foliage application, soil treatment, seed soaking, showing high inhibition activity against several fungal pathogens *in vitro* and reduced infection with root rot disease under field conditions

Abstract

Medicinal (aromatic) plants (MAPs) are playing an important role for the solution of World Health Organization Problem *Health for everyone in 21st Century*. In Lithuania, since 1924 until, medicinal plants collections have been developed in the Sector of Medicinal and Aromatic Plants in Botanical Garden at Vytautas Magnus University (SMAPs BG VMU). In Europe unique collection of MAPs is a base for scientific researches, project-based activities, national and international studies and the object of public education. The topics and tendencies of the research on medicinal herbs have varied since that time quite a lot. Collections of medicinal plants are still an important constituent and object of the phytochemical scientific research process. The methods of chemical investigations have been changing during the distinct research periods (1st – 1924–1949, 2nd – 1949–1984, 3rd – 1984–1999, 4th – 1999–2018). The main objective of research is the introduction and phytochemical investigation of MAPs. Biodiversity of plant resources, scarce information on biologically active compounds and their properties in many species including those naturally growing in Lithuania or introduced, as well as increasing demand for natural food, food supplements and homeopathic medicine have been the main motivation aspects of the ongoing study. MAPs are sources of raw materials, required in pharmacy and phytotherapy are a part of genetic resources of Lithuania. Phenological observation, phytochemical investigation of raw material of MAPs from SMAPs BG VMU revealed that new species from foreign and local flora can be successfully introduced in Lithuania. Lithuania has good growing conditions for a great variety of MAPs.

Keywords: *Medicinal and aromatic plants, introduction, phytochemical analysis, Lithuania*

Introduction

In addressing the issue of the development of high-quality, healthy and environmentally-friendly food technologies raised by the World Health Organization in the European Health Policy document "*WHO Traditional Medicine Strategy 2013-2023*" and in the priority research, the variety of MAPs, rational, sustainable use of them is promoted.

Recently, more and more attention has been paid to the biological properties of introduced as well as local flora plants, their cultivation, medicinal plant raw materials and their phytochemical research **(**Briskin, 2000). In accordance with the requirements of the World Health Organization and Good Manufacturing Practice, medicinal plant raw materials and plant products must comply with safety, efficacy and stability parameters (GASP, 2003; Ph. Eur., 2013;).) MAPs grown in industrial plantations can control and ensure the good quality of medicinal plant material: by conducting plant biological tests, standardizing cultivation conditions, determining the optimum time of preparation of medicinal plant raw materials, drying and other conditions. Now and in the future it is necessary to study the biological properties of the introduced plants, expand the range of these plants, increase their biological diversity and accumulate national genetic resources (Radušienė and Janulis, 2004; Motiekaityte, 2006). For this purpose, since 1924 in the climate conditions of the Republic of

Lithuania, research on the introduction of medicinal plants and herbs has been carried out at SMAAPs BG VMU. Based on national and international complex, interdisciplinary research, a collection of medicinal plants has been developed, which is the subject of studies and research. In 1924-2018, the collection of medicinal plants, research issues and research trends in individual periods (1st - 1924-1949, 2nd - 1949-1984, 3rd - 1984-1999 and 4th - 1999-2018) changed, but the main tasks have remained significant, preparing scientific recommendations for medicinal plant growers and pharmaceutical raw material processing companies (Juknevičienėa and Juronis 2000; Ragažinskienė *et al.,* 2007).

The *aim of this work* is to carry out the long-term (1924-2018) scientific activities in researching the introduction of MAPs, as well as summarizing and evaluating scientific issues and developments.

The aim of the research was to carry out a retrospective analysis of the chemical composition of MAPs, in separate periods: 1st - 1924-1949, 2nd - 1949-1984, 3rd - 1984-1999 and 4th - 1999-2018 during plant introduction period, ex situ long-term outdoor collections at SMAAPs BG VMU in Central Lithuania.

Material and Methods

The object of the research is the development of studies and methods of MAPs their introduction and chemical composition in separate periods. The retrospective analysis of the explorations and methods of chemical composition of prospective MAPs and hop varieties was performed by theoretical descriptive method using scientific publications and reports as well as archival data of Botanical Garden of Vytautas Magnus University (Juknevičienė and Juronis, 2000; Maruška and Kornyšova, 2006; Ragažinskienė *et al.*,2007; Ragažinskiene and Rimkienė, 2003; Stankevičius *et al.,* 2011). MAPs research is carried out according to the scheme presented in Fig. 1.

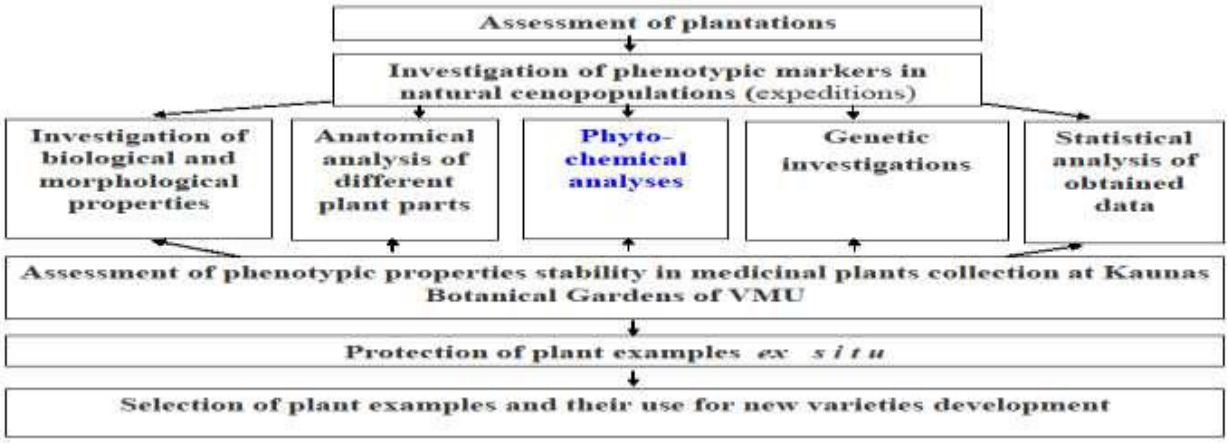

Fig. 1. Schema and Metods of the Introduction and Phytochemical Investigation of MAPs.

Results and Discussion

Retrospective analysis of the development of scientific research on the chemical composition of prospective MAPs. There were four research periods of chemical composition of medicinal (aromatic) plants: the 1st (1924-1949), the 2nd (1949-1984), the 3rd (1984-1999) and the 4th (1999-2018), which took place in the field of plants during introduction, *ex situ* field collections, at SMAPs BG VMU, Central Lithuania. This analysis highlighted the

development of research methods for plant chemical composition at separate periods and the possibility of using medicinal (aromatic) plants and their raw material.

During the 1st period chemical composition of the medicinal, technical and forest medicinal plants and medicinal herbs was carried out in the time of the introduction. 224 plant species accumulated in the collection of medicinal plants, the chemical composition of which is the quantitative analysis of essential oils, was carried out by hydro distillation. These studies supported the selection of 77 viable plant species and their cultivation in Lithuania (Grybauskas, 1954).

During the 2nd period phytochemical laboratory was founded. The chemical composition of medicinal, technical, oil, fermentation plant was investigated - the amount of essential oils by hydrodistilation method, their quality by gas chromatography, during plant introduction. The research direction was "*Sustainable use of the plant world and their protection biological bases*". During this period, the following collections of plants were created and equipped: medicinal plants, hops, rare vegetables, spice and honey plants (Penkauskienė and Rimkienė, 1991).

The 3rd period carried out research in *The consistent of functionality of variety and phytocyanosis and their sustainable use in the improvement of feed.* During this period, the chemical composition of MAPs was investigated: the amount of essential oils - by hydrodistilation method – for aerotherapy for sanatorium treatment. The quality of the medicinal plant raw material was evaluated: the qualitative analysis of flavonoids and phenolic carboxylic acids was carried out using a plane paper chromatography method. Flavanols and leaven were determined quantitatively in the terrestrial and underground parts of the plant by colorimetric methods, nitrates were titrated using ionometric methods and ascorbic acid was evaluated titrimetrically. Also, the sum of oxycinamines was calculated by recounting the chicory acid. All chemical analysis data was counted for an absolutely dry raw material (Juknevičienė and Juronis 2000; Penkauskienė and Rimkienė, 1991).

Field of research of **the 4th period** investigations of MAPs diversity and their introduction, assessment of raw material and rational, sustainable use in medicine, food industry and veterinary.

The value of medicinal plant collections. Since 1924 the pharmacognomic principle has been the development of a long-term inventory and documented collection of medicinal plants. It has already introduced 594 plant species belonging to 373 genera and 88 families. This collection contains 31 rare and endangered species of medicinal plants in Lithuania. Based on long-term introduction and chemical properties, more than 128 species of MAPs have been investigated for the status of Lithuanian national genetic resources. 54 medicinal plant species are on the list of plant genetic resources (ANGI). The 25 varieties and forms of hops are included on the list of medicinal plants and aromatic plant field collections that are assigned to Lithuanian plant genetic resources. Studies were carried out on the basis of the project "*Plant Genetic Resources Research 2000-2008*" (Grant No. 12) of the Ministry of Education and Science of the Republic of Lithuania (Ragažinskienė *et al*., 2007; 2010; Ragažinskienė and Rimkienė, 2003).

There is an exchange of medicinal plant seeds with more than 400 Botanical Gardens from different countries.

Scientific activity. Medicinal plants in collections are the subject of scientific research. Here, complex, innovative, interdisciplinary, interdisciplinary scientific work is being carried out for research of biologically active substances of medicinal (aromatic) plants together with Instrumental Analysis Open Access Center of Faculty of Natural Sciences at Vytautas Magnus University on the basis of scientific projects (Kaškonienė *et al.*, 2011; Maruška and Kornyšova, 2006; Maruška et al., 2010; Stankevičius *et al*., 2011).

The study of the methods of preparation of the medicinal plant raw material and the improvement of the drying technology in the medicinal plant raw material determined the dependence of the content of the bioactive substances – essential oils and flavonoids on the conditions of drying (natural ventilation, air velocity and flowing air flow and temperature), which are selected according to the plant's composition of the raw material components (leaves, stems, grass) and the groups of biologically active substances (Kaškonienė *et al*., 2011; Maruška *et al*., 2010).

Based on the research of these plants, 37 medicinal plant species which are promising for the pharmaceutical and food industry have been selected: *Achillea millefolium* L., *Agrimonia eupatoria* L., *Alchemilla vulgaris* L., *Althaea officinalis* L., *Angelica archangelica* L., *Arctium lappa* L., *Arnica chamisonis* Lessing., *Arnica montana* L., *Aronia melanocarpa* (Michx.) Elliott, *Artemisia absinthium* L., *Bidens tripartita* L., *Borago officinalis* L., *Calendula officinalis* L., *Chamaemelum nobile* (L.) All. = *Anthemis nobilis* L., *Convallaria majalis* L., *Melissa officinalis* L., *Mentha piperita* L., *Echinacea purpurea* (L.) Moench, *Echinacea pallida* (Nutt.) Nutt, *Glycyrrhiza glabra* L., *Geranium macrorrhizum* L., *Hyssopus officinalis* L., *Humulus lupulus* L., *Inula helenium* L., *Juglans regia* L., *Leonurus cardiaca* L., *Nigella damascena* L., *Nigella sativa* L., *Origanum vulgare* L., *Perilla frutescens* (L.) Britton, *Potentilla erecta* (L.) Raeusch., *Potentilla fruticosa* L., *Rhaponticum carthamoides* (DC.) Iljin, *Schisandra chinensis (*Turcz.) Baill., *Scutellaria baicalensis* Georgi, *Viola tricolor* L.

The research findings are presented in monographs, scientific and popular science articles, national and international scientific conferences and recommendations (Bartkienė *et al*., 2015; Ligor *et al*., 2014; Šulniūtė *et al*., 2017; Venskutonis *et al*., 2007).

Scientific knowledge for herbalist business. In the area of herbal development there is cooperation with rural communities. The geographic regions of Lithuania, under various ecological conditions, have been equipped with collections of medicinal plants and testing areas for their cultivation. In addition, scientific methods for the preparation of medicinal (aromatic) plants and medicinal plant raw materials have been introduced. A modern herbal dryer was developed, using alternative solar energy: the European Agricultural Fund for Rural Support Project: Lithuanian Rural Development Programme 2007-2013 project '"Cultivation of medicinal plants and innovative technology using of solar energy for preparation medicinal plant raw materials" (Grant No. 1 PM-PV-10-1-003015-PR001 (2011-2014) (Raila et al., 2009; Maruška et al., 2014).

Legislative justification for science and business. Participating with the Ministry of Health of the Republic of Lithuania in the legislative process, starting from 2013, *Supplemental and Alternative Health Care Act* is being developed.

Conclusion

Introduction studies of medicinal, (aromatic) plants have been carried out at Vytautas Magnus University since 1924.

In the 1st collection, 77 (out of 224) promising medicinal plant species were selected by investigating their chemical composition with hydrodistillation method.

The 2nd period founded the phytochemical laboratory, and the chemical, technical, oil, tartar chemical composition (essential oil content) was investigated by distillation method, their qualitative composition was determined by the gas chromatography method.

The 3rd (1984 – 1999) Chemical composition of medicinal (aromatic) plants: the amount of essential oils was investigated by hydrodistilation method. The quality of the medicinal plant raw material was evaluated: the quality of flavonoids and phenolic carboxylic acids was determined by plane paper chromatography, quantitatively flavonols and leaven - colorimetric, nitrates - by the ionometric method.

During the 4th period the following methods and apparatus are used for the evaluation of the chemical composition of MAPts and hop varieties: the amount of essential oil is determined by methods of hydro-distillation, super-liquid extraction and carbon black microextraction, their qualitative composition - gas chromatography and mass spectrometry, phenolic compounds – effective liquid chromatography, standard spectrophotometry and capillary electrophoresis, the activity of binding of free radicals to plant extracts was evaluated spectrophotometrically, the antioxidant and radical components of the individual extracts.

OCURRENCE OF *TETRANYCHUS URTICAE* ON SOUR CHERRY TREES IN SOUTHEASTERN OF MACEDONIA

Biljana ATANASOVA, Dusan SPASOV, Dragica SPASOVA, Mite ILIEVSKI

Faculty of Agriculture, Goce Delcev University, Stip, Republic of Macedonia

Abstract

The two-spotted spider mite is probably one of the most polyphagous arthropods that feeds on tree fruits. It is distributed worldwide and is an economic pest of many crops. Its innumerable hosts include many weeds, field crops, ornamental plants, vegetables, forage crops, small fruits and tree fruits (apple, pear, peach, nectarine, apricot, cherry (sweet and sour) and plum). The research was conducted during 2017 in sour cherry orchards in southeastern of Macedonia (the region of Stip, Strumica and Gevgelija), before and after the harvest of the sour cherries (01.06. – 30.09.2017). Scouting for mites began prior the harvest. The method of monitoring two-spotted spider mite motile populations consists of sampling 10 leaves from 10 randomly selected trees (100 leaves) on an area of two ha. To estimate the number of mites per leaf, we count the number of leaves that have two or more two-spotted spider mite motile from each sample and follow the presence-absence sampling method look-up table. The results showed that after harvesting the sour cherries, during the summer and autumn, the number of two-spotted spider mite increases and exceeds the economic threshold (8-10 spiders on the leaf), so chemical treatment is required in order to control the population of the spider. The problem in the Republic of Macedonia is that sour cherries producers rarely perform postharvest treatment of the sour cherry trees, so the two-spotted spider mite population increases, which in turn contributes to a reduced yield of sour cherries.

Keywords: *two spotted spider mite, sour cherry, presence, acaricides.*

Introduction

The two-spotted spider mite is probably one of the most polyphagous arthropods and the most destructive within the family of the Tetranichidae (Vassiliou & Kitsis, 2013). It is distributed worldwide and is an economic pest of many crops, having a host range of more than 1100 species of plants (Paulo et al., 2015). Its innumerable hosts include many weeds, field crops, ornamental plants, vegetables, forage crops, small fruits and tree fruits (apple, pear, peach, nectarine, apricot, cherry (sweet and sour) and plum) (Beers H. E. and Hoyt C. S., 1993: http://jenny.tfrec.wsu.edu). *T. urticae* is particularly dominant and destructive in intensive, high-yield cropping systems, and affects crops by direct feeding. In cases of severe infestations, it reduces the area of photosynthetic activity and causes leaf abscission (Gorman et al., 2002). Two-spotted spider mite can be a problem on cherries in hot and dry years. Bronzing is the most common damage caused by high populations of two-spotted spider mites. This phenomenon can cause a reduction in photosynthesis and fruit bud initiation. Bronzing caused by two-spotted spider mite is often more gray in color than bronzing by European red mites (*Panonychus ulmi* Koch). Although bronzing presents an obvious challenge, one of the biggest threats of mites in sour cherries in a hot, dry year is "firing." Firing is an immediate result of increased temperatures and droughty conditions, most often in combination with high mite populations. Firing results in a collapse of a portion of the tree, this malformed segment can be a branch, a terminal, or a whole section of the tree. The leaves of a fired part of a tree turn brown very quickly (Fig. 1), with no prior wilting, and the overall effect is similar to fire blight in apples. Although firing may occur with low mite populations, it is found most commonly, where mite numbers are high.

Figure 1. Sour cherry trees infested with *Tetranichus urticae* in the region of Gevgelija

A major problem in the control of *T. urticae* is the response to develop resistance to many acaricides (Abd El-Moneim et al., 2012). Also, the cherry growers are often faced with the crucial decision of applying an acaricide before or after harvest. If growers intend to spray for mites before cherry harvest, the pre-harvest intervals of most acaricides are 14 days or longer, which is an important factor in the decision making process. Another confounding factor of pre-harvest mite control is that often the mite population is lower early in the season, and the numbers may not warrant an acaricide at that time. The problem in the Republic of Macedonia is that sour cherries producers rarely perform postharvest treatment, so the two spotted spider mite population increases, which in turn contributes to a reduced yield of sour cherries.

Material and Methods

The research was conducted during 2017, in six sour cherry orchards in the region of Stip, Strumica and Gevgelija (two orchards in each region), in southeastern of Macedonia, in the period of 01.06. – 30.09.2017. Scouting for mites began prior the harvest. This pre-harvest monitoring period should begin early enough to consider the long acaricide pre-harvest intervals. A fairly reliable and easy-to-use sampling method for mites is called presence-absence, or binomial, sampling (Jones, 1990). Rather than counting the number of mites on leaves, which is difficult because of their small size, presence-absence sampling requires only that the scout determine whether pest mites are present on each leaf sampled. The method of monitoring two-spotted spider mite motile populations (Morphological Identification of Spider Mites (Tetranychidae) Affecting Imported Fruits: https://www.nappo.org) consist of sampling 10 leaves from 10 randomly selected trees (100 leaves) on an area of two ha. Because spider mites are first, found in the lower center and at the top of tree canopies, spreading to the periphery over time, leaves are selected from inside the canopy, as well as from the edges. Using a 10–20x magnifying hand lens, the number of leaves from each infested tree is counted. The look-up table (Table 1) was used to estimate the number of mites per leaf. The estimated mite density for all 10 trees is collected and divided by 10 to obtain an average for the trees sampled in the block.

Table 1. Web spinning spider mite presence-absence sampling method look-up table (Jones, 1990).

Number of leaves out of 10 with at least one mite present*	Estimated number of mites per leaf
1	0.1

10	--

*Note: for each tree sampled, determine the number of leaves out of 10 with at least one mite present

On the second orchard in each site, after harvesting the sour cherries, acaricide treatment was performed. Two active substances were used: Dimetatoate, with a concentration of 0.15% (13.09.2017) and Abamectin, with a concentration of 0.1% (28.09.2017). After the treatment the leaves of the sour cherries were surveyed again with presence-absence sampling method.

Results and Discussion

During 2017, the control plantations of sour cherries in regions Stip, Strumica and Gevgelija, provided the following condition (Table 2).

Table 2. Average number of two-spotted spider mites on 100 overviewed leaves of sour cherry, in the control plantations, in Stip, Strumica and Gevgelija.

Stip									
	01.06.	15.06.	30. 06.	15.07.	30. 07.	14.08.	30.08.	15.09.	30.09.
Avg	0,65	0,89	2,78	3,26	4,68	5,03	7,92	8,08	4,52
Strumica									
	01.06.	15.06.	30. 06.	15.07.	30. 07.	14.08.	30.08.	15.09.	30.09.
Avg	1,35	2,01	2,46	2,84	4,01	5,03	7,0	8,08	4,88
Gevgelija									
	01.06.	15.06.	30. 06.	15.07.	30. 07.	14.08.	30.08.	15.09.	30.09.
Avg	2,30	3,17	3,96	4,66	6,11	5,39	8,08	8,80	4,88

According to the obtained results (Table 2), the highest occurrence of the two-spotted spider mite is on the plantations in the region of Gevgelija. This part of Macedonia is characterized by higher average temperatures, so there are more favourable conditions for the development of the two-spotted spider mite. In all examined regions, the number of mites increases in warmer months of the year, so its number is the highest in late August and early September.

Biological and cultural control for spider mite management should be the goal of every orchard pest manager. In many situations, chemical control is unnecessary and may only make the mite problem worse. The use of acaricides will eliminate the beneficial predatory mites, which are capable of keeping spider mite populations below economically damaging levels. Another reason to avoid chemical control is that populations of two-spotted spider mites have developed resistance to acaricides (Rothwell N. (2014). Managing two-spotted

spider mites in cherries: http://msue.anr.msu.edu). However, when the number of the two spotted spider mite increases and exceeds the economic threshold (8-10 spiders on the leaf), chemical treatment is required in order to control the population. The use of resistant cultivars is considered the ideal control method because they maintain the mite populations below levels of economic damage, minimize the environmental impact of pesticides at no extra costs to the farmer, and serve as an auxiliary tool in integrated pest management (Karlec et al., 2017).

The first treatment of the sour cherry was done on 13.09.2017, with the active substance Dimethoate, in a concentration of 0.15%. After treatment, it was noted that the number of two-spotted spider mites was reduced by almost 50% (Table 3). Another treatment with the active substance Abamectin was performed on 28.09.2017, in a concentration of 0.1%. When checking the number of two-spotted spider mites, it was determined that its number was reduced to 70% from the from the original population level, before first treatment (Table 3).

Table 3. Average number of two-spotted spider mites on 100 overviewed leaves of sour cherry, in the plantations treated with Dimethoate (0,15%) and Abamectin (0,1%) in regions Stip, Strumica and Gevgelija.

Active substance	Stip		Strumica		Gevgelija	
	15.09	30.09	15.09	30.09	15.09	30.09
Dimethoate	4,68	2,78	4,01	2,44	4,66	2,46
Abamectin	2,59	1,53	3,17	1,31	3,26	1,87

These results indicate that after the harvesting the sour cherries, much more favourable conditions are created for the development of the two-spotted spider mites, thus increasing their number on sour cherries. Moreover, when it exceeds the economic threshold of harmfulness, it is desirable to use chemical means for destroying the spider mites. The problem in the Republic of Macedonia is that sour cherries producers rarely perform postharvest treatment of the sour cherry trees, so the two spotted spider mite population increases, which in turn contributes to a reduced yield of sour cherries. Because of these issues, we recommend applying an acaricide after harvest, when the mite numbers are higher and when the pre-harvest intervals are no longer a concern.

Conclusions

Based on the above the following conclusions can be made:

- The number of the two-spotted spider mites is the highest in the region of Gevgelija, where there are also the most favourable conditions for its development.
- The number of two-spotted spider mites increases in the summer months, reaching the peak at the end of August and early September.
- Treatment of sour cherries with acaricides, after harvesting is necessary to reduce the number of two-spotted spider mites. In this way, the damage from the mites will be reduced and the yield of the crop will increase.

Abstract

Couscous is a traditional dish for Moroccan population, based on wheat semolina and habitually consumed on Fridays and days of family reunion, its design is different according to the regions and according to the availability of the raw material (wheat, barley ...). In order to contribute to the reduction of malnutrition in Morocco, this study was carried out. Legumes including lentils have a great role in human diet, they are commonly consumed for their nutritive value specifically proteins and iron. Lentil is among the oldest and most appreciated grain legumes of the Old World. Thus, the current investigation aims to enhance the nutritive value of conventional Moroccan couscous through its preparation by incorporation of lentil semolina into its components. Four experimental variant proportions of grains legumes semolina (25, 50 and 75%) were analyzed, with couscous made of grains lentil semolina only (100%L) and of grains wheat semolina only (0%L) as control. From nutritive point of view, the higher contents of proteins, iron and potassium were found in couscous with addition of 75% of lentil semolina. In effect, the lower content was recorded for conventional Moroccan couscous, and more the percentage of incorporation increased more its content of proteins, iron and potassium increased. Contrariwise, more the percentage increased more carbohydrates and sodium contents decreased. From technological point of view, the addition of lentil semolina at 25% presented the closest results to the technological parameters of conventional Moroccan couscous. Microbiological tests revealed that couscous of wheat semolina only is a favorable environment for the growth of microorganisms. The nutritional value of lentils and their technological characteristics are useful in increasing nutritional and technological value of fortified conventional Moroccan couscous.

Key words: *Malnutrition, Couscous, Bio-fortification, Legumes, Morocco.*

Introduction

Food habits in Morocco are based on wheat products, as an energy and protein source. Bread and couscous are the most consumed. Couscous is a traditional dish specific to the African countries of the Mediterranean. In Morocco, it is consumed regularly on Fridays and days of family reunion (festivity or death). Also, the manufacture of products derived from wheat and especially durum wheat such as semolina, pasta, industrial couscous is widespread in the agri-food industry (Bar.C, 2001). Otherwise, nutrient deficiencies are a major public health problem in Morocco according to the 2016 World Nutrition Report. They affect nearly a third of the population, encouraging managers to initiate an international program to combat these deficiencies. In fact, one in three children, one in three women and one in five men suffer from nutritional deficiencies; the most widespread concerns mainly proteins and iron. The consequences of iron deficiency are detrimental to individual and community development, affecting work capacity (Basta et al., 1979), school performance (Vega-Franco et al., 1994), and stunting and mental development in children (Shultink et al., 1995, Grantham-McGregor

S). In addition, iron deficiency is manifested by anemia that can attack the immune system and thus promotion the onset of many diseases. This issue costs the Moroccan state more than 2 billion dirhams annually or 5% of gross domestic product in relation to health costs and loss of productivity. It seems that the change in food habits with a high tendency towards animal proteins is at the origin of the increase in the incidence of these deficiencies. Fortification which consists of incorporation, food resources rich in protein or micronutrients, in a staple widely accessible and consumed, figure prominently among the strategies adopted for quality improvement nutritional status of the third world (Serna-Saldivar 1999). The possibility of getting a couscous from other products such as lentils remains an interesting alternative whose purpose is to improve products quality. Legumes present an inexpensive source of proteins with a high nutritional profile and, after cereals, the next most important food source for humans (Butt & Batool, 2010). Lentils are rich in protein (20-36%) and are an excellent source of a large range of micronutrients (Wang, N et al., 2006, Thavarajah, D et al., 2007). They rank among the oldest and most appreciated grain legumes of the Old World (Smartt, 1990). Thus the purpose of this study which aims to contribute to the reduction of the incidence of malnutrition, through the incorporation of grains lentil semolina in conventional Moroccan couscous as a staple food, with studding its effects on their nutritional, technological and microbiological characteristics.

Material and Methods

This study was carried out during 2018 in the laboratories of the National Institute of Agricultural Research (INRA) in Rabat, Morocco. Samples of conventional Moroccan couscous made of durum wheat (*Triticum durum*) only (0%L), fortified couscous with lentil *(Lens culinaris)* semolina at 25, 50 and 75% rates and control couscous made of lentil semolina only (100%L) were analyzed for determining their nutritive value, technological and microbiological quality. All analytical tests were carried out in double replications. Ash content of couscous samples was determined according to AFNOR NF V03-720. Proteins were determined using the total Kjeldahl digestion procedure (McKenzie and Wallace, 1954). Crude fat was quantified using Soxhlet extraction with hexane according to AOAC. Carbohydrate (CHO) was determined by subtraction and calculated using the following equation: %CHO = 100 − (%Fat + %Protein + %Ash + %Moisture) (FAO, 2002), the results give an approximate estimate of the total amount of carbohydrates present in couscous. Minerals were determined using atomic absorption spectroscopy for iron, and using flame photometer (CORNIGEEL) for sodium and potassium (AOAC, 1984). Technological parameters were evaluated using gluten parameter measured by infrared spectroscopy (NIRS), swelling index (J. Abecassis, 1991), color index (NF ISO 11664-4, 2008), and whiteness index was calculated (Angioloni and Collar, 2009). The microbiological tests were based on the contamination level of Total Aerobic Mesophilic Flora (FMAT), total coliforms, and yeasts and molds which were researched according to NF ISO 4833 (1991). The count of each type of microorganism was done according to the law of the weighted average (J.P. Larpent, 1997).

Results and Discussion

The results about nutritive value of different sets of couscous obtained before and after cooking were presented in Tables 1 and 2 respectively. Before cooking, Ash content of conventional couscous, composite couscous and couscous made with lentil semolina only varied between 1.50 and 2.85%, high ash content was recorded for 75% (2.37). After cooking, values varied between 1.88 and 3.33%, high ash content was recorded for 75% (2.55). The ash content of food material could be used as an index of mineral constituents (Sanni et al., 2008). Before cooking, protein content was 17.20, 19.92, 21.27, 22.02 and 23.13%

respectively. After cooking, protein content was 18.98, 20.88, 21.94, 22.02, and 23.82% respectively, couscous made of lentil semolina only yielded higher contents of proteins before and after cooking. The lower content was recorded for conventional Moroccan couscous, and more the percentage of incorporation increased more its content of proteins increased. Therefore, the nutritional value increased. Protein content is an important criterion for assessing quality both for animal feed and for human food (C. Bar, 2001). Before cooking, crude fat varied between 0.20 and 1.19%, and varied between 0.20 and 0.60% after cooking. Between them, the lower percent was recorded for 50% before cooking and for 25% and 50% after cooking. Before cooking, carbohydrates content varied between 59.72 and 66.21%, and varied after cooking between 67.25 and 60.45%. Between them, the lower carbohydrates content was recorded for 50% (60.49) before cooking and for 75% (61.63) after cooking. Almost, more lentil semolina was incorporated into wheat semolina more carbohydrates percentage decreased, results concerning conventional couscous were compared to what was reported by (Stone and Morell, 2009), and generally carbohydrates account for about 65–75% of the mature wheat grain. Before cooking, iron content varied between 1.78 and 6.30mg/100g. After cooking, values varied between 2.36 and 7mg/100g. Between them, more the percentage of incorporation increased more conventional couscous content of iron increased. The results indicated that the incorporation of lentil semolina into wheat semolina affected the content of iron of semolina used for making couscous. Before cooking, potassium values varied between 300 and 852 mg/100g which are comparable to the range of 0.88 to 1.44% potassium (mean 1.16%) obtained by Bhatty (1984), and between 24 and 28 mg/100g for sodium which are also comparable to the range of 0.02 to 0.18% sodium (mean 0.04%) obtained by Bhatty (1984). After cooking, potassium values varied between 468 and 1088 mg/100g, and between 20 and 72 mg/100g for sodium. The incorporation of lentil semolina improved the mineral content. The results about technological parameters of different sets of couscous obtained before and after cooking were presented in Tables 3 and 4 respectively. Before cooking, gluten content of different samples varied between 24 and 53%. After cooking, it varied between 31 and 55 %; it seems that more lentil semolina was incorporated more this content increased, maybe it was due to a gluten contamination. Swelling index showed the following values: 2.11, 1.90, 1.70, 1.89 and 1.91 for 0, 25, 50, 75 and 100% respectively, the higher results were presented in composite couscous made with 25% (1.90) of lentil semolina. According to L.Mezroua (2011), the phenomenon of swelling results from the absorption of different amounts of water by the constitutive elements of couscous grain, he found that couscous made from wheat seems to absorb more water and swell to a level higher than couscous without gluten. The appearance, mainly the color, is an important attribute of the quality of cereal products, which affects their marketing and acceptability. The color index values of different sets of couscous were as following: before cooking, L (clarity index) varied between 55.53 and 70.19, a (brown index) varied between -2.28 and -0.56, b (yellow index) varied between 14.59 and 18.85, and IB (whiteness index) varied between 52,46 and 66,81. After cooking, L (clarity index) varied between 51.67 and 66.68, a (brown index) varied between -2.34 and 0.61, b (yellow index) varied between 15.35 and 25.10, and IB (whiteness index) varied between 45.72 and 63.31. The highest value of clarity index and whiteness index was presented by conventional couscous, and the lowest value of yellow index was presented by the same sample. More lentil semolina was incorporated in conventional couscous more clarity and whiteness index decreased, and more yellow index increased; it seems that lentil semolina color influenced wheat semolina color. The microbiological tests were based on the contamination level of FMAT, total coliforms, and yeasts and molds (Table 5). FMAT is an important hygiene indicator. The presence of fecal coliforms in food supposes a faecal pollution; they are indicators of food quality. Yeasts and molds are indicators of humidity. The results revealed that conventional couscous presented

the highest values of FMAT, fecal coliforms and yeasts and molds compared to couscous prepared of lentil semolina only which presented a high value of FMAT only and total absence of fecal coliforms, and yeasts and molds.

Conclusion

It has been observed that it is possible to use grains lentil semolina to partially substitute grains wheat semolina in the elaboration of couscous without undesirable effects. Nutritionally, the higher contents of proteins, iron and potassium were found in couscous with addition of **75%** of lentil semolina, while carbohydrates and sodium contents decreased; the results revealed that as more and more lentil semolina was added to wheat semolina, there was a positive variation in composite couscous nutritional composition, which can be a good signal to achieve the main objective. From the technological point of view, lentil semolina appeared to be a suitable fortifier; its addition in a portion of **25%** showed the closest results to the technological parameters of conventional Moroccan couscous, more lentil semolina was added more its culinary quality and color were negatively influenced. Microbiological tests revealed that couscous made of wheat semolina only is a favorable environment for the growth of microorganisms and incorporation of lentil semolina may improve its hygienic quality.

Abstract

The green mold and the grey mold, caused by *Penicillium digitatum* and *Botrytis cinerea* respectively, are the major postharvest diseases of tomatoes and citrusand other species as well. Synthetic fungicides are the primary means to control these diseases.However,thechemical residues in the food and environmental safety make it unwanted. Biological control using microbial antagonists is one of the most promising alternatives to chemical fungicides. *Pseudomonas* spp. produce many antifungal metabolites, previously shown to be effective against a wide range of fungi. In this study, the inhibitory effects of *Pseudomonas putida* Q172B, *P. fluorescens*Q110B and *P. fluorescens*Q036B, isolated from tomato roots in Agadir-Morocco, on *B.cinerea* and *P. digitatum* were examined. The effect of *Pseudomonas*strains was observed on the inhibition of mycelium elongation by production of soluble and volatile metabolites. The results showed the antagonism effect of three strains. The inhibition rate ranged from 39 to 54% for *P. digitatum*, and 66% for *B.cinerea* for all three strains. Forvolatile metabolites,100% of mycelium inhibition was recorded in *B.cinerea* for all three strains, but 44% was the maximum mycelium inhibition recorded in *P. digitatum*. Our result highlights that the *P. putida*Q172B and *P. fluorescens*(Q110B and Q036B) can be used as a non-chemical alternative treatment to control postharvest diseases of fruits.

Key words: *Biologicalcontrol, Botrytis cinerea, Penicillium digitatum, Pseudomonas fluorescens, Pseudomonas putida.*

Introduction

Pre- and postharvest diseases of fruit crops are responsible for devastating financial losses to growers and are difficult to manage with current technologies (Wisniewski *et al.*, 2003). Gray mold and green mold disease, caused by *Botrytis cinerea* and *Penicillium digitatum* respectively, are the most serious plant diseases affecting vegetables, ornamentals, and fruit crops produced in commercial greenhouses and fields all over the world. They cause large yield losses in a number of crops inpre- and postharvest (Kiss, 2003; Huang *et al.*, 2011,2012; Wang *et al.*, 2013; Di Francesco *et al.*, 2015). The treatment of those fungiis based by the conventional chemical control through repeated foliar or fruit applications of a combination of protectant and systemic fungicides.However, the growing demand of consumers worldwide for a reduction of pesticide, used on fresh fruits and vegetables, force the farmers to look for another ways. In response to this trend, physical and biological approaches have been evaluated as safer alternative to the use of chemical fungicides (Droby*et al.*, 2002; Zhang *et al.*, 2007). Biological approaches, including the use of antagonistic organisms, natural compounds, cultural practices, and biotechnology, will be used to develop new methods for

managing diseases of fruit crops (Wisniewski *et al.*, 2003). Biological control using a microorganism (or its secretions) to prevent disease, offers an attractive alternative or supplement to fungicides for the management of plant disease, without any of the negative effects of chemical control (Raupach and Kloepper, 1998; Jacobsen *et a*l., 2004).The use of bacteria as an alternative is a promising approach that can be incorporated into integrated disease management (Rosslenbroich and Stuebler, 2000). Several non-phytopathogenic bacteria, were frequently reported to protect plants against various phytopathogens (Van Wees *et al.*, 1997; Trotel-Aziz *et al.*, 2008; Verhagen*et al.*, 2010, 2011) .Various bacterialgenera such as*Bacillus* and *Pseudomonas*, were reported to be effective against a number of diseases of different fruits (Janisiewiczand Roitman, 1988; Janisiewicz. and Jeffers, 1997). Antibiotic production by these bacteria plays a major role in disease suppression (Raaijmakers*et al.*, 2002). The objective of this study is to evaluate the effect of three *Pseudomonas* strains, isolated from the rhizospheric soil of tomato plant, on*P. digitatum*and *B. cinerea*.

Material and Methods

Isolation of bacteria from tomato rhizosphere

The *Pseudomonas*strains were isolated from rhizospheric soil by adding 1 g of rhizospheric soil into 9 ml of sterile physiological water . The sample was diluted and appropriate dilutions were spread on King's B medium (King *et al.*, 1954), supplemented with 100 µg ml^{-1} of cycloheximide (Amkraz *et al.*, 2010). Three replicates were made for each sampleand incubated at 26°C for 48 h. Fluorescent colonies (UV 320nm) were purified and stored at -80°C in 40% glycerol. The three isolates were confirmed as *P. putida*Q172B and *P. fluorescens*(Q110B and Q036B) at Plant Protection laboratory - Microbiology Unit- INRA Agadir Morocco (Qessaoui *et al.*,2017). To evaluate their antagonistic activity, the supernatant were prepared for each bacterium and adjusted to 10^8 $CFUmL^{-1}$.

Isolation of *Penicillium digitatum* and *Botrytis cinerea*

The isolate of *P. digitatum* and *B. cinerea*were collected from the fruits infested of citrus and tomato respectively. The Potato Dextrose Agar(PDA) was used to isolate fungiand to obtain pure culturespurifyfungal. This isolates were confermed as *P. digitatum*and *B. cinerea*at Plant Protection laboratory - Microbiology Unit-INRAAgadir Morocco. Conidial suspensions of each fungal pathogenin Sabauroud Broth medium ($10gL^{-1}$peptone ; $20gL^{-1}$glucose) were adjusted to 10^5 spores mL^{-1}.

In vitro selection of antagonistic fluorescent pseudomonas against*P. digitatum* and *B. cinerea*

In vitro evaluation of three fluorescent *Pseudomonas* isolates were conducted using dual culture technique on PDA (Kaur, 2003). A inoculum of the individual rhizobacterial strains was applied as a stripe of 1.5 cm length equidistantly on three opposite edges of the agar medium in the petri plate using an inoculation loop. A mycelial disc of 5 mm diameter from 7 day-old culture of *B. cinerea* and *P. digitatum* was placed separately at the centre of the petri plate. Three replications were maintained for each rhizobacterium. Plates containing the pathogen alone served as control. The inoculated plates were incubated at 25°C for five days (Kaur *et al.*, 2007). After incubation period, the mycelial growth of *B. cinerea* and *P. digitatum* was recorded and the mycelial growth inhibition percentage (MGIP) was calculated using the formula:

$$\text{MGIP} = \frac{r1 - r2}{r1} \times 100$$

wherer1 is the radial growth of the fungus in the control and r2 is the radial growth of the fungus in the treated plates (Chaurasia *et al.*, 2005; Berrada *et al.*, 2012). The bacterial isolates showing maximum zone of inhibition was selected for further studies.

Production of volatile antifungal compounds (VOCs)

The effects of volatile organic compounds produced by *Pseudomonas* strains on the growth rates and activity of fungi were assessed using experimental systems that had only atmospheric connections according themethod described by Fiddaman and Rossall (1993). The antagonism of *Pseudomonas* was evaluated on King's B medium plates. After incubation for 48 h, the lid of each Petri dish was replaced by a plate containing 6mm plug of the test fungus in PDA medium. The two plates were sealed with parafilm. Controls were prepared without bacteria in the bottom plate. Petri dishes were incubated at 25°C, and observations were recorded after 5 days (Kumari and Khanna, 2014). The percentage growth inhibition (I) by VOC_S was calculated using the same formula:

$$I\% = \frac{r1 - r2}{r1} \times 100$$

wherer1 is the radial growth of the fungus in the control and r2 is the radial growth of the fungus in the treated plates.

Production of hydrogen cyanide (HCN)

To determine the production of HCN, ten *Pseudomonas*isolates were streaked onto KB agar plates supplemented with glycine(4.4 g l^{-1}). After this, the Petri plates were inverted and the filter papers impregnated with 0.5% picric acid (yellow) and 2% sodium carbonate were placed on the lids. Petri plates were sealed with parafilm and incubated at 28°Cfor 96 h. Discoloration of the filter paper from orange tobrown after incubation was considered as bacterial production of cyanide (Bakker and Schippers, 1987; Jha *et al.*, 2009).

Statistical analysis

All statistical analyses were subjected to ANOVA. Data for mycelial growth inhibition percentage (MGIP) and the percentage growth inhibition (I) by VOCs are presented as means ± standard deviation. Statistical significance was defined as$p < .05$ (Newman–Keuls test).

Results and discussion

In vitro selection of antagonistic fluorescent pseudomonas of *P. digitatum* and *B. cinerea*

Alltree fluorescent*Pseudomonas*isolates were testedagainstthe*P. digitatum* and *B.cinerea*strains inPetriplatescontainingPDA medium. All these isolates showed inhibitory activity against two fungal pathogenswithapercentage of inhibitionranging from39 %to54% for *P. digitatum* and 65 %to66% for *B.cinerea* (table 1).*P. putida* Q172B and *P. fluorescens* Q036B showed the highest inhibition of *B.cinerea and P. digitatum*.

Table 1: *In vitro* screening of bacterial isolates based on mycelial growth inhibition and HCN Production

Isolate	Code	*B.cinerea*		*P. digitatum*		HCN Production
		MGPI	I %	MGPI	I %	
P. fluorescens	Q036B	65,28±2,41[a]	100±0.00[a]	54,63±26,71[a]	14,03±2,64[a]	+
P. putida	Q172B	66,86±5,64[a]	100±0.00[a]	50,00±10.00[ab]	18,81±7,72[a]	+
P. fluorescens	Q110B	65,48±5,15[a]	100±0.00[a]	39,17±8.00[ab]	44,48±34,49[a]	+

Production of volatile antifungal compounds (VOCs)

The results of VOCs showed that those three *Pseudomonas* strains produce volatile products effective against *B. cinerea* and *P. digitatum*. An inhibition in the radial growth of the test fungiwas observed during the 5 days of incubation (table 1). These results showed that

inhibition percent ranges from 14% to 44% for *P. digitatum.* For*B.cinerea*, the radial growth is totaly inhibed (100%).

Production of hydrogen cyanide (HCN)

All three antagonistic fluorescent *Pseudomonas* isolates showed the production of HCN as indicated by the discoloration of the filter paper from orange to brown (table1). Two *Pseudomonas* strains QF72B and QF36B were found to be potential producers of HCN, causing color change from yellow to dark brown, whereas Q110B was showed an average production with a orange color (figure1).

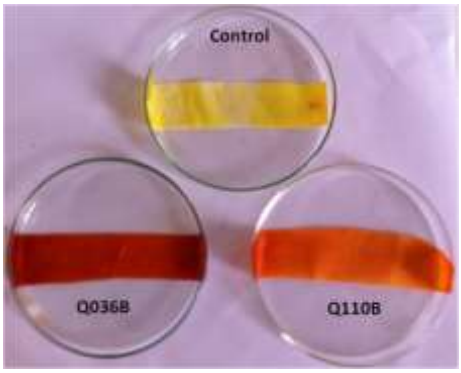

Figure 1: production of HCN on KB agar as indicated by the discoloration of the filter paper when incubated with picric acid and sodium carbonate

Three *Pseudomonas* strains belonging to the species *P. fluorescens* Q036B , *P. fluorescens* Q110B and *P. putida* Q172B have shown an efficient and significant ability to inhibit *P. digitatum* and *B. cinerea*causing green mold and grey mold, respectively. Our results concord with those that report *Pseudomonas*asamajorgenusin thebiocontrolofpathogens(Kaur *et al.*, 2007;Gao *et al.*, 2018). This inhibition canbe explained by their capacity to produce bioactive components. Some beneficial rhizobacteria can reduce pathogenic infections directly by competitionfor space or nutrients (Lugtenberg and Kamilova, 2009; Mitter *et al.*, 2013) and secretion of antibioticssuch as lipopeptides, 2,4-diacetylphloroglucinoland phenazine-1-carboxylic acid (PCA)(Jaaffar *et al.*, 2017; Paulin *et al.*, 2017). Therefore, in our experiments underlying *Pseudomonas* mechanisms against *B. cinerea*, these results are similar to that found by Chang *et al.* (2007) who showed that the supernatant of *Bacillus cereus* Q308 inhibited spore germination and germ tube elongation of *Fusarium oxysporum*, *F. solani*, and *Pythium. ultimum*. The results showed that the isolates were able to produce volatile compound such as HCN. Our results showed that VOCs producing isolates totally inhibited growth of *B.cinerea*. This results are similar with the study of Ramette *et al.*(2003) who reported that the microbial production of HCN is an important antifungal trait to control root infecting fungi.

Conclusion

Because of the potential production of volatile and diffusible antifungal metabolites, selected *Pseudomonas* strains are considered as potentialantagonists against a range of phytopathogenic fungi that infect tomatoand other crops, and thereforecould be used as potential alternative for chemical fungicides in reducing the damages caused by fungal diseases.

RESPONSE OF SPRING BREAD WHEAT QUALITY AND YIELD PARAMETERS TO DIFFERENT DROUGHT SCENARIOS UNDER MOROCCAN CONDITIONS

Sahar BENNANI[1,2]*, Mona TAGHOUTI[1], Ahmed BIROUK[2]

[1]Plant breeding and Genetic Resources Conservation Department, National Institute of Agricultural Research (INRA), Rabat, Morocco

Abstract

Under climate change, the release of productive bread wheat cultivars with high quality standards is a major challenge in Moroccan wheat breeding program. The aim of the present study was to investigate drought stress influence on productivity traits and the main relevant quality parameters (grain protein content, quantity and strength of gluten) and to select new performing genotypes. Fourteen elite and national genotypes of bread wheat were evaluated in two Moroccan contrasting locations (favourable and semi-arid) during two consecutive seasons (2014-2015). Besides, electrophoretic patterns of seed storage proteins profiles using SDS-PAGE technique were performed. Results indicated that 2014 cropping season presented drier climate compared to 2015 season for both experimental sites. The analysis of variance showed significant effects of genotypes, site, year and site x year for yield traits and almost all quality parameters (P<0.001). The mean grain yield ranged from 3.92 t/ha to 2.49 t/ha under favourable and semi-arid conditions respectively. Moreover, protein content varied from 14.44% in semi-arid location to 12.52% in favourable site. The drought affected negatively all parameters at favourable and semi-arid regions. However, the genotypes behaviour at the driest year (2014) was similar for both sites based on mean comparison. Therefore, the genetic differencesin terms of quality were restricted because of drought stress.The correlation analysis showed negative correlation between yield and gluten content (r=-0.32**) at the driest environment. Also, both gluten and protein content showed negative correlation with biomass, plant height and number of grain per fertile spike.

Keywords: *bread wheat, drought, qualityparameters, yield, electrophoretic analysis.*

Introduction

Bread wheat is an important staple crop for food security worldwide, providing more than 20% of calories and protein daily requirements in addition to minerals and vitamins (Ahmed etFayyaz-ul-Hassan, 2015). In Morocco, bread wheat is the main cereal crop, covering more than 70% of cereal area, essentially cultivated under rainfed system (91%) (Jlibene, 2009).

During the last decades, the negative effects of climate change on wheat production and quality have raised, mainly because of drought stress impact, thus hindering to satisfy worldwide consumption needs and threatening worldwide food security in several regions, especially in developing countries. Forecasting models predict more frequent and intense periods of drought, especially in the Mediterranean region (IPCC, 2007; Walter et al., 2011), including Morocco. In this context, the release of productive bread wheat cultivars with high quality standards is a major challenge in current wheat breeding program,as it is associated with a number of negative correlations (Baenziger et al., 2001; Trethowan et al., 2001; Williams et al., 2008).The grain quality is judged principally on the base of its weight (usually thousand grain weight); while flour quality is mainly characterized by its protein and gluten strengthto assess good bread making quality (Békés et al., 2006; Ahmed etUl Hassan, 2015). Besides, high-molecularweight glutenin subunits (HMW-GS) play a critical role in determining dough elasticity (Shewry et al., 2002).

To gain further understanding of the effects of drought stress on grain quality attributes, this paper seeks to (1) analyse the relationship of quality and yield traits under different drought scenarios in Moroccan conditions and evaluate the relative roles of genotype, environment and their interaction in their expression; (2) determine the effects of drought stress on yield and quality parameters of cultivars; (3) determine the electrophoretic pattern of seed storage proteins profiles and (4) select performing genotypes with optimum balance between yield performance and quality parameters.

Materials and Methods

Plant materials and experimental design: Forty spring bread wheat genotypes were chosen based on their broad range of response to drought stress and yield performance and were planted in Randomized Complete Block design (RCBD) with three replications in two contrasting experimental fields (stressed and non-stressed) during 2014 and 2015 cropping seasons. Environments were defined as combinations ofseasons and sites. The germoplasme evaluated were selected from diverse origins: Gladius, Hartog, Drysdale (Australia); Nejmah-11, Nejmah-14, Shihab-12, Al-Zehraa-2, Baasha-21, Amir-2(ICARDA); Attila, Sokoll, SB003, SB165, SB069, SB062, SB109, SB169, SsrT02, SsrT09, SsrT14, SsrT16, SsrT17, SsrW35,SsrW47 (CIMMYT)and Arrehane, Achtar, Marchouch, Kanz, Amal, Massira, Aguilal, Rajae, BT05A104, BT05A106 (Morocco).

Experimental Sites*:* The study considered two contrasting experimental sites in terms of long-term average rainfall, namely "Taoujdate" and "Sidi El Aidi", belonging to the National Institute of Agricultural Research of Morocco. The Taoujdate site (TJ) represents the favorable area (non-stressed site) with an average rainfall of 470 mm. In contrast, Sidi El Aidi(SA) is located in the semi-arid area (stressed site) with an annual average of 300 mm.

Measurements*:* For yield related traits, grain yield (GY), harvest index (HI), grains number (NG), number of fertile spikes per plant (NFSP), number of grains per fertile spike (NGFS), biomass (BY) and plant height (PH) were evaluated.The superiority index (Pi) was calculated based on Lin et al. (1988) equation to determine the best performant genotypes over all environments. For quality traits, thousand grain weight (TGW), gluten content (GC), protein content (PC) and gluten strength (W) were assessed using near-infrared reflectance spectrophotometry analysis (InfraneoChoppin).

Glutenins composition analysis*:* Polyacrylimide gel electrophoresis in the presence of Sodium Dodecyl Sulfate (SDS-PAGE) following Singh et al. (1991) procedure of was carried out to analysegluteniscompostion of the studied germplasm. The HMW glutenin subunits were identified using the numbering system of Payne and Lawrence (1983) and compared with the patterns of known genotypes (standards).

Statistical analysis*:* Data were subjected to analysis of variance for each parameter to detect significance differences using F test, while genotypic means differences were judged by using Bonferroni test. The percentage of variance for each effect was calculated based on sum of squares proportion. Data were also subjected to correlation in order to elucidate the relationships among criteria and their association with grain yield performance.

Results and Discussion

Cropping season's pattern

The 2014 cropping season was drier and hotter than 2015 season for both sites, especially during reproductive stage. Besides, semi-arid site (SA) experienced hotter and drier conditions compared with the favourable site (TJ). Mean temperatures recorded at SA (13.3°C± 1.45) were hotter compared to TJ (11.54°C ± 1.15), especially during winter and autumn. Furthermore, rainfall decreased during 2014 season by 36% (-138mm) in TJ, compared to 24% (-70mm) for SA. The gap between the two sites is much larger in the best

year (-30%) than in the dry year (-13%). This result corroborates the finding of Balaghi et al. (2013)which states that drought affects all Moroccan regions during dry years.

Effects of G, E and G x E on yield and yield related traits

A previous study had already displayed grain yield variations and pattern.The combined ANOVA indicated highly significant variability over years and sites; and among genotypes ($p<0.001$)(Bennani et al., 2017). The mean grain yield ranged from 3.92 t/ha to 2.49 t/ha under favourable and semi-arid conditions respectively.

For yield related traits, the results of ANOVA showed that all factors had significant effect on the different traits studied. The environment had the largest effect exceeding 70% of the total variation (Table 1), which agrees with previous researches (Li et al., 2013).

Table 1: Analysis of variance for the yield and quality parameters

Traits	General Mean	Environment (E)	VE (%)	Genotype (G)	VE (%)	G x E	VE (%)

*, ** and *** represent significant level at <0.05, <0.01 and <0.001 respectively

Drought affected negatively all yield parameters as reported by earlier researches (Li et al., 2013). Based on mean comparisons, the biomass (BY) (-15%) and grain number (NG) (-14%) were the most affected at the driest year in the favorable environment (TJ14) compared to the humid one (TJ15). Whereas, at the semi-arid environment, NFSP (-49.8%) followed by BY (-22.7%) and NG (-20.6%) were the most affected (Table 2). This finding indicates that genotypes responded to the stress by reducing mainly the number of grains, biomass and also number of fertile spikes under more severe stress during anthesis period (Li et al., 2013).

Effects of G, E and G x E on quality traits

Significant differences were observed among genotypes and environments for all quality traits, which agree with Li et al. (2013) and Ahmed etFayyaz-ul-Hassan (2015) findings. In contrast, the interaction genotype x environment was not significant for any of the parameters. Yet, the environment and, to a lesser extent, the interaction were the most important factors explaining from 50 to 70% of traits variations (Table 1) as stated by Li et al. (2013) and Guzman et al. (2016). The Bonferroni test showed that genotypes behavior at the driest year (2014) was similar for both sites, recording the highest values except for TGW.

The thousand grain weight (TGW) was affected negatively by dry conditions either at TJ (-29%) or SEA (-26.4%). However, the slight drought experienced at TJ induced positive improvement in protein content and in gluten content and strength. This finding is sustained by Flagella et al. (2010) and Li et al. (2013) researches, and was associated with modification of source sink balance (Ahmed and Fayyaz-ul-Hassan, 2015), and/or even to synthetized shock proteins as protective role under stress environments (Reynolds et al., 2001). In contrast, negative impact was observed at SA under severe stress for gluten content and

strength, but not for protein content (Table 1). The combination of higher temperatures and severe drought conditions may result in alteration of the bread wheat quality in response to increased climatic variability (Fernando et al., 2014; Guzman et al., 2016).

Relationships among quality and yield traits under different drought scenarios

Important high significant correlations were found between yield and most yield related traits, except for NFSP at optimum conditions (TJ15), NGFS at slight (TJ14) and moderate (S15) stress and PH at the humid year 2015 for both sites (Table 2) depending on drought severity.

Table 2: Mean comparisons (BonferroniTest) and Pearson correlations with grain yield for traits

Traits	Meanscomparisons (Bonferroni Test)				Pearson Correlations (r)

a, b and c represent the groups based on Bonferroni test comparisons

*, ** and *** represent significant level at <0.05, <0.01 and <0.001 respectively

In parallel, all quality parameters were highly correlated between them (P<0.001) (data not shown) except TGW. Gluten content and TGW showed respectively negative and positive correlations with grain yield at the driest environment (SA14), reflecting source sink balance. Other yield components and related traits showed significant correlation with quality traits. The gluten and protein content showed significant moderate negative correlation with NGFS at SA respectively at 2014 (r=-0.31; r=-0.35) and 2015 (r=-0.35; r=0.36) seasons. Besides, plant height presented moderate positive correlation with PC (r=0.31) and W (r=0.41) at slight drought conditions (TJ14) and negative one at the driest environment (S14) (r=-0.37 and r=-0.38 respectively for GC and PC), thus following an opposite pattern of height/grain yield relationships.Both lowest NGFS/ height may enable enough efficient assimilates remobilization for existing grain, even under stress (Ahmed and Fayyaz-ul-Hassan, 2015).

Seed storage proteins composition of genotypes

The frequencies of 9 alleles identified at the 3 loci Encoding HMWGs are shown in table 3. Three alleles were identified at Glu-A1, four at the Glu-B1 and two at the Glu-D1 locus. Glu-A1 (c) was the most common allele with a frequency of 62.5%. The Glu-B1 (i) showed the highest frequency (57.5%). At the Glu-D1, (d) was the preponderant allele in the bread wheat cultivars (92.25%) whereas Glu-D1(a) was present only in three genotypes (7.5%).

Table 3: Frequencies (%) of high molecular weight glutenin subunits in bread wheat at different loci Glu-A1, Glu-B1, Glu-D1

Glu-A1		Glu-B1		Glu-D1	
Subunits (Alleles)	Frequency (%)	Subunits (Alleles)	Frequency (%)	Subunits (Alleles)	Frequency (%)
1 (a)	22.5	6+8 (d)	10	5+10 (d)	92.25
2*(b)	15	7+8 (b)	20.5	2+12 (a)	7.5
Null (c)	62.5	7+9 (c)	10		
		17+18 (i)	57.5		

Results revealed the presence of favorable alleles which increase gluten strength such as 'b' and 'i' at GluB1 and 'd' at GluD1 loci in the majority of the banding patterns of the germplasm analyzed 75.5% and 92.25% respectively (Souza Costa et al., 2017).

Selection of best performing genotypes

Cultivars were found to react differently to water deficit conditions. However, their ranking over environments seems to be unchanged for quality parameters as the interaction was not significant. Based on Pi (data not shown), the best performing genotypes were AUS30355 (Pi=0.11), Gladius (Pi =0.20), Amir-2 (Pi=0.33), AUS30354 (Pi=0.27), Sokoll(Pi=0.36) and Kanz (Pi=0.32) that showed high yield across all the environments (Mean yield varies from 3.69 to 4.02t/ha) . For quality traits, we noted that all genotypes expressed good protein and gluten content for good bread making quality based on standards (CTNCLPD, 2009).

Conclusion

In general, variation was observed in genotypes and environments for each yield and quality parameter. Environment has the largest effects, affecting negatively yield and yield related traits especially biomass, grain number and thousand grain weights under drought conditions. Higher grain yields are mainly related to harvest index, biomass and grain number, while the number of fertile spikes showed great impact at the semi-arid zone. The quality parameters (gluten and protein content, strength) were positively affected by slight/moderate drought impact, while moderate/severe drought affected negatively all the traits (except protein content) due to source sink balance. Grain yield was correlated negatively with gluten content solely at the driest environment, making multi environment assessment for both yield parameters and quality very important in the breeding program. AUS30355, Gladius, Amir-2, AUS30354, Sokoll and Kanz showed high yield across all the environments, and can be recommended as best parents for drought tolerance and quality in the national breeding program.

Abstract

Perennial ryegrass is the main forage grass used in livestock production in Poland. The quality of herbage is influenced mainly by the yield and nutritional value of grass and the presence of undesirable microbiota. Nanotechnology-based plant growth stimulants can improve plant health, germination and yield, but their impact on the microbiota colonizing plants remains unknown. Three types of silver nanoparticles, two types of titanium dioxide nanoparticles, silver nitrate, a chelated form of titanium, and an additional rate of nitrogen were applied in this study. Perennial ryegrass without stimulant treatment was the control. Grass was harvested twice during the growing season, and the biostimulants (10 ppm per 10 m^2) were applied twice after each harvest. Fungi were isolated from tillering nodes after the second harvest. Herbage yield did not differ significantly between treatments, and the highest yield was achieved in the control treatment. The applied stimulants, excluding tannic acid-reduced silver nanoparticles, improved sod density. The largest number of fungi were isolated from the control treatment and the chelated titanium treatment, and the smallest number of fungi were obtained from treatments with an additional rate of nitrogen and the silver nitrate treatment. The control treatment with a higher fertilizer rate was characterized by the highest ecological value (species richness and species diversity). The highest counts of *Penicillium* spp. (eudominance) and *Fusarium culmorum* (dominance) were observed in the titanium chelate treatment. Excluding the control, undesirable fungi were most effectively controlled in the $AgNO_3$ treatment. The remaining biostimulants exerted indirect effects and did not completely eliminate undesirable fungi (*Fusarium* spp., *Cladosporium herbarum*, *Microdochium* spp.).

Keywords: *perennial ryegrass, biostimulants, nanoparticles, fungi*.

Introduction

Perennial ryegrass (*Lolium perenne* L.) is the main forage grass used in animal production in temperate regions. It is characterized by high yield potential and high nitrogen utilization. Perennial ryegrass has high feed value due to its high palatability and desirable chemical composition (Rath *et al.,* 2005). The surface, intercellular spaces and cells of perennial grass plants are colonized by numerous fungal species. Fungi enter into pathogenic, parasitic or mutualistic interactions with the host plant (Perez *et al.,* 2013, Sanchez-Marquez *et al.,* 2012). Pathogenic fungi can decrease the yield of perennial grass, and mycotoxins can compromise the nutritional value of forage (Thom *et al.,* 2014).

Nanotechnology-based plant growth promoters can enhance the growth and development of plants, improve germination rates and protect plants against the harmful effects of pathogenic microorganisms which decrease the quantity and quality of yield (Khodakovskaya *et al.,*. 2009, Tripathi *et al.,* 2011, Wang *et al.,* 2013, Wang *et al.,* 2014). Biostimulants containing nanoparticle adjuvants can be applied together with pesticides to reduce surface tension and

increase adhesion to plant surfaces (Bergeson 2010, Khot *et al.*, 2012). Many nanoparticles have similar properties to commercial pesticides, and they are increasingly used for plant protection (Smith *et al.*, 2008). Carbon-based nanoparticles such as fullerenes, single-wall and multi-wall carbon nanotubules, as well as inorganic nanoparticles, including metals (Au, Ag, Al and Fe) and metal oxides (TiO_2, ZnO, Al_2O_3, Fe_3O_4, Fe_2O_3, NiO, CoO, CeO_2), are most widely used (Wang *et al.*, 2014, Srivastava *et al.*, 2015, Verma *et al.*, 2018).
The aim of this study was to analyze the effects of several nanotechnology-based plant growth stimulants on fungal communities colonizing the stem bases of perennial ryegrass and producing potentially harmful secondary metabolites, and on herbage yield.

Materials and Methods

The study was carried out in the year 2017 on experimental plots in north-eastern Poland, in the didactic-experimental center of the University of Warmia and Mazury in Tomaszkowo near Olsztyn

Suspensions of silver nanoparticles

Suspensions of silver nanoparticles with the size of 10 nm, stabilized with tannic acid (TA), trisodium citrate (SBTC) and sodium hexametaphosphate (SHSH), were used in the study. The solutions reduced with the above compounds had an initial concentration of 100 mg l^{-1} (100 ppm). A solution of silver (V) nitrate ($AgNO_3$) nanoparticles with a concentration of 100 mg l^{-1} was prepared as the reference. The suspensions were reduced and prepared by Magadela Oćwieja, Ph.D. at the Jerzy Haber Institute of Catalysis and Surface Chemistry of the Polish Academy of Sciences in Cracow.

Suspensions of titanium dioxide

Two forms of titanium dioxide, TiO_2 nanoparticles with the size of 21 nm (TP) and a mineral form of TiO_2 with a stable fraction of approximately 700 nm, were purchased from Sigma Aldrich and used to prepare solutions with a concentration of 100 mg l^{-1} (100 ppm). A solution of Tytanit (Intermag, Poland), a commercial plant growth stimulant, with a concentration somewhat higher than that recommended by the manufacturer (100 ppm), was prepared as the reference.

Seed dressing formulation

The tested compounds were used for seed dressing. Grass seed samples of 10 g each were placed in capped plastic containers, and 0.2 g of industrial grade talcum powder, 0.05 g of carboxymethyl cellulose, 2 ml of every tested compound and 1 ml of demineralized water were added. The contents of each container were thoroughly combined by shaking for around 2 minutes. The mixture was dried in a laminar flow cabinet for 30 minutes and stored until sowing. The control were grass seeds combined with carrier solvents, where the active ingredient was replaced with 2 ml of demineralized water.

N1 – NPK mineral fertilizer at 60/30/60 kg/ha;
N2 – NPK mineral fertilizer at 90/30/60 kg/ha;
$AgNO_3$ – silver molecular solution in the form of silver nitrate V at a concentration of 100 mg/l.
TA – silver nanoparticles stabilized with tannic acid;
SHSH – silver nanoparticles stabilized with sodium hexametaphosphate;
SBTC – silver nanoparticles stabilized with trisodium citrate;
TiO_2 – mineral form of TiO_2 with a stable fraction of approximately 700 nm;
TP – TiO_2 nanoparticles with the size of 21 nm;
Tytanit – commercial plant growth stimulant (Intermag, Poland).

Seeding and cultivation

Grass seeds were sown manually at 35 kg ha^{-1}. Plant density was determined in each plot after seedling emergence. Weeds were removed mechanically at regular intervals.

The plot experiment involved three variants: a control treatment without an active ingredient, experimental treatments with NPK fertilization at 60/30/60, and experimental treatments with optimal NPK fertilization for perennial ryegrass at 90/30/60. Plot size was 1 m x 3 m. Every variant was performed in three replications. Grass was harvested twice during the growing season.

Foliar application of plant growth stimulants at the beginning of tillering

The tested growth stimulants were manually sprayed on leaves 4 and 8 weeks after sowing. Each biostimulant was dissolved in demineralized water to produce 2% aqueous solutions. The solutions were applied at 100 l ha^{-1}.

Forage harvest

Grass was harvested twice during the growing season. The collected herbage was weighed immediately after harvest to determine fresh weight, placed in plastic string bags and transported to the laboratory. Sod density was determined after the second harvest based on the 9-point scale proposed by Prończuk (1993).

Fungal cultures and isolation of fungi from plant material

Plant material was prepared for fungal cultures in the laboratory. Twenty-five shoot segments with a length of 1 cm each (one from each plant) were placed on potato dextrose agar (PDA). Plant tissues were previously surface disinfected with 70% ethanol for 5 s, 1% sodium hypochlorite for 20 s, and rinsed three times in sterile deionized water. The samples were incubated for 21 days at a temperature of 25°C. The colony growth index was estimated at 0.75 per leaf. Fungal colonies were transferred to fresh PDA, mycelial samples were collected after 14 days, and the fungi were identified based on the available keys.

Results and Discussion

The highest herbage yield was obtained in the treatment with the highest fertilizer rate, followed by TP and SBTC treatments. Herbage yield was lowest after the application of TiO_2. Sod density, which is determined by germination capacity, was highest in the TiO_2 treatment. Mahmoodzadeh *et al.*, (2013) demonstrated that TiO_2 improved germination capacity and early seedling growth in oilseed rape, whereas Jaberzadeh *et al.*, (2013) found that TiO_2 enhanced the early growth of wheat plants.

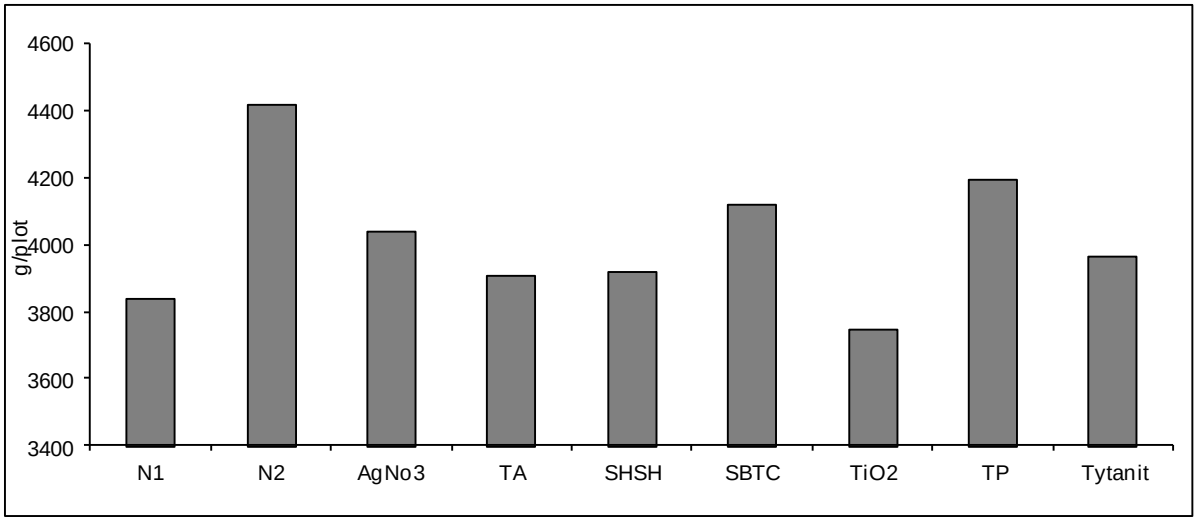

Figure 1. Weight of second-harvest perennial ryegrass herbage.

The highest number of fungal colonies were isolated from the treatment with a lower rate of nitrogen fertilizer and the treatment where the Tytanit biostimulant was applied. The treatment with a lower fertilizer rate was characterized by a high diversity of fungal species,

including four species of the genus *Fusarium*, which could influence the processing suitability of forage and herbage yield. *Microdochium nivale*, the cause of pink snow mold, was isolated from stem bases. The above pathogen was not identified only in treatments protected with silver nitrate, SHSH and TiO_2.

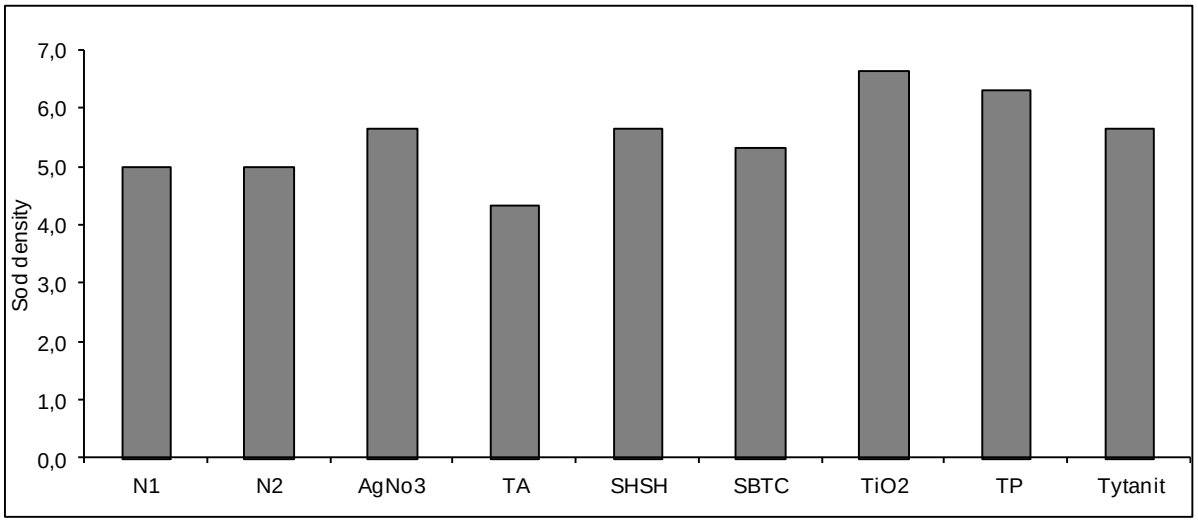

Figure 2. Sod density after the second harvest of perennial ryegrass.

Fungi of the genus *Fusarium* were not isolated from the treatment with a higher rate of nitrogen fertilizer where a total of four fungal colonies belonging to different species were isolated. Only four fungal isolates belonging to three different species were isolated in the silver nitrate treatment. The silver nitrate treatment was least colonized by fungi in the experiment. In a study by Jo *et al.*, (2009), ionic silver and silver nanoparticles effectively eliminated *Bipolaris sorokiniana* from perennial ryegrass inoculated with this fungus.

Conclusions

Titanium dioxide nanoparticles, silver nanoparticles (SBTC) and silver (V) nitrate treatments are characterized by the most desirable ratio of herbage yield to sod density. None of the tested treatments exerted a significant effect on microbial communities naturally colonizing grass surface, but all treatments decreased the abundance and species richness of fungal communities. All biostimulants improved the biometric parameters of perennial ryegrass, but none of them completely eliminated phytopathogens from grass surface.

Abstract

Crops are selected for cultivation in view of economic, technological and organizational considerations, which implies that some plant species are cultivated year by year. Long-term monoculture accelerates soil degradation, and it can decrease the species richness and diversity of soil microorganisms. This study analyzed the rhizosphere soil of winter wheat (*Triticum aestivum* L.) and winter oilseed rape (*Brassica napus* L.) plants grown in a 5-field crop rotation system and in long-term monoculture. The effect of the crop sequence on the counts of bacteria of the genera *Pseudomonas*, *Bacillus* and *Azotobacter*, actinobacteria and the number of TRI5 genes involved in the biosynthesis of mycotoxins in fungi of the genus *Fusarium* was determined. The crop sequence did not affect the counts of *Pseudomonas* and *Bacillus* bacteria and actinobacteria in soil from the crop rotation, but *Azotobacter* spp. were not detected. The number of TRI5 genes was relatively high in each treatment, and no significant differences were detected between treatments. In winter oilseed rape, the number of TRI5 genes was approximately three-fold lower in crop rotation than in monoculture, whereas the reverse was observed in winter wheat. It can be concluded that plants cultivated in monoculture and in crop rotation do not significantly affect the counts of bacteria stabilizing the biological value of soil and, consequently, do not lead to a significant decrease in the abundance of *Fusarium* fungi. Bacteria of the genus *Azotobacter* were eliminated in crop rotation, which indicates that they are sensitive to the crop sequence.

Keywords: *microorganisms, bacteria, monoculture, crop rotation, Fusarium.*

Introduction

Crop species are selected in view of organizational, technological and economic considerations. As a result, the proportion of cereals in the cropping system is high, exceeding 70% in many countries. Cereal production is highly profitable, and cereals are often grown year after year in short-term monocultures. Monoculture increases the risk of stem-base diseases caused by *Fusarium* fungi, *Rhizoctonia cerealis, Gaeumannomyces graminis* and *Oculimacula yallundae* (Korbas *et al*., 2001).

The area under oilseed rape has increased in recent years. Oilseed rape is sown in the same field every 2-3 years, often as a break crop in wheat monocultures (Kurowski *et al*. 2008). A short break or the absence of a break between successive oilseed rape crops in the same field increase the risk of fungal infections which negatively affect cereal stands and compromise yields. In simple crop rotation systems, oilseed rape is exposed to various pathogens, including *Plasmodiophora brassicae*, *Verticillium* spp. and *Sclerotinia sclerotiorum* (Kurowski *et al*., 2008; Korbas *et al*., 2009). Monoculture increases the risk of fungal infections, but it also contributes to the development of beneficial microorganisms. Despite the above, researchers differ in their opinions on the positive and negative effects of monoculture. Soil-dwelling microorganisms are responsible for the cycling of elements, decomposition of organic matter and degradation of xenobiotics (Hayat *et al*., 2010; Jacobsen

et Hjelmsø, 2014). Owing to their unique metabolism, soil microbes promote the growth and development of plants. Soil-dwelling microorganisms can be divided into several groups, including free-living bacteria, endophytic bacteria and symbionts (Glick, 2012; Krawczyk, 2016). Microorganisms are responsible for ecosystem functions, plant health, soil structure and soil fertility. They participate in the interactions between soil abiotic factors and higher organisms, and they are one of the most important determinants of allelopathic effects on other populations (Badura, 2006).

The aim of this study was to determine the effect of the crop sequence on the counts of desirable soil microorganisms, including bacteria of the genera *Pseudomonas*, *Bacillus* and *Azotobacter* and actinobacteria, and the number of TRI5 genes involved in the biosynthesis of mycotoxins in fungi of the genus *Fusarium*.

Materials and Methods

The experiment was performed on a bacterial community isolated from the rhizosphere soil of winter wheat and winter oilseed rape plants grown in monoculture and in crop rotation, with and without fungicide protection. Soil was obtained from a field experiment which has been conducted for 48 years in The Agricultural Experiment Station in Bałcyny by the Department of Agricultural Ecosystems of the University of Warmia and Mazury in Olsztyn (Poland). Soil samples from the winter wheat and winter oilseed rape cultivation were collected from 10 cm depth at the same time (May 2016).

The total counts of saprotrophic bacteria, bacteria of the genera *Pseudomonas* and *Azotobacter*, spore-forming bacteria and actinobacteria were determined on different media. *Pseudomonas* spp. were cultured on Pseudomonas Selective Agar (MERCK) with CFC selective agar (mixture of antibiotics), 16 g of gelatin peptone, 10 g of casein hydrolysate, 10 g of potassium sulfate, 1.4 of magnesium chloride, 11 g of agar, 10 ml of glycerin and 1 l of demineralized water. Spore-forming bacteria were cultured on TSA medium containing (per liter) 15 g of casein peptone, 5 g of sodium chloride, 5 g of soy peptone, 15 g of agar and 1 l of demineralized water. 100 µl of the sample incubated at 80°C for 15 minutes was transferred to the culture medium. Actinobacteria were cultured on a medium composed of 2 g of sodium caseinate, 0.1 g of asparagine, 4 g of sodium propionate, 0.5 g of dipotassium phosphate, 0.1 g of magnesium sulfate, 0.01 g of iron sulfate, 15 g of agar and 1 l of demineralized water. Bacteria of the genus *Azotobacter* were cultured on a medium composed of 1 g of dipotassium phosphate, 0.2 g of magnesium sulfate × water, 1 g of calcium carbonate, 0.2 of sodium chloride, 0.005 g of iron (II) sulfate × water, 10 g of glucose, 15 g of agar and 1 l of demineralized water.

Soil samples of 10 g each were collected from three sites in each treatment, and 10 g of the pooled sample was transferred to an Erlenmeyer flask containing 90 ml of sterile saline solution (0.85% NaCl) and 0.01% Tween 20. The samples were shaken in the Elpin plus 385S laboratory shaker for 30 minutes, and 1 ml of the suspension was transferred to glass test-tubes containing 9 ml of sterile saline solution. The contents of each test-tube were stirred, and 1 m of the suspension was transferred to another test-tube containing 9 ml of saline solution. The above step was repeated to perform serial dilutions with an exponential decrease in concentration from $1 \cdot 10^{-1}$ to $1 \cdot 10^{-12}$. 0.1 ml of the suspension from each solution was sampled and cultured on the appropriate solid medium. Bacterial colonies were counted after 48 h. The experiment was performed in two series (two independent soil samples) with two replications each to produce four results per treatment.

Toxin-producing fungi of the genus *Fusarium* were counted with the use of SYBR Green (5'-GCT GCT CAT CAC TTT GCT CAG-3') and Tox5-2 reverse (5'- CTG ATC TGG TCA CGC TCA TC-3') primers (Schnerr *et al*. 2001). The reaction profile involved initial denaturation at 95°C for 10 minutes, followed by 40 cycles at 95°C for 3 s, 63°C for 6 s, and

72°C for 30 s. The melt curve analysis was performed after cooling to 65°C (20°C/s) and heating to 95°C (0.5°C/s). The DNA isolated from a known number of *Bacillus subtilis* cells and *Fusarium culmorum* spores was used as the reference.
The results were processed statistically by ANOVA and Tukey's test at a significance level of a=0.05 (Statistica 12, StatSoft).

Results and Discussion

Crop rotation increases the availability of nutrients, thus contributing to the diversity of soil-dwelling microorganisms (Pereira *et al*., 2007). In the present study, the crop sequence had no significant effect on the counts of *Pseudomonas* spp., *Bacillus* spp. or actinobacteria, but the growth of *Azotobacter* spp. was not observed in soil samples from crop rotation systems (Fig. 1).

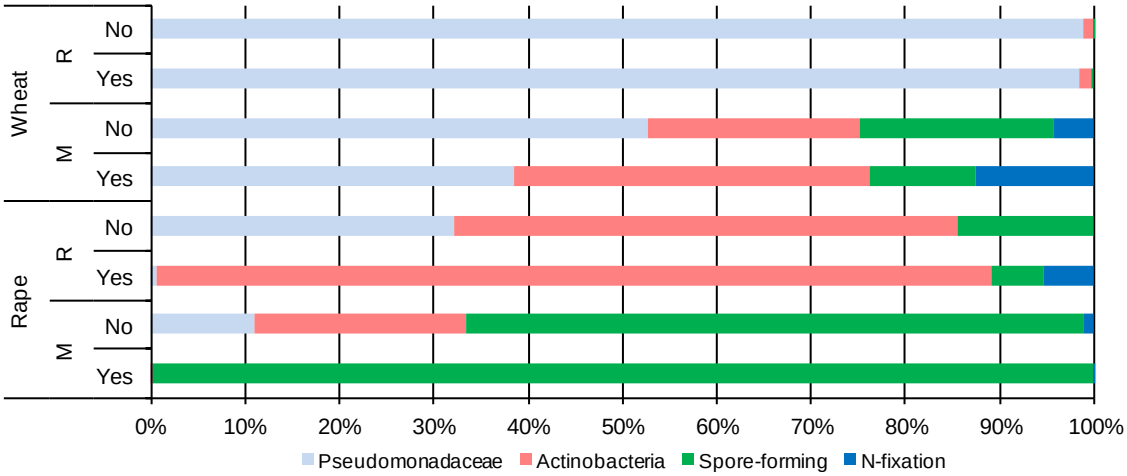

Figure 1. Frequency of occurrence of the analyzed bacterial groups in treatments (M – monoculture, R – crop rotation; Yes – chemical protection, No – no chemical protection)

According to D'Acunto *et al*. (2018), rotations with two to four crops increase soil microbial diversity by up to 4%. However, Jiang *et al*. (2011) and Jangid *et al*. (2011) found that the crop sequence had no significantly influence on bacterial communities. According to the above authors, soil-dwelling microorganisms are affected by other factors, such as soil type or locality.

Table 1. The effect of the crop sequence on bacterial counts (CFU)

Crop	**Crop sequence**	**Bacterial counts (CFU)**
Winter oilseed rape	Monoculture	3496141900 a
	Crop rotation	3688059200 a
Winter wheat	Monoculture	4976088800 a
	Crop rotation	3916700300 a

In the current study, the crop sequence had no significant effect on bacterial counts (CFU) (Table 1). According to the literature, the crop sequence (rotation or monoculture) can significantly affect bacterial communities. Alvey *et al*. (2003) and Xuan *et al*. (2012) demonstrated that the crop sequence induced significant changes in bacterial communities. Navarro-Noya *et al*. (2013) reported that bacterial counts did not differ significantly between winter wheat grown in rotation (winter wheat – corn) or monoculture. In a study by Venter *et al*. (2016), soil microbial diversity in crop rotations increased by 3.5% on average relative to

monoculture. According to the above authors, nearly two-thirds of research studies investigating the diversity of soil microbial communities in the most popular crops did not report significant differences between monoculture and crop rotation.

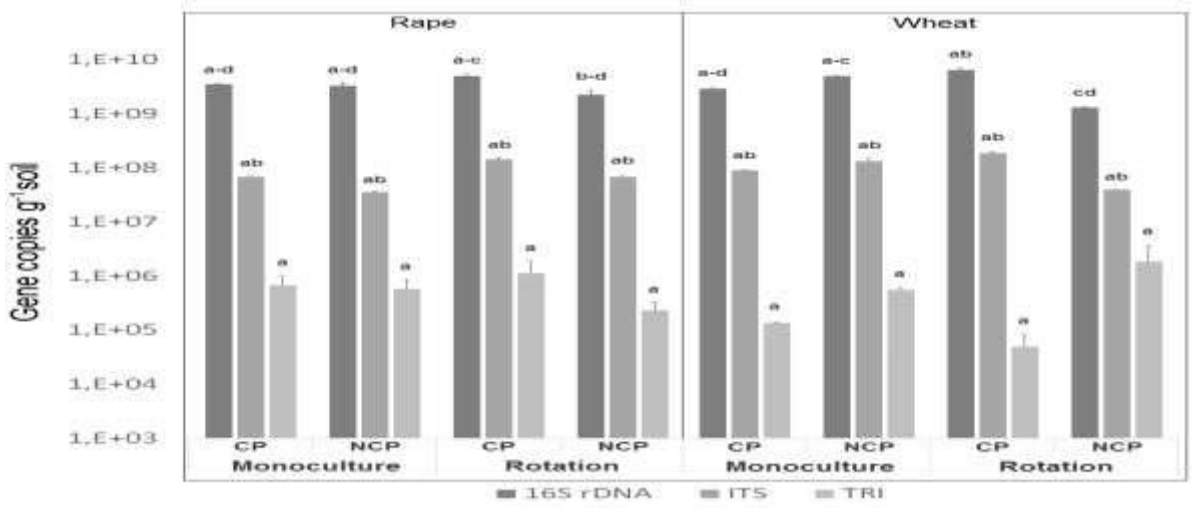

Figure 2. Size of bacterial (16S rDNA gene-dark grey column), fungal (ITS sequence-grey column) and DON-producing *Fusarium* (TRI gene-light grey column) populations quantified by qPCR (CP - chemical protection; NCP - no chemical protection).

In the present study, qPCR revealed the highest number of bacterial genes. The proportion of fungal genes was approximately 25% lower (Fig. 2). In a study by Perez-Brandan *et al*. (2014), the crop sequence significantly influenced the number of isolated fungi which was higher in the corn-soybean rotation than in the respective monocultures. In the above study, bacterial counts did not differ significantly between monocultures and crop rotations. Cereal monocultures are characterized by a higher risk of infections caused by *Fusarium* fungi and mycotoxin contamination of grain (Bateman *et al*. 2007). Crop rotations can decrease the prevalence of infections caused by pathogens of the genus *Fusarium* (Stephens *et al*. 2008). In this study, the number of TRI5 genes was approximately 20-50% lower than the number of bacterial genes in each treatment (mean: $\log_{10}$=5.9), and no significant differences were found between treatments. In winter oilseed rape, the number of TRI5 genes was approximately three-fold lower in crop rotation than in monoculture, whereas the reverse was observed in winter wheat (Fig. 2).

Conclusions

Monocultures and crop rotation systems have no significant effects on the counts of soil bacteria, and do not lead to a significant decrease in the abundance of *Fusarium* fungi. Bacteria of the genus *Azotobacter* were eliminated in crop rotation, which indicates that they are sensitive to the crop sequence.

Abstract

Agrotechnical treatments and plant protection are shaped by communities of soil microorganisms and colonies of crop plants. The quantitative and qualitative structure of soil mycobiota as well as the severity of disease symptoms depend on the potential of the perpetrator, variety resistance, weather conditions and fertilization. Therefore, research was undertaken to find out the quantitative and qualitative structure of the population of fungi associated with the cultivation of spring barley. The analyzed factors of the experiment were the effect of mineral fertilization in various NPK and mineral doses with the application of manure to the soil fungus community associated with the cultivation of spring barley and the identification of fungi isolated steam base. On the basis of the research, it was found that mineral fertilization supplemented with organic stimulates the number of soil microorganisms. The strongest increase in their number is associated with the application of manure together with NPK at a dose of 120/60/120 kg/ha and 40 kg/ha of Mg, while the introduction of calcium in this dose of NPK limits the soil fungi. The use of only mineral fertilizers stimulates the development of pathogens in the soil and inhibits fungi with antagonistic features, especially at doses of 120/60/120 and 120/60/120/40 kg/ha NPKMg. At this dose of NPK, after supplementation of fertilization with manure, there was an increase in the fusarium severity of foot rot, and a high dose of nitrogen (180 kg ha) along with organic fertilization stimulated the severity eyespot of cereal. In the soil fungus group, saprotrophs dominated: *Aspergillus*, *Penicillium*, *Chaetomium* and pathogenic species: *Fusarium*, *Rhizoctonia*, *Botrytis*.

Keywords: *Spring barley, fungi, fertilization*

Introduction

Soil microorganisms may co-determine the quantity and quality of crops. Knowing the interactions between microorganisms with various ecological traits, including pathogens and saprotrophs, that colonize agrocenoses may contribute to the development of an effective strategy for crop protection. Identification of the correlations between pathogens and saprotrophs affords conditions for the implementation of guidelines for integrated plant production and protection. Promoting the growing conditions wherein natural feedbacks in a microorganism community support antagonists could affect a reduction in counts of pathogens (Lenc, 2008). Soil microorganisms constitute 85% of biomass of organisms inhabiting this environment and influence many soil-forming and soil-protecting processes as well as processes which ensure the dynamics of food chain links in the agroecosystem. The rhizosphere and root hair of cereals being at early stages of development are colonized by low numbers of microorganisms, but colonization rate increases at the flowering stage. In the rhizosphere, unlike in the lower soil strata, these communities are significantly more diversified. Often, their quantitative and qualitative potential is correlated with organic remains distributed in the soil. While roots begin to decay, the re-growth of a microorganism population is observed around them, including particularly saprotrophs which are typical of the decomposing plant residues (Gregory, 2006). It is essential to keep a dynamic balance

between saprophytes and pathogens, which may be ensured by optimal fertilization and good practice of using plant protection agents. However, these measures should not disturb the qualitative and quantitative structure of microorganisms which are components of, e.g., mycorrhizas (Johansson *et al*., 2004) and affect the biometry of cultivable plants in the growing period as well as the quality and yield of crop. Dick and Tabatabai (1992) and Acosta-Martinez *et al*. (2007) have proved that organic fertilization had a more beneficial effect on the biological activity compared to mineral fertilization which improves the physicochemical parameters of soil. It needs to be remembered that nitrogen has the greatest impact on plant yield and growth; it affects both the qualitative and quantitative traits of the crop. Positive outcomes of plant fertilization with nitrogen include, primarily, an increased number of spikes and also an increased grain weight per spike, which is a very important yield-increasing factor (Liszewski 2008). When applying nitrogen as a fertilizer, consideration should be given to its form, e.g. in the ammonia form it may reduce the prevalence of *Gaeumannomyces graminis*, whereas in the nitrate form it promotes pathogen development (Kurowski *et al*., 1990). Fertilization may also influence microorganisms antagonistic to pathogens. Considering multi-faceted interactions in the natural environment compared to the in vitro conditions, including the C:N ratio in soils, contents of phosphorus and carbon in soils, their humidity and pH, temperature and UV radiation, and presence of other microorganisms, many authors have indicated no antagonistic traits in representatives of the *Trichoderma* genus against pathogens (Tanaka *et al*., 2006; Kredics *et al*., 2003) and claimed antagonist's effectiveness to be suppressed by the presence of other biological control agents and abiotic factors (Nielsen *et al*., 2014).

Therefore, it seemed advisable to identify the community of fungi appearing during cultivation of barley which is used for various purposes in many European countries even though it does not dominate in the crop structure.

Material and Methods

The experiment was conducted in the years 2015-2016 in Bałcyny. It was established in the random block design with four replications on typical grey-brown podsolic soil originating from light loam (class IIIa in the soil valuation system, very good rye complex). The experimental factors included: (1) types of fertilization: mineral (N) and mineral with manure (M), and (2) doses of mineral fertilizers NPK (1-8: 0/0/0; 60/60/60 ;120/60/60; 180/60/60; 120/60/120; 120/60/180; 120/60/120/40 (Mg);120/60/120/40/2500 (Mg/Ca).

Soil samples were collected with a sterile small shovel from each plot, from of a depth of ca. 15-20 cm close to plants of spring barley of Justina cultivar, at the 30-33 BBCH growth stage. Next, they were transferred onto sterile Petri dishes and transported to the laboratory. Afterwards, bulk samples from respective experimental treatments were prepared under sterile conditions.

The mycological analysis of soil fungi was carried out following a modified method of Mańka (1974). Quartz sand (149 g) was poured to 500-mL conical flasks. The sand was earlier sterilized in an autoclave, under the pressure of 125 atm for 25 min. Once the substrate has been cooled, 1 g of the analyzed soil form the bulk sample made of four replications of a given experimental treatment was added under sterile conditions to the flask, and flask content was mixed by shaking for 20 min. Afterwards, 25 mg of the soil mixture with quartz sand were collected and transferred onto Petri dishes. Thus prepared material was poured with cooled Martin-Johnson medium with rose bengal and streptomycin. Antibiotic addition was expected to inhibit the development of bacterial colonies on the culture medium. After 5 days of incubation in a thermostat at a temperature of 24ºC, colonies of fungi grown on the dishes were inoculated onto potato dextrose agar (PDA). The health status of stem bases was evaluated at the 87 BBCH stage of development using a 3-degreePonchet's scale modified by

Mackiewicz and Drath (1972). Severity of infections was presented in the form of the infestation index computed acc. to the method of Towsend and Heuberger (1943). Fungi were isolated from stem bases following the methodology developed by Martyniuk and Myśków (1983). Segments of stems (1 cm) with disease symptoms were excised from the collected material, rinsed and disinfected in 50% ethyl alcohol and 1% sodium hypochlorite. After 3-fold washing with sterile water, the fragments were placed onto solidified PDA medium. After a few days, the growing fungal cultures were re-inoculated on slants with PDA media and their species composition was determined based on morphotyping. Statistical calculations were based on the Tukey's test p = 0.05.

Results and Discussion

The macroscopic assessment of stem bases revealed no symptoms of take-all of cereals and showed that their infestation by *Rhizoctonia. cerealis* and *R. solani* was low and ranged from 0.5% to 3.0% in the treatment without organic fertilization. The lowest value of the infestation index was determined on the control plot and the highest one on the plot where spring barley was fertilized with the addition of calcium. In the treatment with organic fertilization, the severity of sharp eyespot (*Rhizoctonia* spp.) ranged from 0 to 2.5%, however its symptoms were not observed upon calcium application. The assessment revealed also various severity of the eyespot of cereals. In the experimental treatment with mineral fertilization, the value of the infestation index ranged from 14.0 to 41.5%. The mean severity of the eyespot of cereals reached 27.6%. The lowest infestation by *Oculimcula. yallundae* was reported on the plots with double dose of potassium and with nitrogen dose of 120 kg/ha, whereas the highest one – on plots with minimal doses of potassium and phosphorus, and with nitrogen dose of 120 kg/ha. While evaluating the health status of cereals, attention should be paid to weed control, because the presence of weeds may affect the presence of sources of infection in which the undesirable plants are vectors (Burgieł, 2002). It is also essential to diagnose various types of *O. yallundae*, which as indicated by literature data, differs in the growth rate. Type R develops slowly, whereas type W develops faster. A higher prevalence of type W is noted in Poland, whereas a higher prevalence of type R – in Europe. Today, molecular diagnostics enables even more in-depth evaluation of their pathogenicity (Nicholson *et al*., 1995; Głazek. 2002:). Organic fertilization stimulated the appearance of symptoms of the eyespot of cereals; the infestation index reached 26% on the control plot and was the lowest compared to the other experimental treatments. The strongest spring barely infestation with *O. yallundae* was observed in the treatment in which nitrogen was administered at the highest dose: 180 kg/ha. Fusarium take-all disease was the most severe among all diagnosed diseases. The mean Ip(%) values in the treatment with mineral fertilization accounted for 48.8% and in that with organic fertilization – for 58%. The highest percentage of infested stem bases (Ip(%)=57%) was demonstrated in the treatment including mineral fertilization with magnesium application. In this treatment, the lowest infestation by fungi from the genus *Fusarium* was observed on the control plot, but still it reached as much as 43.5%. Very high severity of the fusarium take-all disease was noted in the treatment involving mineral fertilization NPK 120/60/120 kg/ha coupled with the application of manure. Likewise in the combinations without manure, in this treatment the least severity of this disease was noted on the control plot. The application of magnesium and calcium did not promote health condition of plants. Experiments conducted by other research centers have proved the health status of cereals to depend on nitrogen doses. It's content in fertilizers below 100 kg/ha stimulates *Fusarium*. Pląskowska *et al*. (2002) demonstrated an increase in *F. culmorum* count at this dose of nitrogen, whereas at 200 kg N/ha she reported a high contribution of *F. avenaceum* in the fungi population. Laboratory analyses demonstrated 20 taxa of fungi, among which predominating were pathogens and fungi with weak infectious traits which pose threat to crop yield only under conditions of

plant debilitation. The most often isolated species included numerous representatives of the genus *Fusarium*, among which the highest prevalence was found for: *F. culmorum*, *F. croowellense* and *F. poae*. Also *Cochliobolus sativus* was identified among pathogens, which infested more often the stem base of barley treated only with mineral fertilizers. A study carried out by Baturo (2002) indicates that this pathogen more frequently colonizes plants from bio-cultures than these from the conventional system of cultivation. Detrimental effects of this species were emphasized by Agarwal and Sinclair (1997) who reported that seed dressing is recommended in Norway when the percentage of infested barley kernels exceeds 10% in the case of infestation with *B. sorokiniana* (*C. sativus*) and 25% in the case of infestation with fungi from the *Fusarium* spp. genus. An overview of literature data indicates that *B. sorokiniana* is a factor which deteriorates crop productivity and crop quality when high temperatures and humidity occur in May and values of weather parameters decrease in the subsequent month of the growing period. This dangerous pathogen may constitute a reservoir of infections in the subsequent season, as it survives winter in the form of mycelium on plant residues. In our study, we observed dark necrotic spots which are outcomes of the activity of genes responsible for the synthesis of helminthosporal, polygalacturanase, cellulase, and pectinesterase, which effectively penetrate the cell wall of a host and contribute to hydrogen peroxide production, which ultimately leads to the appearance of black spots of the necrotic cereal tissue. This type of fertilization tangibly promoted the population of fungi with antagonistic traits: *Trichoderma*, *Gliocladium*, and *Penicillium*. Results of our experiment demonstrate that the prevalence and qualitative diversity of taxa are determined by fertilization and doses of mineral fertilizers. A total of 262 isolates were obtained from the soil samples, among which predominating were soil fungi originating from barley culture treated with mineral fertilizers and manure (tab. 1).

N*- mineral fertilization, M**- mineral and manure fertilization

They represented 63.7% of all isolates and their number exceeded almost twice the number of fungal isolates obtained from the soil not treated with manure during spring barley cultivation. 95 isolates were obtained from the soil treated only with mineral fertilizers, which constituted 36.2% of the total pool of microorganisms. The lowest pool was achieved in the treatment in which soil was treated with mineral fertilizers including magnesium and calcium and with organic fertilizer. Simultaneously, as many as 46 isolates were obtained from the soil not treated with calcium, which is indicative of the inhibitory effect of this element on the development of soil microorganisms. Literature data demonstrates that an increase in nitrogen dose compared to potassium dose may contribute to cereals lodging, stimulates threat posed by pathogens, and ultimately leads to the loss of crop. In addition, experimental plots on which soil was treated with calcium and with only mineral fertilizers were characterized by decreased population numbers in the microorganism community. A similar trend of microorganism count increase upon the use of manure was demonstrated upon NPK and Mg treatment at 120/60/120/40 kg/ha during spring barley cultivation. This experimental combination also contributed to the highest count of fungi population among all plots treated only with mineral fertilizers compared to all other treatments with mineral fertilization. Small differences in counts of microorganisms under the influence of the applied fertilizers were demonstrated in treatments with the same doses of phosphorus and potassium (60 kg/ha) and with nitrogen used in doses of 60 and 120 kg/ha. The highest counts of potentially saprotrophic fungi were determined in the samples of soil treated with organic fertilizer (75 isolates). A lower contribution of saprotrophs was noted upon mineral fertilization (48 isolates) compared to the treatments with manure. The quantitative structure of pathogens proves small differences in this ecological group of microorganisms compared to the prevalence of saprotrophs and fungi with antagonistic traits. Higher counts in the fungi community were determined for these capable of decomposing dead organic matter, their higher prevalence was recorded particularly after manure application together with mineral fertilizers compared to the population of saprophytic fungi isolated from the soil treated only with mineral fertilizers. Almost three times higher prevalence was determined for the fungi potentially antagonistic to pathogens of cultivable plants in the treatment involving the use of manure. The number of isolates obtained from soil samples after mineral fertilization reached merely 14, whereas that obtained after manure application increased to 58 isolates. Among the antagonists, we identified the genus: *Gliocladium*, *Trichoderma* and *Penicillium*, but only in the treatment with manure application. In this treatment, also *Penicillium* genus was prevalent, whereas *Trichoderma harzianum* was detected in only one isolate and originated from the soil treated only with mineral fertilizers. The analysis of fungi community in particular treatments of spring barley culture with mineral fertilization at the following NPKMg doses: 120/60; 120/40; 60/120/40 60/120 kg/ha and with manure application revealed the preponderance of saprophytic fungi over the other ecological groups of fungi. An important recommendation for fertilization in the agricultural practice may be the application of manure to soil together with NPK in 120/60/180 doses, which in our study ensured no pathogenic fungi in the analyzed samples. In the control plot without organic fertilizers administered during spring barley cultivation, the prevalence of fungi antagonistic to pathogens turned out to be the highest. An overview of literature indicates that soil

microorganisms are classified into three groups: these having a positive effect on plants, these with neutral effect, and these eliciting adverse effects. A balance occurs between these three groups in the rhizosphere in natural or minimally transformed ecosystems (Nannipieri et al., 2003; Paul *et al*. 2000). The inhibiting effect of the plant growth-promoting rhizobacteria (PGPR) has been confirmed in the case of the following pathogens: *Verticillium* spp., *Sclerotium rolfsii*, *Thielaviopsis basicola*, *Pythium* spp., *Rhizoctonia solani*, *Phytophthora* spp., *G. graminis*, *Aphanomyces* spp., and *F. oxysporum* (Kloepper *et al*., 1999). In our experiment, the use of as high nitrogen dose as 180 kg per ha coupled with manure application resulted in a low prevalence of the pathogenic fungi in the soil, which increased at nitrogen doses of 60 and 120 kg per ha. This indicates that the poorly fertilized plant may be more often infected by soil pathogens, whereas at high nitrogen doses the assimilation apparatus of plants responds in making epidermis cells more delicate, thereby allowing the pathogens to easier penetrate host tissues. An equilibrium between the groups of microorganism with a tendency for an increased prevalence of fungi displaying antagonist traits was achieved in the treatments with a high dose of nitrogen coupled with calcium application. It needs to be emphasized, however, that in this group of soil samples from all plots the pathogens represented a more numerous group of microorganisms than their antagonists did, and that no microorganisms competitive to pathogenic fungi were identified in the treatment with magnesium application at 40 kg/ha and in the treatments with NPK doses of 120/60/120 kg/ha. Considering the biological activity of soil, the balance between groups of microorganisms colonizing the microrhizosphere may ensure soil fertility. The biological equilibrium is achieved in agroecosystems through optimal fertilization as well as rational, integrated use of crop protection agents (Johansson *et al*., 2004).

In summary, it needs to be emphasized that the quantitative structure of microorganisms in the soil and the activity of metabolites they synthesize, including enzymes and antibiotics, are determined many factors like e.g. water-air regime, soil pH or organic matter content. These, in turn, constitute a flexible model modifiable by the type of tillage including agrotechnical measures with fertilization treatments. The optimal mineral fertilization has a positive impact on the productivity of plants and their health status in the growing period, which ultimately determines grain quality. Knowing the pool of microorganisms accompanying the cultivation of agricultural crops is an element necessary to establish soil abundance in microorganisms posing potential threat to the quantitative and qualitative structure of crops and these which play the role of natural biostimulants of plants by improving their productivity. Analyses of the biological activity of soil are part of an integrated methodology for plant protection against pathogens.

Conclusions

Results of the study addressing soil fungi contaminating spring barley crop demonstrate that mineral fertilization coupled with organic fertilization stimulates counts of soil microorganisms. The greatest increase in their count occurred upon the use of manure together with NPK at a dose of 120/60/120 kg/ha, which additionally stimulated the severity of fusarium take-all of cereals. The application of calcium at this dose of NPK reduced the pool of soil fungi. Introducing only mineral fertilizers to spring barley cultivation stimulated pathogens development in the soil and inhibited the growth of fungi with antagonistic traits, particularly at the following doses: 120/60/120 kg/ha NPK and 120/60/120/40 kg/ha NPKMg. The soil fungal community was predominated by saprotrophs: *Aspergillus*, *Penicillium*, *Chaetomium*, and pathogenic species: *Fusarium*, *Rhizoctonia*, and *Botrytis*. Negligence of fertilizing measures and using only mineral fertilizers with calcium in the agricultural practice leads to the accumulation of pathogenic fungi in the soil and may deteriorate the health status of spring barley. The predominating symptoms of foot rot of spring barley Justina cv. were the take-all disease and eyespot of cereals. Fungi of the genus *Rhizoctonia* were of marginal

significance to the health status of spring barley. The high dose of nitrogen (180 kg/ha) coupled with organic fertilization increased eyespot severity. The predominating fungi among the isolates obtained from spring barley stem base included: *F. culmorum*, *F. croowellense*, *F. poae*, *A. alternata*, and *Gliocladium roseum*. The application of natural fertilizers stimulated the quantitative and qualitative structure of fungi colonizing the stem base of spring barley.

Abstract

Biological control is an increasing group of plant protection methods. In comparison to fungicides, the biological control agents have a weaker impact on the natural environment. Among the various methods, the usage of antagonistic bacteria is of the outmost importance in ensuring protection against phytopathogenic fungi. The beneficial strain of bacteria can inhibit the growth of phytopathogens by using several strategies and may promote the growth of plants it colonizes. The aim of this study was to determine i) evaluation of multi-trait plant growth promoting parameters of *Bacillus* sp. SP-40; ii) the antagonistic action of used strain on *Fusarium* spp. Growth on selective medium, dual-culture test, and PCR identification of gene response to fungistatic substance production were performed to enable detection of antagonistic traits of *Bacillus* sp. SP-40. Relationships between antagonist, pathogen and plant were examined as well. Study results showed the antagonistic effect of the tested strain against *Fusarium culmorum* and *F. oxysporum* on appropriate growth media. Chitinolytic and cellulolytic activities of *Bacillus* sp. SP-40 were determined either on the selective medium. The ability of fungistatic metabolite production (surfactin, bacilysin, fengycin, bacillomycin and iturin) was affirmed by PCR. The antagonistic strain grew at 10 to 37°C, pH 5 to 9, and NaCl 5% and was resistant to $CuSO_4$ and common fungicides, insecticides and herbicides. The fluorescence microscopy analysis demonstrated that the antagonistic strain colonized *Fusarium* mycelium (hyperparasitism). Results of water-agar test showed that wheat kernels inoculated with the *Bacillus* strain were more resistant to *Fusarium* spp., and seedlings had improved health status and biometric properties. In conclusion, *Bacillus* sp. SP-40 application caused significant inhibition of *Fusarium* spp. growth on both culture medium and wheat seedlings.

Keywords*: Biocontrol, antagonistic bacteria, wheat*

Introduction

Soil is an environment inhabited by organisms being important in ensuring the proper functioning of an ecosystem. Soil microorganisms are strongly associated with the metabolism of the organic and mineral matter and with the circulation of elements in the natural environment, hence it is essential to preserve their biodiversity. An agroecosystem is an important element of nature transformed by man and its task is to provide food to the global population. However, the use of chemical agents and too dynamic plant production contribute to soil degradation and to impairment of biochemical and biological processes, which results in depletion of both biodiversity and numbers of microorganisms (Heijiden *et al*., 2008; Hinsinger *et al*., 2009).

An interesting research issue is the exploitation of microorganisms for plant growth stimulation and for plant protection against agrophages. Bacteria used to this end develop at various temperatures and remain active even at a temperature of 4°C. They produce lytic enzymes, like e.g. cellulase, lipase and protease, which are indicative of their effective organic matter degradation and nutrients redistribution, as well as of their potential to degrade undesirable microorganisms. Ecological preparations have recently become common on the

market of plant protection agents and fertilizers. Bacteria enhancing the growth of plants are referred to as plant growth-promoting bacteria (PGPB) or plant growth-promoting rhizobacteria (PGPR). These microorganisms develop in soil, rhizosphere and rhizoplane by entering into symbiotic reactions with plant root, and display a variety of properties, like e.g.: root growth stimulation, enhancement of nutrients uptake, production of phytohormones, secretion of siderophores, and synthesis of antibiotics, enzymes and substances which minimize negative outcomes of the biotic and abiotic stress. Some of the PGPRs are also commonly used in biocontrol of phytopathogens (Ahemad and Kibret, 2014; Beneduzi *et al*. 2014).

Bacteria promoting plant growth and enabling biocontrol are representatives of the following genera: *Azotobacter*, *Bacillus*, *Burkholderia*, *Enterobacter*, *Pseudomonas*, *Rhizobium*, and *Serratia*, but this group may be significantly larger (Ahemad and Kibret, 2014).

Recent works have reported on the strong effect of bacteria from the *Bacillus*, *Pseudomonas*, and also *Actinomycetes* genera on the stabilization of soil equilibrium, particularly in natural ecosystems. These bacteria produce multiple active substances which display strong fungistatic activity and, therefore, can be used as natural plant protection agents (Ayuso-Sacido and Genilloud 2004; Svercel et al., 2009; Mora *et al*., 2011) Production and application of such antibiotics is difficult, hence the most effective method is to use commercial strains of PGPB which not only promote plant growth but are also effective in minimizing the incidence of crops diseases. The aim of this study was to investigation of potential biological control of *Fusarium* sp. by antagonistic strain of bacteria that possesses many traits of plant growth promotion.

Material and Methods

Collection of soil samples and isolation of microorganisms

One kilogram of soil was collected from a stand where flaxseed was cultivated in a monoculture (48 years). The sample was transported to the laboratory and subjected to further handling procedures. First, its serial dilutions were prepared (from 10^{-1} to 10^{-10}). Then, bacteria were isolated from each dilution by inoculation onto a solid culture medium (tryptic soy agar – TSA) and incubated at 28°C for 48 h. Multiple microorganisms were isolated and their colonies displayed various morphological traits. By using methods described below, one strain which displayed the strongest antagonistic potential against *Fusarium* was isolated from this material. Its affiliation to the genus *Bacillus* was confirmed by 16S rDNA sequence analysis conducted as described in our previous work (Przemieniecki *et al*., 2018).

Determination of the antagonistic potential – dual culture

The experiment was conducted on a PDA (potato dextrose agar) medium by inoculating the culture of the tested bacteria and a phytopathogenic fungus (*Fusarium culmorum* or *F. oxysporum*) 3 cm away from each other. Thus prepared cultures were incubated at 28°C for 72 h, then mycelium growth was measured and expressed in percentage relative to the control (i.e. sterile demineralized water instead of the bacterial suspension).

Determination of selected traits promoting plant growth.

Chitinase – capability of bacteria to produce chitinase was analyzed in a culture medium composed of: monopotassium phosphate – 1.0 g, magnesium sulfate (VI) – 0.5 g, sodium chloride – 0.5 g, iron (II) sulfate (VI) – 0.01 g, manganese sulfate (VI) – 0.01 g, ammonia nitrogen — 0.3 g, agar – 15 g, and colloidal chitin – 1 g (Roberts and Selitrennikoff, 1988).

Cellulase – capability of bacteria to produce cellulase was determined on a culture medium composed of: monopotassium phosphate – 0.5 g, magnesium sulfate (VI) – 0.25 g, cellulose – 2 g, agar – 15 g, and Congo-Red – 0.2 g (Lu *et al*., 2015).

Phosphate solubilizing bacteria (PSB) – these bacteria were examined on the Pikovskay's medium composed of: glucose – 10 g, calcium phosphate – 2.5 g, ammonia sulfate (VI) – 0.5

g, sodium chloride – 0.2 g, potassium chloride – 0.2 g, yeast extract – 0.5 g, magnesium sulfate (VI) – 0.002 g, and iron (II) sulfate (VI) – 0.002 g (Nautiyal, 1999).

Assessment of activity of *Bacillus* sp. SP-40 depending on culture medium

The assessment was carried out by inoculating an overnight culture onto the TSA medium (tryptic soy agar) and its incubation at 28°C for 48h. Afterwards, colony growth potential (size, density, thickness) was evaluated compared to the control culture (TSA medium, pH~7). Colony growth was tested in the culture medium with pesticide supplementation (dose recommended by the manufacturer), NaCl concentrations of 1-7%, pH values of 5-9, and temperature ranging from 4 to 37°C (Przemieniecki *et al*., 2018).

16S rDNA sequencing

Whole DNA was isolated using a Genomic Mini AX Bacteria Spin (A&A Biotechnology), as described in our previous work (Przemieniecki *et al*., 2018). The isolated DNA was sent to an external company which performed the sequencing procedure (starters 27F-1492R).

Detection of genes responsible for the production of fungistatic substances

Genes were detected with the polymerase chain reaction (PCR) method (Mora *et al*., 2011 with modifications by Zhao *et al*., 2014) using the following starters:

Surfactin
SRFAF (TCGGGACAGGAAGACATCAT),
SRFAR (CCACTCAAACGGATAATCCTGA);
Bacilysin
BACF (CAGCTCATGGGAATGCTTTT),
BACR (CTCGGTCCTGAAGGGACAAG);
Fengycin
FENDF (GGCCCGTTCTCTAAATCCAT),
FENDR (GTCATGCTGACGAGAGCAAA);
Bacillomycin
BMYBF(GAATCCCGTTGTTCTCCAAA),
BMYMR (GCGGGTATTGAATGCTTGTT);
Iturin
ITUCF (GGCTGCTGCAGATGCTTTAT),
ITUCR (TCGCAGATAATCGCAGTGAG).

Fluorescent microscopy

Microscopic imaging was conducted with an epifluorescence microscope (Carl Zeiss). Visualization was enabled by Acridine Orange (Sigmal Aldrich). Observations were made for the mycelium grown in the dual culture assay. Images taken were subjected to processing which had no effect on the quality of results.

Seed experiment

The analyzed strain was used to dress seeds of spring wheat. Pots (120 mL) were filled with 50 mL of an aqueous agar (1%) contaminated with spores of *F. culmorum* and *F. oxysporum* with a density of 10^6, and then 20 seeds of he spring wheat cultivar Bombona were placed on the agar. Incubation was conducted in a phytotron for 14 days under the following regime: day (25°C, 12h) and night (17°C, 12h), and humidity of 80%. After incubation, analyses were conducted for: number of germinating seeds, plant height, plant colonization by the mycelium, and health status of seedlings. Non-dressed seeds cultured on the medium without fungal spores, and infected culture medium with non-dressed seeds served as the control.

Results and Discussion

The analysis of results of the antagonistic potential revealed that the growth inhibition zone in the dual culture test on PDA medium reached 30 mm in the case of *F. culmorum* and 21 mm in the case of *F. oxysporum*. Results were statistically significant at p=0.005 (very highly significant) compared to the control culture.

Parameters of evaluation in the control treatment were statistically significantly different at p=0.05 from these noted for the background and the treatment with inoculated seeds

Treatment*	Phyllosphere	Roots	Infestation
Control for *F. oxysporum*	3.0	3.0	2.0
Background	4.8	3.8	0.3
Bacillus sp. SP-40	4.5	3.5	1.0

No significant differences were found at p=0.05

*0-no germination or dead plant, 1-infected seedling with 75% necrosis, 2-seedling with severe symptoms of infection and 50% necrosis, 3-seedling with severe symptoms of infection and 25% necrosis; 4-seedling with symptoms of infection and necrosis below 10%; 5-completely healthy seedling with potential sporadic necrotic lesions

The analysis of traits describing the physiological parameters of bacteria from the PGPB group (Table 1) demonstrated that the tested bacterium developed at all analyzed temperatures. The poorest development of the test strain was observed at a temperature of 4 ^{o}C, however it still maintained its activity at this temperature. Its best development was observed at 28°C. The test strain displayed good or moderate activity at temperatures of 11, 22, and 37°C. It was also able to grow in the acidic and alkaline medium, and reached optimal growth at pH 7. In addition, it turned out resistant to salinity (even 5% NaCl), but despite preserved activity at the highest tested NaCl concentration, its growth potential was found to decrease significantly. A halo zone was observed on selective media, which was indicative of strain capability for solubilization of inorganic phosphates (making phosphorus available to plants) and for degradation of chitin (production of chitinases). Colony swarming and low susceptibility to plant protection agents confirm this strain's usability in plant cultivation. The tested bacterial strain possessed all genes responsible for the production of fungistatic antibiotics (Photo 1). These assembly of active substances is typical of the bacteria from the genus *Bacillus* spp., which is their additional diagnostic trait. Microscope observations (Photo 2) revealed the ability of test strain cells to colonize *F. culmorum* mycelium along the hyphae. The clustering of microorganisms was increasing towards the mother colony (inoculation site). Culture inoculation with *Bacillus* sp. SP-40 strain significantly reduced seed infestation by *Fusarium culmorum* (improvement by 90%) and by *F. oxysporum* (improvement by 50%). An improvement was also observed in seedling growth in the treatment with the inoculated strain of the test bacteria compared to the control treatment, whereas the length of the aerial part and root of the seedlings did not differ statistically from that of the plants grown from non-inoculated seeds sown on the sterile medium (background). As demonstrated by Zhao *et al*. 2014, the antibiotic-producing *Bacillus subtilis* SG6 strongly inhibited *F. culmorum* development and caused deformations of mycelium hyphae. In addition, its application enabled significant reduction in the severity of Fusarium head blight (FHB) in field conditions as well as deoxynivalenol (DON) degradation. Microscope observations proved that the *B. subtilis* SG6 strain, likewise *Bacillus* sp. SP-40, was attached to fungus surface and colonized spores of *F. culmorum*. Our previous research (Przemieniecki *et al*., 2018) proved that the use

of *B. substilis* in wheat cultivation improved crop productivity and ensured crop protection against pathogens from the genus *Fusarium*. Seed inoculation with *B. subtilis* sp. SP-A9 strain contributed to a significant increase in grain yield.

Conclusion

With the increasing use of chemicals in agriculture, the threat to the natural environment and humans is becoming more and more real. For this reason, a search is underway for novel environment-friendly methods of plant protection and fertilization, like e.g. the application of useful microorganisms. In this study, were proved that the *Bacillus* sp. SP-40 strain isolated from arable soil displayed many traits enabling plant growth promotion and that it well adapted to various environments. Study results demonstrated also its antagonistic potential against very harmful phytopathogens from the genus *Fusarium* and its capability to colonize mycelium hyphae, which is indicative of its hyperparasitic character. The above findings coupled with results of a test indicating improvement in the health status and development of wheat seedlings confirm usability of this strain in biofertilization and biocontrol.

Abstract

The tomato leafminer, *Tuta absoluta* (Meyrick) (*Lepidoptera:Gelechiidae*) is one of the most damaging invasive moths, threatening the tomato crop worldwide. It originates from South America and it was reported for the first time in Europe, in Spain, in 2006. It was reported even in Norway, in 2017. Having a spreading speed of more than 800 km in a year, *T. absoluta* reached Romanian borders most probably in 2009, when it was first found in Botoșani County. After this first interception, the pest spread in neighbouring counties as Maramures (2009), Bihor (2010), Arad (2010), Ilfov (2010) and Mures (2010). Although sustained efforts have been made to limit the spread and the Plant Protection Authority launched a national monitoring plan in 2011, while the pesticide companies have held numerous farmers' awareness sessions on the high potential of pest damage and the popularization of control measures, *T. absoluta* continues to spread in the main vegetable basins: Hunedoara (2013), Calarași (2011), Ilfov (2013), Galați (2015). According to the recent field reports, the pest started to be present outside protected areas (greenhouses and plastic film tunnels) and affect the open field tomatoes (Paradisverde, 2018). Also, the pest is now affecting and is now infesting sweet pepper, eggplants and other crops and weeds.
In this paper current status of *T. absoluta* in Romania, nine years after its first interception, is presented. Considering the pest adapts very fast to different climate conditions, it is obvious that control measures are imperatives and knowing the real spread in the territory could help Romania to take the appropriate measures.

Keywords: *Tuta absoluta; invasive pest; spreading map; Romania; citizen science.*

Introduction

The tomato leafminer, *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae) has conquered almost 60% of the total area cultivated with tomato, becoming one of the biggest problems for the vegetable producers mainly in Europe and Africa, following its escape from its native area, more than 10 years ago. It is a pest that may destroy the tomato crop completely, in a very short time, due to its extremely prolificacy and high capacity to adapt to various environmental conditions. The European Plant Protection Organisation recommended *T. absoluta* as a quarantine organism and it was included in 2004 in A1 list, as a harmful organisms not known to occur in the EPPO area (EPPO, 2004). After entering Europe (2006) and fast spreading, the pest was transferred to A2 list in 2009 (EPPO Database, 2018). Currently, the pest is spread in more than 30 European countries. In 2016, symptoms of *T. absoluta* attack were observed in Uzbekistan, which led to speculation about its presence in Central Asia (Fayad and Adiga, 2017). A recent publication confirmed the presence of *T. absoluta* in tomato greenhouse in Kyrgyzstan (Uulu *et al*., 2017) while WKN (2017) confirmed it for the first time on the southwest coast of Norway. In 2018, it was found in Lesotho (IPPC, 2018), a country where more than 80% of the territory is located at altitudes above 1800 m and in Tajikistan (Saidov *et al*., 2018).

In Canada, the United States of America, China etc., where the pest is strictly regulated as a quarantine pest, *T. absoluta* was not found until now. The United States banned the import of tomatoes from the countries where the pest is known to occur, including Romania, since 2011 (MADR, 2011).

In Romania, the pest was found for the first time in 2009. According to the National Phytosanitary Authority, *T. absoluta* was first reported in Botoşani County and then in Maramureş County (Leaotă, 2009), while Băeţan et al. (2013a) reported the first appearance in June 2009, in one market in Oradea city (Oradea County), on tomato imported from Spain. In 2010 the pest spread rapidly in Bihor, Arad, Ilfov and Mureş counties (Cean et Dobrin, 2009). In all these cases the pest was detected on tomatoes, exclusively in protected areas. At the same time, *T. absoluta* larvae have been identified on tomato fruits imported from Spain and Turkey, the respective samples coming from Cluj, Covasna and Vaslui counties (Cean and Dobrin, 2009). Immediately after the introduction to a new area, chemical treatments with synthetic insecticides were applied, as an attempt of eradication/containment of the pest. According to Zlof and Suffert (2012), in the countries with high pest pressure, growers have been spraying intensively, with up to 25 sprays per season. Because of the difficulties encountered in stopping the spread of *T. absoluta,* some countries adopted emergency control measures. According to EU notifications received from Member States, as 2008/C159/04, in Spain, until January 2009, farmers could claim financial compensation for control measures against *T. absoluta* in tomatoes, peppers, potatoes and eggplants crops (EU, 2007).

The National Phytosanitary Authority of Romania (National Phytosanitary Agency in 2011), developed and implemented in 2011 the "National Pest Control Plan for *Tuta absoluta*", which includes the monitoring plan and valuable information to prevent new outbreaks and to limit the spread. There is no economic threshold for *T. asboluta,* the treatments being applied immediately after the first adults are caught in the pheromone traps. However, as people were not too aware of the plan and measures, the expected effects were unsatisfactory.

The objective of the present paper is to highlight the level of farmers knowledge related to the *T. absoluta* in Romania, and to update the distribution map of this pest in Romania.

Material and Methods

The paper is based on an extended review of data collected from various internet data bases and social media posts. Also, a four questions online survey was carried out in the period February – May 2018, on a sample of maximum 20000 potential respondents.

The social media campaigne included a questionnaire with four questions about the year of first finding, the place of first finding (open field or protected area), the control measures taken by the farmers, what information would they look for in a control guide for *T. absoluta*.

The email campaigne included the same set of questions, that was sent by email to around 50 people.

The interest about tomato leafminer in the scientific environment, vegetable growers and pesticides supliers was also evaluated.

Results and Discussion

The interest and knowledge about *Tuta absoluta* in the scientific environment

In March 2010, in Maramureş County, at one workshop organised by the Maisadour semences seed company, the Maramureş Phytosanitary Office director, Valer Vele and the engineer Melania Oltean, introduced for the first time farmers with a new pest, tomato leafminer: insect description, spread pathways, control measures that should be taken (Gherman, 2010; TLPlus, 2017). The same phytosanitary agents responded whenever necessary in the written and audio-visual press, to warn the farmers and hobby producers about the risks posed by the pests populations' growth.

The scarce scientific publications seems not to take in consideration the economic importance of the pest. Besides the two first articles published by Cean and Dobrin (2009) and Cean (2011), about the identification and spread of this pest, only two more papers presented the spread of *T. absoluta* in the country. *T.absoluta* was indicated as a new pest for Oltenia region (Mitrea, 2013), on the sandy soils between Olt and Jiu River and in Boiu-Sicuia *et al.* (2017) found the pest in Muntenia region, Giurgiu and Ilfov counties. Băeţan (2015) dedicated a special chapter to this pest in his PhD thesis and also published four articles about tomato leafminer feeding behaviour and the spread of the pest in western Romania (Băeţan *et al*., 2013a, 2013b, 2015a, 2015b). Two teams made researches about the insecticides efficacy: Bratu *et al*. (2015) regarding spinosad, emamectin-benzoate and imidacloprid and Costache *et al*. (2014) regarding Neem saponins, *Quassia amara* and *Quassia amara*+ potassium salt. Around ten articles were published in the national Plant Health review (Sănătatea plantelor), mainly about the control strategies (Dobrin, 2013; Rinichita, 2016; Rosca, 2018).
In 2018 the National Phytosanitary Authority published a guide for the identification and control strategies of tomatoes grown in greenhouses, where a chapter is dedicated to the "Integrated Management Toolkit of the harmful organism *Tuta absoluta* Meyrick".

The interest and knowledge about *Tuta absoluta* of farmers and hobby producers
To determine the interest of farmers in *T. absoluta*, a national survey was designed. Out of ten horticultural and hobby-gardening groups where the questionaire was intended to be published, only six Facebook groups administrators agreed to publish it. From a total of around 20000 possible respondednts, only 8 answered (table 1). 7 answers were received (0,035%) on Facebook, of which three answers were enshuring that no *T. absoluta* was in their crops, in Cluj and Olt counties. On the email campaign, out of 50 emails, only 4 answers were received, which means 8% answer rate. Only one farmer agreed to allow us to monitor the population with a feromonal trap (Russel IPM lures), in March 2018, in a speenach plastic tunnel, in Bucharest (Figure 1).

Table 1. Farmers answers in *T. absoluta* survey on different social-media and email campaigns

Farmer location	**Year**	**Area of growing**	**Crop**	**Control**
Bragadiru (Ilfov)	2012	protected area	tomatoes	feromonal traps, emamectin benzoat 9,5 g/kg
	2015	open field	tomatoes	
	2018	protected area	tomatoes seedlings	
Bucharest	2015	protected area	tomatoes	clorantraniliprol
	2018	protected area	spinach	
Bragadiru (Ilfov)	2012	protected area	tomatoes	feromonal traps
Oradea (Bihor)	2012	protected area	tomatoes	formaline*, rotation
Câmpina (Prahova)	2014	protected area	tomatoes	
Şercaia (Braşov) Organic farmer	2016	protected area	tomatoes	sticky traps, repelent herbs macerate
Novaci (Giurgiu)	2013	hidroponics	tomatoes	clorpirifos metil 225 g/l on foil, DiPel®
Gheorghe Lazăr Ialomita	2013	open field	tomatoes, sweet pepper, egg-plants	clorantraniliprol

*for soil desinfection; source: author's elaboration based on the questionnaire survey results.

We could notice a certain reticence in the approach of the subject "*Tuta absoluta*" among the farmers, for different reasons. The most important could be the fear of rejection or marginalization, which could lead to the impossibility of capitalizing tomato production or tomato seedlings. Another reason might be the misleading informations which were published in a few articles, regarding the status of *T. absoluta* as a quarantine pest. According to this status, by law, it is recommended to destroy the attacked crops and to restrict the tomatoes cultivation in that area.

Regarding the guide for tomato leafminer control, the majority asked for biocontrol measures, the optimum climate condition for the pest and only one about precise treatments scheme with efficient chemical insecticides.

Figure 1. *T. absoluta*- captured adults on pheromone trap (Bucharest, March, 2018)

The interest and knowledge about *Tuta absoluta* in the commercial environment (pesticide suppliers)

The pesticide supliers were very active in disemination, organizing workshops, symposiums, conferences, open days. Few examples are given in table 2.

Table 2. Events organised by pesticides supliers

Organizer/ Place	**Date**	**No. of participants**	**Take-away message**
Marcoser, Braila	November 2014	70 farmers	The spread and losses caused by the pest in Braila are more and more severe
Syngenta, Prahova	December 2016	no data	Pest in all vegetable basins of the country, on tomatoes, potatoes, eggplants, resist up to -18°C.
Cilieni Olt	January 2017	100 farmers	Farmers were interested about *T. absoluta* control
Marcoser, Buzau	January 2017	90 farmers	The farmers were interested in *T. absoluta*, a special sessions was dedicated for the pest
Syngenta	October 2017	no data	Present in all vegetable areas, severe damage in Buzau, Galati and Ialomita counties in 2017
BASF, Galati	February 2018	no data	Presentation of a new portofolio of products against *T. absoluta*

Updated spread map of *Tuta absolut*a in Romania

By gathering all the written data we could access, an approximate distribution map of *T. absoluta* in Romania is presented (Figure 2). There were several other discussions with different consumers, researchers, pesticide supliers persons, in which the presence of the pest was mentioned in other counties, but in the lack of evidence, they could not be taken in consideration for the present map. Instead, these indications will be the basis for the future field inspections.

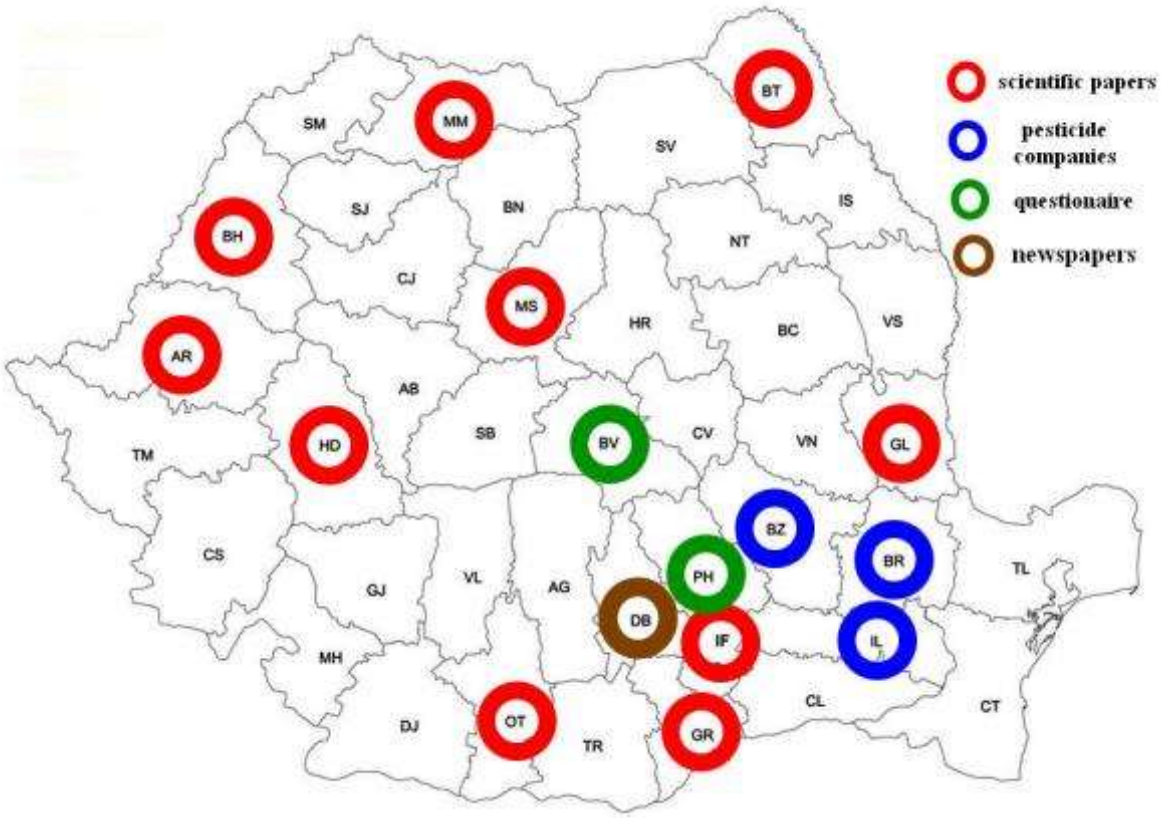

Figure 2. The current distribution of *T. absoluta* in Romania

The Ministry of Agriculture finally acknowledged in August 2018 that the threat of *Tuta absoluta* spread in all country is real and publicly asked for all farmers' involvement in control actions (Ziare, 2018, Agrointel, 2018), due to massive damages that initially started in Buzau, Galati, Ialomita (Agerpres, 2016).

Conclusions

Out of the 42 Romanian counties, the presence of *T. absoluta* was indicated in ten by scientific papers, in three by the pesticides suppliers, in two counties by our citizen science initiative and in one by a newspaper article. The three counties (Cluj, Covasna and Vaslui) where the pest where only intercepted in the import samples were not mentioned in our current distribution map. The few respondents to the e-mail and online groups survey were quite open in providing details about their work and the problems they had encountered with the tomato leafminer. There is some reticence in addressing this topic, fact which might be explained by the fear of losing the production, the future clients and even the crop. The pesticide suppliers were very active in informing farmers about the risk of infestation, pest descriptions, preventing methods, chemical control of the pest. Phytosanitary authorities have developed and implemented the national phytosanitary rules to monitor *T. absoluta* and some local staff (County Phytosanitary Offices) of the National Phytosanitary Authority supports farmers and other people involved in vegetable crops through guides, notifications and phytosanitary warning bulletins. In spite of the efforts made by the National Phytosanitary Authority in order to prevent the introduction and spread of tomato leafminer in the country, the pest continues to raise serious problems in most of our tomato production vegetable basins.

Abstract

Development of technologies for specialized food products, including functional orientation, is one of the priority tasks of ensuring the quality of life of the population. Bakery products, being a product of mass consumption, can improve the structure of the population's nutrition. In this case, the dosages of the components should not only ensure the improvement of the ingredient composition, but also preserve the traditional organoleptic characteristics. For this purpose, the effect of amaranth extrudate on certain baking and functional-technological properties of flour was investigated depending on the size of the grinding and the ingredient composition of the flour mixtures. Based on the analysis of fat-emulsifying, fat and water binding abilities, the most variable in its application fineness of the grind was determined - 0.125 mm and less. 12 model mixes of flour from an amaranth extrudate and wheat flour of the highest and the first grade with various dosages were made. The optimal dosage is determined from the color flour position. A decrease in the amount of gluten was established with an increase in the mass fraction of the amaranth extrudate in the flour mix and a change in its quality. It is shown that a rational dosage of the enriching ingredient should be established taking into account the initial characteristics of batches of wheat baking flour.

Keywords: *Amaranth, extrudate, protein, functional and technological properties, enrichment.*

Introduction

One of the important tasks of recent relevance to the food industry and the agro-industrial complex of the Russian Federation is the search for and use of non-traditional raw materials in food technologies. Often it has a high content of nutrients - vitamins, minerals, proteins, etc., missing in the diet of the population. One of the representatives of this raw material is amaranth - an annual herbaceous plant with small flowers collected in thick spicate-paniculate inflorescences. More than a few dozen species of amaranth are bred in some countries as an agricultural crop. The average protein content in the amaranth is 16-18%, also it has a high content of phosphorus and calcium, vitamin E and squalene (up to 8%) - antioxidant and anticarcinogenic. Amaranth is widely used in various food technologies [Saratovskiy, 2014], in our studies it is considered as a promising enriching ingredient in the flour group of food products [Lomova, 2017]. One of the most important problems of creation enriched foods is to save its traditional view, smell and taste. This process is quite difficult because of unconventional characteristics of non-traditional raw materials and requires a few studies.

Material and methods

Several varieties of amaranth selection were screened at the Voronezh State Agricultural University and Federal State Scientific Institution and Federal Research Center for Vegetable Growing, and the light-colored grade Universal was identified as the most promising for use in bakery products [Stakhurlova, 2017]. The variety is high in protein (26%), crude fiber, copper and iron. For further processing of raw materials extrusion was chosen, because extruded products are better absorbed by the organism, since in the process of hydrothermoplastic treatment, partial degradation of the polymers of the raw material occurs [Ostrikov, 2003]. Through the laboratory mill flour was obtained with different granulometry

- 1 mm and less, 0.315 mm and less and 0.125 mm and less. Flour is a mass of light cream color with the aroma acquired after extrusion, characteristic of fried foods. To assess the properties of flour used in complex food systems, a number of technological parameters are measured, such as water and fat-binding capacity, fat-emulsifying capacity, mechanical and osmotic properties, structural anisotropy and many others. The key functional properties from the standpoint of compatibility in the formulations of food products are their water-, fat-binding capacity. This is due to the fact that the consumer properties of food systems obtained with the use of extrudates, significantly depend on the content of water and fat in them [Bogatyirev, 1994]. Solubility and water retention are important indicators which can demonstrate the ability of the extrudate to bind water and dissolve in it, characterize its carbohydrate composition, as well as its consumer properties and partial digestibility of the product [Ostrikov, 2003]. The fat-emulsifying ability of the flour was determined by suspending and emulsifying in a centrifuge. The ratio of the volume of the emulsion to the volume of the total system was estimated. To determine the water binding capacity (WBC), the sample with distilled water was centrifuged. The unadsorbed water was drained, the tubes were weighed. WBC was calculated as the ratio of the mass of water bound with flour to the original mass of the latter. One of the factors affecting the appearance of the finished bakery product, in particular, the color of the crumb, is the whiteness of flour. The whiteness is determined by the parts of the grain from which it was ground, as well as the size, the additives introduced, the storage parameters, etc. The higher the whiteness of the flour, the more starch in its composition, thanks to this the baking turns out to be lush and with a uniformly porous, "beautiful" crumb. Such flour is widely used - but contains a minimum amount of fiber, it almost lacks minerals and vitamins. The whiteness of 12 samples of mixtures of wheat flour (high and first grades) with amaranth extruded flour was investigated in order to determine the most suitable bread for baking. The determination was carried out through a laboratory whiteness meter "Blick-R3" in accordance with GOST 26361-2013. The number of automatically measured fields on the flour sample was 10. The amount of gluten was determined by a standardized method (GOST 27839-2013). The quality was examined with the help of a digital deformation meter of gluten, IDK-5M. All measurements were made in triplicate, for the final values ware taken the average ones.

Results and discussion

The results of the studies fat-emulsifying ability are shown in Figure 1.

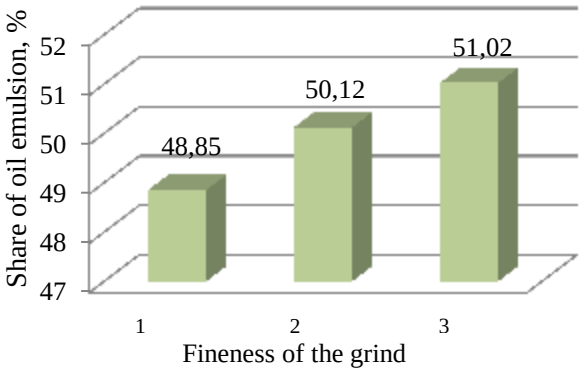

Figure 1 – Fat-emulsifying ability of the amaranth flour with the different fineness of the grind: 1 –1.0 mm and less; 2 – 0.315 mm and less; 3 – 0.125 mm and less

As shown by the results of research, the best fat-emulsifying ability was noted in amaranth flour with a grind size of 0.125 mm and less. That causes the expediency of its use in the formulations of fat-containing semi-finished products, for example, a biscuit or sugar cookie test. The introduction of amaranth flour into model mixtures increases their fat-emulsifying

ability, which can also contribute to the formation of a more porous structure of comfortable confectionery products. The results for determining the fat-binding capacity are shown in Figure 2.

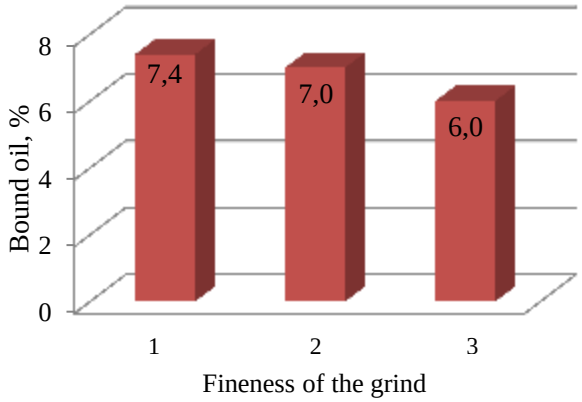

Figure 2 – Fat-binding capacity of the amaranth flour with the different fineness of the grind: 1 –1.0 mm and less; 2 – 0.315 mm and less; 3 – 0.125 mm and less

As the results of the research showed, amaranth flour with a grind size of 1.0 mm and less possesses a higher binding capacity, which makes it possible to recommend its use in bakery recipes with a high-fat content.

The results of WBC are shown in Fig. 3.

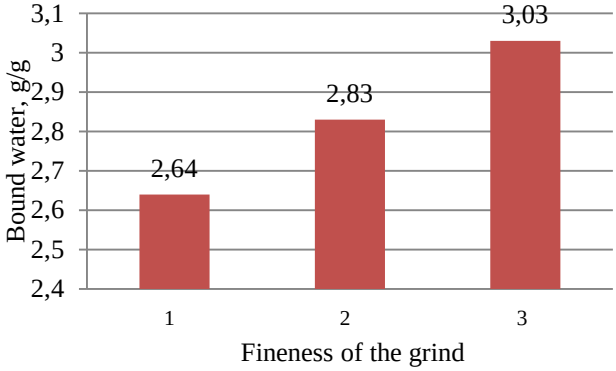

Figure 3 – Water-binding capacity of the amaranth flour with the different fineness of the grind: 1 –1.0 mm and less; 2 – 0.315 mm and less; 3 – 0.125 mm and less

As the results of the research showed that amaranth flour with a grind size of 0.125 mm or less has a better water-binding capacity in comparing with the rest samples, which allows expecting from bakery products with the introduction of amaranth flour of this size improved the shape and causes the expediency of its introduction into molded articles.

Thus, the study of the functional and technological properties of whole-hulled amaranth flour made it possible to draw the following conclusions:

- properties of flour from the extrudate, as well as the direction of its use, depending on the size of the grind;
- flour with a particle size of 0.125 mm and less is advisable to use in formulations of fat-containing flour confectionery and baked bread from high-quality wheat flour;
- flour with a size of 1.0 mm and less has a higher binding capacity, which allows us to recommend it in the technology of products with a high fat content and in shaped bakery products - due to low water binding capacity.

So, in further studies it was decided to use flour with a grind size of 0.125 mm and less. Figure 4 shows the obtained values of whiteness in mixtures of wheat flour of the highest

grade with flour of amaranth extruded with the following dosages: sample No. 1 - control (without amaranth flour); №2 - the ratio of wheat and amaranth flour 95:5; №3 - 90:10; №4 - 85:15; №5 - 80:20; №6 - 75:25; №7 - 70:30.

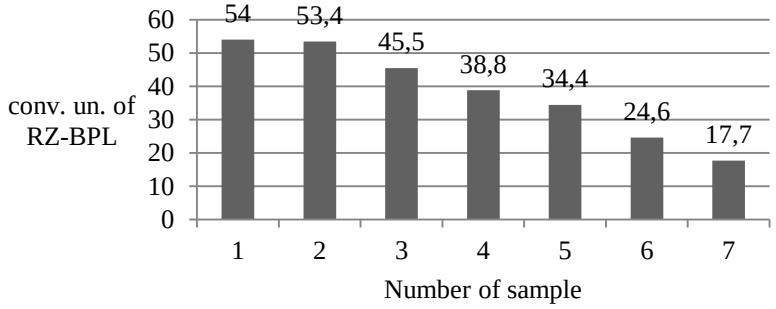

Figure 4 – Results of the study of whiteness in mixtures with wheat flour of the highest grade

Figure 5 shows the obtained values of whiteness in mixtures of wheat flour of the first grade with amaranth flour. The samples have the following relationships: No. 1 - control (without amaranth flour); №2 - the ratio of wheat and amaranth flour 95: 5; №3 - 90:10; №4 - 85:15; №5 - 80:20; №6 - 75:25; №7 - 70:30.

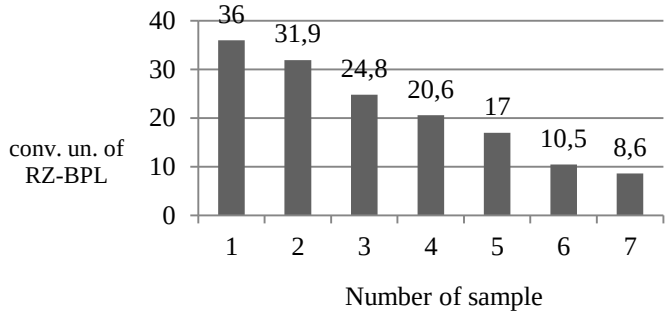

Figure 5 – Results of the study of whiteness in mixtures with wheat flour of the first grade

It was found that whiteness decreases with increasing dosage of amaranth flour in both cases. It was noted that a mixture of high-quality wheat flour with 15% amaranth flour has a whiteness of wheat flour of the first grade. Proceeding from this, it can be assumed that products baked from this mixture will not differ in color from the usual product. We assume that products made from 20% amaranth flour and 80% of the higher wheat grade will have a cream color in comparison with the traditional crumb color. The next indicator for the analysis was the content and quality of gluten, which affect the shape, condition of the crumb and other characteristics and largely determines the baking properties of the flour mixture. To assess it, the following indicators were determined: quantity and quality. Figure 6 shows the results of determining the content of gluten in mixtures of wheat flour of superior quality and flour from an amaranth extrudate. As the results of the studies show, an increase in the proportion of amaranth extrudate naturally leads to a decrease in the amount of gluten in the mixture. At the same time, a 20% dose can be considered a critical point, since further increase in the mass fraction of the amaranth extrudate determines the characteristics of the mixture, which does not allow providing traditional quality characteristics of the finished products.

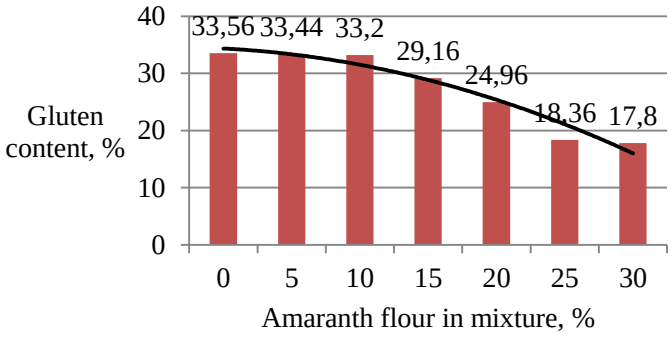

Figure 6 – The content of gluten in mixtures of wheat flour of highest grade and amaranth flour

Figure 7 shows the dynamics of changes in gluten content in mixtures of wheat flour of the first grade and amaranth.

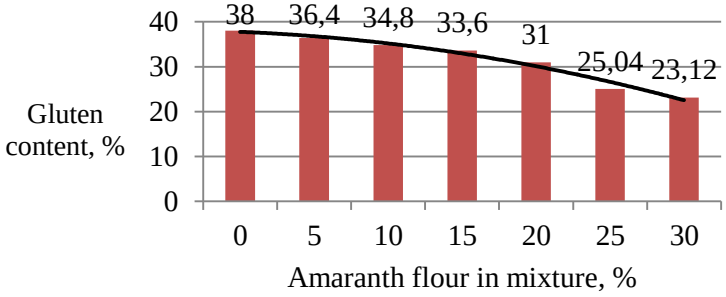

Figure 7 – The content of gluten in mixtures of wheat flour of first grade and amaranth flour

While maintaining the general dependence, the first grade of wheat flour baking can be mixed with flour from the amaranth extrudate in a ratio of 75:25. But at the same time it is necessary to pay attention to the fact that the sample of wheat flour of the first grade, accepted in the studies, initially had high baking properties. Next, the quality of gluten in the test mixtures was examined, results in Figures 8 and 9.

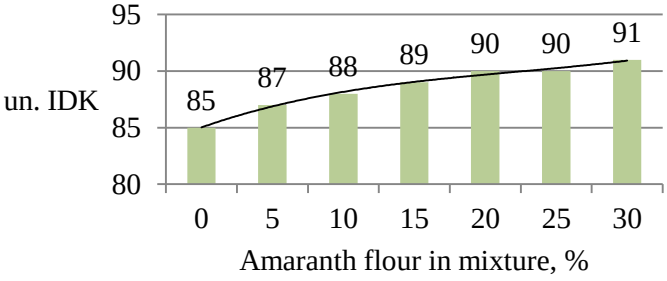

Figure 8 – Quality of gluten in mixtures of wheat bakery flour of highest grade and amaranth flour

The decrease in the quality of the gluten of flour mixture with increasing the proportion of amaranth extrudate is probably related to the water-absorbing capacity of the ingredients of the mixture. The studies conducted by us showed that the swallowing ability of the wheat flour sample of the highest grade is 1.97 g/g, while the amaranth extrudate is 3.88 g/g. Accordingly, the extrudate "pulls" water onto itself, preventing the formation of an elastic

gluten skeleton. It should be noted that the established change occurs in the limit of 6 units the IDK is unlikely to radically affect the quality of finished products.

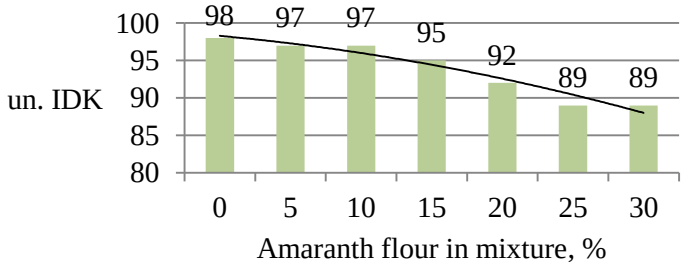

Figure 9 – Quality of gluten in mixtures of wheat bakery flour of first grade and amaranth flour

A different dependence was obtained for the flour mixture of wheat flour, baking and amaranth extrudate. But the flour sample initially had a much worse IDK characteristic. In addition to the redistribution of moisture (the water-absorbing capacity of the sample of wheat flour of the first grade was 2.11 g/g), the acidity parameters of the mixture of the activity of own proteolytic enzymes of flour could play a role in the dependence obtained. To confirm this dependence, a block of additional studies should be carried out that makes it possible to theoretically explain the regularities obtained by the influence of the amaranth extrudate on the qualitative characteristics of flour mixtures. But at the same time, it is necessary to note the individual nature of the effect of the enriching ingredients, depending on the characteristics of the batters used.

Conclusion

The conducted researches showed:

- the introduction of the amaranth extrudate naturally reduces the amount of gluten of the flour mixture. The dosage of the amaranth extrudate, which guarantees the traditional quality of baked goods, is largely determined by the characteristics of the batters used, but generally does not exceed 20-25 %, in our case it will be probably 15-20%;
- Amaranth extrudate also affects the quality of gluten, which is determined by its high water-absorbing capacity and the redistribution of moisture between the main biopolymers of the flour mix. But on the whole this influence is not so crucial as the amount of gluten.

In general, studies of functional-technological and baking properties have shown the possibility of forming high consumer properties of bakery and flour confectionery products with the introduction of extruded amaranth flour into the formulation.

DEVELOPMENT OF CURD PRODUCT ENRICHED WITH OAT BRAN

Antonina RYPNEVSKAYA*, Aleksandr DIACHKOV

Perm State Agro-Technological University, Agro-Technologies and Forestry Faculty, Department of Fruit and Vegetable Growing Storage and Processing of Agricultural Products, Russia
*Corresponding author: Antoninapavlovna@yandex.ru

Abstract

The most important task of any state is the preservation and promotion of the population'shealth.The health of every person and nation is mainly determined by their rations. The malnutrition impairs metabolism and functional capacity of the digestive, heart-vascular system, nervous system and other systems. The unfavorable ecological situation, extensive use of antibiotics and chemicals, stress and other factors leading to a violation to of normal intestinal microflora, digestion and metabolism, reduce immune activity in the human body and provoke growth of the disease. The article deals with the problem of dietary food deficit. Curd product with the addition of bran was developed for the solution of this problem. The advantages of using curd product and oat bran are analyzed,andthe main properties such asproduct-quality index, vitamin and mineral composition are shown. The quality indicators for the acceptance of raw milk and oat bran are presented. When working with a curd productphysicochemical and sensorystudies were carried out. All the studies were carried out in the laboratories of the Perm State Agro-Technological University, Russia.

Keywords:*Curd products, Oat bran, Diet, Dairy products, Health.*

Introduction

With malnutrition, metabolism is disrupted, as well as disrupting the digestive, cardiovascular, nervous and other systems. Adverse ecological situation widespread use of antibiotics and chemicals, stresses and other factors lead to violations of the normal microflora of the intestine, digestion and metabolism, which reduces the immune activity of the human body and contributes to the increase in the incidence. Recently, the issue of products for dietary nutrition, their development and introduction to the consumers has gained popularity. The deficit of these products is associated with the lack of knowledge of the population about them, as well as their small assortment. Improving the structure of nutrition and public health is one of the main concepts of the state policy in the Russian Federation and the countries of the world. For protein productsthe most suitable basis with dietary properties are dairy products, in particular curd and curd products (Penzinaetal.,2013). Curd product is the most balanced in composition, nutritional and biological value for a person's diet. Supplement the diet can be food fibers, vitamins, minerals can be by combining dairy raw materials with components of plant origin. The proteins in curd are more readily digested than the protein in milk. It has been estimated that regular milk is only **32% digested** after an hour in the digestive tract, **whereas 91%** of **curd**is digested within the same period of time. It is, therefore, an ideal diet for those with sensitive digestive systems, particularly young children and elderly persons. (VahRehVah., 2007). Technologically, the proteins of milk are its most important constituents. They play important, even essential, roles in all dairy products. The roles played by milk proteins are nutritional, physiological, and physicochemical. (Hui., 2006) Vegetable raw materials are represented by grain crops and products of their processing: flour, bran, cereals. Bran is anunwanted product of grain processing. It is the outer shell of cereal, which is valued for the high content of insoluble fiber, vitamins of group B, E, PP, macro- and microelements (iron, phosphorus, sodium, magnesium, calcium and potassium) (Zhetesov.,2017). The use of bran has a positive effect on the work of the body: digestion

improves; there is a clearing of the body of heavy metals, toxins; contribute to the elimination of toxins; lowers blood sugar; contribute to rapid satiety and well satisfy hunger (Penzina.,2013).

Materials and Methods

As a material for the research, raw milk, purchased on a domestic farm, was used. In the laboratory, a curd product was obtained from this raw material. In addition to the curd product, the main component was oat bran,it was added to the finished product in a percentage of 5%, 12% and 30% of the weight of the finished curd product**.**

Milk raw materials were investigated for sensoryindicators – taste, color, odor. A research was made of the physicochemical parameters – fat, SNF, protein, density, acidity, added water. To research the indicators of milk-raw materials, «Ekomilk M» a milk quality analyzer was used. The curd product, with the addition of oat bran, has also undergone sensoryand physicochemical research - taste, color, odor, consistency, acidity, moisture, proteins, fats, carbohydrates, energy value. To research the curd product, the following equipment was used –«K 139 VELPSCIENTIFICA» Kjeldahl Apparatus, drying cabinet laboratory SNOL, centrifuge Funke-Gerber Nova Safety.

The research was carried out in the laboratories of the Perm State Ago-Technological University at the Department of Fruit and Vegetable Growing, Storage and Processing of Agricultural Products, as well as in the researchLaboratory for the development of Agro-Technologies. This experiment was conducted in one repetition, as further study of the product continues. At the time of the experiment, four batches of each variant.

Results and discussion

The main component of the curd product is raw milk were the final result of the finished product depends on its quality and indices.

Sensory indicators of the quality of raw milk, investigated in accordance with GOST 31449-2013 «Raw cow's milk. Specifications» (Table 1).This standard applies to cow raw milk (hereinafter referred to as milk), subjected to primary treatment (purification from mechanical impurities and cooling to a temperature of (4 ± 2) ° C) after milking and intended for industrial processing.

Table 1.Sensory parameters of raw milk

Indicator name	Characteristic			
	GOST 31449-2013	Sample 1	Sample2	Sample3
Consistency	Homogeneous liquid without sediment and flakes	Homogeneous liquid without sediment and flakes	Homogeneous liquid without sediment and flakes	Homogeneous liquid without sediment and flakes
Taste and smell	Pure, without foreign smells and tastes, not peculiar to fresh milk. Allowed slight forage taste and odor	Pure, without foreign smells and tastes	Pure, without foreign smells and tastes	Pure, without foreign smells and tastes
Color	From white to light cream	White	White	White

According to the sensory indicators, milk raw materials meet the requirements presented in the Russian Federation.

Important indicators for assessing the quality of milk are also physicochemical studies GOST 31449-2013 «Raw cow's milk. Specifications» (Table 2).

Table 2. Physicochemical parameters of raw milk

Indicator name	Indicator value			
	GOST 31449-2013	Sample 1	Sample2	Sample3
Mass fraction of fat,%, not less than	2.8	2.98	3.01	3.07
Mass fraction of protein,%, not less than	2.8	2.99	3.00	2.98
Th^0	From 16.0 to 21.0	18.00	18.00	17.00
Nonfat milk solids (SNF), %, not less than	8.2	8.70	8.76	8.69
Clean group, not lower than	II	II	II	II
Density, kg/m^3, not lower than	1027.0	1029.95	1030.15	1029.85

Milk raw materials purchased on domestic farming meet all quality indicators and is a good raw material for the production of a curd product with the addition of oat bran. This milk produces a curd product with a fat content of 2.5%.

At the moment, a large number of bran is produced from different plant species. Oat bran is a biologically valuable product and for the balance of proteins, fats, carbohydrates and energetic value (Table3). When oat bran is added to the curd product, it is worth considering the percentage ratio in the amount of 5%, 12% and 30%.

Table 3.Component composition of bran by species

Indicator name	Rice	Oat	Wheat	Rye
Energy value (calories)	316.00	246.00	216.00	221.00
Proteins (g)	13.35	17.30	15.55	11.20
Fats (g)	20.85	7.03	4.25	3.20
Carbohydrates (g)	28.90	66.20	64.51	32.00

Oat bran is an appropriate option, since it contains an average number of kilocalories, in contrast to others, contains the greatest amount of protein, which is ¼ of the daily intake rate.

The positive side of oat bran is the amount of carbohydrates in it. Carbohydrates are contained in the form of fiber, and it slows the absorption of sugar and fat, reduces the release of insulin in response to carbohydrate food, improves intestinal motility and helps maintain a sense of satiety (Grenchuk., 2018).

The main component of this product is a curd product, oat bran should be added to its composition. Curd product is a fermented milk product that is made from clabber by heating and removing whey. This product is traditional for Eastern and Northern Europe.

Curd product contains essential amino acids, vitamins A, B1, B2, B4, B5, B6, B9, PP, C, E, B12, H beta-carotene, rich in folic acid, calcium, iron, sodium, magnesium, copper, zinc, fluorineand phosphorus. Due to its rich composition, the curd product is well absorbed and improves the activity of the gastrointestinal tract. The recipe of the curd product with the addition of oat bran has two main components(Krus.,2006) (Table 4).

Table 4.The recipe for a curd product with the addition of oat bran

Product (g)	Control	Sample 1(5%)	Sample2 (12%)	Sample3 (30%)
Curd product	100	95	88	70
Oat bran	-	5	12	30
In total		100		

Curd product is obtained from raw milk by ripening and further heat treatment. Oat bran is steamed with hot water at t = 100˚C. The finished product is checked by independent experts, onsensory indicators (Table 5). The curd product is checked for quality indicators in accordance with GOST 31453-2013 «Tvorog. Specification».The standard applies to cottage cheese, packaged in a consumer container, made from cow's milk and / or dairy products, intended for direct use in food.

Table 5.Sensory parameters of the curd product with the addition of bran

Indicator name	GOST 31453-2013	Control	Sample 1(5%)	Sample2 (12%)	Sample3 (30%)
Consistency and appearance	Soft, smearing or crumbly with or without detectable particles of milk protein	Soft, smearing	Soft, smearing, small inclusions of bran	Soft, smearing, significant presence of bran	Soft, smearing, with a lot of bran
Taste and smell	Pure, dairy, without foreign flavors and odors	Pure, dairy, without foreign flavors and odors	Sour-milk, with a slight aftertaste of oat bran	Sour-milk, with a taste of oat bran	Sour-milk, tastes of oat bran predominate
Color	White or with a cream tint, uniform throughout the mass	White, uniform throughout the mass	White, with small patches of brown	White, with significant pieces of brown	Light cream, with brown bran particles

The control sample fully complies with GOST 31453-2013 «Tvorog. Specification», this means that the raw milk of good quality and deviations in the production of the curd product is not observed. Appearance of all samples varies considerably (Picture 1).

Sample 1 (5%). Has a slight external difference from the control sample, in appearance there are insignificant inclusions of oat bran, the consistency remained unchanged, there is a slight taste of bran, the color is white with brown impregnations.

Sample 2 (12%). This sample has a more pronounced taste of oat bran, in appearance there is a noticeable increase in the percentage of bran, compared to sample 1 and control. The color of the curd product is white, but with a high content of brown spots.

Sample 3 (30%). Appearance immediately shows that the curd product contains a significant amount of oat bran. The color became light cream with brown bran stains, a pronounced taste of the presence of oat bran. The appearance of this sample is immediately distinguished from the others in appearance.

Picture 1. Appearance of the samples under study
Control sample(A); sample 1 (B); sample 2 (C); sample 3 (D).

In addition to the sensory changes, the component composition of the curd product was also changed due to the addition of oat bran (Table 6).

Table 6. Ingredients of the curd product with the addition of bran

Indicator name	GOST 31453-2013	Control	Sample 1 (5%)	Sample2 (12%)	Sample3 (30%)
Proteins (g) not lower than	17.2	22.83	22.20	21.22	19.08
Fats (g) not lower than	1.80	2.50	2.50	2.50	2.50
Carbohydrates (g) not lower than	1.40	1.40	4.63	10.40	20.79
Humidity (%), not more than	76.00	55.20	42.10	39.87	34.50
Th^0, not more than	230	130	130	130	130
Energy value (calories)	101.00	101.00	102.25	104.40	105.50

All samples have the same fat content, this is due to the small amount of fat content in oat bran and when mixing bran with curd product, the fat remains unchanged.The calculation of the smallest significant difference (Table 7).

Table 7. Fat content in samples

Indicator name	Repetition				Sums V	Average value
	1	2	3	4		
Control	2.7	2.6	2.3	2.4	10	2.50
Sample 1 (5%)	2.2	2.6	2.5	2.5	9.8	2.50
Sample2 (12%)	2.3	2.4	2.8	2.7	10.2	2.50

Conclusions

Curd products with the addition of oat bran can be used in dietary nutrition. This product contains a small amount of fat, but a large amount of carbohydrates and proteins, which gives this product a good reputation. The recommended sample is sample 3 (30%). This sample has a pronounced taste of oat bran, which gives the product an unusual taste. According to the component composition, the sample is high-grade in proteins and carbohydrates, which is the most important in dietary nutrition.

Abstract

Regardless of their major role in crop productivity, increased and long-term use of mineral fertilizers in agricultural production has raised concerns causing numerous environmental problems. This could be overcome by partial replacement of mineral fertilizers using bacterial inoculants, which could lead to the improvement of physical, chemical and biological soil properties, as well as help to ensure that the supply of nutrients contributing to optimized yield of crops. The study evaluated the effect of application of different rates of composite mineral fertilizers and their combination with bacterial inoculants (N-fixing *Klebsiella planticola* and *Enterobacter* spp.) on macronutrients content in straw of winter wheat and its yield. Unfertilized treatment was used as a control. The contents of nitrogen, phosphorus, potassium and crude proteins in plant samples were determined at the beginning of tillering and in full grain maturity stage, at the end of the wheat vegetation. Measuring of the straw yield was carried out at the end of the vegetation. The results of the study showed that the use of high rates of composite mineral fertilizers and their combination with bacterial inoculants resulted in increased contents of nitrogen, phosphorus, potassium and crude proteins in the wheat straw, which was noticeably observed in the stage of tillering. The highest increase in the straw yield was obtained by the same mentioned treatments, although the combination of bacterial inoculants and low rates of mineral fertilizers resulted in higher yields comparing to the use of solely low rates of mineral nutrients.

Keywords: *Wheat straw, yield, chemical composition, bacterial inoculants, composite mineral fertilizers.*

Introduction

Wheat (*Triticum aestivum* L.) is grown on every continent thanks to the large polymorphism. Along with maize, wheat represents a major crop in agricultural production in Serbia, where its cultivation in the period 2000-2009 occupied an average area of 600,171 ha with an average grain yield of 3.47 t ha^{-1} (Jocković *et al*., 2010; *Mladenov et al., 2011*). The yield and quality of wheat grain depend mainly on the balanced mineral nutrition, which is correlated with the type of soil, climate factors in the region and other agroecological factors. Nevertheless, creating an optimal conditions for growing wheat in order to achieve higher grain yields is primarily related to application of nitrogen fertilizers (Đekić *et al*., 2017). Similar could be said for the wheat straw, whose yield, besides mineral nutrition, depends on variety, soil and climate conditions. Wheat straw is the agricultural product obtained from different parts of wheat plant like stem, leaves etc., after the grain and chaff have been removed. Straw makes up about half of the yield of wheat. It has many uses, primarily as fuel, livestock bedding and fodder. An accurate content of macro and micronutrients in wheat straw can vary from cultivar to cultivar, stages of plant growth, climatic conditions and the nature of soil and fertilizers used (Safdar *et al*., 2009; Yasin *et al*., 2010; Saleem Khan and Mubeen, 2012).

Regardless of their major role in soil fertility and wheat productivity, increased use of mineral fertilizers in agricultural production can causes environmental contamination (Acosta-Martinez and Tabatabai, 2000; Alizadeh and Ghadeai, 2006). The problems concerned can be overcome by partial replacement of these fertilizers by application of microbial inoculants, in order to inhibit or stimulate certain cellular processes, including mineralization ones, thus leading to the improvement of physical, chemical and biological soil properties (Milošević *et al*., 2003; Pešaković *et al*., 2008). Regarding the preceding comments, the main purpose of this study was to evaluate the effect of different rates of composite mineral NPK fertilizers (N:P:K=15:15:15) and their combination with selected bacterial inoculants on macronutrients content in wheat straw and its yield.

Material and methods

The study was conducted on Mladenovac experimental station of Institute of Soil Science, located about 55 km south-east from Belgrade in Serbia, in 2006/2007. Average monthly air temperatures and precipitation sums for the investigated period along with multi-annual average (1990-2007) are presented in Table 1. Monthly air temperatures during the vegetation period of wheat (October 2006 - July 2007) were considerably higher in comparison with multi-annual average. The distribution of precipitation from the period January - June in 2007 was favorable, except in April, when it was measured only 3.8 mm of precipitation.

Table 1. Average monthly air temperatures and precipitation sum for the period 2006/2007 and multi-annual average.

Month	Year				Average (1990-2007)

Average	12.8	14.0	-	-	12.7	-
Total	-	-	749.3	839.0	-	688.6

The studied type of soil was Eutric Cambisol (WRB, 2014). The experiment was set up in a randomized block design on 9 x 6 m^2 plot size, with three replications, based on the following variants: control (Ø, non-fertilized soil); 60 kg ha^{-1} N and P_2O_5, and 40 kg K_2O ha^{-1} (N1); 120 kg ha^{-1} N, P_2O_5 and K_2O (N2); *Enterobacter* sp. strains + 60 kg ha^{-1} N and P_2O_5, and 40 kg K_2O ha^{-1} (ES+N1); *Enterobacter* sp. strains + 120 kg ha^{-1} N, P_2O_5 and K_2O (ES+N2); *Klebsiella planticola* + 60 kg ha^{-1} N and P_2O_5, and 40 kg K_2O ha^{-1} (KP+N1); *Klebsiella planticola* + 120 kg ha^{-1} N, P_2O_5 and K_2O (KP+N2). Winter wheat (cv. Evropa 90) was used as a test plant in the trial and sown and harvested in optimal terms (1st decade of November in 2006, 3rd decade of June in 2007, respectively). Mineral fertilization was carried out manually for each experimental plot using composite NPK fertilizer in relation N:P:K = 15:15:15. Nitrogen (N) fertilizer was applied in the form of urea with 46% N, phosphorus (P) - in the

form of monoammonium phosphate (MAP) with 52% P_2O_5 and 11% N, and potassium (K) - as a 40% potassium salt (potassium chloride, KCl). The established amounts of potassium and 1/3 of nitrogen fertilizer were applied in the fall 2006 before sowing, and the remaining 2/3 of nitrogen fertilizer was applied during March in 2007 at the stage of tillering. The procedure for obtaining the bacterial inoculums for fertilization was previously described in study of Stanojković *et al*. (2012). Bacterial fertilization was carried out using plastic haversack sprinkler with 300.00 cm^3 m^{-2} of diluted liquid bacterial inoculums made from the pure cultures of associative N-fixing bacteria *Klebsiella planticola* (strain TSHA-91) and *Enterobacter* strains KG-75 and KG-76 and tap water. The first soil and foliar fertilization with bacterial inoculums was carried out in the stage of 2-3 formed leaves, and the second - in the tillering stage, a few days after fertilizing with mineral nitrogen. *K. planticola* was obtained from the stock culture of the Microbiology Laboratory of Faculty of Agronomy (Čačak, Serbia) and cultivated for 24 h at 28°C ± 1 on the slanting nutrient medium, while *Enterobacter* strains were obtained from the stock culture of the Microbiology Laboratory of the Center for Small Grains (Kragujevac, Serbia), where they have been isolated from the rhizosphere of wheat. These strains were cultivated for 48 h at 28°C ± 1 on the slanting nutrient medium. The preliminary analysis of the study soil, after the samples were air-dried and passed through a sieve, included the following chemical parameters: soil acidity (pH in H_2O and 1M KCl, v/v - soil:H_2O=1:5, soil:1M KCl=1:5) was analyzed potentiometrically, using glass electrode (SRPS ISO 10390, 2007); total nitrogen (N) was analyzed on elemental CNS analyzer Vario EL III (Nelson and Sommers, 1996); available phosphorus (P_2O_5) and potassium (K_2O) were analyzed by Al-method according to Egner-Riehm (Riehm, 1958), where K_2O was determined by flame emission photometry and P_2O_5 by spectrophotometer after color development with ammonium molybdate and stannous chloride; humus content was determined using Tiurin's method, modified by Simakov (Ostrowska *et al*., 1991). The yield of wheat straw without grain and chaff from each experimental plot was measured and determined directly on plots at the end of the vegetation and calculated into t ha^{-1}. The content of macronutrients in wheat samples was determined at the beginning of tillering (vegetation stage I, S1) and at the end of the vegetation period (vegetation stage II, S2). The content of phosphorus (P) and potassium (K) was determined by so called "wet" combustion, i.e. they were heated to boiling with the mixture of concentrated sulfuric (H_2SO_4) and perchloric ($HClO_4$) acids. In the obtained solution, P was determined by spectrophotometer with molybdate, and K – by flame emission photometry (Jakovljević *et al*., 1985). The content of nitrogen (N) was analyzed using elemental CNS analyzer, Vario model EL III (Nelson and Sommers, 1996), while the content of crude proteins was calculated on the basis of N content according to Licitra *et al*. (1996), using the following formula: crude proteins (%) = N (%) x 6.25 (factor for conversion of nitrogen content to crude protein). The obtained data on soil properties were presented as arithmetic means of three replicates, standard deviation values and intervals. The effects of different fertilization treatments on chemical parameters tested and yield were evaluated using ANOVA (SPSS 20.0, Chicago, USA), followed by Duncan's Multiple Range Test (DMRT). Significant differences between means were tested by the LSD test at P = 0.05 and P = 0.01.

Results and discussions

The main chemical characteristics of the study soil are presented in Table 2. According to the reference values (Šestić *et al*., 1969), the soil is characterized by very acid reaction with pH in 1M KCl 4.06, high available potassium, medium to high available phosphorus, and medium humus and total nitrogen supply.

Table 2. Main chemical characteristics of the studied Eutric Cambisol

Chemical parameter	Value (means ± standard deviation)	Intervals
pH in H_2O	4.90±0.03	4.87-4.92
pH in 1M KCl	4.06±0.05	4.00-4.10
Total N (%)	0.136±0.005	0.132-0.141
Humus (%)	2.19±0.01	2.18-2.19
Available P_2O_5 (mg $100g^{-1}$)	15.73±0.31	15.51-16.09
Available K_2O (mg $100g^{-1}$)	25.30±0.30	25.08-25.65

By analyzing the content of macronutrients in plant material at the end of the wheat vegetation period it was determined that the content of total nitrogen, phosphorus, potassium and proteins significantly depended on the fertilization treatment applied (Table 3).

Table 3. Effect of the fertilization treatments on macronutrients content in wheat straw and its yield (in t ha^{-1}).

Application of high rates of mineral NPK fertilizers and their combination with bacterial inoculants has caused a significant increase in the share of nitrogen, phosphorus, potassium and crude proteins in the plant material compared to the other tested variants, which was noticeably observed in the stage of tillering, the vegetation period in which the plant growth and accumulation of nutrients are the most intensive (Čurić, 1982). This excess of microbiologicaly fixed nitrogen along with higher amounts of mineral nitrogen influenced positively on the accumulation of macronutrients in the study plant material, which is in accordance with previous researches (El-Sirafy *et al*., 2006; Behera and Rautaray, 2010).

The present study also indicated a little increase in the share of macronutrients in plant material in variants where microbial inoculation of soil and plant along with low rates of mineral NPK fertilizers was applied comparing to the application of solely low rates of mineral fertilizers. Similar results were obtained in the study of Cvijanović *et al*. (2007). The analysis of the yield of wheat straw (based on Duncan's test) showed highly significant yield differences between the applied fertilization treatments (Table 3). The highest increase in

yield was obtained by combined application of bacterial inoculants used and high rates of mineral NPK fertilizers. This was also observed in treatments with combined usage of bacterial inoculants and low rates of mineral NPK fertilizers where it was obtained higher yield comparing to the traetments with solely low rates of mineral fertilizers. Behera and Rautaray (2010) also found higher straw yields in biofertilizers + 50% NPK treatments than in treatments with solely 50% NPK. According to Josipović *et al.* (2005), the character of the applied fertilizers effects on the yield of crops also depends on the weather conditions specific to each year. It is assumed that good distribution of rainfall and temperature in the period November 2006 - June 2007 contributed largely to the achieved yields of wheat straw in the investigated agro-ecological conditions.

Conclusion

The present study demonstrated the significant positive effects of combined application of bacterial inoculants studied (*Klebsiella planticola* and *Enterobacter* spp.) and high and low rates of the composite mineral fertilizers on the yield of wheat straw (without grain and chaff). The same results were obtained regarding the effects of the mentioned applied combinations on the contents of total nitrogen, phosphorus, potassium and crude proteins in the analyzed plant material, which was noticeably observed in the stage of tillering. These data suggest that the studied bacterial inoculants can be used in further studies as the potential agents of new biofertilizers for improved wheat production and other agriculture crops.

Abstract

The oriental fruit moth *Grapholita (Laspeyresia, Cydia) molesta* Busck (Lepidoptera: Tortricidae), also known as the oriental peach moth, is one of the most destructive and economically important pests of stone and pome fruits worldwide. In Serbia, *G. molesta* represents one of the most damaging pests of peach fruits. In this work, pest susceptibility to insecticides based on indoxacarb, deltamethrin, spinetoram, and azadirachtin was assessed. Field trials were carried out in Vojvodina, the northern region of the Republic of Serbia, at localities Čerević and Mala Remeta. Trials were designed according to the EPPO method, following the pest biology and crop phenophase. Before and during the experiment, the flight of *G. molesta* adults was monitored using pheromone traps to determine the optimal timing for insecticide distribution. Products based on indoxacarb (Avaunt 15 EC), deltamethrin (Decis 2.5 EC), spinetoram (Delegat 250 WG) and azadirachtin (Ozoneem Trishul 1% EC) were 0.33, 0.5, 0.2 and 5.0 L ha^{-1} sprayed, respectively. Assessment of spray distribution efficiency was based on the number of fruit damaged by caterpillars, on a base of 100 fruits per repetition scrutiny. The results were processed using ANOVA and Fisher LSD test, while the efficiency was determined according to Abbott. Spraying application showed a efficiency in both trial localities in between 79-87% (indoxacarb), 74-91% (deltamethrin), 84-88% (spinetoram) and 74-80% (azadirachtin), compared with the untreated control sample. The highest efficiency at both sites was given by products based on deltamethrin and spinetoram, while azadirachtin had the lowest efficiency. Assessment of the number of damaged fruits was done for the all investigated insecticides, and it was at a significantly lower level in all treatments in comparison to control indicating the high sensitivity of the *G. molesta* to the tested insecticides.

Keywords: *Prunus persica, insects, plant protection, pesticides*

Introduction

Peach (*Prunus persica* L.) is one of the most widespread species of fruit in the world. Orchards are located in moderately warm areas of Europe and Asia, and in other continents also. Perspectives for growing peaches in the Republic of Serbia are very good within the areas that are known as favourable for its cultivation. Due to its rapid grow rate, peaches achieves maximum growth with a full production capacity of fruits (30, 40 t/ha and more) in six growing seasons. Despite the production is not endangered by many pests, that lead to a minimal use of chemical control actions (Mratinić, 2012), there are few pests that are often encountered during the orchard management. The most significant peach pests are Oriental fruit moth (*Grapholita molesta*), Peach twig borer moth (*Anarsia lineatella*), Aphids (*Myzus persicae* and *Brachycaudus persicae*) and the Red fruit spider (*Panonychus ulmi*). The oriental fruit moth *Grapholita (Laspeyresia, Cydia) molesta* Busck (Lepidoptera: Tortricidae), also known as the oriental peach moth, is one of the most destructive and economically important pests of stone and pome fruits worldwide. The oriental fruit moth is regularly found

in all peach plantations in central Serbia and is the economically important pest of the peach fruit production (Stamenković, 2005). In this contribution we assess the pest susceptibility to insecticides based on indoxacarb, deltamethrin, spinetoram and azadirachtin.

Material and Methods

Field trials for insecticidal control of *G. molesta* were carried out in Vojvodina, the northern region of the Republic of Serbia, at localities Čerević and Mala Remeta in 2017, in the 5 year old peach orchards, variety "Royal Gem". The trials were set before the fruit caterpillars infestations following the pest biology and crop phenophases, and designed according to EPPO method. The flight of *G. molesta* moths was monitored using the pheromone traps before and during the experiment, to determine the optimal timing for chemical protection. Products based on indoxacarb (Avaunt 15 EC), deltamethrin (Decis 2.5 EC), spinetoram (Delegat 250 WG) and azadirachtin (Ozoneem Trishul 1% EC) were foliar-applied at a rate of 0.33, 0.5, 0.2 and 5.0 L ha^{-1}, respectively, and compared with the untreated control sample. Insecticide distributions were performed on May 27, 2017. (Čerević) and on May 29, 2017. (Mala Remeta), at the beginning of the emergence of caterpillars during the second brood. Insecticide distributions were carried out with a Solo® backpack sprayer with an estimated use of 1000 litre of water/ha. Assessment of spray efficiency was based on the number of fruit damaged by caterpillars, with an overview of 100 fruits per repetition (two weeks after treatment and before harvest). The results were processed using ANOVA and Fisher LSD test for a confidence interval of 95% in statistical software R. ver 3.2.2, while the efficiency was determined according to Abbott.

Results and Discussion

The results of the efficacy test for Decis 2.5 EC, Delegat 250 WG, Avaunt 15 EC and Ozoneem Trishul 1% EC in the control of the oriental fruit moth (*G. molesta*) in peach plantations at localities Mala Remeta and Čerević are shown in table 1. The efficacy of the insecticides 14 days after treatment at locality Mala Remeta ranged from: 82.4 % (Decis 2.5 EC), 88.2% (Delegat 250 WG), 82.4% (Avaunt 15 EC) and 76.5% (Ozoneem Trishul 1% EC). After 24 days, the efficacy ranged ranged from: 73.7 % (Decis 2.5 EC), 84.2% (Delegat 250 WG), 78.9 % (Avaunt 15 EC) and 73.7% (Ozoneem Trishul 1% EC). The efficacy of the insecticides 14 days after treatment at the Čerević site ranged from: 91.3 % (Decis 2.5 EC), 87.0% (Delegate 250 WG), 82.6% (Avaunt 15 EC) and 78.3% (Ozoneem Trishul 1% EC). After 24 days of treatment, the efficacy ranged from: 90.3 % (Decis 2.5 EC), 83.9% (Delegat 250 WG), 87.1% (Avaunt 15 EC) and 80.6% (Ozoneem Trishul 1% EC).

Based on the results achieved, all the applied preparations showed satisfactory efficacy in the control of *G. molesta*. At both localities, the Ozoneem Trishul 1% EC (azadirachtin) showed the lowest efficacy and the highest was recorded in tests with Decis 2.5 EC (deltamethrin) and Delegate 250 WG (spinetoram). Although azadirachtin showed the slightly lower efficacy, its significance in pest management is reflected through the characteristics which it owns: natural (botanical) product, definitely non-toxic, 100% biodegradable, environment-friendly, entirely safe for humans and beneficial insects. The number of damaged fruits in both evaluations at the localities Mala Remeta and Čerević, was significantly lower to control which indicates a high sensitivity of the oriental fruit moth population to the studied insecticides.

The control of these tortricids mainly relies on insecticide sprays (Knight and Light, 2013), but also this control mean is threatened by the widespread development of resistance (Rodríguez et al., 2011). In 2014, six experiments were carried out in highly infested orchards in Emilia Romagna (Italy) in order to assess the efficacy of spinetoram in control of the *Cydia pomonella*. The results showed the significant activity of spinetoram with a significant reduction of the pest population (Boselli and Scannavini, 2014). Results of field experiments

(Marčić et al., 2009) have indicated a high efficacy of azadirachtin (NeemAzal-T/S) in control of *Cacopsylla pyri* and *Panonychus ulmi*. The effectiveness of insecticides (deltamethrin and indoxacarb) applied to larvae of the codling moth, *Cydia pomonella* L, was tested by Pasquier and Charmillot (2003). Both insecticides were toxic to the pest, which produced 88.6% (indoxacarb) and 99.5% (deltamethrin) mortality to codling moth larvae. The efficacy studies in chemical control of *G. molesta* should be permanent. Monitoring of the sensitivity for investigated species will take into consideration the tolerance, as well as the cross-resistance, have already been recorded worldwide (Charmilot et al., 2003).

***** $\bar{x}$ - -average number of damaged fruits; Sd± - standard deviation; E%-efficacy;

Conclusions

Based on the conducted tests to control the oriental fruit moth (*Grapholita molesta*) in two sites in Republic of Serbia (Mala Remeta and Čerević) during 2017, we propose the following conclusions:

- Results indicate high efficacy of all scrutinized insecticides: indoxacarb (Avaunt 15 EC), deltamethrin (Decis 2.5 EC), spinetoram (Delegat 250 WG) and azadirachtin (Ozoneem Trishul 1% EC), both evaluated 14 and 24 days after treatment.
- Products based on deltamethrin and spinetoram showed the highest efficacy, while azadirachtin had the lowest efficacy.
- Assessment of the number of damaged fruits for the all studied insecticides, reported a significantly lower level of infestation in comparison to the control, indicating a high sensitivity of the *G. molesta* to the tested insecticides.

Abstract

In this study, a method for the determination of indoxacarb residues in peach fruits was developed and validated. Indoxacarb belongs to oxadiazine insecticides voltage-dependent sodium channel blockers, IRAC 22A. Maximum residue level (MRL) for indoxacarb in peach fruits, set by EU legislation is 1 mg/kg. For determination of indoxacarb residues, the QuEChERS method coupled with high-performance liquid chromatographic (HPLC) analysis were carried out. The HPLC Agilent 1100 system with diode array detection and Zorbax Eclipse XDB-C18 column (50 mm × 4.6 mm, 1.8 μm) were used. The mobile phase was water and acetonitrile (25:75). The flow rate was maintained at 1.0 ml/min in isocratic mode and the injection volume was 20 μl. Chromatograms were extracted at 310 nm. Under these conditions retention time of indoxacarb was 1.501 min. Method validation was performed taking into consideration linearity, recovery, precision, matrix effect, limits of detection and quantification, completely fulfilling the SANTE/11813/2017 criteria. The limit of detection and limit of quantification were 0.006 mg/kg and 0.018 mg/kg, far below the MRLs established for indoxacarb. The average recovery ranged from 83.3 to 91.6%, for three fortification levels. The precision of the method, expressed as RSD, was 0.1% and the matrix effect was 102.39%. The results obtained in this study confirm that the proposed method can be used for the determination of indoxacarb residues in peach fruits.

Keywords: *indoxacarb, peach, residues, method validation.*

Introduction

Peach production is obstructed by a great number of pests and diseases. According to significance and frequency of occurrence, *Cydia molesta*, the Oriental fruit moth or peach moth proved to be the most important pest. First damages are visible on young shoots as wilting and drying. Symptoms on fruits, mostly made by larvae of the following generations are visible later (Gvozdenović, 1997). Lack of the adequate protection causes significant and often, even complete decay of the plantation.

With the aim of *Cydia molesta* population control in peach plantation, products based on dimethoate, chlorpyrifos, α-cypermethrin, deltamethrin, λ-cyhalothrin, pyriproxyfen and chloranthraniliprole were registered. Waiting period of these products is within the interval of 14-28 days.

As many years lasting use of products belonging mainly to pyrethroids causes the occurrence of Cydia molesta populations resistant to these compounds, the aim is to introduce new active ingredients with different action mechanism, such as insecticide indoxacarb. The mechanism of action of indoxacarb consists in blocking sodium channels, which leads to the cessation of feeding, paralysis and death of the insect. It acts primarily digestively, but it has also contact action (MacBean, 2012). According to IRAC classification, it belongs to the group 22,A (IRAC, 2017). MRL for indoxacarb in peaches in EU (Anonimus, 2018), as well in the Republic of Serbia (Official Gazette, 2018), is 1.0 mg/kg, with 14 days waiting period of products based on indoxacarb. Indoxacarb residues are expressed as a sum of indoxacarb and their R enantiomer.

Inadequate use and failure to comply waiting period can cause the occurrence of residues of used products for crop protection in the quantity above MRL. Due to this, control of their content in agricultural products by use of corresponding methods is extremely important. According to the available literature data, the analysis of indoxacarb residues in different products of plant and animal origin has been accomplished by use of GC/EC and LC-MS/MS. After extraction of the samples with acetone and n-hexane (1:2 v:v), purification was accomplished by use of SPE cartridges. Limit of detection (LOD) of this method is 0.0015 mg/kg and 0.0006 mg/kg for GC-ECD, i.e. LC-MS/MS, and the achieved yield of extraction was 72.08 and 113.74% (Xu *et al*., 2008). Determination of indoxacarb enantiomers in cucumber, tomato, apple, pear, and soil samples were performed using high performance liquid chromatography and a Chiralpak AS-H column with n-hexane-ethanol (95 + 5, v/v) as the mobile phase (Cheng *et al*., 2010). In cabbage, indoxacarb was extracted using standard QuEChERS method (Urvashi *et al*., 2012). The objective of this study was validation of the method for determination of indoxacarb residues in peach fruits.

Material and methods

Chemicals and standard solutions

Analytical standard of indoxacarb 97% purity were obtained from Dr Ehrenstorfer, Germany. Acetonitrile (MeCN; HPLC grade) was purchased from "J.T.Baker" (Darmstadt, Germany), while ultrapure water was obtained from TKA apparatus (Germany). The dispersive SP extraction (Cat. No. 5982-5650) and clean-up (Cat. No. 5982-5356) kits for QuEChERS sample preparation were purchased as ready-to-use from Agilent Technologies (USA). A stock solution of indoxacarb was prepared in acetonitrile at a concentration of 91 μg/ml. Working standard solutions for HPLC analysis were prepared by appropriately diluting the stock solution with acetonitrile, achieving concentrations from 0.036-0.91 μg/ml. Stock solutions were stored at −20 ± 2°C, and working standard solutions were stored in the dark ⩽4°C.

Sample preparation

For the analysis untreated peach fruit samples was used. Untreated samples were previously crushed and homogenized. For the recovery experiment, such prepared sample (10 g), the adequate quantity of indoxacarb standard of the end concentration of 0.1, 0.5 and 0.91 mg/kg was added and left in the fridge overnight. The extraction of indoxacarb from peach fruits was carried out with QuEChERS method (Anastassiades et al., 2003; Lehotay, 2007). Briefly, 10 ml of acetonitrile was added, vigorously shaken for 1 minute manually, then 1 minute on vortex, after which followed adding of prepared buffer mixture of salt (Agilent Cat. No 5982-5650). It was immediately intensively shaken 1 minute by hand and 1 min on the vortex. Then, the cuvettes were transferred to the ultrasonic bath for 10 minutes and centrifuged for 5 min at 3000 rpm (Figure 1).

Figure 1 Determination of indoxacarb in peach fruits – extraction and clean-up

An aliquot of 6 ml was transferred from the supernatant to a centrifuge tube and cleaned by dispersive solid-phase extraction with 900 mg of magnesium sulfate, 150 mg of PSA and graphitized carbon black. Afterward, centrifugation was carried out at 3000 rpm for 5 min. An aliquot (3 ml) from the supernatant was evaporated till volume of 1 ml, filtered through a 0.45 μm PTFE filter (Millipore, USA) and then analyzed by HPLC–DAD.

Apparatus and chromatographic analysis

Indoxacarb residue analysis was performed with Agilent technologies 1100 Series high-performance liquid chromatographic system equipped with a diode array detector, while the separation was performed on a C18 column (50 × 4.6 mm, 1.8 μm). The mobile phase was (water and acetonitrile, 25:75, v/v) with a flow rate of 1.0 ml/min and detection wavelength of 310 nm.

Results and discussion

The method for the determination of indoxacarb is based on use of reverse-phase high performace liquid chromatography. In figures 2 and 3 are presented chromatograms of indoxacarb standard in acetonitrile and in peach matrix, as well as their overlapped spectra (Picture 4), under the aforementioned conditions.

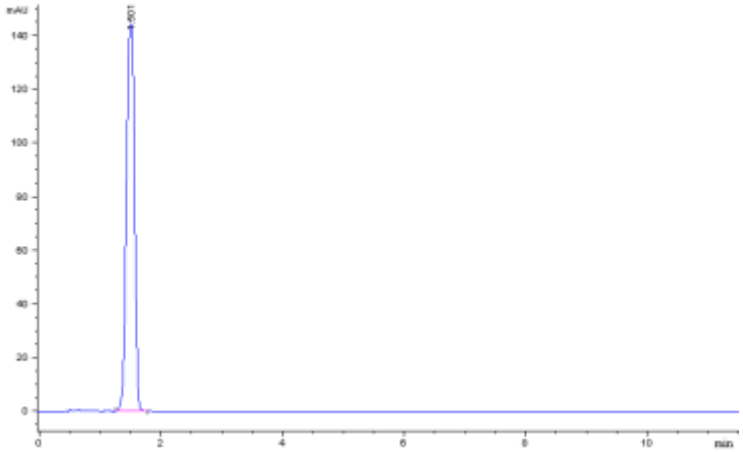

Figure 2 Chromatogram of standard indoxacarb standard solution in acetonitrile with a mass concentration of 1.0 μg / ml

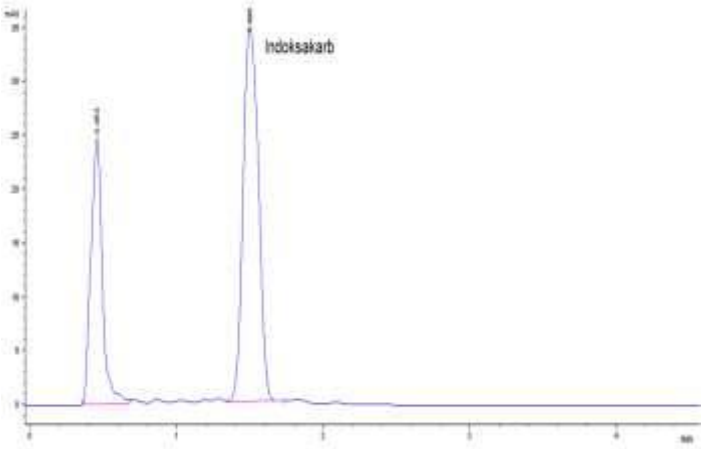

Figure 3 Chromatogram of indoxacarb standard solution in peach matrix with a mass concentration of 0,2 μg/ml

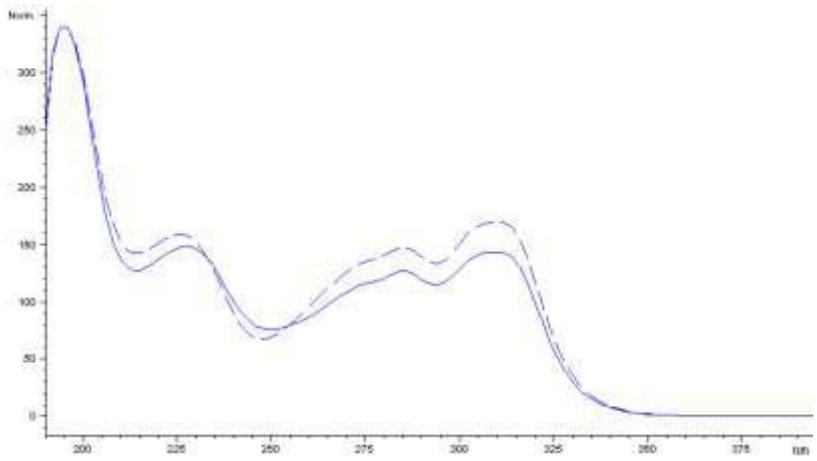

Figure 4 Indoxacarb overlapped spectrum in acetonitrile solution and in a peach matrix

The retention time of indoxacarb under the set conditions was found to be 1.501 min. Evaluation of the chromatographic conditions was carried out through the detector response linearity, the precision, and accuracy of the method, the matrix effect, as well as by determination of the detection and quantification limits.

Table 1 Validation parameters for indoxacarb determination in peach fruits

Linearity, 0.036-0.91 µg/ml	**Precision, RSD**	**Recovery**	**LOD**	**LOQ**	**ME**
r^2=0.996	0.01%	83.3 to 91.6%	0.006 mg/kg	0.018 mg/kg	102.4%

The linearity of the detector responses were evaluated at a concentration range between 0.036-0.91 µg/ml using five calibration solutions prepared in acetonitrile. In the range of the tested indoxacarab mass concentrations, a good linearity of the detectors was achieved. (r^2=0.996). The LOD (limit of detection) and LOQ (limit of quantification) were 0.006 mg/kg and 0.02 mg/kg, which are below MRL for indoxacarb set by EU (1.0 mg/kg) and Serbian legislation (0.5 mg/kg). Precision value was evaluated trough repeatability and expressed as relative standard deviation (RSD). The repeatability was checked by analysis of the indoxacarb standard prepared in peach matrix (0.6 µg/ml) on the same day, five times. Relative standard deviation (RSD) of the peak areas was 0.01%, fulfilling the criteria of RSD ≤20%. A critical aspect of pesticide residue analysis is the purification process, which is required to isolate the residues from matrix components and to reduce matrix effects (Lehotay et al., 2010). Matrix effect, i.e., signal suppression or enhancement, of the studied insecticide in peach matrix, was evaluated. For this study, the matrix effects were examined comparing the slopes of calibration curve of matrix-matched standards (MMC) and solvent-based standards (SC). Indoxacarb standards were prepared in blank matrix extract in five concentrations between 0.036-0.91 µg/ml. The influence of the peach matrix on indoxacarb signal by applicatin of this method is 102.39%, which indicates the absence of a significant impact of the matrix of the studied fruit species on the determination of indoxacarb, having in mind that good laboratory practice considers acceptable deviation of ± 15%. The accuracy of the method was carried out using blank sample spiked with a standard solution of indoxacarb insecticide at three levels. The mean recoveries for indoxacarb were 83.3 to 91.6%. According to the EU validation guideline for pesticide residues, mean recovery values should be within

the range of 70–120%, which was achieved by this method. Results of the recovery achieved in this study confirmed that the optimal recovery was obtained for indoxacarb in peach samples.

Conclusions

A simple and fast HPLC-DAD method for the determination of indoxacarb insecticide residue in peach fruits was developed. Reverse phase and isocratic elution conditions enable efficient separation of investigated insecticide. The proposed method has been validated with good recoveries and linearity, low LODs and LOQs, lower than MRLs, fulfilling the SANTE/11813/2017 criteria. The results obtained in this study confirm that proposed method is easy and reliable for the determination of the analyzed indoxacarb insecticide residues in peach fruits.

EFFICACY OF INSECTICIDES ON *THRIPS TABACI* LINDEMAN ON ONION

Jelena PERENČEVIĆ, Vladimir SABADOŠ

Agriculture Extension Service "Sombor", Serbia
*Corresponding author: agroso@mts.rs

Abstract

In recent times a new technology of onion production has been introduced with getting high yields by sowing at 5cm spacing, the onion is obligationally foliarly treated with a growth hormone, maleic hydrazide in order to inhibit sprouting of stored onion bulbs in warehouses for purposes of favourable sales. In vegetation one of the most important pests is *Thrips tabaci* Lindeman, which regularly appears, it lives hidden, but the damage from *Thrips* many pathogens use as an open window for infection. The onion is used fresh for human consumption. In order for the onion production to be safe, the control of the onion demands the use of ecological and toxicological favourable insecticides. In field micro assays of 2016 and 2017 we setup assays and examined the efficacy of formetanate hydrochloride, abamectin, spirotetramat and spinosin active ingredients'. Efficiency of insecticides used in these assays depended on their persistence and ecotoxicological characteristics. On basis of the assay results, respecting the modification modes of insecticide mechanisms, formetanate hydrochloride is used at the beginning of the flight. Spirotetramat is added, which affects the new hatching of larvae, and for the time close to sowing of onion bulbs, abamectins and spinosins are used.

Key words: *onion,trips, Thrips tabaci, suppression, spirotetramate.*

Introduction

The production of onions in Serbia is taking a more important place per area and per yield. The technology of high yields requires production from seeds and the use of maleic hydrazide which secures firm bulbs and long storage in warehouses. The use of maleic hydrazide determines the production conditions:

a) Sowing of onion seeds is done by spacing of about 5.5 cm, depending on the number of rows in the garden bed,
b) Uniform germination, and
c) Healthy plants that adopt maleic hydrazide.

The most important is keeping the onion healthy i.e. avoid damages of *Thrips tabaci* (Thysanoptera, Thripetidae). This insect cutting the cuticle of the cell tissue, to suck the juices and inject eggs into the leaf tissue, creates an entrance for some pathogens (Brian, 2010; hasimran et all, 2015; Hault at all, 2016; Pouriau at all, 2019).

Photo 1. Antennae of *T. tabaci* with 7 segments (photo J. Perenčević)

Thrips regularly fly to the onion already at the beginning of vegetation and feed for two to 2 and a half months. This extended flight in the same timerepresents a problem in controlling population. Also, they live hidden and additional problem is highly efficient application of insecticides i.e. access of a.i.

The market accepts bulbs of certain standards - bulbs of 5-7 cm in diameter, 2 leaf scales, swollen base, non germinated bulbs and that are health safe. Having this in mind, the aim of this work was to test the effects of some specific insecticides on the *T. tabaci* control in quantities adapted to high technology. Choosed a.i. are at the same time ecotoxicologicaly favourable for use in onions protection.

Material and Methods

In 2016 an assay was set up on a winter onion cultivar Stutgarter Riesen within an experimental field of an Agricultural extension service with five variants, 3 treatments in 3 repetitions (Table 1).

The treatments were setup spatially by random block design. The experimental unit is one plant. One repetition is done on 15 randomly selected plants of a bed of 3 X 1.6m in size. The number of thrips was determined under the leaf petiole. We registered larvae and adults.

Threshold spraying is at the beginning of the flight of adult T.tabaci. The onion was treated the first time on May 13th, 2016, when it's flight was determined, then on May 19th and June 1st. (Table 1)

Table 1: Treatments in 2016, time application, variants and insecticide rates

Application date	Variant	Treatments	Active matter	Qty per ha
05/13/2016	**I**	Dicarzol 50 SP	formetanat hydrochloride	1 kg
05/19/2016		Dicarzol 50 SP + Movento 100 SC	formetanat hydrochloride spirotetramat	1 kg 1 L
06/01/2016		Lasser240 SC	spinosad	0.4 L
05/13/2016	**II**	Kraft 1.8 EW	abamectin	1.5 L

09/19/2016		Movento 100 SC		1.0 L
06/01/2016	**IV**	Lasser 240 SC Kontrola	spinosad	0.4 L
05/13/2016	**V**	Dicarzol 50 SP	formetanat	1.0 kg
05/19/2016		Dicarzol 50 SP	hydrochloride	1.0 kg
06/01/2016		Dicarzol 50 SP		1.0 kg

In 2017 we set up assays with onion sets of the Holland yellow cultivar, in five variants, 4 treatments and 3 repetitions. The experimental unit was one plant. One repetition was on an area of 4 rows, 5 meters, a spacing of 0.6 meters, 15 plants each were checked. The onion was checked on May 18th and 27th, June 5th, 13th and 20th, 2017. We counted larvae and adults using a 10x magnifying glass. We used the same insecticides as in the previous year in five variants of assays, but the treatment intervals were different. The assessment of the insecticide efficacy was made on the same day of the inspection. As in 2016, at the end of the assay, the bulbs were counted and measured according to variants and repetitions. The results were processed by the variant analysis.

Insecticides we used were:

1. Dicarzol 50 SP on basis of formetanat hydrochloride (carbamates). It falls into the cholinesterase inhibitores on CNS (IRAC 1A). It is considered the specific for the control of thrips, it especially has a good effect on the adults and larvae of the *T.tabaci,* and *F. occidentalis* as well. Dicarzol SP 50 was registered in Serbia in 2013, for controlling *T.tabaci* on onions at a quantity of 1 L ha^{-1}, with a waiting period of 28 days, so it is recommended for the first phase of onion development.

2. Lasser 240 SC on basis of spinosad, is an activator of nicotinic acetylcholine receptors, but on different places (IRAC 5) on neonicotines. As a product of fermentation of soil bacteria *Saccharopolyspora spinosa*, light decomposes it so it's effect is short. It is a lactone with great molecular weight (722), which limits the reception by the plant. Spinosad is adapted through the cuticle of the epidermal cell of the leaf, from where the thrips suck the juices for nutrition. It is ecotoxicologicaly favorable and it is also registered for organic production of vegetables. It is considered as the specific for the Thrips control, and especially on *Frankliniella occidentalis* and *T. tabaci*. It is recommended for the last sprinkling before harvesting of onions. It is applied a maximum of 3 times successively. It has a waiting period of 3 days on onion.

3. Movento 100 SC. Active ingridient is an spirotetramat which inhibits the new fat synthesis (IRAC 23), so the optimal time of use is at thrips larvae hatching time or those that do not have fat. The efficacy on the adult and larvae L2 and L3 is very limited, so it is recommended only in conditions of low or middle number of thrips. In the assay a quantity of 1 L ha^{-1}or with somewhat greater quantities that is registered (0.75 L ha^{-1}), because the insecticides were used in longer intervals between treatments. Movento is registered for use on tomatoes with a waiting period of 3 days.

4. Kraft 1.8 EW Active ingridient abamectin is an abamectin which stimulates the release of gama aminobutyric acids, inhibitor of the transfer of nerve signals and activates chlorine canals on CNS (IRAC 6). Produced during fermentation of soil bacteria *Streptomices avermitilis*. It falls into lactones or substances with great molecular weight (873.1) or is adopted only through cuticles in the epedermal cells of the leaf from which the thrips suck the juices. It has a greater number of metabolites which breakdown quickly in light. It is used in the afternoon when the temperature is slightly lower and the relative humidity is greater. Abamectin is also used for the last sprinkling, because it has a shorter waiting period of 14 days on tobacco, and on beans and soy beans 7 days. In order to ensure a somewhat longer efficacy between two treatments, we used a lager amount than registered or 1.5 L ha^{-1}. In the application of insecticides, wetting agent Trend 90 in a concentration of 0.1% was added.

Results and Discussion

1. Density of *T. tabaci* on check in 2016 year

On the check of May 13th, we determined that adults flew onto onions, which have a characteristic of the T.tabaci variety and among others were also seven antannae (picture 1). The population of *T.tabaci* comprises mainly of females with a lesser presence of males. The females lay a great number of eggs by rasping with ovipositors into the tissue base of the onion leaf where the larvae and adults feed (picture 3). A total of 14 *T.tabaci* adults were found (Table 1). The action threshold is the presence of *T.tabaci*, so treatments with insecticides were carried out.

Tab.1: Infestation of *T.tabaci* on the Untreated in assesments in 2016

Treatments	Preparation	Number *T.tabaci* at the time of assesment			
	Qty per ha	May 13	May 19	May 27	June 1
Untreated	-	14	21	213	197

In the assessment of May 19th, a greater number was determined (21), and on May 27th, a more massive flight of adults and hatching of larvae occured (213). In the assessment of June 1st, there were no new flights of adults, so the number of the adult *T.tabaci* was somewhat reduced (197). The number of *T.tabaci* on the 45 checked onion plants was not significant and great damage should not be expected on the onion in this year on the assayed area.

Photo number 2: Insecticide efficacy variant I on the *T.tabaci* (photo J. Perenčević)

In relation to the Untreated, Dicarzol 240 SP was used in the first treatment, then in the second with the addition of Movento 100 SC and in the third treatment Lasser 240 SC, which significantly reduced the number of *T.tabaci* larvae, and in the inspection of June 11th, only 29 larvae and adults (Table 2) or less than one thrips per plant were registered.

Photo number 3: Larve *T.tabaci* in small social group in feeding place (photo J. Perenčević)

Photo number 4. Damage of *T.tabaci* on onion stalk epidermis (photo J.Perenčević)

Tab.2: Efficacy of insecticides and variant I on *T.tabaci*

Treatments	Preparation Qty per ha	Treatment times	Number *T.tabaci* in inspections			
			May 13	May 19	May 27	June 1
Before treatment		Before setting of assay	4			
Dicarsol 50 SP	1 kg	May 13	-	8		
Dicarsol 50 SP +Movento 100 SC	1 kg 1 L	May 19	-	-	8	
Lasser 240 SC	0.4 L	May 27	-	-	-	29

3) Efficacy of insecticide variant II. on the *T.tabaci*

In this variant similar results were received as in the previous variant I. In this variant similar results were obtained as in the previous variant I. Kraft 1 EW as an adulticide in the first, Kraft 1.8 EW+Movento in the second treatment and in the third treatment only Lasser 240 SC, have shown similar efficacy in relation to *T.tabaci* (Table 3) or in relation to the Untreated number was significantly reduced.

Tab.3: Efficacy of insecticide variant II to *T.tabaci*

Treatments	Preparation Qty per ha	Treatment time	Number *T.tabaci* in inspections			
			May 13	May 19	May 27	June 1
Before treatment	-	Before treament	10			
Kraft 1.8 EW	.5 L	May 13		5		
Kraft 1.8 EW 1.5 lit/ha+Movento 100 SC 1.0 lit/ha		May 19				
Lasser 240 SC 0.4 lit/ha	0.4 L	May 27				43

4) Insecticide efficacy variant III on *T. tabaci*
The application of Movento 3 times as a larvicide, a certain increase of the number of adults on May 19 and May 27 was determined, in relation to the application of adulticides in previous variants. However, Movento affected the neonate larvae and on May 27th, a similar number of *T.tabaci* (49) was determined as in previous variants (Table 4).

Table 4: Efficacy of insecticide variant III on *T.tabaci*

Treatments	Preparation Qty per ha	Treatment time	Number *T. tabaci* in inspections May 13	May 19	May 27	Jun 1
Before treatment	-	May 13	3			
Movento 100 SC	1 L	May 13		19		
Movento 100 SC	1 L	May 19			12	
Movento 100 SC	1 L	May 27				49

Broj T.tabaci u poredima

5)Efficacy of insecticide variant V on *T. tabaci*
In implementation of Dicarzol 50 SP as an adulticide, there was no significant increase in the number of *T. tabaci* in the phase of adult flight, but Dicarzol had a weaker effect on larvae and adult *T.tabaci* were registered.

Table 5: Efficacy of insecticide variante V on *T.tabaci*

Treatments	Preparation Qty per ha	Treatment time	Number *T.tabaci* in checks May 13	May 27	May 27	June 1
Before treatment	-	-	4			
Dicarzol 50 SP	1 kg	May 13		14		
Dicarzol 50 SP	1 kg	May 19			14	
Dicarzol 50 SP	1 kg	May 29				54

The onion was not treated after July 1st, 2016. During the assessment on July 27th 2016 or 27 days after the last treatment, we recorded a difference in the number and weight of the onion bulbs per variant (Table 6).

Table 6. Number, bulb weight and % of dry matter of the Stuttgarden Riesen cultivar

Variants	Number of bulbs on an area of 40.5m^2	Bulb weight in kg on an area of 40.5m^2	% dry matter
	327	38.31	12.7
1.Kraft	311		
2.Kraft+Movento		38.35	14.78
3.Movento			
Movento 3x	326	39.10	15.18
Untreated	312	36.25	14.32
Dicarzol 3 x	319	38.59	14.16

A greater weight of the bulbs was determined in insecticide implemented variants in relation to the Untreated.
The greatest bulb weight was at the implementation of Movento. However, the statistical analysis of the bulb weight (LSD 0.05 =1.59, 0.01=2.31) showed that there is no significant influence of the application of insecticides on the mortality and feed of the thrips expressed in

the bulb yield. The increase of dry matter after the treatment of the onion with Movento is a more reliable answer of the onion, but because of the previous irrelative differences, this should be understood as a possibility (Tabela 6). Number of *T.tabaci* at the Check on onion surfaces in 2017 year

Table 7 Number of *T.tabaci* at Untreated plot

Check day	Number of ***T.tabaci*** per repetations							
	I repeat		II repeat		III repeat		Total	
	Adult	Larvae	Adult	Larvae	Adult	Larvae	Adult	Larvae
May 18.2017	8		6	6	4	1	18	9
05/26/17	1	16	3	39	4	26	8	81
05/05/17	13	49	16	225	15	120	44	394
06/13/17	9	0	6	197	31	146	46	423
06/20/17	3	92	11	252	2	258	16	602

In the Check of May 18, the flight of *T.tabaci* adults was determined (18). Nine larvae were found or hatching began the prior week. Treatment was performed on May 18.
The first time massive flight of adults was determined in period between June 5th and 13th in 2017. The onion was in good health, which increased the fertility of the females and the time and number of larvae (June 20th, 602 larvae) or 13 thrips per plant. A high number of *T. tabaci* presumes a reduction in the yield of onion bulbs. At the treatment with Dicarzol 50 SP, Dicarzol 50 SP + Movento 100 SC, 2 times and Lasser 240 SC, 2 times, the number of *T.tabaci* at the Untreated on June 20th 2017, determined 8 adults and 64 larvae. At the treatment with Kraft 1.8 EW, Movento 100 SC, 2 times and Lasser 240 SC, 2 times, the maximum number of T.tabaci was on June 13th, when 36 adults and 103 larvae were found, but on June 20th, 36 adults and 80 larvae were found. At the treatment with Movento 100 SC, 3 times, Lasser 24O SC, 2 times, the maximum number was on May 26th, when there were 10 adults and 148 larvae, but in the last Check on June 26th, there was 11 adults and 82 larvae.
At the treatment with Dicarzol 50 SP, 3 times, Lasser 240 SC, 2 times, on June 5th on the onions there were 28 adults and 123 larvae, but at the last inspection there were 17 adults and 67 larvae. As can be seen, at all treatments in relation to the Check, a very high efficacy was achieved or there was no significant damage. Number of bulbs and yield of onion on insecticide variants on the Holand yellow cultivar in 2017

Table 8: Imact of used insecticides on onion yield

Variants	Yeald per repeatation in kg			±SD	Total kg	Increase of yield in relation to Untreated (%)
	1	2	3			
1. Dicarzo 50 SP Dicarzol 50 SP+Movento100 C 2 x Lasser 240 SC	16.2	19.7	16.8	17.57 (1.87)	53.70	110.14
2. Kraft 1.8 EW Kraft 1.8 EW+Movento 100 SC Dicarzol SP 50	18.9	19.8	17.2	18.63 (1.32)	55.90	116.2
3. Movento 2 x Kraft 1.8 EW 2x	20.3	16.2	18.5	18.33 (2.06)	55.0	114.9
5. Dicarzol 4 x	18.6	14.5	17.4	16.70 (2.37)	50.10	104.7
4. Untreated	17.3	14,1	16.5	15.95 (1.66)	47.85	100.0

LSD 0.05=3.65 LSD 0.01=5.30

A determination was made of the increase of yield of onion bulbs at treatments with insecticides and especially when Movento was used 2 times. However, analysis show that this increase is not statistically significant. The strategy in controling *T. tabaci* on the onion is on maintaining a low number. Strongly recommended the first application of insecticide after adult eclosion. In the other hand, in practice spraying is often in condition of high population of *T. tabaci*. But, it is impossible to control high trips population as a consequence of hidden insect life on the plant. This was proven also in assays of both years. In the first part of vegetation during the time of intensive growth of the onion, a greater quantity of insecticides is used with spraying interval of 6 days. The economic thresholds are different and depend on the sensitivity of the onion to the of *T.tabaci*. Granshaw (2004) suggests 15 to 30 thrips per plant as a threshold level. However, at the application of spirotetramats (Movento), because of slower action, a threshold of 1 thrips per plant is suggested. In our assays, at the application of the mentioned insecticides in various combinations, the number of *T.tabaci* was continiously under the thresholds.

Conclusion

T. tabaci on the onion is successfully controlled with insecticides of different mechanisms, and have effect on the adult and the larvae such as formetanat hydrochloride, abamectin, spinosad and spirotetramat. Onions are most sensitive at the beginning of growth when protection should be carried out.Insecticides applied after adult eclosion .

Spirotetramat acts on the neonate larvae but through inhibition of synthesis of fat and the reduction of the fertility of the female. By adding an adulticide, such as Dicarzol 50 SP, Kraft 1.8 EW and Lasser 240 SC to the spirotetramat, a synergetic effect on the adult, neonate larvae and the reduction of the fertility of the female is obtained. In practical conditions, on greater areas, these preparations have satisfied protection of the onion.

Abstract

Turkey oak is one of the most common oak species in Serbia. Its wood has a high calorific value, and that is why it is commonly used for firewood in Serbia. In the last few years the oak started to dieback, mainly in the northern parts of Serbia. Because of this, and many other reasons like the negligible presence of young stands in the total area, and the prevailing vegetative origin of, Turkey oak forests must be regenerated. For the natural regeneration of its forests, a significant amount of healthy acorn is needed. Unfortunately, Turkey oak acorn is frequently infested by insects. We focused on the influence of the damage caused by of one of them, *Curculio glandium* (Marsham, 1802) on the Turkey oak acorn germination. The research was conducted on three localities in the vicinity of Belgrade. Five trees from which the acorns were collected were selected at each site. Acorn rate of infestation and germination were then analyzed. The infestation rates ranged from 24 to 60% depending on the tree. There were no statistically significant differences in the infestation rates between the different localities and the individual trees. A statistically significant difference in germination was found between undamaged and damaged acorns. The average germination rate was 35.8% for the damaged, and 66.1% for the undamaged acorns. A significant difference in germination was also noted between the localities where the acorns were collected. The germination of the damaged acorns was significantly influenced by their dimensions as well. The larger acorns had a higher germination rate.

Introduction

Turkey oak (*Quercus cerris* L.) is one of the most common oak species in Serbia. Its forests cover an area of about 345.200 ha (Bankovic et al. 2009) which is circa 15.3% of the total forest area in Serbia. Its wood has a high calorific value, but poor mechanical properties (Soskic 2006) and that is why it is most commonly used for firewood. In the last few years, the oak started to dieback in the northern parts of Serbia (Karadzic et al. 2017). Because of this, and many other reasons, like the negligible presence of young stands in the total area, and the prevailing vegetative origin of its forests (Bankovic et al. 2009) Turkey oak forests must be regenerated. For their natural regeneration, a significant amount of healthy acorn is needed. Unfortunately, oaks acorn is infested by a large number of pests (Hrasovec & Magdalenic 1996; Hirka 2003; Csoka & Hirka 2006; Drekic 2006; Drekic & Mihajlovic 2007, 2011; Bak-Badowska et al. 2017; Kanjevac et al. 2017). We investigated the influence of one of them - *Curculio glandium* (Marsham, 1802) (Coleoptera, Curculionidae) on Turkey oak acorn germination. Females of *C. glandium* lay their eggs in young oak acorns. Eggs hatch and the larvae start to feed on the acorns cotyledons. After the acorns drop off the trees, the larvae complete their postembryonic development, abandoning the infested fruit by a circular exit hole to bury in the ground for overwintering. The adults emerge in the spring. A portion

of the population remains in diapause in the larval stage for several years. (Forrester 1990, Mihajlovic 2008, Drekic 2007).
C. glandium is always present in oak forests in Serbia. According to Mihajlovic (2008) at normal population density 10 to 30% of acorns is infested, but during outbreaks all of the acorns (100%) can host a grub.

Material and methods

The research of the influence of *C. glandium* (Marsham. 1802) on the germination of Turkey oak acorn was carried out in 2017. The acorns were collected on three localities in the vicinity of Belgrade: Lipovica (44°38'48"N, 20°24'22"E), Zuce (44°40'59"N, 20°31'47"E), Kosutnjak (44°46'19"N, 20°25'31"E) in February. Five trees from which the acorns were collected were selected at each locality. Acorns from one tree represented one sample. One hundred acorns were randomly selected from each sample to quantify the infestation rate, based on the presence of exit holes. Then, 30 damaged and 30 undamaged acorns were taken from each sample to determine their germination rates. The acorns were placed in plastic containers filled with sand which was sterilised for 6 hours at the temperature of 200ºC. The germination rate was determined after 28 days. Acorns not used for the analyses above were used for obtaining the adults.
All the data obtained were analysed in Statistica 8.0. (StatSoft) Software. The significance of the differences in observed properties was determined by one-way ANOVA, at the level of significance $p<0.05$.

Results and discussion

The breeding got only adults of one weevil species: *C. glandium*. Its larvae damaged an average of about 39% of acorns (Table 1). No statistically significant differences in the infestation rates between the localities and individual trees on them were determined ($p>0.05$). According to Mihajlovic (2008), this infestation rate is above normal for Turkey oak in Serbia. It is considerably greater than that which Csoka & Hirka (2006) recorded on *Q. cerris* in 2001 and 2002 (3% and 18%) in Hungary.

Table 1. *C. glandium* infestation rate (%)

	Locality		
Tree number	Kosutnjak	Lipovica	Zuce
1	47.0	39.0	50.0
2	36.0	34.0	55.0
3	24.0	47.0	25.0
4	32.0	30.0	40.0
5	60.0	34.0	38.0
$\bar{x}$	39.80±14.00	36.80±6.53	41.60±11.63
$\bar{x}$	39.40 ± 10.54		

After analysing the acorns collected from each tree on each locality, it was determined that the acorns damaged by *C. glandium* were larger, i.e. they had a larger diameter ($F=10.15$, $p<0.05$). Dong et al. (2012) got similar results while examining the acorns of *Q. aliena* Blume attacked by the weevil *C. davidi* Fairmaire & L., 1878.

Table 2. Average dimensions of the analysed acorns (cm)

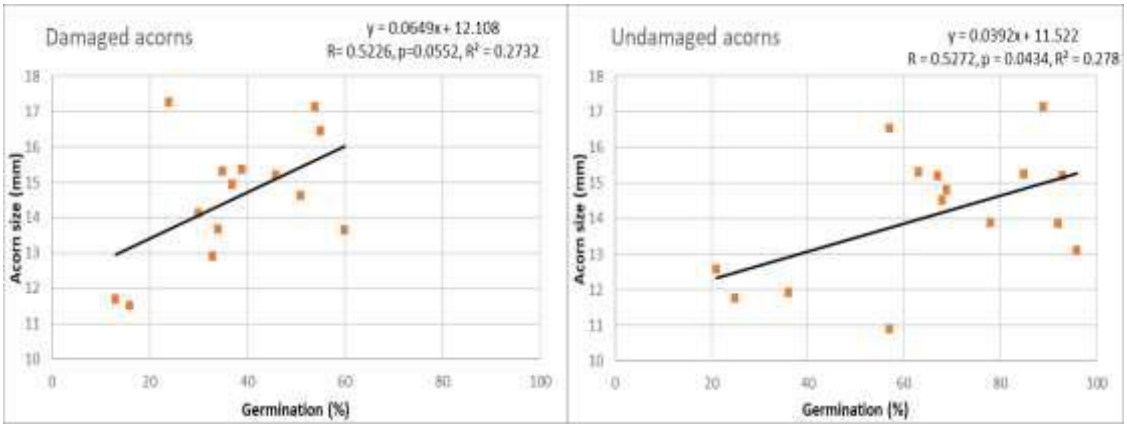
Locality	Dimension			
	Length		Diameter	
	undamaged	damaged	undamaged	damaged
Kosutnjak	27.58±4.33	27.58±3.44	13.69±2.24	13.79±1.89
Lipovica	27.58±2.80	27.85±3.27	14.90±2.01	15.62±3.27
Zuce	27.52±3.99	28.16±3.51	14.02±2.27	14.78±2.30
$\bar{x}$	27.56±3.72	27.86±3.40	14.26±2.22	14.75±2.18

Damage caused by *C. glandium* significantly affected the acorn germination rates ($F=35.51$, $p<0.05$). The average germination rate of the damaged acorns on all three localities was 35.75±15.58%, and of the undamaged 66.09±24.76%, which is 84.87% higher. Statistically significant differences in germination rates between the localities existed in cases of both damaged ($F=5.34$, $p<0.05$) and the undamaged ($F=7.73$, $p<0.05$) acorns. The highest germination rate was recorded on the acorns collected on locality Lipovica, and the lowest on those collected on locality Zuce. Individual trees did not influence germination rates ($p>0.05$). This difference in germination rates between the damaged and undamaged acorns is considerably higher than that which Hirka (2003) determined in Hungary.

Table 3. Acorn germination rates (%)

Tree Number	Locality					
	Kosutnjak		Lipovica		Zuce	
	undamaged	damaged	undamaged	damaged	undamaged	damaged
1	67.0	30.0	85.0	55.0	69.0	35.0
2	63.0	37.0	92.0	39.0	57.0	24.0
3	25.0	16.0	89.0	54.0	78.0	34.0
5	68.0	51.0	96.0	60.0	36.0	33.0
6	57.0	13.0	93.0	46.0	21.0	0.0
$\bar{x}$	56.0±17.86	29.4±15.60	91.0±4.18	50.8±8.29	52.2±23.49	25.2±14.75
$\bar{\bar{x}}$	42.7±21.13		70.9±22.07		38.7±23.33	

The existence of a positive correlation between the acorn diameters and germination rates in cases of both damaged and the undamaged acorn was determined based on the results of the regression analysis (Graph 1). Such a relation between the acorn dimensions and germination rates was also determined by Forrester (1990) and Ramos et al. (2013). According to them, that relation is even more pronounced if the acorns are damaged. Forrester (1990) and Hirka (2003) explain that by the fact that a single larva consumes a certain amount of food to finish its development. In large acorns that amount comprises a smaller part than in small ones. Because of that, the seedlings in larger acorns have a better chance of survival.



Graph 1. Influence of diameter on acorn germination rate

Results of the research conducted showed that *C. glandium* significantly reduced the acorn germination rates. They also showed us that a part of the damaged acorns still germinated (around 36%). How many of them will germinate depends on the genetic variability of the trees, severity of the damage on the acorn, the place of the damage on the acorn and environmental conditions (Forrester 1990; Yu et al. 2003; Hirka 2003; Csoka & Hirka 2006; Hou et al. 2010; Dong et al. 2012; Ramos et. al 2013; Oltean et al. 2014; Bak-Badowska et al. 2017; Bartlow et al. 2018). However, plants which grow from the damaged acorns generally grow slower and are physiologically weaker. They have a smaller height, girth, size of the leaves, amount of dry plant mass, amount of nitrogen, chlorophyll, and further (Yi & Zhang 2008).

Conclusions

Based on the above, the following conclusions can be made:

- *C. glandium* infested about 39 % of the acorns;
- Damaged acorns were larger that the undamaged ones;
- The damage caused by *C. glandium* lowered the germination rates significantly;
- The damaged acorns had a germination rate of about 36%
- The germination rates of the damaged and undamaged acorns varied significantly between the localities;
- Larger acorns had a higher germination rate.

TERBUTHYLAZINE APPLICATION WITH HERBICIDES OF DIFFERENT MODE OF ACTION IN MAIZE CROP

Maja MESELDŽIJA*, Milica DUDIĆ

Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia
*Corresponding author: maja@polj.uns.ac.rs

Abstract

Based on the damage caused by weeds in maize crops, the efficiency of a large number of commercial preparations with different active ingredients was examined in order to suppress dominant weed species. The experiment with terbutylazine in combination with S-metolachlor and mesotrione was placed at the following locations: Zobnatica, Ruski Krstur and Gornja Badanja (Serbia). Efficacy and phytotoxicity was evaluated according EPPO/OEPP standards. The dominant weeds were: *Abutilon theophrasti* Medic., *Amaranthus retroflexus* L., *Ambrosia artemisiifolia* L., *Avena fatua* L., *Bilderdykia convolvulus* L., *Cannabis sativa* L., *Chenopodium album* L., *Chenopodium hybridum* L., *Cynodon dactylon* (L.) Pers., *Cirsium arvense* (L.) Scop., *Datura stramonium* L., *Galinsoga parviflora* Cav., *Helianthus annuus L., Hibiscus trionum* L., *Matricaria chamomilla* L., *Mentha arvensis* L., *Polygonum aviculare* L., *Plantago minor* L., *Potentilla reptans* L., *Rumex patientia* L., *Solanum nigrum* L., *Sonchus arvensis* L., *Taraxacum officinale* Web., *Veronica persica* Poir., *Xanthium strumarium* L. At the present weed flora in the location of Gornja Badanja, the combination of terbutylazine and S-metolachlor, applied after sowing and before the emergence of weeds and maize, had a low efficiency (59.70-66.30%). At the location of Ruski Krstur, the combination of terbuthylazine (125 g/l) and mesotrione (50 g/l), foliar applicated, had a satisfactory efficiency (88.61%) during the first and good efficacy (94.72%) during the second assessment of the present weed flora. Combination of terbuthylazine (326 g/l) and mesotrione (50 g/l), foliar applicated, had a satisfactory (81.94%) and good efficiency (92.77%) on the present weed flora at the location of Zobnatica.

Keywords: *Maize, Weeds, Terbutylazine, Mesotrione, S-metolachlor*

Introduction

Maize (*Zea mays* L.) is the third most important cereal crop in the world after wheat and rice (Mhlanga et al., 2016). Due to weeds, worldwide yield losses in maize are estimated to be around 37% (Oerke and Dehne 2004), therefore, weed control plays an important role in maize production, ensuring an acceptable yield. Weed control in maize is carried out mainly by mechanical and chemical methods, but use of herbicide is increasing, along with increases in growing areas and production costs (Kir and Dogan, 2009). Serbia quickly and efficiently adopted the achievements of modern phytomedicine, and great success has been achieved in weed control (Stefanović et al., 2011). In recent years, the focus has been shifted to foliar herbicides, with the aim of achieving their maximum efficiency, primarily due to the reduced efficiency of soil herbicides under conditions of insufficient rainfall, the limitations of using terbuthylazine, the emergence of resistant weed populations, and the introduction of foliar herbicides that are extremely effective in suppressing a large number of weed species (Radivojević et al., 2015). The application of herbicides is the most effective and economical agronomic practice for weed management in all major field crops, contributing significantly to increased crop yields (Bartucca et al., 2017). Maize crop is often characterized by a complex of weed flora, which consists of broadleaved and grass weeds (Pannacci and Onofri, 2016). This weed flora have been controlled with pre-emergence applications based on herbicide terbuthylazine, because of its broad controlled weed spectrum, superior residual

activity, great crop tolerance, good efficacy, and suitability as a partner for other active ingredients (Schulte et al., 2012). In order to minimize the application cost and optimize weed control efficacy, the use of combinations of pre- and post-emergence herbicides, as well as herbicide mixtures, has become the rule in many countries, what represents an important tool to avoid problems related to herbicide resistance (Pannacci and Onofri, 2016).

Terbuthylazine is a broad spectrum chloro-triazine herbicide that acts as a powerful inhibitor of photosynthesis (Tariba Lovaković et al., 2017). It is used for weed control in pre- and post-emergent treatment of a variety of agricultural crops as well as roads, industrial area, and railways (EFSA, 2017). Depending on the soil characteristics, terbuthylazine has a very high soil persistence, it can be present up to 17 months after the field treatments (Stipičević et al., 2015). Terbuthylazine is used as a substitute for atrazine, which has been banned in EU countries (Tariba Lovaković et al., 2017). In 2011, the European Food Safety Authority (EFSA) provided an extensive peer review of data concerning the environmental behavior and fate, ecotoxicology and mammalian toxicology, and risk assessment of terbuthylazine (EFSA, 2011). Based on these conclusions the European Commission approved the inclusion of terbuthylazine in Annex I of Council Directive 91/414/EEC and its use only as a herbicide until December 2021 (Commission Implementing Regulation (EU), 2011). S-metolachlor belongs to the acetamides chemical group and is generally applied during pre-planting, pre-emergence, or post-emergence (Milan et al., 2015). S-metolachlor is a selective herbicide, absorbed by shoots and hypocotyls, and inhibits weed germination. Terbuthylazine and S-metolachlor are widely used to control weeds in maize. Mesotrione is another important herbicide, provides pre- and post-emergence control of broadleaf weed species, primarily in maize (Mendes, 2017). It is a member of the triketone family of herbicides that is applied mainly in combination with other herbicides (Milan et al., 2015). Mode of action is to inhibit the enzyme 4-hydroxyphenylpyruvate dioxygenase (HPPD), which affects carotenoid biosynthesis (Mitchell et al., 2001).

The aim of this study was to determine which combination is most effective for the existing weed flora in the application of terbuthylazine with soil and foliar herbicides, depending on the weediness, agro-ecological conditions, in purpose of profitability of agricultural production.

Material and Methods

The research was conducted during 2016 and 2017 at the following locations: Zobnatica, Ruski Krstur and Gornja Badanja (Serbia). Herbicides efficiency trail was set up in maize crop by random block system, with elementary plots of 25 m^2 in 4 repetitions. Control plot, not treated with herbicides, was also included. The experiment was set up according to the EPPO/OEPP standards (2008), in order to test the efficacy and phytotoxicity of the applied herbicides in different amounts and combinations. Tests with soil and foliar herbicides were made depending on the presence and dominant weed flora. Weed control included pre-emergence treatment, where terbuthylazine was applied in combination with S-metolachlor, and post-emergence treatment in the 4-6 leaf phase of maize where terbuthylazine was applied in combination with the herbicide mesotrione. The efficacy of the treatment and the intensity of weediness was determined by counting weeds per m^2 in two assessment, 14 and 28 days after treatment in a post.em. application of herbicides, and 28 and 42 days after treatment in a pre.em. application. Based on the obtained data, the coefficient of efficiency Ce (%) of herbicides is calculated by the formula Dodel loc. cit. Janjić (1985) and represents a relative ratio between the number of destroyed weeds compared to the weeds number in the control. Visual assessment of the phytotoxicity was performed according to the European Weed Research Council (EWRC) scale (1-9). Data were analyzed statistically using analysis of variance, F, and LSD tests.

Results and Discussion

At the investigated locality of Zobnatica, Gornja Badanja and Ruski Krstur, where experiments on the efficacy of herbicides were set, the following weed species were identified: *Abutilon theophrasti* Medic., *Amaranthus retroflexus* L., *Ambrosia artemisiifolia* L., *Avena fatua* L., *Bilderdykia convolvulus* L., *Cannabis sativa* L., *Convolvulus arvensis* L., *Chenopodium album* L., *Chenopodium hybridum* L., *Cynodon dactylon* (L.) Pers., *Cirsium arvense* (L.) Scop., *Datura stramonium* L., *Panicum crus – galli* L., *Galinsoga parviflora* Cav., *Helianthus annuus L., Hibiscus trionum* L., *Matricaria chamomilla* L., *Mentha arvensis* L., *Polygonum aviculare* L., *Plantago minor* L., *Potentilla reptans* L., *Rumex patientia* L., *Setaria glauca* L., *Solanum nigrum* L., *Sorghum halepense* (L.) Pers., *Sonchus arvensis* L., *Taraxacum officinale* Web. *Veronica persica* Poir., *Xanthium strumarium* L.

During 2016, at the locality of Gornja Badanja, application of the pre-emergence herbicides, S-metolachlor and terbuthylazine, during the first and second assessment of efficiency gave the following results presented in table 1.

Table 1. The presence of weeds in maize crop, and the efficacy of herbicides after the first and second assessment, locality of Gornja Badanja

Terbuthylazine in a higher amount (326 g/l) in combination with mesotrione (50 g/l), foliar-applied, in the first and second assessment had good efficacy (> 90%) on: *Abutilon theophrasti* Medik., *Amaranthus retroflexus* L., *Chenopodium album* L., *Datura stramonium* L., *Helianthus annuus* L., *Hibiscus trionum* L., *Solanum nigrum* L. Satisfactory efficacy (75-90%) in the first assessment was on: *Bilderdykia convolvulus* L., *Chenopodium hybridum* L., *Datura stramonium* L., *Hibiscus trionum* L., and in the second on: *Ambrosia artemisiifolia* L., *Bilderdykia convolvulus* L., *Cannabis sativa* L. Low efficacy (<75%) of tested herbicides in

first and second assessment was on: *Convolvulus arvensis* L., *Panicum- crus-galli* L., *Sorghum halepense* (L.) Pers.

At the locality of Ruski Krstur, during 2017, a combination of two active substances (mesotrione 50 g/l and terbuthylazine 125 g/l) during the first and second efficacy assessment gave the following results presented in table 3.

Table 3. The presence of weed species and the efficacy of herbicides after the first and second assessment, locality of Ruski Krstur

Weed species	First assessment			Second assessment		
	Control	Tvister (mesotrione 50 g/l + terbuthylazine 125 g/l)		Control	Tvister (mesotrione50 g/l + terbuthylazine 125 g/l)

Total number of weeds	**70.25**	**8.00**	**88.61**	**99.75**	**5.75**	**94.72**
Phytotoxicity (EWRC scale 1-9)	**-**	**1**	**1**	**-**	**1**	**1**

Good efficacy (> 90%) of post emergence applied herbicides, terbuthylazine and mesotrione, in the first and second assessment was on: *Amaranthus retroflexus* L., *Datura stramonium* L., *Solanum nigrum* L., *Setaria glauca* L., *Sorghum halepense* (L.)Pers., *Veronica persica* L., *Xanthium strumarium* L. Tested herbicides in the first assessment had satisfactory efficacy (75-90%) on *Ambrosia artemisiifolia* L., *Chenopodium hybridum* L., and in the second on *Chenopodium album* L. Low efficacy (<75%) was on *Convolvulus arvensis* L., and *Chenopodium album* L.

Pannacci and Onofri (2016) showed that herbicide mixtures with terbuthylazine gave the highest control of weeds, confirming terbuthylazine as the main herbicide for weed control in maize, although thiencarbazone-methyl + isoxaflutole or s-metolachlor + mesotrione represent two valid alternatives in order to reduce the treatments based on terbuthylazine or to replace it in the future.

Based on the statistical analysis of data, there are statistically significant differences between the control, the untreated variant and the treated variants (tab. 4-6), which indicates the efficacy of the applied herbicides.

Conclusions

On the basis of results of the three field experiments on maize, 29 weed species were determined, of which 25 broadleaved and 4 grass weeds. The combination of herbicide S-metolachlor and terbuthylazine on present weeds in Gornja Badanja had low efficiency (59.70–66.30%). During 2017, at Zobnatica, the combination of herbicides terbuthylazine (326 g/l) and mesotrione (50 g/l) had a satisfactory efficiency during the first assessment (81.94%), and good efficiency (92.77%) during the second assessment on the present weed flora. At the experimental field in Ruski Krstur, terbuthylazine in a lower amount (125 g/l) in combination with mesotrione (50 g/l), had a satisfactory efficiency (88.61%), and good efficiency (94.72 %) on the present weed flora. This combination of herbicide terbuthylazine and mesotrione was the most effective in this study.

THE IMPORTANCE OF A CROP ROTATION ON MAIZE PRODUCTIVITY

Milan BRANKOV*, Milena SIMIĆ, Vesna DRAGIČEVIĆ, Branka KRESOVIĆ, Marijenka TABAKOVIĆ, Snežana MLADENOVIĆ DRINIĆ

Abstract

One of important measures in agriculture is a crop rotation. It is known that a crop rotation is associated with high yields, and suppressing of pathogens and weeds. It is a cheap measure – only decision is needed. On the other hand, a crop rotation gives possibility to use different crops and different pesticides (herbicides), what could be beneficial in anti-resistant strategy. The aim of this work was to evaluate maize growing in a crop rotation with winter wheat and maize monoculture. The field trial was set up in 2009 on an experimental field of the Maize Research Institute "Zemun Polje" in Serbia. This paper presents the results from 2017– after eight years of growing maize in monoculture and after four maize-winter wheat rotations. Maize hybrids ZP 677 and ZP 606 were tested in the experiment. Herbicide combination of isoxaflutole and s-metolachlor was applied (in recommended and ½ of recommended dose) for weed control. The effects of the crop rotation on maize were evaluated by observing the leaf area and plant height (at the anthesis stage), as well as the grain yield. In the crop rotation treatments the leaf area and plant height were significantly higher when compared to maize grown in monoculture. Irrespective to unfavourable meteorological conditions, both hybrids had higher yields when grown in rotations with winter wheat, in comparison to monoculture.

Keywords: *Maize, maize-wheat rotation, monoculture*

Introduction

Integrated Weed Management System (IWMS) implies a holistic approach that can integrate a large number of methods and measures that place plants in much better possition than weeds (Harker and O Donovan, 2012). It means that, in case of weeds, do not use only herbicides for weed suppresion, but also others tools – nonchemical tools for weed suppresion. Usage of IWMS gives long-term advantages in weed control, avoiding or delaying some negative effect of herbicides application (e.g weed resistance, soil contamination etc.). Accoring to Swanton and Weise (1991) herbicides should be one of the solutions in weed management strategy, not the only one. Crop rotation is one of the method for weed suppresion and it gives a huge advantages when is applied. Advantages of crop rotation are: preserving land quality, reducing herbicide usage and provides higher grain yields achieving (Liebman et al., 2001). In case of weeds, crop rotation influence directly on weeds by reducing their number. Accriding to Bastiaans (2010) weeds life cycle and spreading are lower in crop ratation compared to monoculture. On the other hand, cultivating plants in monocultures can lead to changes in the floristic composition, contributing to the spread of resistant and therefore harmful weeds (Stefanović et al., 2011). The aim of this research was to examine potentially positive effects of crop production in relation to cultivation of corn in monoculture using herbicides, by maize measuring leaf area, plant height and grain yield.

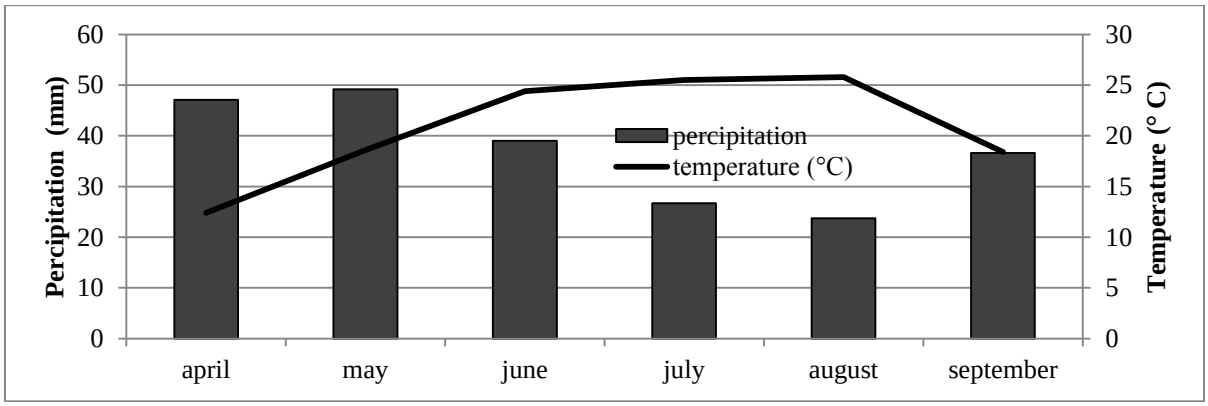
Material and Methods

The study of the effects of maize growing in monoculture and crop rotation with winter wheat began in 2009 at the field of the Maize Research Institute in Zemun Polje, on weak-carbonate chernozes. The experiment examined the influence of maize cultivation in monoculture and crop rotation with wheat. This paper presents the results obtained in 2017, that is, after eight

years of corn cultivation in monoculture and crop rotation. In each field, two hybrids of corn, hybrid of the older generation - ZP 677 and newer generations - ZP 606 were sown. The weeds in the experiment were suppressed by the herbicidal combination of isoxaflutol (Merlin flexx) and s-metolachlor (Dual Gold) in the recommended dose (RD) and ½ recommended doses. In the control variant, herbicides were not applied and it remained stunted until the first weed count. Influence of different growing systems on maize were tested by measuring leaf area, plant height in anthesis stage and grain yield after harvest.

The meteorological data are presented in Graph 1. The year 2017 was very warm, with high spring temperatures and optimal precipitation. The second part of the vegetation season was extremely warm, while the precipitation was insufficient for corn growing and developing. Obtained data were statistically processed by ANOVA and differences between means were tested by LSD test

Graph 1. Meteorological conditions in Zemun Polje during the vegetation period in 2017



Results and Discussion

According to obtained data, significant influence of applied treatments on maize parameters were recorded (Table 1). Leaf area and plant height values were significantly higher for both hybrids grown in crop rotation compared with maize monoculture. In treatment with ½ of RD maize hibrid ZP 677 had the highest values of leaf area, while the highest leaf area in ZP606 was recorded in RD treatment. Similar results were observed on maize height. Also, maize growing in crop rotation with winter wheat shows positive effects on tested parameters even in control treatments. Positive effect of maize growing in crop rotation with winther wheat was reported by Spasojević (2014). In his research, significant influence of crop rotation were observed on maize parameters, compared to maize grown in monoculture.

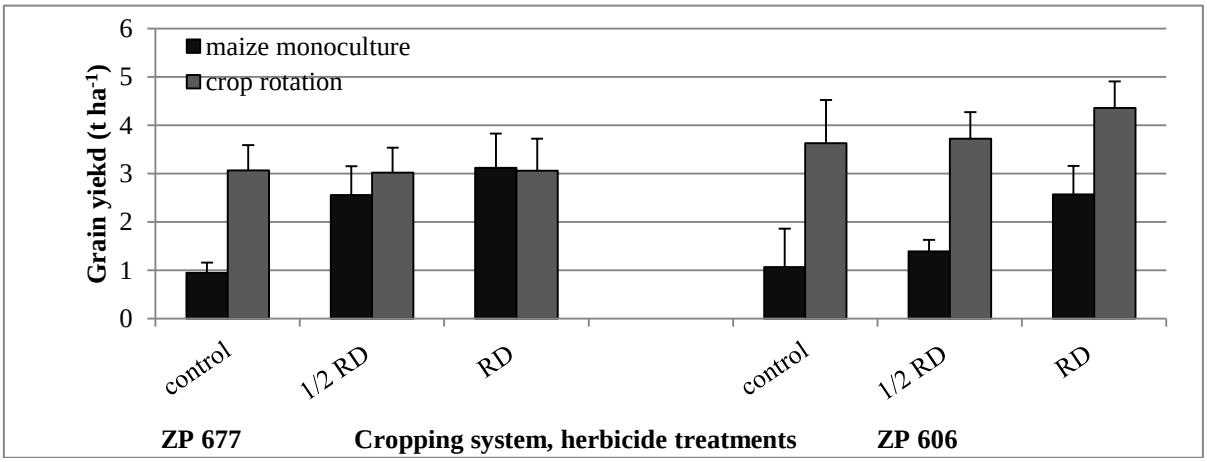
Table 1. Effects of applied treatments on maize parameters

	Leaf area (cm^2)			Maize height (cm)		
ZP 677	Herbicide treatment					
	control	½ RD	RD	control	½ RD	RD
Monoculture	1719.0	3903.6*	3870.7*	92.3	177.5*	183.4*
Crop rotation	3036.2	6496.6*	5099.6*	93.4	181.1*	178.8*
	Leaf area (cm^2)			Leaf area (cm^2)		
ZP 606	Herbicide treatment					
	control	½ RD	RD	control	½ RD	RD
Monoculture	1730.2	4282.1*	4223.6*	175.1	224.5*	213.8*
Crop rotation	4099.2	6453.1*	6942.0*	163.4	216.0*	215.6*

* - $p<0,05$ – statistical significant difference, RD – recommended dose

In the study year, meteorological conditions, especially in the second part of the vegetation, had an impact on the grain yield of both maize hybrids. The advantage of growing in crop rotation for hybrid ZP 677 was recorded in control treatments (3 t ha^{-1} in relation to 1 t ha^{-1} in monoculture). Unlike hybrid ZP 677, the hybrid of the newer generation ZP 606 had a significantly higher grain yield on all treatments in crop rotation, compared to the monoculture. Even with this hybrid, meteorological conditions influenced the reduction in yield, but to a lesser extent compared to ZP 677. The highest yield was recorded in the treatment of the recommended dose of herbicides (4.2 t ha^{-1}) (Graph 2). Among other things, the yield of maize to a great extent depends on the presence of weeds. Reduction in yield can also be over 90% if we do not apply weed control measures, and at global level, the average global loss caused by weeds is about 10% (Oerke, 2006). The decrease in the presence of weeds is directly related to the increase in yield, which is the direct effect of fertility and the application of herbicides (Simic et al., 2016). Kovačević et al. (2008) claim that the use of crop rotation in corn leads to a reduction in the presence of weeds, and therefore an increase in yield.

Graph 2. Grain yield of corn hybrids depending on the breeding and application system of herbicides



$LSD_{0.05}$ (hybrid): 1,29; $LSD_{0.05}$ (cropping system):1,24; $LSD_{0.05}$ (treatment): 1,00

Conclusions

Maize growing in crop rotation with winter wheat gives huge advantages and can be one of the solutions in IWMS. All tested parameters, leaf area maize height and grain yield, had the higher values in treatments included crop rotation. Herbicide application helped by weed suppresion, so even ½ of recommended rate of pre-em herbicides can significantly influence on weeds. This means that simple crop rotation of maize with winter wheat can be an important tool for achieving higher yields, and off course solve problem with weeds.

Abstract

Potato tuber moth (PTM), *Phthorimaea operculella* Zeller, represents a very dangerous potato pest in the warmer parts of the world. The harmfulness of the insect impact is reflected in the high level of tuber damage (up to the complete yield loss), as well as the complexity of its control. The damages caused by PTM to the potato production are considered to be quite significant at the locations with highest potato yields and production in Serbia. This paper will show the results of the monitoring of the occurrence and the number of imagoes (moths) of pests by using pheromones traps during 2016 and 2017 within the field experiments in the Rasina District (Serbia). The field experiment was set up at four locations. Pest control was based on the application of agro-biological and biological measures, starting from planting the potatoes, through the entire vegetation period, harvesting and storage of the tubers. The obtained results show the economic justification (13 percent lower cost of production) of agro-technical and biological measures of potato moth control in order to obtain a quality and both health and safe product, while preserving the environment at the same time.

Keywords: *Potato tuber moth, Potato, Rasina District, Biological measures, Economic justification.*

Introduction

Potato moth, *Phthorimaea operculella* Zeller (Lepidoptera: Gelechiidae), represents a very dangerous pests of potatoes of warmer parts of the world, in addition to damage which is caused by the complexity of its suppression. Until recently, in Serbia, this pest was almost known only from literature, where the description was given with the poor measures of suppression and emphasized that it was not present in Serbia, but in tropical and sub-tropical areas, and in the area of the former Yugoslavia in Dalmatia and Macedonia (Tanasijević and Ilić, 1969 Tanasijević and Simova-Tošić, 1987; Igrc, 1983; Milošević,2009). The moth life cycle, under optimum conditions, lasts 30 days, so that in one year it can have up to 12 generations. An adult female, during the 10-15 days of life, lays eggs on a leaf, a tree and a tuber from which becomes larvae within 5 days (Raman, 1980). During the period of eight days, larvae eat food, creating mines into a leaf, pulling themselves up in a stalk and a tuber. The maggot stage lasts for 6-9 days (Alvarez et al., 2005). The first official data on the presence of pests in Serbia, in Leskovac area, originated in 2011 (Jovanović et al., 2013). Since 2011 pests have appeared in other areas in Serbia, as well. It will be present in Serbia and other countries in the future and can lead to major problems in the production of potatoes. In the period from 2015 to 2017, huge damage caused by this insect has been recorded in many potato production areas in Serbia, mainly in warmer locations at lower altitudes. Pests cause damage to the field and warehouse. A female lays eggs on the stalk and a leaf of potatoes, through the cracks in the ground and on the tubers where a few days later larvaes appear. The leaf with mines loses its function, and the stalks above the site of damage is decaying. In the tubes, the caterpillars make halls and such tubers can not be used due to the

high degree of damage. Damage to the tuber is the place where the injured tissue of the tuber and the pathogen causative agent of the potato tuber disease are in contact. Thus, as a secondary phenomenon, mass diseases caused by mushrooms and bacteria which causes the damp and dry decaying of the tubers, appeared (Hanafi, 1999). After extracting the tubers from the soil, in the open and in the warehouse, to their consumption, if there is an imago, the female has the ability to reproduce again.

Pest control is based on a series of measures from the planting of potatoes during the entire vegetation period, during the extraction and storage of the tuber (measurements in the field, measures taken during removal of the tuber and measure in the storage). In this paper will be presented an economic analysis of the cost-effectiveness of biological measures that reduce the number of pests and avoids its presence on above biomass and tubers, thereby reducing or completely avoiding damage in relation to chemical protection measures.

Material and Methods

In the paper, we will present the influence of Potato moth on potato plants and tuber in the Rasina District (Mačkovac, Počekovina, Radmanovo, Graševci) through gross margin (GM) cost calculation. Experiment has performed during 2016 and 2017 year by using the pheromone traps (RAG) and visual inspection of plants in the field. Data are calculated through the gross margins of the economic viability of the biological in relation to the chemical measures of the protection. The basic elements for calculation of the gross margin used in research: yield and prices, quantity and value of fertilizers, pesticides and fuels, as well as the costs of contracted services. The original data are collected in Serbian dinars (RSD), but all prices are given in EUR. Prices are calculated based on Serbian National Bank average exchange rate against major world currencies for particular year. Indicators of production value, total variable costs and gross margin are calculated according to the methodology provided by Serbian Agriculture Advisory Service. For the purpose of research we are used the Microsoft Excel for data processing and GM calculating.

Results and Discussion

In the observed period, monitoring indicates to a trend of rapid growth in the number of pest populations. The total catch on the traps at the locality of Mačkovac was 91 (2016) and 120 (2017), on the traps at Počekovina locality 28 (2016) and 53 (2017), while on the locality of Graševci and Radmanovo there were no catches of this pest. These two sites are located at an altitude of 1500 meters, which proves the previously stated claim that there is no potato moth on these altitudes. The economic threshold of harm of this type of species is 15-20 catchable imago on one trap per day. In 2016, individual specimens of potato moths were occasionally caught from the end of June to the middle of August, and then only one prominent maximum of the flight, at the end of August and the beginning of September, appeared. Unlike 2016, in 2017, the period of the year was significantly earlier and longer. The three maximum flights were recorded at the end of June, at the end of July, at the beginning of August and at the end of August.

Successful suppression and maintenance of the potato moth under the threshold of harm for potato producers is possible only by combining all available measures. Measures that are used to struggle moth damage can be divided into preventive and direct (Raman, 1980; Tsedaley 2015). Preventive measures for the control of potato moths are aimed at reducing the risk of moth attacks, and by direct measures, using insecticides, we reduce its number and the ability of an adult insect to lay eggs. Within the examination of the biological measures of the fight, in order to avoid the female laying eggs on the tubers, we prepared the soil for planting well, the plant was slightly deeper (10-15 cm) and there was good soil coverage, by forming a regular and high bank, in order to prevent "Collapse" of banks due to frequent irrigation and

heavy rains in order to protect the tubers until the moment of extraction. For planting we used undamaged tubers and planting was done earlier. By maintaining soil moisture, by more frequent irrigation with smaller inlet norms (15-20 l m-2, up to a maximum of 25 l), up to one week before taking the potato out, we avoided creating cracks in the soil through which the female is reaching the tuber on which it lay eggs. Continuous monitoring of the appearance, number and development of moths has been performed. Immediately after the formation the scarfskin of the tubers, it was accessed by their removal.
The average yield of potatoes in 2016 was 20000 $kgha^{-1}$., while in 2017 it was 28000$kgha^{-1}$. For the yield of potatoes, it can be said that it shows oscillations. The average price in 2016 was 0,1694 EUR / kg. while in 2017 it was 0,1864 EUR / kg. The average value of total variable costs in 2016 on farms that did not apply chemical measures of the fight was 2 244,53 EUR/ ha. The average value of the gross margin was 1 178, 94 EUR / ha. While in holdings, where chemical fighting measures were applied in 2016, the average price of variable costs amounted to 2 917, 66 EUR / ha. The average value of the gross margin was 506,05 EUR / ha. In 2017, the results were the following: at farms where chemical measures were not applied in order to save the total variable costs were 2 244,54 EUR / ha, while the gross margin was 3 009,45 EUR / ha. In the holdings where the protection measures were applied, the total variable costs were 2 917, 67 EUR / ha, the gross margin was 2 336, 57 EUR / ha. The results of the analysis show that the omission of the chemical treatment of the gross margin was increased by 506,42 EUR / kg in 2016, while the 2017 was increased by 672, 88 EUR / ha. From all of the above mentioned, we see that the justified omission of chemical treatment, with the adequate application of agro-technical and biological measures of fighting in order to suppress the potato moth, positively affects the gross margin of potatoes.

Conclusion

A potato moth is a pest that is present and will remain in Serbia until the conditions for its development are favorable. In order to reduce the number of pests, and to protect potatoes and prevent the occurrence of damage, it is necessary to apply a series of measures that individually applied can not produce great effects. Therefore, they need to be applied integrally by all potato producers. This requires the State, as well as the competent Ministry through the Regional Agricultural Advisory Services and Local Self-Governments, to educate the manufacturers which measures to apply in order to reduce or avoid damages from this dangerous pest. In this paper, economic cost-effectiveness and justification of the potato moth contamination by applying agro-technical and biological measures of protection using the gross margin, are shown. Gross margin is the result of the impact of yield, prices and variable costs. In the case where the price is the same, and the yield differs, the difference in treatment is reflected in the costs, therefore in the total gross margin and amounts to 25% of the more profitable production by using a new protection model. In the case where the yield is the same and the price varies, the difference is in the total gross margin and is 11% in favor of applying the new protection model. In case where both the yield and the price are the same, the difference in the total gross margin is 13 % in favor of the application of the new protection model. Of course, if both price and the yield are higher, the conventional treatment is reduced considerably. But in the case when the price and yield are lower , then it is necessary to consider how profitable the conventional treatment system is, if we look at the analysis which show how profitable the new protection model is.

Abstract

The greatest challenge for the world in the upcoming period will be to feed itself without ruining its environment. An increased use of pesticides and mineral fertilizers has resulted in a large production of diverse agricultural crops and thousands of new products, which have enabled the regular supply of the market and good nutrition of the population. Due to great competition and demand, many farmers tend to use organophosphate pesticides excessively in order to increase yields. However, when spraying, farmers should, must to adhere but do not adhere to the instructions for the safe use of pesticides, i.e. they do not use appropriate personal and protective gear, which enables pesticides to enter the blood stream through inhalation and dermal exposure, negatively affecting their health. In this paper, the authors compared the relationship between the length of exposure to organophosphate pesticides and signs of disease caused by direct exposure to pesticides during spraying. In the Rasina District, the Republic of Serbia, 80 farmers were interviewed by using pre-designed questionnaires over the course of 16 months. The farmers who had been exposed to pesticide spraying reported acute signs and symptoms resulting from that exposure, such as blurred vision, burning eyes, redness and skin itching, difficulty in breathing, excessive sweating, dry throat and burning in the nose. The duration of the symptoms depended on the length of the exposure. It was concluded that there was need for raising awareness among farm sprayers on the safe use of pesticides and use of personal and protective gear while handling pesticides.

Keywords: *Organophosphate pesticides, exposure, pesticide spraying, farmers, protective gear.*

Introduction

Occupational exposures to Plant Protection Products (PPP) occur during the production, transportation, preparation and application of pesticides in the workplace (Ye et al., 2013). Exposure to pesticides is one of the most important occupational risks among farmers in developing countries (Coronado et al., 2004). Occupational exposure to pesticides is of great interest in order to identify the hazards of pesticide use and the establishment of safe methods of pesticide handling. Pesticides exposures both occupationally and environmentally cause a range of human health problems. A series of studies have documented that the easy availability of pesticides in farming households makes it a preferred means of self-harm. It has been estimated that there are 250 000 deaths annually from pesticide self-poisoning worldwide, accounting for 30% of the suicides globally (Gunnell et al., 2007).

Acute toxicity is normally the result of a single exposure and the symptoms are seen within a comparatively short time of exposure, usually within hours or days. Acute health effects may include irritation of skin or eyes or respiratory irritation. Long-term exposure to organophosphate pesticides can cause various health problems. Organophosphates are associated with well-known acute health problems such as nausea, dizziness, vomiting, headaches, abdominal pain, and skin and eye problems (MacFarlane et al., 2013; Reifenrath, 2007). A vast majority of the population in Serbia is engaged in agriculture and is therefore exposed to the pesticides used in agriculture.

In developing countries including Serbia, farmers who are engaged in the occupation of spraying pesticides in crops and plantings get the direct exposure of pesticides due to unsafe and non-preventive work practices. They do not use the Personal Protective Equipments like safety masks, gloves etc. during the aerial spraying of pesticides resulting in the entry of pesticides in the blood stream via respiratory tract through inhalation which can adversely affect respiratory system (Fareed et al., 2013). Respiratory symptoms, such as coughing, wheezing and airway inflammation, are commonly observed among people exposed to pesticides (Ye et al., 2013). Pesticides being used in agricultural tracts are released into the environment and come into human contact directly or indirectly. Humans are exposed to pesticides found in environmental media (soil, water, air and food) by different routes of exposure such as inhalation, ingestion and dermal contact. Exposure to pesticides results in acute and chronic health problems. These range from temporary acute effects like irritation of eyes, excessive salivation to chronic diseases like cancer, reproductive and developmental disorders etc (Yassi et al., 2001). The results of the study indicate the possibility that organophosphate pesticides play a role in genetic tissue damage, in the production of free radicals, in neuro-psychological disorders, and in diabetes (Jamal et al., 2016, Narayan, et al., 2013; Taghavian et al., 2016).

Organophosphates is common name for phosphorous thioesters and esters acid. In health and agriculture Organophosphates refers to a group of insecticides or nerves Agents that inhibit acetylcholinesterase, an enzyme that catalyzes the neurotransmitter hydrolysis acetylcholine in cholinergic synapses in the central and peripheral nervous system. Organophosphate pesticides are a class of chemicals defined as esters, amides, or thiol derivatives of veosfor, phosphonic, and phosphorothiocidic acid (Kavvalakis and Tsatsakis, 2012; Mangas, et al., 2016). It is necessary to emphasize that most organophosphate pesticides due to rapid degradation do not stay in the body for more than a few days (Kavvalakis and Tsatsakis, 2012). On the other hand, the highly reactive nature of organophosphate pesticides can lead to toxic effects.

Material and Methods

This paper is based on the results of the questionnaire survey on agricultural holdings in the Rasina District, the Republic of Serbia, which is famous for fruit and wine production. The study was conducted on apple-growing farms. According to the data from the Census of Agriculture (RIS, 2012), apple tree is grown in the Rasina District on an area of 1142 ha. The research was conducted in the period from May 2016 to August 2017, when Apple plantations are sprayed with organophosphate pesticides for control of pest Codling moth, *Cydia pomonella* . Usually spraying duration was from 07:00a.m. to 10:00a.m., then from 04:00p.m. to 07:00 p.m., two days per week. The farmers were examined during working days after the pesticide spraying. The organophosphate pesticide used in this study is chlorpyrifos. Respondents were exposed for six to sixteen months for this research.

Interview questionnaire

The questionnaire was designed to outline the details of land ownership, plantation where the farmers is currently working, exposure to organophosphate pesticide the use of pesticides, precautions taken, signs and symptoms related to pesticide exposure etc. Farmers who sprayed chlorpyrifos were asked if they experienced symptoms (blurred vision, itching eyes, skin infections / itching, excessive sweating, dry throat, difficulty breathing / coughing, burning nose) during or immediately after pesticide spraying. Some of these signs (blurred vision, excessive sweating and itching) were observed at the time of interview. Symptom details were collected as reports done by the farmers. The questionnaire provided information about the type of sprinklers used by the farmers for spraying, such as tractor sprayers and sprinklers. During the research, none of the respondents took precautions or used personal and

protective gear that include: protective suit, adequate protective gloves, respiratory protection masks, eye protection glasses and boots.

Data collection

The survey was conducted on a total number of 80 farmers, who were males and ranged between 20-65 years of age, belonging to same socioeconomic status. Farmers who participated in the survey were randomly selected on the basis of the initial questionnaire filled out, the fruit cultivation they grow, as well as on active engagement (full-time) for the preparation, storage and spraying of the pesticides on apples for at least six months. Analysis was done on four groups of subjects based on the duration of organophosphate exposure (i.e 15 subjects with 6 months of exposure, 20 subjects with 12 months exposure and 25 subjects with 16 months exposure). The study was compared with 20 healthy males having no previous or current occupational exposure to pesticides which were taken as control group from near by areas with same socioeconomic status. Questionnaires were asked to be filled by the all four groups of subjects. The questionnaire provided detailed information regarding the socioeconomic status, family history and personal habits which were recorded for each respondent. The purpose of the academic research was explained to all the participants and their consent is obtained.

Results and Discussion

On the basis of the questionnaire it was found that the subjects exposed to organophosphate pesticide via spraying the pesticides in their farms from 12 months and 16 months showed more prevalence in general health symptoms immediately after the spraying. The symptoms were of general nature like blurred vision, skin redness, white patches, excessive sweating, shortness of breath etc.(Table 1). An interesting aspect of this research was the prevalence of ophthalmological problems arising due to organophosphate pesticide spraying being dose and duration dependent. In the 6 months exposure period only 6.66% respondents complained of blurred vision whereas in 12 months it was 10% and in 16 months it was 36% being the highest. In the control group of same age and same social status it was only one respondents who complained of a blurred vision in 16 months of exposure, that may be because of age or environment. Burning of eyes was highly prevalent among pesticides sprayers. In 12 months of exposure duration 15% respondents complained of this symptom, and in 16 months 20% farm sprayers complained itching in their eyes which was quite significant. It was observed that there were no symptoms in the control group who were of the same age and socioeconomic status. With regard to the skin related problems in the 6 months of exposure duration only 13.33% respondents complained of skin rashes, whereas in the 12 months 20%, and in 16 months 60% of respondents complained of skin patches, redness and irritation which was also found to be highest in the longer exposure duration period. In the control group it was observed that there were no skin symptoms found in the non exposed workers. Similarly in present research respiratory related problems like excessive sweating, dry / sore throat, running / burning nose and shortness of breath / cough were found quite common in the farm pesticides sprayers exposed to organophosphate pesticides from 6 months, 12 months and 16 months. Table 1 shows that in the 6 months exposed sprayers 13.33% subjects showed excessive sweating and shortness of breath during the pesticide spraying as compared to their well matched controls. While in 12 months exposed sprayers the prevalence of symptoms were found higher, 30% sprayers complained the problem of excessive sweating, 15% sprayers reported dry throat, 25% reported burning nose, and 25% farm sprayers reported shortness of breath. Whereas in controls only one subject reported shortness breath. In the 16 months of exposure, 52% sprayers complained of excessive sweating, 32% reported dry throat, 44% reported burning nose, and 48% reported shortness of breath and cough.

While from the control group only one subject showed excessive sweating and coughing.(Table1)

Table 1. Showing the effects of organophosphate pesticides for 6, 12 and 16 months of exposure on the general parameters of eyes, skin and respiratory related symptoms in the four groups examines .

Exposure Duration	Symptoms → Groups of Subjects↓	Burning/ Stinging / Itching eyes	Blurred vision	Skin redness/white patches on skin/ skin scaling	Excessive sweating	Dry/ Sore throat	Runny/ Burning nose	Shortness of breath/ cough
6 Months	Group -1 (15)	0	1s-6.66%	2s-13.33%	2s-13.33%	0	0	2s-13.33%

*Source: Author's elaboration based on the questionnaire survey results.
*Note: s- subjects

From the findings of this research it can be seen that the signs and symptoms are significantly related to the duration of the exposure. Therefore, the research clearly shows that subjects who have been exposed to organophosphate pesticides for prolonged periods through spraying show a greater number of symptoms. The research showed that exposure to pesticides was mainly due to inhalation, dermal route and swallowing, since no farmer used a protective suit, adequate protective gloves, respiratory protection masks, eye protection and boots, which is mandatory prescribed in the instructions for use pesticides. It is important to note that during the interviews of the participants it was established that the farmers did not shower regularly. Most farmers in this study were not familiar with the health hazards caused by inadequate handling of organophosphates. Entrants reported two or more of the above symptoms within 24 hours of spraying and are thought to have suffered acute pesticide poisoning.
It was found that physiological changes caused by organophosphate pesticides in the above mentioned groups included ophthalmic changes, dermatological and respiratory disorders. In this regard, it is mentioned that continuous and direct exposure to pesticide eyes leads to complications such as blurred vision and eye pain (Mishra et al., 1985). Exposure to unprotected eyes by pesticides led to absorption in the eye tissues causing potential toxicity (Jaga and Dharmani, 2006). Visual problems (itching / burning eyes, blurred vision) can be related to the direct contact of pesticides with eyes due to non-compliance and non-change of eye protection measures such as protective glasses, so these findings are corroborated by this research (Singh & Kaur , 2012). The effects of organophosphate on the skin also depended on exposure time (Kishi et al., 1995). It was observed that the skin is the primary way of exposure to pesticides for farmers who handle sprays. Excluding acute poisoning, contact dermatitis is considered to be the most common health effect of pesticides, either through irritating or allergic mechanisms (Spiewak, 2000). All this confirms the previously stated assumption that the negative effects of the use of organophosphate pesticides can be minimized by the adequate application of protective equipment. The results of this study have shown similarity to some earlier toxicological tests done elsewhere. In Canada, a cross-section study of pesticide-related use and effects on the respiratory system of farmers was

carried out and the use of pesticides is associated with isolated asthma and a change in lung function (Senthilselvan et al., 1992). A worker cross – section study at the pesticide packaging also showed that, compared with the controls, pesticide-producing workers have a significantly higher risk of developing respiratory symptoms, including chronic coughing for women, nose and throat irritation for men and women (Zuskin et al 2008). These observations are in line with this research , where it has been found that most of the symptoms relate to skin and respiratory problems for farmers who have been exposed to pesticides for a long time.

Conclusion

This paper provides information related to the short-term effects of organophosphate pesticides on agricultural producers in the Rasina District, the Republic of Serbia, who worked in the most unfavorable environment without any protective gear . From the foregoing, three conclusions can be drawn. Firstly, it is necessary to continually educate farmers on the adequate use of protective gear in the handling of organophosphate pesticides, since the negative effects of organophosphate pesticides can be minimized by the adequate application of protective gear. Secondly, it is important that future research determines the correlation between the length of exposure to organophosphate pesticides, the dose of organophosphate pesticides and health problems. Thirdly, it is necessary to inform the farmers who are exposed to organophosphate pesticides about the importance of regular medical examinations.

Abstract

Wheat is exposed to attack of many pathogens, so it is essential to establish their occurrence and intensity every year. Septoria leaf blotch of wheat, caused by the fungus *Septoria tritici*, is one of the most common diseases in the world and shows the significant effect on wheat production. One of the reasons for more intensive occurrence of the disease is introducing into production shorter stem cultivars, having lower leaves closer to the ground, which facilitates infection of plants during autumn. This paper aimed to establish attack intensity of the disease in some winter wheat cultivars in the conditions of natural infection. The field trials were carried out during 2014/2015 and 2015/2016 in the locality Leposavić-Lešak, at fields of the Agricultural School, with ten cultivars studied as follows: Pobeda, Evropa 90, Renesansa, Simonida, NS 40s, Zvezdana, Planeta, Kruna, Sirtaki and Euklid. Sowing was done by sowing machine. Every cultivar was sown in 46 rows, 50 m long. Soil was fertilized before sowing by 300 kg ha^{-1} of mineral fertilizer (NPK 15:15:15), and additionally, during tillering stage, by 200 kg ha^{-1} of nitrogen fertilizer LAN. The rest agrotechnical measures applied on the trial were standard. One hundred randomly selected plants were sampled from every cultivar, and grading of attack intensity in both investigation years was done during the first week of June, according to the scale of Gešele (1978), by determining infection intensity from 0-100%. The highest average infection intensity in 2015 was observed in cultivars Pobeda and NS 40s (40%), and the attack intensity in most of cultivars (Renesansa, Planeta, Kruna and Euklid) was graded as 20%. In 2016 the cultivar Pobeda also showed attack intensity of 40%. Blotches covering 30% of leaf area were observed in cultivars NS 40s, Zvezdana and Sirtaki. Infection intensity in the cultivar Kruna amounted 10%.

Keywords: *Winter wheat, Cultivars, Pathogen, Intensity, Disease.*

Introduction

Wheat (*Triticum aestivum* L.) is the most important field crop which currently occupies large area throughout the world. Denčić *et al.*, (2009) have pointed to wheat as one of the most important components of human diet according to its nutritive value. Genetic potential of Serbian cultivars for grain yield is above 12 t ha^{-1}, but the obtained average grain yield is significantly lower. Genetic potential use efficiency depends on weather conditions, applied agrotechnical measures, as well as on resistance of grown cultivars to diseases (Denčić, 2006). Having in mind parasites, i.e. causal agents of various plant diseases, as a significant factor influencing grain yield, it is essential to establish their occurrence and intensity every year. Septoria leaf blotch of wheat (*Septoria tritici*) is a disease occurring during whole vegetation period, and is one of the most common diseases in the world which shows the significant effect on wheat production. Jevtić *et* Arsenijević, (1995) point to one of the reasons for more frequent occurrence of the disease being introduction of cultivars with lower habit (dwarf and semi-dwarf cultivars), that have lower leaves closer to the ground, which enables infection during autumn. Dwarf and semi-dwarf cultivars demand an altered agrotechnique (more intensive fertilization and higher crop density), which also acts in favor

of infection. In proper conditions, primary infection occurs early and might be observed after emergence of second leaf of wheat. The attack causes necrosis of infected plant tissue, which gradually wilts and often adheres to the ground (Telečki *et* Jevtić, 2009). *Septoria tritici* is currently considered as one of the most influential parasites for global wheat production, and it is the main wheat disease in many regions throughout the world (Eyal *et al*., 1985). Greater damage can be observed in favorable weather conditions, when the disease spreads from lower leaves to upper ones. Necrosis of strongly infected leaves leads to decrease of assimilation area, which causes lowering grain yield and deteriorating grain quality (Balaž *et al*., 1995). Wiese (1987) stated that the disease was registered in about 50 countries. Leroux *et al*., (2007) and Stammler *et al*., (2008) reported Septoria leaf blotch as one of the most important diseases in Northern Europe, and Garcia et Marshall (1992) stated the same for the grain production areas of the USA. The estimated grain yield loss caused by this pathogen in Western Europe amounted between 30 and 50% (Royle *et al*., 1986).

Climate of Serbia is very favorable for occurrence and development of the disease, so it is classified in the group of very harmful diseases. Occurrence of this disease in many locations of Serbia was reported previously by Arsenijević (1965), Kostić *et* Smiljaković (1966) and Ivanović et *al*., (2001). Jevtić *et al*., (2008) stated that Septoria leaf blotch of wheat occurred regularly in Serbia, with a high infection intensity. Grujić *et al*., (1998) established by their investigation in three locations in Serbia during 1998, that the average infection intensity for 141 cultivars was 50.35%. Gudžić *et al*., (2012) reported that in 2011, at pseudogley soil type, the average infection intensity for 10 cultivars amounted 27%. Kalentić *et al*., (2006) observed significantly stronger attack of Septoria leaf blotch on winter genotypes in regard to spring ones. This paper aimed to establish attack intensity of the disease in some winter wheat cultivars in the conditions of natural infection.

Material and Methods

The investigation was carried out in the locality Leposavić-Lešak (Serbia), at fields of the Agricultural School, during 2014/2015 and 2015/2016. Coordinates of the location were the following: latitude 43º10', longitude 20°44', altitude 558 m. The following cultivars were investigated: Pobeda, Evropa 90, Renesansa, Simonida, NS 40s, Zvezdana, Planeta, Kruna, Sirtaki and Euklid. In both trial years sowing was carried out within optimal terms (October 17th, 2014 and October 24th, 2015). Sowing of the studied cultivars was done by sowing machine. Every cultivar was sown in 46 rows, 50 m long. Soil was fertilized before sowing by 300 kg ha^{-1} of mineral fertilizer (NPK 15:15:15), and additionally, during tillering stage, by 200 kg ha^{-1} of nitrogen fertilizer LAN, while weed control was done combining herbicides Tezis and Bonaca in the dose recommended by the manufacturer.

One hundred randomly selected plants were sampled from every cultivar, and grading of attack intensity in both investigation years was done during the first week of June, according to the scale of Gešele (1978), by determining infection intensity from 0-100%.

Results and Discussion

The investigation results showed Septoria leaf blotch registered at the all studied cultivars in both years (table 1). The average attack intensity in 2015 was 26%, while in 2016 it amounted 24%. During 2015 in cultivars Renesansa, Planeta, Kruna and Euklid attack intensity was 20%, which made 40% of the total studied cultivars. Leaves of cultivars Simonida, Zvezdana and Sirtaki were 30% covered by blotches caused by the parasite *Septoria tritici*. In the cultivar Evropa 90 attack intensity of 10% was observed. Pobeda and NS 40s showed the highest susceptibility, and attack intensity on them was 40%.

Table 1. Intensity of *Septoria tritici* attack to winter wheat cultivars

No	Cultivar	2015	2016
		Attack intensity	Attack intensity
1	Pobeda	40	40
2	Evropa 90	10	20
3	Renesansa	20	20
4	Simonida	30	20
5	NS 40s	40	30
6	Zvezdana	30	30
7	Planeta	20	20
8	Kruna	20	10
9	Sirtaki	30	30
10	Euklid	20	20
Average		26 %	24%

The results collected in 2016 showed several cultivars (Evropa 90, Renesansa, Simonida, Planeta and Euklid) having attack intensity of 20%. Leaves 10% covered by the blotches in 2016 were observed in the cultivar Kruna. Values of attack intensity of cultivars Zvezdana and Sirtaki were the same as in 2015, and amounted 30%, together with the cultivar NS 40s. The highest average infection by the parasite *Septoria tritici* in 2016 also was observed in the cultivar Pobeda, 40% once again. Septoria leaf blotch is the disease which represents a problem and a limiting factor in successful wheat production. Besides favorable weather conditions, development of the disease is stimulated by growing susceptible cultivars and amount of inoculum from previous vegetations (Kalentić *et al*., 2006). Creating and growing resistant cultivars has a great importance in wheat protection from the causal agent of Septoria leaf blotch. Based on their investigation, Jerković *et al*., (2005) pointed out to existing differences among cultivars in resistance to the most important causal agents of wheat diseases, while Palmer *et* Skinner (2002) stated that commercial cultivars had no adequate resistance to this parasite.

Conclusions

Septoria leaf blotch of wheat is the disease regularly occurring in Serbia, where causes economically significant damage, and shows significant effect on wheat production.

Good resistance to *Septoria tritici* in both investigated years showed cultivars Evropa 90 and Kruna. Pobeda was the most susceptible cultivar, because it had infection intensity of 40% in both 2015 and 2016. Majority of cultivars used currently for wheat production are susceptible to the causal agent of Septoria leaf blotch. Therefore, wheat breeding for resistance to this pathogen ought to be one of main goals in creating new cultivars. In addition to selection and growing resistant cultivars, adequate attention should be paid to agrotechnical and chemical measures that ought to be applied during vegetation period of wheat.

Abstract

Western corn rootworm *Diabrotica v.* sp.*virgifera* is a pest native to America. Nowdays it presents economically one of the most important maize pests in Europe. A field experiment was carried out in Bečej (Serbia) during 2014 with Serbian maize cultivar NS-640. In experimental field, 96 plants were selected, marked, and arranged in 48 pairs. The number of leaves and plant height were recorded.. The maximum leaves number on C (control plants) was 15 during all five observations. The maximum leaves number on D (infested plants) was 14 in the first two and 15 in the last three observations. The maximum measured height on C (control) plants during five observations during vegetation was 180, 195, 300, 320 and 320cm, respectively. The maximum measured height on D (infested) plants during five observations was 178, 192, 295, 295 and 295cm, respectively. Statistical analysis shows significant differences between C and D plants based on their leaves number during the first three observations, while there were no differences between plant heights during all five observations.

Keywords: *Western Corn Rootworm, artificial infestation, maize, height, leaves*

Introduction

Western corn rootworm (WCR) *Diabrotica virgifera* sp. *virgifera* Le Conte (Coleoptera, Chrysomelidae) is maize pest native to America. WCR is first detected in Europe, in the early nineties in Serbia (Bača, 1993). Today WCR is economically very important pest of European maize fields (EPPO, 2017), with possibility to spread up to 100 km per year (Baufeld, 2003; MacLeod et al., 2004).WCR can feed on more than 20 plants from family Poaceae, but development and survival is possible only on the maize which represents reproductive WCR host plant (Clark and Hibbard, 2004). It is a univoltine, oligophagous pest, and it causes serious consequences on maize roots, on above - ground parts and on maize yields (Bača, 1993; James et al., 2005; Hummel et al., 2008; Ciobanu et al., 2009).The most important damages on maize are caused by larvae (Ciobanu et al., 2009; Wesseler and Fall, 2010). Larval attack leads to the plant lodging, and due to symptom known as "goose neck", only characteristic for WCR presence (Wesseler and Fall, 2010). Plant lodging causes mechanical losses (inability to harvest maize during mechanical harvesting) as well physiological (due to inability of the injured roots to uptake water and nutrients) (Tollefson, 2007; Dun et al., 2010). The aim of this research was to examine the impact of WCR larvae on maize morphology (i.e. leaf number and plant height) after plants were artificially infested with eggs in root zone. .

Material and method

The field experiment was carried out in Bečej municipality area, autonomous province of Vojvodina, Northern Serbia. It was performed from 2nd June until the 19th September 2014, with Serbian maize cultivar NS 640. The field chosen for experiment represents is with a low natural WCR infestation. During the experiment, 96 maize plants were selected, labelled and arranged into pairs. The plants were sawn in two rows with 1 m distance between labelled

plants. In each pair, one plant was artificially infested in root zone with 4 mL of WCR eggs 0.125% agar suspension (D plants). One mL of suspension contained 136 eggs. The other plant from the pair was the control plant, marked as C. The same amount of distilled water (4 mL) was injected in the root zone of plant C. After artificial infestation field experiment was inspected every week during four months. Inspection of plants included the measurement of heights and counting the number of leaves. The measurements of plant high were made using simple meter. Plant inspection was conducted five times on 26th June, 2nd July, 16th July, 24th July and 7th August. The differences between the heights and number of leaves among C and D plants were analysed using Two-sample t-test (Test for equality of sample variances) Gen Stat 12Th edition.

Results and discusion

During first observation the number of leaves on C plants was ranged from 8 to 15. The majority of C plants were with 12 leaves, while only one C plant had 15 leaves (Figure 1). During the second observation the number of leaves on C plants was ranges from 10 to 15. The highest number of C plants (21 plants) was with 13 leaves. During the first observation also only one C plant was with 15 leaves (Figure 1). During the third observation the number of leaves on C plants was ranges from 12 to 15. The highest number of C plants (24 C plants) was with 14 leaves, while the highest leaves number (15) was recorded on 17 C plants (Figure1). During the fourth and fifth observation the same leaves number were recorded and ranged from 12 to 15. The highest number of C plants (23 plants) was with 14 leaves, while the highest number of leaves (15) was recorded on 22 C plants (Figure1).

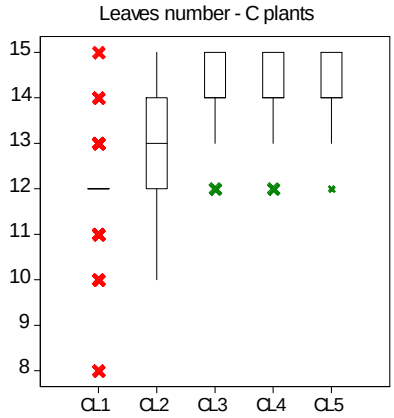

Figure 1. Number of leaves on C plants (C–control plants; L–number of leaves; 1-5 observation)

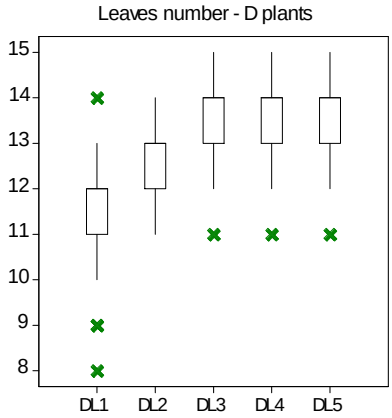

Figure 2. Number of leaves on D plants (C–control plants; L– number of leaves; 1-5 observation)

Statistical analysis shows highly significant differences in the number of leaves on C plants between 1st and 2nd as well 2nd and 3th observation, while there are no differences between 3th and 4th and 4th and 5th observation (Table 1).

Table 1. Differences between number of leaves on C plants during the field inspection

Year	Observation Leaves number	Means values ± STDTV		F	Sig.
		C plants	C plants		
2014	1st - 2nd observation	11.83 ± 1.260	12.98 ± 0.934	1.82	0.001**
	2nd -3th observation	12.98 ± 0.934	14.19 ± 0.734	1.62	0.001**
	3th -4th observation	14.19 ± 0.734	14.38 ± 0.672	1.19	0.195ns
	4th -5th observation	14.38 ± 0.672	14.38 ± 0.672	1.00	1.000ns

During the first observation number of leaves on D plants was ranged from 8 to 14. The majority number on D plants (27 plants) was with 12 leaves, with exception of one plant

with 8 and one with 14 leaves (Figure2). During the second observation number of leaves on D plants was ranged from 11 to 14. The majority number of D plants (19 plants) was with 12 leaves, while the highest leaves number (14) was recorded on 8 D plants (Figure 2). During the third observation number of leaves on D plants was ranged from 11 to 15. The highest number of D plants (22 plants) was with 14 leaves, while the highest number of leaves (15) was recorded on 7 D plants (Figure 2). During the fourth and fifth observation the same leaves number were recorded and ranged from 11 to 15. The majority number of D plants (23 plants) was with 14 leaves, while the majority number of leaves (15) was recorded on 10 D plants (Figure 2).

Statistical analysis shows highly significant differences in the number of leaves on D plants between 1st and 2nd as well 2nd and 3th observation, while there are no differences between 3th and 4th and 4th and 5th observation (Table 2).

Table 2. Differences between number of leaves on D plants during the field inspection

Year	Observation Leaves number	Means values± STDTV		F	Sig.
		D plants	D plants		
2014	1st - 2nd observation	11.48 ± 1.130	12.65 ± 0.838	1.82	0.001**
	2nd - 3th observation	12.65 ± 0.838	13.65 ± 0.887	1.12	0.001**
	3th - 4th observation	13.65 ± 0.887	13.83 ± 0.859	1.07	0.295ns
	4th - 5th observation	13.83 ± 0.859	13.83 ± 0.859	1.00	1.000ns

Statistical analysis shows highly significant differences in number of leaves between C and D plants during 3st, 4st and 5th observation, while there are no differences during the first two observations (Table 3).

Table 3. Differences in leaves number between C and D plants during the field inspection

Year	Observation	Leaves number Means values± STDTV		F	Sig.
		D plants	C plants		
2014	1st observation	11.48 ± 1.130	11.83 ± 1.260	1.24	0.150ns
	2nd observation	12.65 ± 0.838	12.98 ± 0.934	1.24	0.069ns
	3th observation	13.65 ± 0.887	14.19 ± 0.734	1.46	0.002**
	4th observation	13.83 ± 0.859	14.38 ± 0.672	1.63	0.001**
	5th observation	13.83 ± 0.859	14.38 ± 0.672	1.63	0.001**

During the first observation maximum and minimum measured heights on C plants were 180 and 110 cm, respectively. Average height of C plants in the 1st observation was 161.9 cm (Figure 4). During the second observation maximum measured heights on C plants was 195 cm, while minimum was 120 cm. Average measured heights in 2nd observation on C plants was 178.4 cm (Figure 4). In the third observation maximum heights on C plants was 300 cm and minimum 180 cm. Average heights during 3th observation on C plants was 248.9 cm (Figure 4). During the fourth and fifth observations the same maximum, minimum and average heights on C plants was recorded - 320 cm, 210 cm and 264.1 cm, respectively (Figure 4).

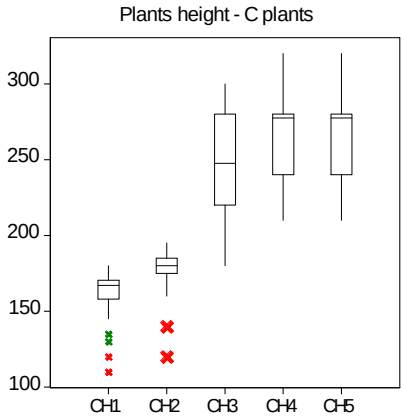

Figure 4. Plants height on C plants (C–control plants; L–leaves number; 1-5observation)

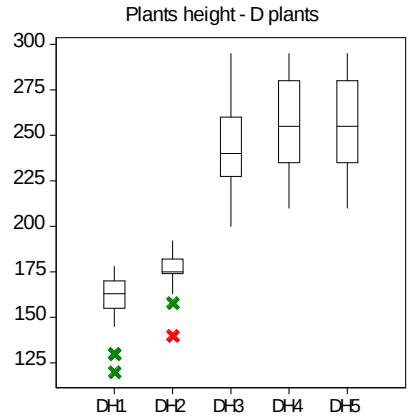

Figure 5. Plants heights on D plants (C–control plants; L–leaves number; 1-5observation)

Statistical analysis shows highly significant differences in plants height on C plants between 1st and 2nd as well between 2nd and 3th observation, while there are no differences between 3th and 4th and 4th and 5th observation (Table 4).

Table 4. Differences in plants height on C plants during the field inspection

Year	Observation Plants height	Means values ± STDTV		F	Sig.
		C plants	C plants		
2014	1st - 2nd observation	161.9 ± 14.53	178.4 ± 12.85	1.28	0.001**
	2nd - 3th observation	178.4 ± 12.85	248.9 ± 31.76	6.11	0.001**
	3th - 4th observation	248.9 ± 31.76	264.1 ± 28.60	1.23	0.015ns
	4th - 5th observation	264.1 ± 28.60	264.1 ± 28.60	1.00	1.000ns

During the first observation maximum and minimum measured heights on D plants were 178 and 120 cm, respectively. Average height of D plants in the 1st observation was 160.7 cm (Figure 5). During the second observation maximum measured heights on D plants was 192 cm, while minimum was 140 cm. Average measured heights in 2nd observation on D plants was 176.9 cm (Figure 5). In the third observation maximum heights on D plants was 295 cm and minimum was 200 cm. Average heights during 3rd observation on D plants was 243.7 cm (Figure 5). During the fourth and fifth the same maximum, minimum and average heights was recorded on D plants - 295 cm, 210 cm and 253.4 cm, respectively (Figure 5).
Statistical analysis shows highly significant differences in plants height on D plants between 1st and 2nd and 2nd and 3rd observation, while there are no differences between 3rd and 4th and 4th and5th observation (Table 5).

Table 5. Differences in plants height on D plants during the field inspection

Year	Observation Plants height	Means values± STDTV		F	Sig.
		D plants	D plants		
2014	1st - 2nd observation	160.7 ± 12.83	176.9 ± 9.243	1.93	0.001**

During the research in conditions of artificial WCR eggs infestation, Popović (2017) did not found statistically significant differences in plant height and plant diameter between artificially infested and un-infested maize plants. In the research of Tanasković et al. (2016) WCR eggs infestation caused 95.7% damages on infested plants with different rate of root damages. In conditions of artificial WCR eggs infestation Tanasković et al. (2017) reported significant differences in the level of root damages and root mass between infested and un-infested (control) maize. Artificial infestation with WCR eggs in the research of Popović et al. (2017) shows no differences in the root damages and root mass, between infested and un-infested plants. The differences between root damages on infested and un- infested plants were higher than differences in their root mass (Popović et al., 2017). These results are quite different in comparison with results recorded during this research. The available literature reports similar research of artificial WCR eggs infestation (different number of eggs), but points out consequences to the population density, size, longevity, and fecundity of emerged females. There are no available data about the influence on plant morphology parameters.
Artificially infested maize roots with WCR larvae in the research of Gavlovski et al. (1992) did not differ in fresh or dry weights or in plant heights. On the other hand, Riedell (1989) reported results of experiment with infestation with 150 second instar WCR larvae. Obtained results indicate differences in plants height, ears length and width, shoot fresh weight, ear dry weight, and husk dry weight between infested and un-infested maize plants.

Conclusion

According to this research, artificial infestation in conditions of low natural infestation caused significant statistical differences in number of formed leaves and plants height on C and D plants between 1st and 2nd and 2nd and 3th observation. Statistical analysis shows significant differences between C and D plants based on their leaves number during the first three observations, while there no differences between plant heights during all five observation.

Abstract

The *Colletotrichum* spp. fungus, the anthracnose causers, are cosmopolitan and extremely aggressive. Like herbal parasites, fungus *Colletotrichum* can cause economic losses on cereals, legumes, vegetable and fruit cultures. Inoculation under controlled conditions was examined for the pathogenicity of the studied isolates of *Colletotrichum* sp. according to different plant species. In this experiment, a total of 15 plant species from 6 botanical families were inoculated. The experiment includes 10 plants of alfalfa, birdsfoot trefoil, red clover, soybeans, peas, beans, field bindweed, flax, vetch, common sainfoin, fodder kale and pepper, per isolate. The plants were inoculated by stinging and by applying parts of the colony of examined isolates at the point of the sting. Ten plants per isolate of the Timothy-grass, cat grass, wood bluegrass is inoculated by spraying a spore suspension at tested isolates. In this research, ten isolates of *C. trifolii, C. destructivum* and *C. linicola* were used. Reactions to inoculated plants that proved to be experimental hosts of the investigated isolates *Colletotrichum* spp. were mostly balanced. Around the inoculated places, the distinct necrotic strips of light brown to dark brown were distinguished. After five days, changes in the appearance of leaves necrosis and drying of plant top inoculated with isolates from the genus *Colletotrichum* were observed. The aim of this research is the ability to monitor the emergence of primary infections in the wild, for forecasting and suppressing illnesses on alfalfa.

Keywords: *Anthracnose; alfalfa; Colletotrichum destructivum*; *C. linicola*, *C. trifolii, experimental hosts*

Introduction

In countries of subtropical and tropical climates, diseases can cause significant economic losses on a large number of agricultural crops during vegetation, as well as after harvesting and during the storage. In moderate climatic zone, pathogens *Colletotrichum* spp. primarily cause the rotting and the decay of stored fruits and vegetables (Freeman *et al*., 1998).

Like all herbal parasites, *Colletotrichum* spp. fungi can cause economic losses on cereals, legumes, vegetable and fruit crops. They are significant pathogens in numerous forest and ornamental plant species, and their presence is also recorded in plants from spontaneous flora (Bailey *et* Jeger, 1992). Symptoms of infection can occur on all underground and above the ground plant organs: roots, tubers, stems, leaves, flowers and fruits. On the affected plant tissue, they cause the appearance of circular, necrotic, embedded spots, with numerous concentrically arranged fruit-bearing bodies, acervuli, from which, in the yellowish-orange matrix, conidia is released (Freeman *et al*., 1998). Species of the genus *Colletotrichum* are known as epiphytic, endophytic and saprobic organisms (Sutton, 1992; Peres *et al*., 2005).

The aim of this research is to observe the emergence of primary infections in the wild, for forecasting and suppressing illnesses on alfalfa.

Material and methods

Inoculation in controlled conditions was used to examine the pathogenicity of the studied isolates of *Colletotrichum* sp. in different plant species, i.e., an experimental set of hosts was determined. For this purpose, a total of 15 plant species from 6 botanical families were inoculated:

- Fam. Fabaceae: alfalfa (*Medicago sativa* L.), red clover (*Trifolium repens* L.), birdsfoot trefoil (*Lotus corniculatus* L.), vetch (*Vicia sativa* L.), beans (*Phaseolus vulgaris* L.), pea (*Pisum sativum* L.), soy (*Glycine hispida* Max.) and sainfoin (*Onobrychis sativa* Lam.);
- Fam. Brassicaceae: oilseed rape (*Brassica napus* L.);
- Fam. Poaceae: timothy-grass (*Phleum pretense* L.), orchard grass (*Dactylis glomerata* L.) and bluegrass (*Agrostis alba* L.);
- Fam. Solanaceae, pepper (*Capsicum annuum* L.);
- Fam. Convolvulaceae, bindweed (*Convolvulus arvensis* L.) i
- Fam. Linaceae, linseed (*Linum usitatissimum* L.).

The experiment included ten plants of alfalfa, birdsfoot trefoil, red clover, soy, pea, beans, bindweed, linseed, vetch, sainfoin, oilseed rape and peppers per isolate. The plants were inoculated by pricking them and applying parts of the colony of examined isolates to the site of the prick. Prior to inoculation, the plants were sterilized by spraying the stems with 96% ethyl alcohol. After inoculation, the plants were kept in a humid chamber at a temperature of 25°C over a period of 72 hours in the constant darkness. Injured, but uninoculated plants, kept under the same conditions were used as the control.

Ten plants per the isolate: timothy-grass, orchard grass and bluegrass were inoculated by spraying the suspension of the spores of tested isolates at a concentration of $4\text{-}6x10^4$ conidia per ml (Mould *et al*., 1992). Conidia concentration was determined using hemocytometer (thoma chamber). Plants aged 6-7 weeks were cut before the inoculation, and then sprayed with suspension of the conidia of the tested isolates.

For this experiment, eight isolates were used: Coll-4 characterized as *C. trifolii* and reference isolate CBS 158.83 and isolates Coll-8, Coll-9, Coll-18, Coll-48, Coll-68, Coll-75 which are characterized as *C. destructivum* and their control isolate CC657 and isolate Coll-44 characterized as *C. linicola*.

Isolates were selected based on their morphological characteristics. All the inoculations were done by inoculum from fungi cultures aged 10 days and raised on PDA medium. The changes were monitored on a daily basis, lasting 15 days.

Results and discussion

The study of the range of experimental hosts of 10 isolates of phytopathogenic fungi from the genus *Colletotrichum* spp., classified into three morphological groups included a total of 15 plant species from six botanical families. Reactions on the inoculated plants that proved to be experimental hosts of the investigated isolates *Colletotrichum* spp. (alfalfa, red clover) were mostly uniform. Around the inoculated spot, the concave necrotic splotches of light brown to dark brown could be distinguished. After five days, changes in the shape on the leaves in the form of necrosis and drying of peak parts were observed in the plants inoculated with isolates Coll-4 and CBS 158.83 belonging to the species *C. trifolii* and with the Coll-8, Coll-9, Coll-18, Coll-48, Coll-68, Coll-75, CC576 belonging to the species *C. destructivum*. Similar reaction was found in the plants that were inoculated with the isolate Coll-44 identified as *C. linicola* (Table 1). The pea proved to be sensitive to isolates of the species *C. trifolii* (Coll-4 and CBS 158.83) and *C. destructivum* (Coll-9, Coll-18, Coll-48, Coll-68, Coll-75, CC657). Around the inoculation spot, the concave, necrotic, brown to dark brown splotches appeared (Figure 1a, 1b, 1c). Very soon after the inoculation and the occurrence of necrotic splotches

around the inoculation spot, changes were observed in the form of leaf necrosis and drying of the peak parts of the plants (Figure 2a, 2b, 2c).

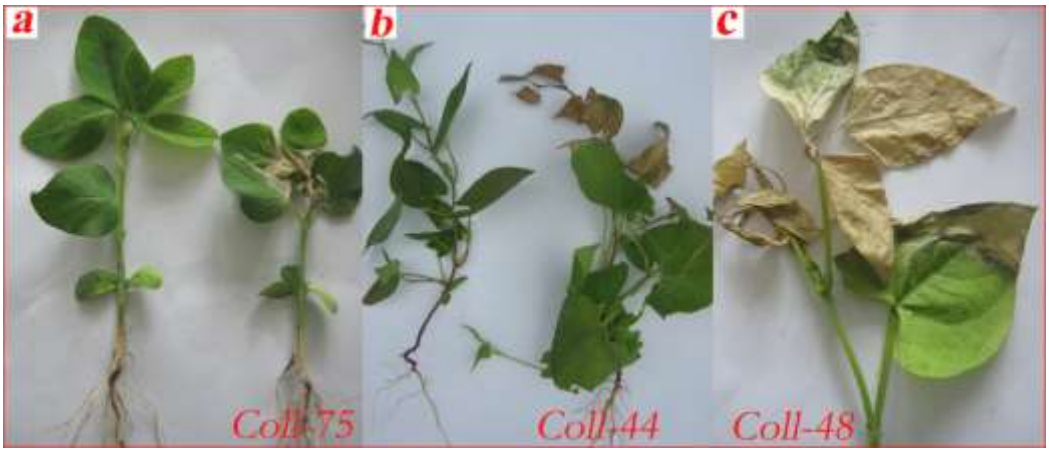

Figure 1. *Colletotrichum* spp. Soy infected with isolate Coll-75 (*C. destructivum*) (control - left, infected plant - right) (a), bindweed infected by isolate Coll-44 (*C. linicola*) (control - left, infected plant - right) (b), beans infected by isolate Coll-48 (*C. destructivum*) (c)

Isolates of *C. destructivum* (Coll-8, Coll-9, Coll-18, Coll-48, Coll-68, Coll-75 and CC657) have been shown to be pathogenic to bean plants (Figure 1c). After four weeks of inoculation, black fruit-bearing bodies (acervuli) were formed (Figure 2a). However, the isolates of *C. trifolii* (Coll-4 and CBS 158.83) did not cause any changes to the beans, and neither was the isolate *C. linicola* (Coll-44).

Figure 2. *Colletotrichum* spp. Symptoms on bean (appearance of acervuli), isolate Coll-9 (*C. destructivum*) (a), bindweed, isolate Coll-44 (*C. linicola*) (b), after four weeks and symptoms on linseed (necrosis) four days after inoculation, isolate Coll-44 (*C. linicola*) (c)

There was no change in the development of symptoms after artificial inoculation on inoculated plants of timothy-grass, orchard grass, oilseed rape, bluegrass and pepper. The three investigated species of the genus *Colletotrichum* were unable to infect any of the studied plants.

A total of 15 plant species from six botanical families were included in the study of the experimental hosts of 10 isolates of various species of the genus *Colletotrichum*. The plant species included in these researches have been selected as related species that are often grown in with alfalfa as mixed crops or are adjacent crops that are close to the alfalfa fields or are frequent weed species present in and around the alfalfa field. The sensitivity of these plants would indicate their possible role in the epidemiology of the genus *Colletotrichum*, the alfalfa pathogen, because they could act as a reservoir of pathogenic inoculums. These studies will continue, by expanding the number of species involved in the research, as well as attempts to detect latent or infectious diseases with lesser symptoms.

Selected isolates exhibited different ability to infect studied plants, and on plants that were infected, symptoms of necrosis and dryness developed. On the plants there were formed, more or less concave, necrotic splotches, dark brown to almost black, around an inoculated site. After 15 days of inoculation in all susceptible plants, whole plants wilted.

Isolate Coll-4 as well as the standard *C. trifolii* CBS 158.83 exhibited a uniform action on the tested plant. After inoculation, the isolates caused the occurrence of necrotic spots and the drying of all the inoculated alfalfa and red clover seedlings, exhibiting high infectivity. Both isolates exhibited high specialization for the infection of alfalfa and red clover. It should also be noted that the isolate Coll-4 has caused significant symptoms on the plants of vetch and pea, which makes it highly infectious. No isolate was able to infect sainfoin, timothy-grass, oilseed rape, orchard grass, bluegrass, soy, beans, birdsfoot trefoil, bindweed, linseed and pepper. Considering the *C. trifolii* hosts, the literature data indicate that this species exclusively parasites in the alfalfa and red clover. One group of authors stated that this species, although the primary pathogen of alfalfa, is able to infect other plants such as beans and gourds (Baxter *et al*., 1983; Liu *et al*., 2007). The results obtained in these researches are in full agreement with the statements of these authors.

The second morphological group of isolates identified as *C. destructivum* Coll-8, Coll-9, Coll-18, Coll-48, Coll-68, Coll-75, and the standard for *C. destructivum* CC657 also exhibited relative equivalence in terms of infectivity for the studied plants. They caused the occurrence of necrotic splotches and the extinction of seedlings of alfalfa, red clover, beans, pea, soy and birdsfoot trefoil. In birdsfoot trefoil only Coll-9 and Coll-18 isolates did not cause any changes. In the vetch plants, they caused an infection of smaller intensity. All seven isolates failed, under the conditions of the experiment, to infect other studied plants such as: sainfoin, ti,othy-grass, oilseed rape, orchard grass, bluegrass, bindweed, linseed and pepper. In relation to the *C. destructivum* host range, numerous authors (Baxter *et al*., 1983; Koch *et al*., 1989; Latunde-Dada *et al*., 1997; O'Connell *et al.*, 2004; Latunde-Dada and Lucas, 2007; Hyde *et al*., 2009) stated that it is broad and includes legumes such *Glycine max*, *Leucaena leucocephala*, *Lotus* spp., *Melilotus albus*, *Phaseolus lathyroides*, *Trifolium* spp., *Vigna unguiculata*, *Coronilla varia*, as well as tobacco (*Nicotiana tabacum*), dodder (*Cuscuta* spp.) and *Arabidopsis thaliana*. The results obtained during these studies are consistent with the above notes.

The third morphological group, the isolate Coll-44 identified to the level of the genus as *C. linicola*, exhibited a significant specialization in terms of the range of hosts. This isolate caused the occurrence of necrotic spots and wilting of all of the alfalfa, red clover, vetch, bindweed and linseed. This isolate was not able to infect other test plants: sainfoin, timothy-grass, oilseed rape, orchard grass, bluegrass, pepper, birdsfoot trefoil, beans, pea and soy, thus expressing similarity to the species *C. linicola*. Hyde *et al*.(2009a and 2009b) and Tunali *et al*. (2008) stated that linseed and bindweed are the hosts for the *C. linicola* species, while Latunde-Dada and Lucas (2007) noted alfalfa as an experimental host of *C. linicola* species. Considering the results of morphological identification and partial molecular characterization,

this isolate, Coll-44, shows a great similarity to *C. linicola*, which is further confirmed by a specific range of experimental hosts. Of all the examined isolates, only Coll-44 exhibited significant pathogenicity for linseed and pepper, which significantly differed from the other two determined species, *C. trifolii* and *C. destructivum*. Given the extremely complicated taxonomic status of species *C. trifolii, C. destructivum* and *C. linicola*, Johnston *et al*. (2000) stated that there are no general rules concerning their relationship between the pathogen and the host, and Freemen *et al*. (1998) emphasize that the separation of species based on the plant-host relationship does not have to be a reliable criterion, especially in the case of polyphagous, cosmopolitan and genetically variable species.

Conclusion

The study of experimental hosts confirmed the formation of morphological groups of isolates. Isolates of the first group identified as *C. trifolii*, exhibited a high level of specialization for infecting alfalfa and red clover plants. A group of isolates identified as *C. destructivum* also exhibited a high level of specialization by infections in alfalfa, red clover and bean seedlings. The third morphological group of isolates was identified as the genus *C. linicola* (Coll-44) exhibited a high level of specialization in alfalfa, red clover, linseed and bindweed plants.

THE RESULTS OF INVESTIGATION THE IMPACT DIFFERENT COLORS NETWORKS ON YIELD AND QUALITY OF PEPPERS

Vladimir SABADOŠ, Olivera SEKULIĆ, Danijela DOROTIĆ

Agriculture Extension Service "Sombor", Serbia
*Corresponding author: agroso@mts.rs

Abstract

The disadvantages of extreme high temperatures accompanied by low relative humidity, leave a whole range of consequences for most vegetable crops, first of all disruption of physiological processes, reduction in yield and quality of yields, more intense occurrence of diseases and pests. In order to reduce the negative impact of high temperatures and the direct impact of UV rays on the yield and quality of the peppers on the field of Agriculture Extension Service "Sombor" (Serbia), performed a trial experiment with the application of different color nets: blue, green, black, white and yellow. The trial experiment was performed during four years from 2014 to 2017. The results of the experiments show that the application of shading networks affect the lushness, renaissance, quality of peppers, reduction of diseases, pests, protection from the city and increase of yield. The trials were conducted with mulching with black foil in ''drop by drop'' system. In this way of production, the advantages of shading networks are simple and mobile construction, as well as the ability to use it for many years. The disadvantages of shading networks were a significant investment in production during the first year as well as the lack of effect in favorable weather conditions for the production of peppers. The application of this technology is recommended for the production of peppers on smaller surfaces as it contributes to stable and quality production.

Keywords: *High temperature, color networks, peppers.*

Introduction

In the second half of the last century, science and profession began with serious warnings that humankind on the earth's ball threatened climate change. From the middle of the last century, especially since 1970, there has been a trend of increasing the average global air temperature. High temperatures strongly affect the intensity of transpiration. Plants respond to stress by decreasing the intensity of breathing and synthesizing nutrients, as well as by increasing the reflection of radiation energy. Physiologically, injuries to plants and plant parts obtained from high temperatures depending on the intensity and length of exposure. Direct injuries lead to an imbalance of metabolism and changes that are present as membrane injuries, loss of fat, protein, and denaturation of nucleic acids (Ilić Z., et al., 2007).

In order to protect the plants and yields of the pepper from the undesirable effect of high solar radiation, it is used to shade the crops by using colored networks. Nets in color represent an additional tool in the management of light quality.

Picture number 1. The influence of high temperatures on yields of peppers (burns) on the field of PSS Sombor (photo V. Sabadoš).

Material and methods

In order to enable the production of high - quality vegetables in vegetable production, the most modern technological solutions are applied. In order to contribute to the reduction of the negative impact of extremely high temperatures we used the shading nets in the trial field of Agriculture Extension Service "Sombor" (Serbia) as a special agrotechnical measure, characteristic for the production of peppers, which significantly contributes to the reduced negative effect of abiotic factors on the growth, quality and yield of peppers. At the end of the 1960s, shading net was used in Europe. The most famous factories were a location in England and Italy. Over time, this technology has found a way into other parts of the world. Nets, in addition to basic protective use, have the function of protection against birds, insects, and wind. The benefit of the color network includes an extension of harvest time, increased yields, improved quality and agro-economic performance of the yield (Shalom Y. and Gussakovsky E.E., 2004). Filtered sunlight through a photoselective net, shows the influence and quality improvement and yield (Oren - Shamir et al., 2001). In order to solve the problem in the field of Agriculture Extension Service "Sombor" (Serbia), its implemented trial experiment with different colors of the shading net: Blue, green, black, white (rarely and dense) and yellow. An experimental trial was set in the period from 2014 to 2017. The varieties of peppers that were represented for a period of 4 years are in Madona, Slonovo uvo, Strižanka, Duga bela, Župska rana, Savo and Šorokšari. Madonna is a medium-sized variety in the type of "kapija" intended for cultivation in a protected area and an open field. The yield is fleshy, regular with two chambers, weighing 100 - 400 grams. In technological maturity, the color of the yield is yellow and in the botanical is red. Slonovo uvo is pepper "ajvaruša" with very large and fleshy fruits. The plant is very lush, forms the fruits with two or three chambers. The color of the yield from dark green turns into dark red. Slonovo uvo reaches a mass of 150-250 grams. Strižanka is in the type of "polubabura", it is yellow in technological maturity, and in the biological intense red color. It is suitable for consumption in fresh condition and industrial processing. It achieves good yields in a protected area. Duga bela is a medium early variety, strong, compact, high growth. The yield is long in the type of "kapije" that is milky white in technological maturity and in biological red color. Župska rana is a very early pepper variety. The plant is strong, compact, high growth and hanging yields. The yield is long in the type of the "kapije", which is in the technological maturity of yellow color and in the biological intense red color. The yield is light yellow, sweet and hanging. It is recommended for field production in protected areas. Šorokšari is a medium late variety. The plant is strong, compact, low growth. The fruit is in the type of "babure".

Characteristics of shading net

Manufacturers offer nets that range from 10 to 90%. Recommended vegetable density are nets that shine from 30 to 40%. They are most commonly produced from high-density polyethylene and can be used for more seasons. Shading nets are made of UV - resistant material and are suitable for use over several seasons, minimum two. Setting up nets is relatively simple. When installing the structure, it is necessary to lift the pillars over which the net is clinging and stretching. Nets are manufactured in different diameters of 1.20, 2.00, 3.60, 4.00, 6.00 and 7.50 mm depending on the purpose.

Picture number 2. Different dimensions of shading net

Nets can be found in different colors. Although it is said to be a shadow net, it at the same time reduces the amount of light, the intensity of UV rays and the temperature. Shading nets have additional functions such as making cold for domestic livestock and pets. Trials filed with the use of shading net is set in 3 repetition, the size of plots 5m², in the "drop by drop" system with the application of a mulch foil. With each variant, a control plot was set up.

Results and discussion

Results of the experiments in 2014 year

During of 2014, on-field Agriculture Extension Service "Sombor" made a trial with few different varieties of pepper: Madona, Slonovo uvo, Strižanka, Duga bela and Župska rana. Three different colors of the net were used: Blue, Green, and Yellow. In addition to the variant with the nets, a control plot was also installed.

Picture number 3. In the field of Agriculture Extension Service "Sombor" during 2014, three different colors of the network were used: Blue, Green, and Yellow (photo V.Sabadoš)

Table 1. Results in 2014 year

Variety	Control		Blue net		Green net		Yellow net	
	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage
Madona	32,5	32,0	31,8	10,0	30,2	8,0	24,7	18,0
Slonovo uvo	31,9	35,0	27,8	26,0	32,2	11,0	23,2	16,0
Strižanka	48,9	29,0	43,3	29,0	37,1	20,0	32,2	16,0
Duga bela	53,7	12,0	50,6	12,0	46,6	10,0	43,0	5,0
Župska rana	38,1	22,0	40,7	12,0	36,8	10,0	28,6	5,0

Results of the experiments in 2015 year

During of 2015, on-field Agriculture Extension Service "Sombor" made a trial with three varieties of peppers: Ljubov dlan, Slonovo uvo and Savo. Three different colors of the net were used: White (rarely), White (dense), Black and Green. In addition to the variant with the nets, a control plot was also installed.

Picture number 4. In the field of Agriculture Extension Service "Sombor" in 2015, four different colors of the nets were used: White (rarely), White (dense), Black and Green net (photo V.Sabadoš)

Table 2. Results in 2015 year

Variety	Control		White net (rarely)		Black net		Green net		White net (dense)	
	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage
Ljubov dlan	24,6	43,0	37,7	2,0	38,3	13,0	40,6	6,0	34,3	4,0
Slonovo uvo	19,2	36,0	44,4	5,0	53,0	10,0	38,8	3,0	45,3	8,0
Savo	16,2	61,0	27,6	5,0	27,6	9,0	26,4	7,0	37,8	13,0

Results of the experiments in 2016 year

During of 2016, on the field Agriculture Extension Service "Sombor", made a trial with three varieties of peppers: Ljubov dlan, SLonovo uvo i Šorokšari. Three different colors of the net were used: White (rarely), White (dense), Black and Green. In addition to the variant with the net, a control plot was also installed.

Picture number 5. In the field of Agriculture Extension Service in 2016 years, four different colors of the net were used: white (rarely), white (dense), black and green net (photo V.Sabadoš)

Table 3. Results in 2016 year

Variety	Control		White net (rarely)		Black net		Green net		White net (dense)	
	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage
Ljubov dlan	12.5	25.9	15.8	22.7	15.1	21.2	14.6	17.2	17.2	13.6
Slonovo uvo	10.5	23.5	23.2	22.7	16.5	23.3	16.3	24.0	19.7	17.3
Šorokšari	22.7	33.1	24.7	10.9	16.7	11.5	17.5	23.5	16.2	10.7

Results of the experiments in 2017 year

During of 2017, on the field of Agriculture Extension Servis "Sombor", made a trial with three varieties of pepper: Ljubov dlan, Slonovo uvo i Šorokšari. Three different colors of the net were used: White (rarely), White (dense), Black and Green. In addition to the variant with the nets, a control plot was also installed.

Picture number 6. In the field of Agriculture Extension Service "Sombor" in 2017 four different colors of the net were used: White (rarely), White (dense), Black and Green net (photo V.Sabadoš)

Table 4. Results in 2017 year

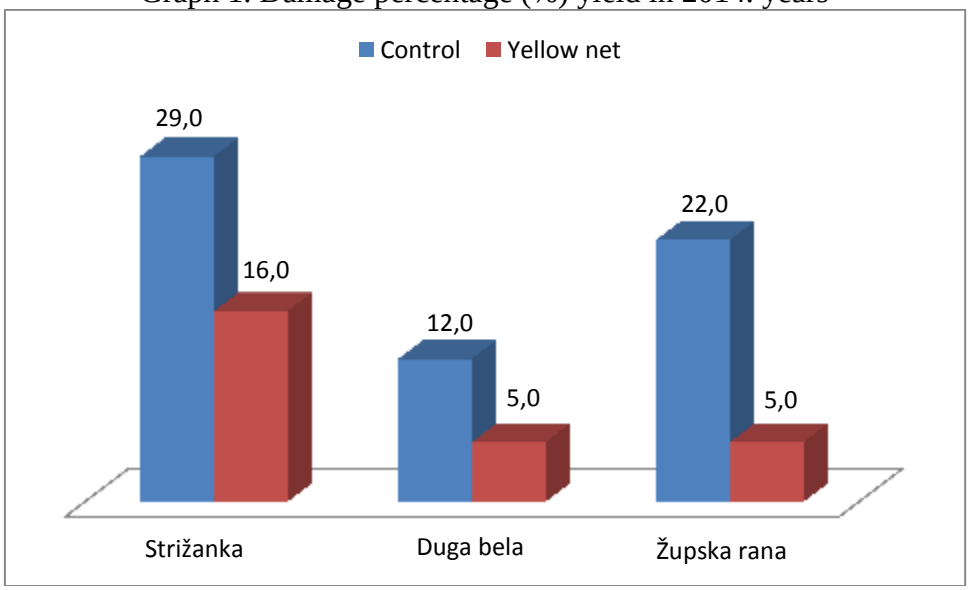
Variety	Control		White net (dense)		Black net		Green net		White net (rarly)	
	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage	Yield t/ha	% Damage
Ljubov dlan	32.1	12.6	25	6.5	42.6	14.7	54.2	8.3	47.4	12.4
Slonovo uvo	20.6	19.8	17.1	8.2	23.8	13.2	39.3	11.7	33.0	11.1
Šorokšari	27.8	19.9	19.3	12.3	17.8	18.8	20.8	14.0	14.1	16.8

Conclusion

The application of this technology is recommended for the production of table peppers on smaller surfaces, but it is also interesting for the production of blue eggplant and tomatoes. The benefit of a network of colors includes an extension of harvest time (early and later maturation) yield increase, quality improvement and total agroeconomic yield performance. (Shahak Y. and Gussakovsky E.E., 2004). In addition, the importance of network applications is also reflected in the protection of plants from the hail and insects.

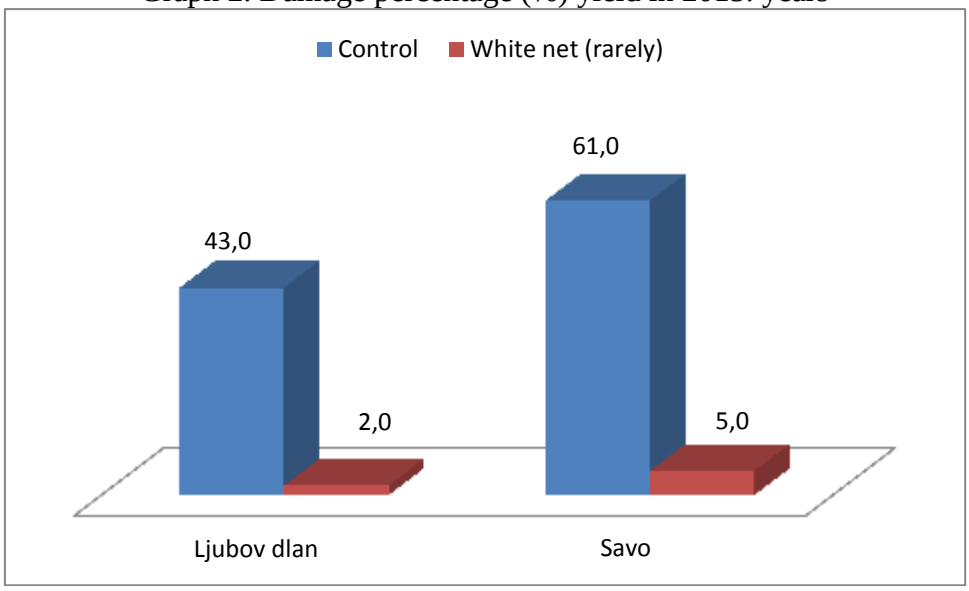
In 2014, for all the tested net (Table 1), the best results were obtained by applying a yellow net in the three examined variables, and we got lower damages than the control (Graph 1).

Graph 1. Damage percentage (%) yield in 2014. years



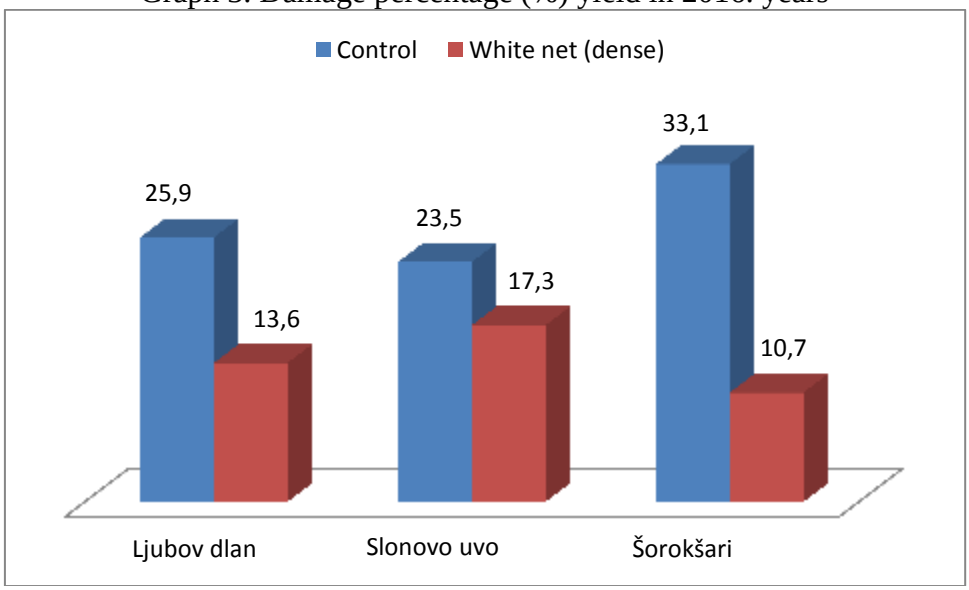
In 2015, for all the tested net (Table 2), the best results were obtained by using the white (rarely) net in the two examined variables and we got lower damages than the control (Graph 2).

Graph 2. Damage percentage (%) yield in 2015. years



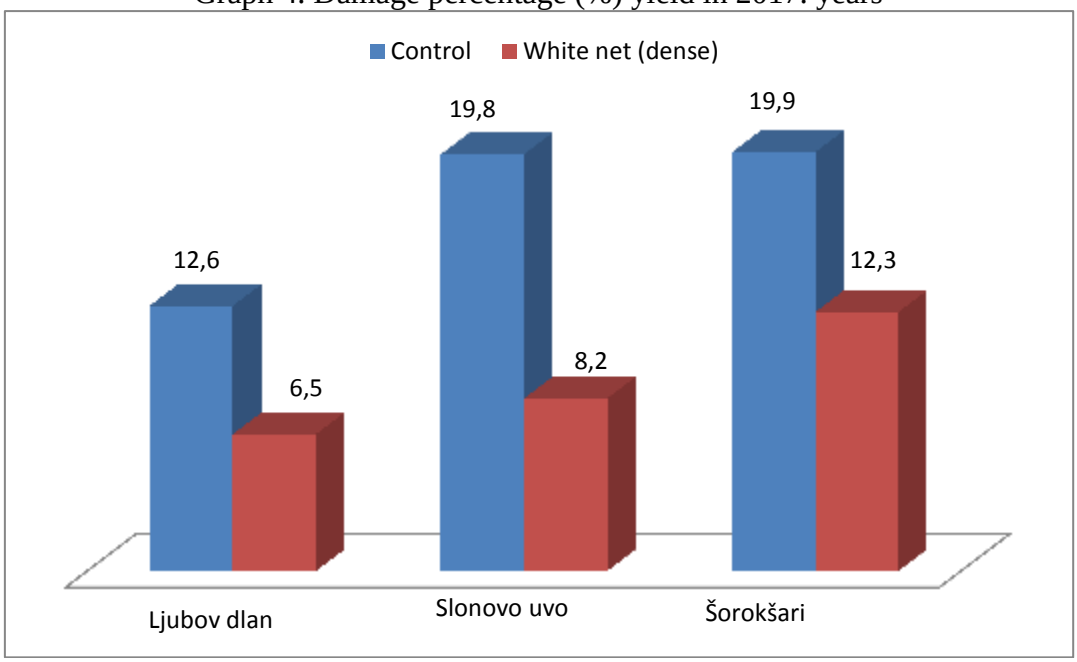
In 2016, in all the tested net (Table 3), the best results were obtained by using a white (dense) net in the three examined variables, and we got lower damages than the control (Graph 3).

Graph 3. Damage percentage (%) yield in 2016. years



In 2017, in the case of all the tested networks (Table 4), the best results were obtained by using a white (dense) net n the three examined variables, we got lower damages than the control (Graph 4)

Graph 4. Damage percentage (%) yield in 2017. years



Also, we continued testing different colors net in 2018. The disadvantages of shading nets are a significant investment in production in the first year. The benefits of the shading nets are simple and mobile construction, the use of nets for many years, the possibility of using incentive means for purchasing shading nets, stable and quality pepper production. Agronomic professions and science responded in time and tried to reduce the negative impact of climate change and abiotic stress on plants by introducing new breeding technologies, tolerant varieties, and hybrids.

Abstract

Lactic acid bacteria (LAB) are commonly used and generally regarded as safe. The most significant contribution of these microorganisms to the product is to preserve the nutritive qualities of the raw material through an extended shelf life and the inhibition of spoilage and pathogenic bacteria. LAB may positively affect taste and aroma of foods. LAB can maintain the balance of gut microbial flora, enhance resistance to diseases and show immunomodulatory activities. Certain LAB strains also have other significant functions such as antioxidant activity. Antioxidant properties of some LAB strains may be derived from antioxidases such as superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GSHPx). SOD, CAT and GSH-Px catalyze the decomposition of superoxide anion radical scavenger, hydrogen peroxide and hydroxyl radicals/hydrogen peroxide respectively. LAB play major role during meat fermentation as they contribute to final product quality and safety. The role of LAB in fermented meat products has been investigated widely, and some LAB strains have been shown to contain antioxidant properties *in vitro*. Studies indicated that *Pedioccocus* and *Lactobacillus* species had antioxidant properties. It has been shown that lipid and protein oxidation in sausages were significantly reduced by *Pedioccocus pentosaceus*. *Lactobacillus* species were also suggested as antioxidant agents for production of fermented meat products. In this review, studies using LAB as antioxidant agent in meat and meat products are presented.

Keywords: *Meat products, Lactic acid bacteria, Antioxidant*

Introduction

The most of lactic acid bacteria (LAB) is known as "Probiotics". Probiotics have been defined as "live microorganisms, which when administered in adequate amounts, confer a beneficial health effect on the host (FAO/WHO, 2002). LAB are Gram positive bacteria, widely distributed in nature, and industrially important as they are used in a variety of industrial food fermentations. Antioxidants are substances that retard the oxidation of easily oxidizable biomolecules, such as lipids and proteins in meat products, thus antioxidants improve the shelf life of products by protecting them against deterioration caused by oxidation. The use of antioxidants in food industry is controlled by regulatory laws of a country or international standards. Although there are many compounds that have been proposed to possess antioxidant properties to inhibit oxidative deterioration, only a few can be used in food product manufacture (Coda *et. al.,* 2012). In the United States, the use of antioxidants is subject to regulations of the Federal Food, Drug and Cosmetic Act, Meat Inspection Act, Poultry Inspection Act, and other state laws (Shahidi and Zhong, 2005). Oxidative damage plays a pathological role in human body. However, ingestion of antioxidative supplements, or foods containing antioxidants, may reduce the oxidative damage in the human body (Wang *et. al.,* 2006). In response to recent demand for natural products, consumers are willing to pay significant premiums for natural foods (Sebranek and Bacus, 2007). Therefore, many researches have been focused on finding natural and safe antioxidants (Embuscado, 2015).

Recently, meat safety concerns have focused on the potential carcinogenicity of red meat and processed meat, as described by the International Agency for Research on Cancer (Xiao *et. al.*, 2018). Therefore, it is important to use natural solutions to minimize oxidative rancidity and increase products' shelf-life in the meat and poultry meat industry (Naveena *et. al.*, 2008). Of various sources, probiotics have been considered as an emerging source of effective antioxidants. Due to their long tradition of safe use and potential therapeutic benefits, the role of probiotics as an antioxidant has been started to be widely investigated (Mishra *et al*., 2015). This review intends to summarize the effects of LAB to respond to oxidative stress and oxidative-stress related problems.

Importance of Antioxidants in Meat Products

Lipid oxidation is one of the major causes of quality deterioration and is also important because it can negatively affect sensory attributes such as color, texture, odor, and flavor as well as the nutritional quality of the product (Nunez de Gonzalez et al., 2008). The meat industry uses nitrates and nitrites for the stabilization of the meat color (Honikel, 2008), prevention of the development of pathogenic microorganisms, inhibition of lipid oxidation and enhancement of product flavor (Pegg and Shahidi, 2000). Despite the antioxidant power of nitrites and nitrates, industries are searching to find healthier and greener alternatives to stop or minimize the use of these chemicals which have been surrounded with claims of negative health effects (Gassara *et al.*, 2015). These issues are focusing the meat and poultry meat industry to find economic and natural antioxidant sources without negatively affecting the quality of finished products and consumer health (Karre *et al.*, 2013).

An antioxidant can be defined as "any substance that, when present in low concentrations compared to that of an oxidisable substrate, significantly delays or inhibits the oxidation of that substrate"(Halliwell and Gutteridge, 1995). Antioxidase can transform peroxide and oxygen free radicals into hypotoxic or nontoxic compounds for antioxidant activity via oxidoreduction. These compounds mainly include superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GSH-Px). SOD, a main antioxidant component in cells, is a specific superoxide anion radical scavenger. CAT, as an indicator of peroxidase, catalyzes the decomposition of hydrogen peroxide. And GSH-Px can scavenge hydroxyl radicals and hydrogen peroxide (Zhang *et al.*, 2017). Synthetic antioxidants such as butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), tert-butylhydroquinone (TBHQ), and propyl gallate (PG) have been used as antioxidants in meat and poultry meat products (Biswas *et al.*, 2007). In response to recent claims that synthetic antioxidants have the potential to cause toxicological effects and consumers' increased interest in purchasing natural products, the meat and poultry meat industry has been seeking sources of natural antioxidants (Karre *et al.*, 2013). The role of LAB in fermented meats has been studied widely (Fadda *et. al.*, 2010), and certain LAB strains have been determined to contain antioxidant properties *in vitro*. It has been shown that numerous LAB species have SOD, GSH-Px, CAT, and NADH oxidase activities to prevent deleterious oxidative effects (Noonpakdee *et al.*, 2004).

Usage of Lab and Probiotic Lab with *Antioxidant Properties* in Meat Products

LAB strains are essential agents during meat fermentation for contributing to final product quality and safety (Liu *et. al.*, 2011). The probiotic strains which have proteolytic, lipolytic, esterolytic and other enzymatic activities, citrate utilization, and bacteriocin production may be selected for application in meat fermentations (Belgacem *et al.*, 2010). There is also considerable evidence that probiotic LAB have antioxidative properties that may be effective against oxidative stress in humans (Kullisaar *et al.*, 2003). Some studies have shown that the antioxidant activities of some LAB strains may be attributable to antioxidases (SOD, CAT, GSHPx) and their activities (Kullisaar *et. al.*, 2002). The intracellular extracts of some LAB

have metal ion chelating ability, reactive oxygen species scavenging ability, and reduction activity (Lin and Yen, 1999; Zhang *et. al.*, 2005). Several studies have shown that some LAB, including *Lactobacillus plantarum*, *Lactobacillus rhamnosus*, *Bifidobacterium breve* and *Bifidobacterium lactis*, can bind and remove heavy metals such as cadmium (Cd) and lead *in vitro* (Halttunen *et. al.*, 2008). The capacity to accumulate selenite (Se_{4+}), an essential element showing antioxidant properties (Thirunavukkarasu *et al.*, 2004) has been described for some isolates of *Enterococcus* (Pieniz *et al.*, 2011) and other LAB (Svoboda *et al.*, 2009).
Free radical scavenging activity was also described to intracellular extracts of some LAB, such as *Lactobacillus delbrueckii* (Lin and Yen, 1999), *Lactobacillus acidophilus* and *Bifidobacterium longum* (Lin and Chang, 2000). The antioxidant activity of some species of LAB has been demonstrated by *in vitro* enzymatic assays (Lin and Yen, 1999). Both intact cells and intracellular cell-free extracts of *Lactobacillus acidophilus* ATCC 4356, isolated from human intestines exhibited 1,1-diphenyl-2-picrylhydrazyl (DPPH) free radical scavenging and linoleic acid peroxidation inhibition *in vitro* (Lin and Chang, 2000). Pieniz *et al.* (2014) observed the antioxidant effects of *Enterococcus durans* LAB18s by different methods, including scavenging of (2,2 azino-bis(3-ethylbenzothiazoline-6-sulfonic acid)) ($ABTS^{+}$) and 2,2-diphenyl-1-picrylhydrazyl (DPPH) radicals, and thiobarbituric acid reactive substances (TBARS) method.
Zhai *et al.* (2015) reported that *Lactobacillus plantarum* CCFM8610, showed the best binding ability and tolerance to Cd among all tested 33 strains of LAB. This strain also exhibited relatively good antioxidative properties and resistance to the simulated gastrointestinal conditions. Chen *et al.* (2015) determined the antioxidant activity of four LAB strains, isolated from Harbin dry sausage, and evaluated their antioxidant properties in both *in vitro* and a sausage model. The results of *in vitro* study showed that *P. pentosaceus* had the strongest H_2O_2 resistant ability, hydroxyl radical and DPPH radical scavenging activity, and highest reducing power and inhibition of lipid peroxidation, as well as high SOD and GSH-Px activities. Enterococci possess a competitive advantage over other microbiota in meat fermentations. The antimicrobial and antioxidant capacities of the *E. faecium* isolates from meat and dairy products revealed that indicate they could be very useful in food fermentation and feed composition. They could particularly help to inhibit pathogenic microorganisms as well as oxidative spoilage in foods and feeds (Pieniz *et al.*, 2015). *Takeda et al.* (2017) used *Lactobacillus sakei* strain no. 23 and *Lactobacillus curvatus* strain no. 28 in fermented sausage production. Researches indicated that the sausages fermented with these strains showed significantly higher antioxidant activity than those without LAB or fermented by each LAB strain. Zhang *et al.* (2017) compared the antioxidant activities of *L. curvatus* SR6 and *L. paracasei* SR10-1. The results showed that *L. curvatus* SR6 and *L. paracasei* SR10-1 significantly enhanced the antioxidant activities of sausage extracts.

Conclusions

LAB are commonly used in meat industry for fermentation and probiotic source. It has been shown that Lab are also have potential to be used as antioxidant agents in the processing of meat products. More research is needed to extend the knowledge on possible usage of LAB as antioxidant source in meat product processing.

Abstract

Humans have been seeking solutions for healing diseases encountered in different periods of their lives by applying different treatment methods and cures against different diseases. Natural plant products have been used throughout human history for various purposes. In fact, written records of the use of herbal medicine date back more than 5,000 years, and for much of history, herbal medicine was the only medicine. Due to complementary effect of medical treatments, alternative herbal medicine practices and cures are becoming increasingly important in developed countries. These products are complex mixtures of organic chemicals that may come from any raw or processed part of a plant. On this purpose the questionnaires were carried out in Serik, Aksu, Manavgat, Kumluca, Demre and Finike districts and villages of Antalya (Turkey) and 43 different questions were asked to 200 people living in the countryside. The alternative utilization of local plants by residents, the purpose of utilization, the consumption way, the contribution to their budget and the collection sites and collection ways were determined. As a result of this study, purslane (Portulaca oleracea L.) has been determined as most consumed plant as food material while tea and goosefoot (Chenopodium album L.) were the most commonly used plants. In disease treatments plants were mostly collected from field edges and fresh leaves were consumed. Leaf, stem and flowers were commonly used in treatments of diseases such as influenza, bronchitis and blood pressure and were commonly used as cough remover, pain reliever. These herbs are less expensive and they're a safer means of treatment than conventional medications

Keywords: *Rural areas, treatment, Antalya, weed, survey, medicinal plant.*

Introduction

Throughout their lives mankind utilize weeds for different pupropses. This purposes proved that weeds are not only harmfull also beneficial (Özer ve ark., 2003). This situation which is called ethnobotanic (human-plant relations) is short; utilization of plants by people to meet various needs and their effects on plants. Medicinal plants include plants or herbal products used in the treatment or prevention of diseases. According to the definition by World Health Organization (WHO) in 1980 medicinal plant is defined as a plant variety that can be therapeutic or preventive against certain diseases, main agent of chemical pharmaceutical synthesis (Yıldırımlı, 2004; Yapıcı ve ark., 2009). Across the world approximately 15% of 300.000 plant species are known to have pharmaceutical properties. (Palhares ve ark., 2015). Ethonobotanical studies in Anatolia dates back to beginning of Republican period and these studies are increasing day by day (Çubukçu ve Özhatay, 1987; Bulut, 2006; Doğanoğlu ve ark., 2006; Koçyiğit ve Özatay, 2006; Satıl ve ark., 2008; Yapıcı ve ark., 2009; Sarı ve ark., 2010; Kendir ve Güvenç, 2010; Faydaoğlu ve Sürücüoğlu, 2011; Tulukcu ve Sağdıç, 2011; Oğuz ve Tepe, 2017).

Alternative medicine İis the use of traditional and natural plants for treating diseases. Although some of diseases have the ability to gain resistance to synthetic medicines in a short period of time, this resistance can not be gained against herbal medicines (Özer ve

ark., 2004). The alternative medicine, called complementary medicine, is usually made with herbal products. Alternative medicine is usually applied to chronic diseases in which modern medicine is not effective. Herbal products used for alternative medicine can be used against different pathogensincluding HIV, cancer and hepatitis (Şarışen ve Çalışkan 2005; Anonim, 2009). Alternative medicine or complementary medicine is a method of treating diseases with natural herbal products (with tea or plant mixtures). These plants can either be collected from the nature or can be buy from herbalists. But the most important thing that should not be forgotten is that alternative medicine is defined as a complementary medicine and it must be remembered that the utlizisation amount creates poison (Özer ve ark., 2004; Şarışen ve Çalışkan 2005). Expert control is essential in the consumption of these plants.These plants natural plants are not only used as alternative medicine, but also in different forms such as fuel, food, shelter, spices, tea, animal food and others. In this study, a questionaire was carried out in Antalya to determine the utilization level of plants in disease treatments and other ways.

Material and method

On this purpose field studies and the questionnaires were carried out in June-September 2017 in Serik, Aksu, Manavgat, Kumluca, Demre and Finike districts and villages of Antalya (Turkey) and 43 different questions were asked to randomly selected 200 people living in the countryside.

The alternative utilization of local plants by residents, the purpose of utilization, the consumption way, the contribution to their budget and the collection sites and collection ways were determined. In addition plant observations were conducted to approve the situation of plants. The results were statistically analyzed in Plant Protection Deepartment of Faculty of Agriculture in Gaziosmanpaşa University.

Results and discussion

In this study, the socio-demogogic structure of the residentials of antalya, the plants they used, the usage forms and the diseases they treat were tried to be determined. As a result of these questionnaire, it was determined that the average age of the respondents was 37.79, the 62% of the respondents were female, 82% were married, and 34% were high school graduates. The study revealed that 29.5% of the respondents both work as worker and has an agricultural income. The participants of the questionnaire consists of livestock farmers who also consume naturally grown plants. Among natural plants kuzu kulağı was found to be collected most (53%) in winter and 81% were collected in summer. In addition 15 people who participated in the study stated that they collected more than 2 kg of semiz otu and 14 people declared that they used it in their daily consumption. Semiz otu was not only the most collected plants but the most purchased plant (13%). In general, it was determined that although fields were found suitable for collection of plants semiz out and mullet were collected from forest and katır tırnağı from seasides.

Oguz and Tepe (2017) found that plants such as sorrel, poppy were used mainly in Yüksekova. The utiliation may vary depending on local flora and wide acreage of Anatolian.

As a result of questionnaire it is determined that these plants are mainly used as food materials, the seeds, sirens, poppies and water are used for the medicine production, and also sage, lemon, thyme, mint, chamomile, rosemary, hibiscus, the sorrel were processed for tea production. The leaves were mostly used of these plants (95%) and they were collected from the fields (92%). According to Tulukçu and Sağdıç (2011), a similar results were obtained in Konya province.

Most of the collected vegetables were consumed freshly (98%), whereas these plants consumed predominantly in salads (93.5%) and meals (87.5%). Faydaoğlu and Driveroğlu 2011 mentioned the use of these plants as food and spices and raw material in medicines. Our results indicates the usage as green manure and fuel oils.

Farmers stated the possibility of pesticide residue risk (%58,5) harmfull effect on helth when directly consumed (%45,5) and they mentioned different methods such as peeling (%41), soaking in vinegar added water (%84), washing (%77,5) and utilication of alternative chemical to minimize negative effect (%3). The study by Tiryaki et al. (2010) showed that the residues of pesticides have negative effects on humans and that people are not sufficiently informed on this issue. Our work revealed that about half of the people living in the rural areas have knowledge of the effects of these pesticides on human health.

In terms of alternative medicine, 65% of the respondents stated that they prepared the medicine solution from the plants they collected and mostly prefer fresh plants (48.5%) and mainly use plant leaves (56.5%). The most commonly treated diseases are; (2%), cardiovascular diseases (11%), diabetes (29%), cancer types (6,5%), rheumatic diseases (3%), influenza (65%), hemorrhoids (16.5%), cough reliever (56.5%), pain killer (49%), blood pressure (26.5%), kidney disorders (21.5%) and others (0.05). It is known that naturally grown plants are being used to treat different diseases, which is indicated in the result of various ethnobotanical studies in different regions of our country. Yapıcı et al. (2009), reported the use of plants as wound healing, cough suppressant, sugar and kidney disorders, as a liver treatment and as a bile-reducing agent. Oguz and Tepe (2017) found that they used to treat constipation, intestinal disease, diabetes, rheumatism, headache, painkillers, heart diseases, etc. in their studies in Yüksekova. Several studies including our stud proved these results.

Conclusion

Nowadays studies regarding plant usage especially as alternative medicine have been significantly increase. Many plants have already been used in daily consumption for health for years. However, due to uncontrolled usage the necessity of control arise.

In this study it was observed that in rural parts of Antalya most of the plants were utilised as food or medicine production. The most commonly treated diseases are; prostate, flu, bronchitis, hemorrhoids, cardiovascular diseases, diabetes, cancer types, rheumatic diseases, cough suppressant, pain reliever, blood pressure, kidney disorders. In addition dried usage as tea and spice and usage as green manure soil fertilizer have been revealed.

The study is important in terms of determining the level of knowledge on the plant collection period, collection locations pesticide residues. Especially in regions with higher pesticide problems like Antalya more care should be taken in utilizing natural plants.

There is a need to work to increase the level of awareness of people to benefit more from these plants. Because many plants use limited consumption. Workshops should be organized by qualified experts to increase the level of avareness and information about the benefits and consumption of naturally grown plants should be given. Due to many plants have toxic varieties and their use can lead to serious problems the consumption must be under conrol of doctors.

In conclusion in Anatolia, rich in the point of plant species, the ways of benefiting from plants should be controlled and developed more scientifically.

Abstract

Weeds compete with crop plants for water, light, and nutrients leading to direct and indirect crop losses. Furthermore some weed species were a good hosts for many pathogens and insect. *Viscum album* is a semi-parasitic plant on fruit trees and schurbs which approximately provides only about half the nutrients on its own. *Viscum album* is found parasitic on more than 100 different genera and 230 different species which uses hosts for water and nutrient. This weed is reported parasitising many host plants across Turkey but host status in Northwestern Marmara Region of Turkey is not known. A field study was carried out in three provinces in Northwestern Marmara Region of Turkey to identifiy hosts frequency and density of *V. album*. The parasitic weed was mostly found in wild pear, pear, almond, plum, apricot, oak, spruce tree, willow, cherry and poplar trees in Edirne, Kırklareli and Tekirdağ provinces (Turkey). The incidence of weed was higher in Tekirdağ especially on pear trees. Tree death due to higher weed infection was observed on cherry and pear trees. According to our observations a correlation between the number of mistletoe shrubs on the host and tree health status was observed in infected fruit trees. Significant increase in damage on trees was determined paralel to increase of number of misletoe schrubs. Dried branches were observed in upper parts of infected trees. The infections in upper branches were found more destructive on examined trees. The geographic distribution map, occurance rate, host status and damage level were comprehensively detailed.

Keywords: *Misletoe, Hosts, Northwestern Marmara Region.*

Introduction

Viscum album, commonly known as European mistletoe, is a species of mistletoe in the family Viscaceae. This plant is a semi-parasitic perannial evergreen plant that grows on the stems and branches of deciduous species of trees. European misletoes have yellow-green color, egg-shape to elongated form leaves, yellow flowers, nearly in 1 m diameter green brown branches.

Misletoe cause significant reduction on growth and fruit production of host plants. These plants has higher transpiration rate and lower leaf water potential. Thus plant has lower water use efficiency for photosynthesis and consumes host plants water. This may create drough stress in host plants and may significantly affetc plant growth under low rainfall conditions (Mathiasen et al. 2008; Rigling et al. 2010; Mutlu et al., 2016). In addition many fungi and bacteria may invade into host trees from misletoe infeted canes (Varga et al. 2012).

Mistletoe is mostly polinated by insects such as sap-sucking bugs (*Cacopsylla visci, Pinalitus viscicola* and *Hypseloecus visci*,), the Mistletoe Marble Moth (*Celypha woodiana*), the Mistletoe Weevil (*Ixapion variegatum*) but wind polination is also reported (Hawksworth & Wiens 1996; Barney et al., 1998; Brigges, 2010).

On the other hand birds are responsible for dispersal of weed seeds. More than 11 bird vectors of European misletoes were reported including European bee-eater (*Merops apiaster*), Blackcap (*Silvia atricapilla*), the great tit (*Parus major*), the Eurasian jay (*Garrulus*

glandarius), Eurasian magpie (*Pica pica*), Eurasian blue tit (*Cyanistes caeruleus*), the Eurasian nuthatch (*Sitta europea*), the common wood pigeon (*Columba palumbus*). This evergreen plant has small white berries which contain 1-4 seeds and birds comes to feed even in winter. When feeding sticky misletoe seeds stick to their beaks. After birds ingest seeds by feeding they excrete seeds onto tree branches where the seeds germinate and begins to uptake water and minerals from its host plant with its newly emerged haustoria. Mistle thrush (*Turdus viscivorus*), fieldfare (*Turdus pilaris*), waxwing (*Bombycilla garrula*) can disperse seeds by this way in 20 km distance. Blackcap (*Sylvia atricapilla*) is another vector which only eats berry and leaves seed on bark (Zuber, 2004).

European mistletoe is divided into several subspecies. These species are morphologically very similar so that host plant is the easy way to differentiate. In Europe, four subspecies including *Viscum album subsp. album, V. album subsp. abietis*; *V. album subsp. austriacum; Viscum album subsp. creticum* were recorded (Zuber, 2004; Varga et al., 2014).

At present misletoe is widely distributed throughout Europe, Asia and America (Watson 2001). Several studies revealed presence and damage of European misletoe in wide range of host plants. The number of host plants and distribution rate arise due to higher incidence rate of vectors. Approximately 452 species in 96 genera of 44 families were identified as a host of misletoe (Barney et al., 1998). More than 118 hosts mainly *Tilia cordata, Betula pendula, Acer platanoides, Sorbus aucuparia, P. canadensis, P. nigra,* and *Salix alba* were determined in Poland (Stypinski 1997; Kolodziejek et al., 2013). Three trees including *Populus nigra, P. canadensis* and *Malus domestica* were found as preliminary hosts in Belgium (Stanton et. al., 2010). In Croatia, 52 hosts (33 autochthonous and 15 allochthonous species, two cultivars and two hybrids) recorded whereas host number decrease to 25 hosts (21 autochthonous and four allochthonous species) in Slovakia (Idzojtic et al., 2006). The majority of hosts belonged to the Rosaceae, Salicaceae, Aceraceae, Betulaceae, Fagaceae, Juglandaceae, Tiliaceae, Hippocastanaceae, Ulmaceae, Oleaceae, Fabaceae, Moraceae and Viscaceae families.

On the other hand, *Viscum album* was found in the trees of whitethorn, wild pear, pear, almond, apple, plum, apricot, sour cherry, locust, Canada poplar and willow in Turkey (Üstüner et al., 2015). According to Iversen (1944), both summer and winter temperatures restrict the geographic distribution of mistletoe. *V. album* can grow in an average temperature above 15°C lowest temperature and can tolerate without frost damage till –8°C in winter (Skre, 1979). Most parts of Turkey has quiet temperate weather which creates appropriate condition for misletoe ditribution, seed germination and growth. The climate cconditions are quiet well for polinator insects and vector birds as well.

This study was carried out in Northwesteern Marmara Region of Turkey. A survey was carried out in Edirne, Kırklareli and Tekirdağ Provinces. The current host status of misletoe is not well known. The geographic distribution map of misletoe in three provinces, occurance rate, host status and damage level were comprehensively detailed.

Material and method

A four year field survey was carried out in the summer of 2013-2017 to assess the distribution of the European mistletoe. Field observations were carried out in 6 different localities, 16 locations in Edirne, Kırklareli and Tekirdağ Provinces. The survey area covered approximately 9.000 km^2 area. GPS coordinates of survey area are 41°16'19" N - 26°41'05" E; 40°39'52" N - 26°42'00" E; 40°45'44" N - 26°40'05" E; 40° 57' 51.7500" N - 27° 6' 35.4312" E; 40° 38' 58.2612" N - 27° 8' 43.8360" E; 40° 42' 8.5320" N - 27° 15' 51.9228" E; 40° 42' 40.6944" N - 27° 10' 39.7128" E; 40° 57' 21.6864" N - 27° 26' 27.6684" E; 40° 41' 17.5128" N - 26° 10' 13.1268" E. The Region has humid and semi-humid weather with annual average temperature of 8-15°C. Several plant obersvations were performed on walnut, oak, peach,

pear, wild pear, wild cherry, cherry, pomegranate, apple, willow, poplar, oak, spruce, acacia, appricot, plum, lime, pine, plane, ash.
Leaf and flower samples were collected from predominant host trees (Figure 1). Each samples were put into pocket, labeled seperately and brought to laboratory in cold bag.

Figure 1. Flower and leaf of European misletoe *Viscum album*

The herbarium of misletoes were prepared by slow drying of plants in air flow incubator at 30°C. Herbariums of weed were deposited in Tekirdag Viticulture Research Institute. Identification of mistletoes were carried out by examining plant morphology, flower colour, host plant. The identifications were performed in Herbology Laboratory at Gaziosmanpaşa University, Turkey.
Presence or absence of misletoe was recorded in location. The infection degree of host plants was assessed using skala of Spálavský, 2001: 0 – No infection: no mistletoe was found on the tree (0 %), 1 – Rare occurrence: the tree is partially infected (1–10 %), 2 – Scattered occurrence: - 11–40 % of crowns on tree are infected 3 – Abundant occurrence: the tree is infected with higher misletoe volume approximately 41–70 %, 4 – Mass occurrence: The tree is infected strongly; 71–100 % of tree is infected.

Results and discussion

The european misletoe *Viscum album* was identified on wild pear (*Pyrus elaeagrifolia*), pear (*Pyrus communis*), almond *(Amygdalus communis*), plum (*Prunus domestica*) , apricot (*Pyrus armeniaca*), oak (*Quercus ilex*), spruce tree (*Picea* spp.), willow (*Salix* spp.), cherry (*Prunus avium*), acacia (*Robinia pseudoacacia*), whitehorn (*Crataegus monogyna*) and poplar (*Populus nigra*) 11 trees in Edirne Kırklareli and Tekirdağ. The parasitic weed was mostly found in wild pear, pear, almond, plum, apricot, oak, spruce tree, willow, cherry and poplar trees in Edirne, Kırklareli and Tekirdağ provinces (Turkey). No mistletoe shrub was found on coniferous trees, apple, pomegranate, walnut, lime, plane and ash trees during our field experiments. Tepe (1997) and Üstüner et al. (2015) obtained similar results in Central and Southern Anatolia. Tepe (1997) stated higher incidence of weed infestation in *P. communis*, *P. armenica*, *Amygdaus* spp., *P.elaegnifolia*. The infection degree of host plants was given in Table 1.

Table 1. Host plants and infection degree of host plants in Northwestern Marmara Region of Turkey

Host plant	Infection degree	Host plant	Infection degree
Pyrus elaeagrifolia	1	*Quercus ilex*	0
Pyrus communis	2-3-4	*Crataegus monogyna*	2
Amygdalus communis	2	*Populus nigra*	2
Picea spp.	1	*Prunus domestica*	1-2
Salix spp.	1	*Prunus armeniaca*	1-2
Malus domestica	0	*Tillia cordata*	0
Robinia pseudoacacia	1	*Juglans regia*	0
Prunus avium	3-4-5	*Fraxinus*	0
Quercus ilex	0	*Pinus* spp.	0
Crataegus monogyna	2	*Platanus* spp.	0

The incidence of weed was higher in trees in Tekirdağ especially on pear trees. Poplar was another forest tree highly attached with parasitic weed along roads in some locations in Tekirdağ. About 2/4 of poplar trees in İbribey location of Malkara was infected and the infection degree on trees was inside the scale of 11-40 %. There are many reports on frequent distribution of poplar (Pochzai et al., 2011). In addition higher incidence was observed on wild pear, almond and plum trees in Edirne and Kırklareli

According to our observations a correlation between the number of mistletoe shrubs on the host and tree health status was observed in infected fruit trees. There is large difference between the bush number and the host trees. The bush number on trees ranged between 2 to 21 in host plants. The higher bush number and schrub number was counted on pear, wild pear and poplar trees while this number was lowest in spruce tree and willow

Becides dried branches were significant in upper parts of heavy infected trees. The infections in upper branches were found more destructive on examined trees. Significant increase in damage on trees was determined paralel to increase of number of misletoe schrubs. Thus tree death due to higher weed infection was observed on cherry and pear trees. Two cherry trees in Malkara and one pear tree in Şarköy was almost dead due to heavy weed damage (Figure 2).

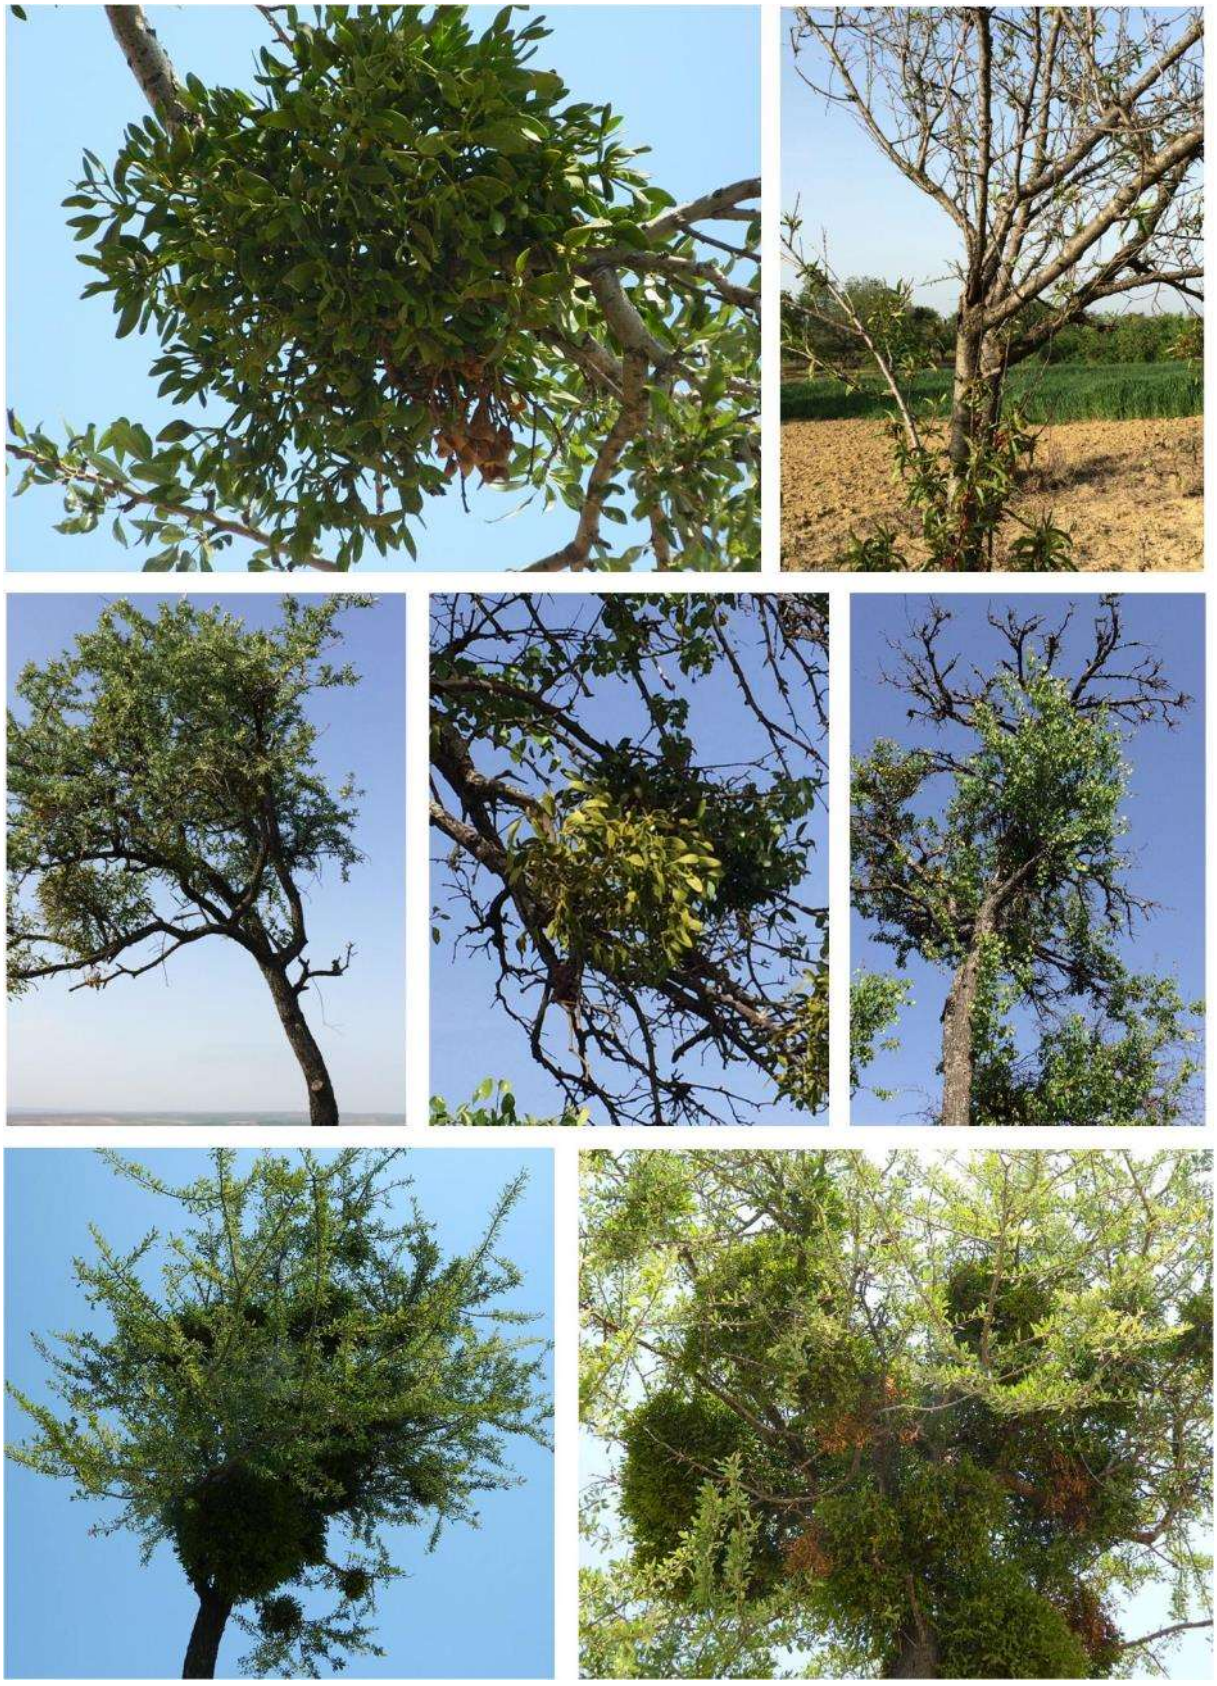

Figure 2. Mistletoe infected plant and weed shrubs on host trees

Conclusion

Viscum album semiparasitic weed was identified in 12 different host plants. Most frequent plants were cherry, pear, wild pear and poplar. The damage level and shrub number varied depending on host plant. The control of mistletoe dispersal is not so easy due to several vector birds in the environment. On the other hand climate conditions are very suitable for seed germination and weed growth. Several precautions like cutting and throwing away shrubs in infected trees can be done to minimize weed distribution in the region

EFFECTS OF ANTAGONIST BACTERIA AGANIST WALNUTS BACTERIAL BLIGHT DISEASE IN *IN VITRO* CONDITIONS

Bilgen YÖRÜK, Cansu AYVAZ*, Mustafa MİRİK

Namık Kemal University Department of Plant Protection, Tekirdağ, Turkey
*Corresponding author :coksel@nku.edu.te

Abstract

Walnut (*Juglans* spp.) crops are among the most economically important tree crops worldwide and cultivated to a different extent in all conditions. Bacterial blight (*Xanthomonas arboricola* pv. *juglandis*) is one of the main diseases of walnut that reduce the yield. Bacterial symptoms have been reported on all succulent tissues such as shots, leaves, buds, female flowers, catkins and nuts. The walnut leaves are more susceptible than other plant parts. Points of infection begin as water-soaked areas which develop into brown necrotic areas. Walnut bacterial blight is difficult to control because the bacteria overwinter and survive in dormant buds. So biological control is very important against walnut blight. The aim of this study was to determine whether bacterial antagonist could be used to control *Xanthomonas arboricola* pv. *juglandis.* In total, 69 potentially bacterial antagonists were isolated of healthy walnuts leaves. These samples were screened for their biological control activity against *Xanthomonas arboricola* pv. *juglandis* with dual culture methods in *in vitro* conditions. As a result of these study 48 antagonist bacterial strains obtained effective against *Xanthomonas arboricola* pv. *juglandis* with inhibition zone diameter ranging from 4.6 to 16.6 mm. Interestingly, among 21 effective antagonist bacteria, all of them totally inhibited the growing ability of pathogen *Xanthomonas arboricola* pv. *juglandis*. We clearly observed that these antagonist bacteria have a higher efficacy for *Xanthomonas arboricola* pv. *juglandis* biocontrol.

Keywords: *Xanthomonas arboricola* pv. *juglandis, juglan, biological control, dual culture method*

Intoruction

Walnut blight disease, caused by *Xanthomonas arboricola* pv. *juglandis* (Xaj), is one of the most important and common bacterial disease which effects production of walnut (*Juglans regia* L.) plants. Typical symptoms occur on all succulent tissues including shoots, leaves, rachis, petioles, buds, female flowers, catkins and nuts. Infections begin as translucent water-soaked areas which develop into brown to blackish greasy necrotic areas (Miller and Bollen, 1946). Lesions, which are often surrounded by a yellow-green halo, are initially circular but often expand into angular spots. Bacterial walnut blight caused by *Xanthomonas arboricola* pv. *juglandis* (Xaj) is one of the most serious and economically important diseases of walnut, occurring in all major walnuts-growing areas of the world (CABI-EPPO, 2001). There are no effective control methods, thus bacterial walnut blight may cause considerable yield losses (up to 70%) under favorable conditions for the disease (Gironde et al., 2009; Lang and Evans, 2010; Mulrean and Schroth, 1981). Copper-based compounds have been the only means of control for more than 40 years, but their efficacy is often limited (Gardan et al., 1993). Copper-resistant strains of Xaj have been isolated from walnut orchards where intensive copper spraying was used for disease control (Gardan et al., 1993). The way to reduce the damages caused by this disease has been to use periodical copper treatments although they are not always effective (Brault et al., 1990, Gardan et al., 1993, Radix et al., 1998) Biological control of walnut blight pathogen may be an alternative to chemical control. The aim of this

study was evaluated the effectiveness of potential antagonist bacteria against *Xanthomnas arboricola* pv. *juglandis* in *in vitro.*

Material and method

Survey

In the years 2016 and 2017 between May and July, leaf and fruit spots were observed on walnut cultivars grown in different orchard in Kütahya in Turkey. Leaves showing potential symptoms of walnut bacterial blight were collected. The samples were cut from trees and placed into paper bags and transported in the laboratory. A total of thirty five diseased plant samples were collected.

Isolations from diseased samples

Small pieces of tissue from leading edges from spots were macerated in 3 mL of nutrient broth and allowed to release 10 or 15 min. The suspensions were streak into nutrient agar (NA). Yellows colonies were grown on NA and considered as Xanthomonas.

Pathogenicity test on walnut fruits

Inoculums of each isolate were prepared from 48 hour bacterial cultures grown on NA. The bacteria were inoculated on immature walnut with sterile needle and incubated at 25 ^{0}C for three or five days.

Biochemical tests

Isolates were tested for Gram reaction, levan production, arginine dihyrolase, pectolitic activity on potato, hypersensitive reaction on tobacco and starch hydrolysis (Lelliott et al. 1996, Scaad et al. 2001).

Isolation from healthy samples

Healthy walnut leaves samples were collected and bacteria were isolated on King's medium B. Colonies were observed. After that the isolates were suspended and injected in tobacco leaf tissue between veins after 24 h.

Results and discussion

Pathogenicity and biochemical tests from diseased samples

All strains from walnut produced water suckedgi spot and necrotic area on immature walnut. According to pathogenicity test result, obtained re-isolate on immature walnut. All starins were negative for levan, arginine dihyrolase, pectolitic activity and positive for starch hydrolysis and hypersensitive reaction on tobacco. According to test result twenty strains identified as *Xanthomnas arboricola* pv. *juglandis.*

Isolations from healthy samples

All isolates weren't caused water sucked spots of tobacco leaf tissue between veins after 24 h.
Effects of antagonist bacteria were used against *Xanthomnas arboricola* pv. *juglandis* in petri dishes. Sixty-nine candidate antagonist bacteria were selected according to result of hypersensitive reaction and investigated for their ability to suppress bacterial growth *in vitro* conditions by dual culture test. Totally of forty-eight antagonist bacterial strains obtained effective against *Xanthomnas arboricola* pv. *juglandis* with inhibition zone diameter ranging from 4.6 to 16.6 mm.

All the isolates studied, originating from diseased and healthy walnut leaves. They were identified with biochemical and pathogenicity tests.
Candidate antagonist bacteria isolates were selected with hypersensitive reaction on tobacco leaves. According to results of dual culture test among totally of twenty one the most effective antagonist bacteria, all of them totally inhibited the growing ability of pathogen *Xanthomnas arboricola* pv. *juglandis*. Bacterial isolates could be use a possible bio-control agent against walnut bacterial blight disease.

Conclusion

Further studies should be conducted on identification and determination of mode of actions and *in vivo* activities of the most efficient bacterial isolates against disease agent.

Abstract

The lucerne beetle, *Gonioctena fornicata* (Brüggeman) (Coleopteran: Chrysomelidae)causes significantdamages on alfalfa. Both adults and larvae eat the leaves, flowers, leaf buds, young shoots and leaf stalks of alfalfa. Biological control methods are environmentaly safe and friendly ways of controling this pest. Entomopathogenic fungi are promising biocontrol agents for this pest under field conditions. At the present study, control potential of the entomopathogenic *Beauveria bassiana* isolate (GOPT-228) were tested against adults of *G. fornicata* at five different concentrations ($1x10^3$, $1x10^5$, $1x10^7$, $1x10^8$, and $1x10^9$ spores/ml). The experiment was laid out in completely randomized block design with 5 replications and replicated 2 times. Mortalities were recorded on the 1st, 3rd, 5th, and 7th days of incubation. Dead insects were transferred in humid sterile 90 mm glass petri dishes for 14 days to determine the mycosis rates. Mortality has been observed from the 3rd day and increased with increase in incubation period and inoculum concentration.Mortality rate of 100% was obtained at the end of the 7thin $1x10^9$spores/ml.The results showed that *B. bassiana* with LC50 and LC90 equal to 2×10^5 and 4.8×10^7 spores/ml The results of the study showed that B. bassiana isolate GOPT-228 can be used as a bioinsecticides against *G. fornicata* adults.Further study will be conducted to see performance of the isolate under field conditions.

Key words: *Entomopathogenic, Beauveria bassiana,Gonioctena fornicate, lucerne beetle*

Introduction

Alfalfa, *Medicago sativa* L., is a perennial flowering plant of the pea family (Fabaceae) and cultivated as significant forage crop lasting longer period than any other crop. Alfalfa has a very great yield potential, and it is also one of the most palatable and nutritious forage crops. Due to the high protein and vitamin content, alfalfa is the main component of the diet of dairy cattle (Mustafa et al. 2014). Lucerne beetle *Gonioctena fornicata* (Chrysomelidae) occurs in central and southern Europe, Turkey and most parts of the world, where it causes serious damage to *M. sativa* (Heyden et al. 1906, Blunck 1954). The beetle overwinters in the adult stage in its breeding-places, at a depth of 5-20 cm or more in the soil. Adults become active in spring, when the days become sunny and warm, with the air temperature above 20 ^oC and the soil temperature at least 11 ^oC. Emergence from the soil takes place over 15 days or more, and the beetles move to alfalfa plants and feed on the young leaves (Kovancı, 1982, Yıldırım et al., 1996). In Turkey, both adults and larvae feed on *M. sativa,Vicia sativa* and *Trifolium sp*.. Both the larvae and adults damage alfaalfa, eating the leaves, buds, leaf buds, young shoots and tips of stems (Kasap, 1988, Aslan et al., 2003; Coşkuncu and Gençer, 2006). In May, losses can exceed 60% of green mass and reach 100% of seeds (Grigorov, 1976). This pest gives one generation a year. The natural enemies of this species in the Turkey are insufficiently known.Burgio et al. (1992) examined the efficacy of the biological insecticide Novodor FC, which is a *Bacillus thuringiensis* subsp. t*enebrionis*-based formulation, against young (first- to third-instar) larvae and adults of *G. fornicata*. The young larvae and adults of this pest were fed on lucerne leaves (Medicago sativa) treated with 5 ml Novodor FC per litre

of water. All the larvae were killed within 2 days of feeding on the treated leaves. Adult mortality was significantly increased (by 44%) after 5 days of feeding on treated leaves, and after 7 and 10 days it had reached 52 and 72%, respectively. Atay et al. (2015) suggested entomopathogenic *Beauveria bassiana* isolates can be used for the control of *G. fornicata*. The local *B. bassiana* isolates usedagainst the adults, caused more than 90% mortality after 7 days.Biological control methods are environmentaly safe and friendly ways of controling this pest.

Aim of the present study was to evaluate the susceptibility of the adult stage of *G. fornicata* to infection by the isolate of GOPT-228 *B. bassiana* isolate.

Material and Methods

Fungal Isolate Entomopathogen *Beauveria bassiana* isolate GOPT-228 were selected for the experiment based on its tendency to sporulate at 27 ^{o}C and high virulance. *Beauveria bassiana* culture was obtained from culture collection in Phytopathology laboratory, Department of Plant Protection, Faculty of Agriculture at Gaziosmanpasa University Tokat, Turkey.

Invitro Bioassay. The isolate GOPT-228 was grown on Potato Dexrose Agar (PDA) medium at 27 ^{o}C for 4 weeks to get sporulation. The conidia were harvested under sterile conditions by flooding the plate with 10 ml sterile distilled water containing 0,02% tween 80 then scraping the colony with sterile glass hokey stick. Spore suspension was filtered through four layer steril cheeseclotes to remove mycelia. The concentrations of conidial suspensions were determined, using a Neubauer hemocytometer.The conidial suspensions were stored at 4 ^{o}C for up to 1 week until used in the assays. The viability of conidia was determined by spread-plating 0.1 ml of the suspension on the PDA plates. A sterile microscope cover slip was placed on each plate. Plates were incubated at 27 ^{o}C and examined after 24 h. The percentage of germination was determined by counting 100 spores for each plate, and over 95% of the spores germinated.For the dose-mortality test, *Gonioctena fornicata*adults were collected from infested alfalfa fields in Tokat province, Turkey. Healthy adults were randomly selected and used for bioassays. Conidial suspensions of fungal isolates were prepared as described above, and a series of dilutions was preparedas 1×10^3 , 1×10^5, 1×10^7 , 1×10^8 , and 1×10^9 conidia/ml.Ten adults were dipped inconidia suspension for 5 seconds than transferred into the glass petri dish (90 mm in diameter) containing fresh alfalfa as a food.The experiment was laid out in completely randomized block design with 5 replications and replicated 2 times. The control insects treated withsterile distilled water containing 0.02% tween 80. Mortalities were recorded on the 1st, 3rd, 5th, and 7th days of incubation. Dead insects were transferred in humid sterile 90 mm glass petri dishes for 14 days to determine the mycosis rates.

Statistical analysis

The data was analyzed by analysis of variance (ANOVA) and the means compared by Tukey's multiple comparison test. All statistical analyzes were carried out using the SPSS Release 16 packet program. Lethal concentrations (LC_{50} and LC_{90}) values were calculated by probit analysis (Finney 1978).

Results and Discussion

Limited number of researchers performed studies on effectivness of entomopathogenic *Beauveria bassiana* against *Gonioctena fornicata*(Atay, et al., 2015).However use of entomopathogenic fungi to control the other alfalfa weevils have been studied by various people worldwide (Roberts et al., 1994, Radcliffe and Flanders, 1998, Mustafa et al., 2014, Yücel et al., 2015, Reddy 2016). *B. bassiana* was found to be an effective controlling agent for *G.fornicata.* However, there existed a range in mortality according to the concentration of

conidia incorporated in the tereatment. Previous studies showed an increase in mortality at the higher conidia concentration produced the highest percentage of mortality (Atay, et al., 2015).The results of present study agrees with the results where higer dosage produced the highest percentage of mortality (Atay, et al., 2015).Theisolates tested and type of formulation used may also essential to an understanding of the conciderable differences in the activity of isolates tested in different studies. *B. bassiana* isolate GOPT-228 found to be pathogenic to the*G.fornicata* tested. Mortality produced by the fungus was confirmed on the basis of the steriomycroscop observarion of mycelial growth on the cadavers. In the dose-response tests of *B. bassiana*GOPT-228 adults'mortality has been observed from the 3rd day and increased with increase in incubation period and inoculum concentration. Themortality reached 100% within 7 days after inoculation of the conidial concentration of 1×10^9conidia/ml, and there was a significant difference among concentrations (df= 5, $P < 0.05$) (Table 1). Adults' mortality rate also reached 84% within 7 days after application of the 1×10^8conidia/ml concentration, and there was a significant difference among concentrations (df= 5, $P < 0.05$) (Table 1).The LC_{50} and LC_{90} values of isolate *B. bassiana*GOPT-228 were calculated as 2×10^5 and 4.8×10^7conidia/ ml against adults based on probit analysis, respectively (Table 2).Mycosis was observed on all the treatments accept the control.

Table 1. Mortality of *Gonioctena fornicata* exposed to different doses (1×10^3, 1×10^5, 1×10^7, 1×10^8, and 1×10^9 conidia/ml) of *Beauveria bassiana* isolates GOPT-228 and controls over 7 days after treatment

INVESTIGATION OF TOMATO YELLOW LEAF CURL VIRUS (TYLCV) STRAINS IN CUKUROVA REGION

Eray ATALAY, Muharrem A. KAMBEROGLU

Department of Plant Protection, Institute of Basic and Applied Sciences, Cukurova University, Turkey
*Corresponding author: eatalay89@hotmail.com

Abstract

Tomato yellow leaf curl virus (TYLCV) is a viral agent causing significant economic losses worldwide on tomato (*Lycopersicum esculentum*) cultivation in greenhouses. The symptoms caused by TYLCV on infected tomato plants are stunting, small chlorotic leaves with upward curling. Many different strains of TYLCV have been reported from various parts of the World. There are many difficulties in the symptom based differentiation of this virus. This study was carried in 2017 to identify and characterize TYLCV strains in Cukurova region, south-eastern Mediterranean coast of Turkey. With this aim, a total of 83 tomato leaf samples were collected and tested on TYLCV presence by PCR. Two different strains of TYLCV (TYLCV-IL, TYLCV-Mild) were identified in Cukurova region with strain specific primers. Samples that gave no PCR products with TYLCV-IL and TYLCV-Mild specific primers were tested with set of primers amplifying the coat protein (CP) coding gene. Phylogenetic analysis of selected TYLCV-IL and TYLCV-Mild isolates proved that they were related to other isolates from several countries. Although, phylogenetic analysis of CP of the two isolates from Mersin province had similarities with most of the TYLCV strains and isolates from other countries. These results showed that TYLCV had many viral variants being a threat for tomato cultivation in greenhouses in the Mediterranean region of Turkey and should be further investigated in detail.

Keywords: *TYLCV, PCR, Characterization, Tomato, Turkey*

Introduction

Tomato is one of the most consumed vegetable which can be cultivated in greenhouses or field all around the world and also in Turkey. It's the seventh most cultivated plant after maize, rice, wheat, potato, soybean and cassava (Bergougnoux, 2014). There are many known viruses effecting the quantity and quality of tomato cultivation. *Tomato yellow leaf curl virus* (TYLCV) belongs to *Begomovirus* genus in *Geminiviridae* family with single stranded DNA (ssDNA) genome structure. TYLCV infected tomato plants are declined with small chlorotic and upward curled leaves from margins (Hull, 2009). This DNA virus can cause almost 100% yield losses with early infection, especially in autumn sessions' greenhouse tomato cultivation (Czosnek, 2007). The first report of TYLCV presence in Cukurova region was published in 1978 (Yilmaz, 1978). TYLCV-Israel and TYLCV-Mld strains are detected in the most of the countries as major viral agents for tomato cultivation (Lefeuvre *et al.*, 2010). The aim of our study was to investigate the presence and diversity of TYLCV's common strains (TYLCV-IL and TYLCV-Mild) by using PCR based approach and phylogenetic analysis.

Material and Methods

Material

The survey was conducted in the autumn 2017 in tomato cultivation areas at Adana and Mersin provinces of Cukurova region of Turkey. The young leaf samples were collected from 83 tomato plants with the suspicion of TYLCV infection.

Methods

Infected plant leaves with TYLCV symptoms (upward curled and chlorotic leaves, stunted plants) were sampled, put in plastic bags and brought to laboratory under optimum conditions. The leaf samples were stored +4°C prior to DNA extraction. Four primer sets for TYLCV-IL TYv2337-TYc138 (Anfoka *et al.,* 2009) with TYLCV1840F-IL2642 (Lefeuvre *et al*., 2007); for TYLCV-Mild: TYLCV1840F-Mild2354R (Lefeuvre *et al*., 2007); for TYLCV coat protein : V1 (Kim *et al*., 2011) were used for PCR based detection PCR products were analysed in agarose gel electrophoresis. PCR products of selected isolates were sequenced by Erdem Lab, Turkey.The obtained sequences of selected isolates were analysed with MEGA7 programme (Kumar, 2016). The aligned sequences were compared after BLAST analysis and phylogenetic trees were reconstructed (Neighbour-joining method– Bootstrap: 1000 replicates).

Results and Discussion

The characteristic symptoms of TYLCV which cause declined tomato plants with upward curled chlorotic leaves were observed during our survey and described symptoms were also reported by numerous authors (Antignus and Cohen, 1994; Rochester *et al.,* 1994; Crespi *et al.,* 1995; Bananej *et al.,* 2004; Köklü *et al.,* 2006; Boukhatem *et al.,* 2008; Pakniat *et al.,* 2010; Van Brunschot *et al.,* 2010; Al-Ali *et al.,* 2016) as typical symptoms for TYLCV infected tomato plants..

DNA isolation of 83 tomato leave samples with suspicion of TYLCV was done and all the samples was tested to investigate the presence of TYLCV strains by molecular methods with using primers sets given in Table 1.

Table 1. Primer sets to detect TYLCV

Primer Sets	**Primer Sequence (5'-3')**	**PCR products**	**Ref.**	**Diagnosis**
TYv2337 TYc138	ACGTAGGTCTTGACATCTGTTGAGCTC AAGTGGGTCCCACATATTGCAAGAC	634 bp	Anfoka *et al.,* 2009	TYLCV-IL
V1 (CP)	ATGTCGAAGCGWCCA TTAATTTKRTAYTGAATCATAGAA	777 bp	Kim *et al.,* 2011	Coat Protein
TYLCV-1840F Mild-2354R	GGTCTACGTCATCAATGAC AGGGAGCTAAATCCAGTT	514 bp	Lefeuvre *et al.,* 2007	TYLCV-Mild
TYLCV-1840F IL-2642R	GGTCTACGTCATCAATGAC ACACCGATTCATTTCAAC	802 bp	Lefeuvre *et al.,* 2007	TYLCV-IL

One isolate from Adana (Sarıçam) were positive for TYLCV-Mild. In addition to this, two isolates from Mersin were mixed infected with both strains. To be able to confirm the presence of TYLCV-IL, a different primer set (TYv2337/TYc138) was used and 15 positive isolates were detected from Mersin province. Primer set for V1 (coat protein coding region) was used for isolates which were negative for both strains, despite the fact that they were showing similar symptoms. PCR products of a fragment from a TYLCV's coat protein genome region were observed in five isolates from Mersin.

Seven TYLCV-IL (634 bp), one TYLCV-Mild (514 bp), and two of TYLCV's V1 coat protein region (777 bp) isolates were sequenced. Obtained sequences were aligned with the sequences of isolates from other countries. Reconstructed phylogenetic trees are given in figures 1-3.

Table 1 Example of Coding TYLCV isolates in Cukurova region

Name	Viral agent	License Plate	County	Isolate No.
TYLCV-33:E:1	TYLCV	33(Mersin)	E(Erdemli)	1
TYLCV-01:S:1	TYLCV	01(Adana)	S(Sarıcam)	1

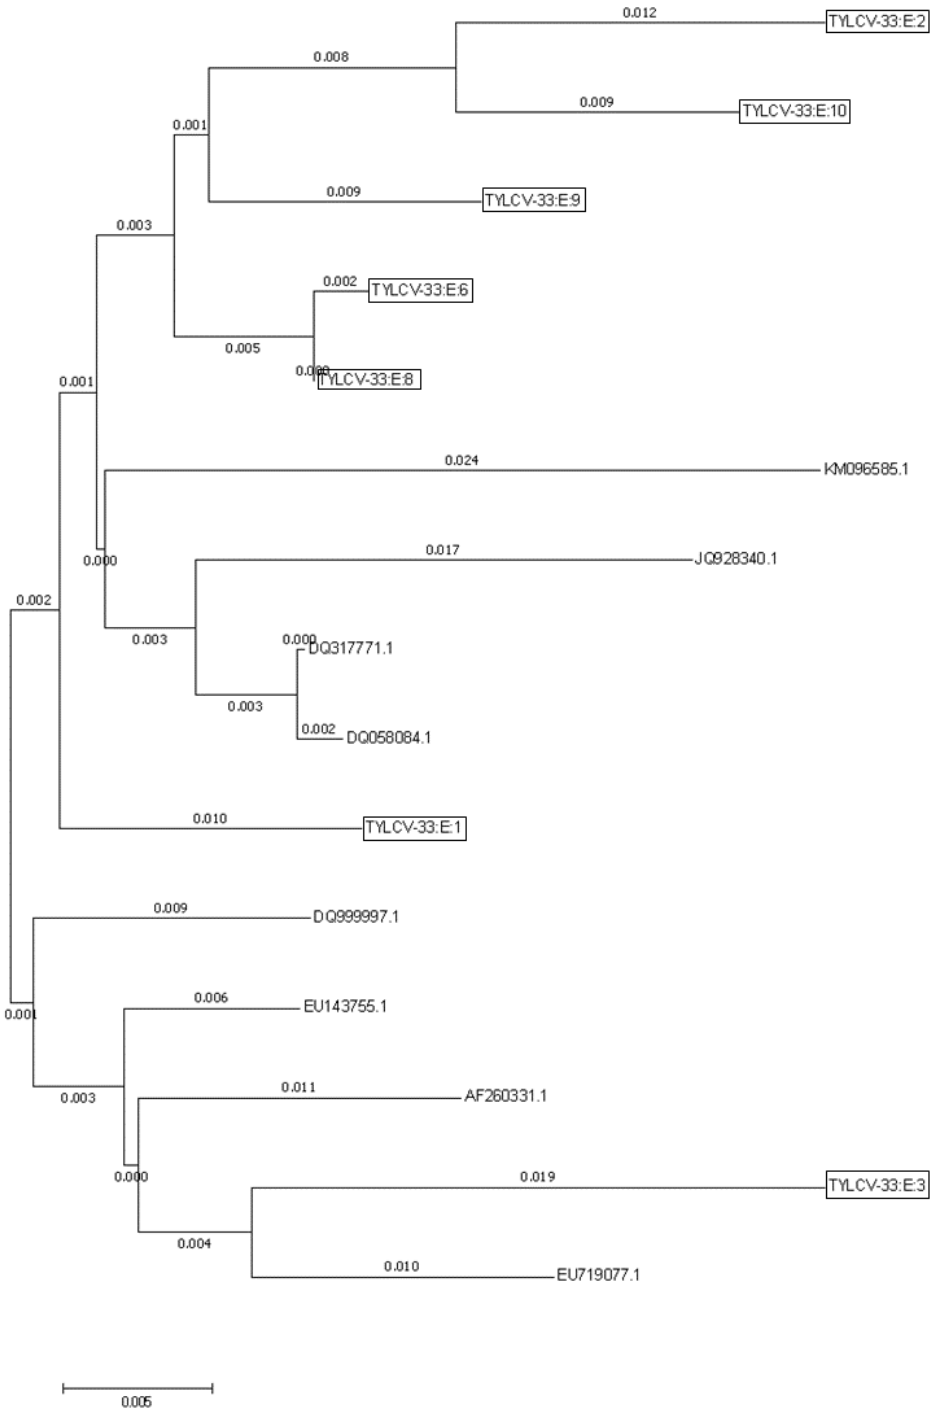

Figure 3. Phylogenetic tree reconstructed from the nucleotide sequences of the TYLCV isolates amplified with TYv2337/TYc138 primers

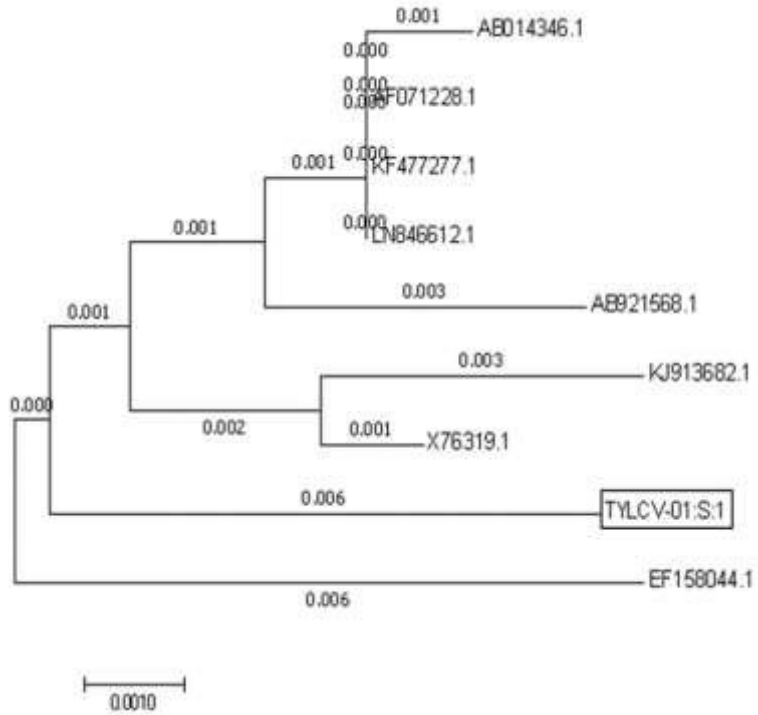

Figure 4. Phylogenetic tree reconstructed from the nucleotide sequences of the TYLCV isolates amplified with TYLCV1840F-Mild2354R primers

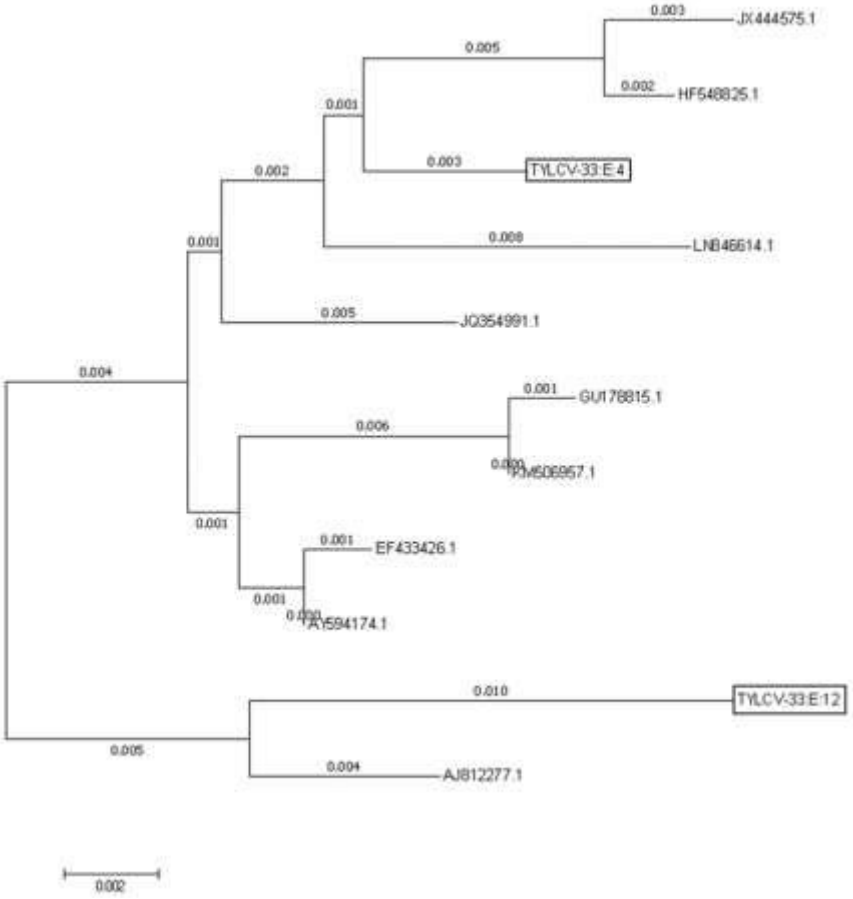

Figure 5. Phylogenetic tree reconstructed from the nucleotide sequences of the TYLCV isolates amplified with V1 primers

Our study is the first report regarding the molecular detection of the TYLCV strains in Cukurova region, south east region of Mediterranean. The presence of TYLCV was first reported in 1978 (Yılmaz., 1978). Köklü *et al.* (2006) also reported the presence of TYLCV in this region in one sample using molecular techniques. In this study, we analyzed 83 samples from different parts of the Cukurova region. According to the results, TYLCV-Mild was detected in 3,6% of the samples, and TYLCV-IL in 18% of the samples. in 6% of the samples we were unable to identify the TYLCV strain. In the rest of the 60 samples (72,4%) TYLCV was not detected by PCR method.

Conclusion

Our results showed that TYLCV is significantly present in analysed samples from the Cukurova region Further studies should be conducted including a greater number of samples throughout the Cukurova region. A combination of biological and molecular tests may give appropriate and precise results on the TYLCV presence. The design of a new strain-specific primers for TYLCV detection may also be a proper way to improve diagnostics.

Abstract

The pine processionary moth (*Thaumetopoea pityocampa* (Den. & Schiff) (Lepidoptera: Thaumetopoeidae), which is a common pest spread all over the world, causing economic loss, as well as health problems in humans and animals. Since mechanical and chemical control methods against the pine processionary moth have not achieved permanent or prolonged success and due to the negative effects of chemical control on resistance and environment, the importance of biological control measures has been emphasized in recent years. *Bacillus* spp is an important entomopathogen, especially in the biological control against Lepidoptera. In this study, 3 different doses (0.75, 1.5 and 3 g/1 lt water) of a commercial preparation containing *B .thrugiensis var κurstaki* obtained from Kazakhstan Research Institute were applied in 4 replications to the larvae of pine processionary moth obtained from natural populations. 1 kg plastic containers were used in the study and 10 larvae were placed in each container. The study was conducted at 22 ± 2 o C and 70% humidity. The study was observed for 5 days and deaths were noted. At the end of the 5th day of the study, the mortality rate was 60% for dose 0.75 g/1 lt water, 75% for dose 1.5g/1lt water and 90% for dose 3g/1lt water. As a result, it has been determined that the *B. thrugiensis var. κurstaki* preparation can be used at a dose of 3g/1lt water in the control of the pine processionary moth.

Keywords: *Bacillus thrugiensis var. κurstaki*, commercial preparation, pine processionary moth, *Thaumetopoea pityocampa.*

Introduction

One of the factors that threatens sustainability of forests in Turkey is pests. Among these pests, pine processionary is important due to the harm it does. Pine processionary (*Thaumetopoeo pityocampa* Schiff) is a moth that gives damage in pine forests particularly in Mediterranean, Egean, and Marmara regions. *Thaumetopoea pityocampa* Schiff is a pest that lives by feeding on acicular leaves of Calabrian pine (*Pinus brutia*), black pine (*Pinus nigra*), aleppo pine (*Pinus halepensis*), and scotch pine (*Pinus sylvestris*) in Turkey (Özkazanç, 2002). This pest feeds on pine leaves and spins a web on these trees. Pine processionary is reported to cause a loss around 60% in our forests (Anonymous 1995; Kanat *et al* 2002, 2004). Also, trees that are weakened due to this pest feeding on them become vulnerable for secondary pests such as scoltyds. In addition to these damages, the hair on larvae cause respiratory distress, conjunctivitis and allergic reactions such as asthma in humans and animals (Ekerbiçer, 2002; Kanat,2002). As fighting against pine processionaries is difficult, chemical and mechanical treatments are frequently used. Due to negative effects of chemical treatments on the environment and human health, biological treatments are becoming more common. In biological fighting against pine processionaries, there are studies on the use of parasites and predators (Bescelli 1969, Torun, 1975, Eroğlu & Oğurlu 1993, Avcı, 2000, Kanat & Mol 2008) and the use of microbial preparates (Bescelli 1969, Özkazanç 1986, Orhankaya & Can 2004). Entomopathogens play important roles in natural regulation of various pests and harmful populations. Many types of entomopathogens (fungus, bacteria,

nematod) are produced commercially and are being used as a biological treatment in fighting againsts pests around the world.

Bacillus thuringiensis (Bt) is a gram positive soil bacteria that has an economical value, and has a toxic effect on various larvaes of pests. Bt has been used as a bioinsecticide successfully in organic farming. Bt products maintain control by causing damage in the midgut of larvaes during larva state of various species of pests or by caousing septisemia (Raymond, 2010). Commercial formulations of parasporal crystal proteins produced during sporulation are done and used for biological control (Tamez-Guerra,2004). Bt strains are the most commonly studies entomopathogen due to being environmentally safe and species-specific (Han,2004). Insecticidal crystal proteins (ICP) show toxicity against several agricultural and forest pests as well as disease vectors. Different strains of Bt have limited or comprehensive toxic effect on pests from the orders of Lepidoptera, Diptera and Coleoptera. Studies on the effect mechanism of Cry toxins are mostly focused on Lepidoptera pests (Bravo, 2007). While these products are commonly used as biological treatment around the world, its use in our country is limited. However, recently several researchers in our country have been conducting comprehensive research on Bt products (Kurt, A., 2005; Bozlağan, İ.,2007;Tatar D.2008; Sezen K.2008; Azizoğlu U 2009;Öztürk F2008; Bozloğan İ 2010;Yılmaz S2011, Yılmaz S.2011, Azizoğlu U2011, Tekin S 2012).

This study aims to examine the effects of a commercial preparate (Ak kolebek) with B. thrugiensis var κurstaki obtained from Kazakhstan Research Institute on larvae of pine processionary obtained from pine trees on Ondokuz Mayis University campus.

Material and Methods

The larvae of *Thaumetpoae pitycompae* used in this study were obtained from the cultured larvae sacs that were obtained from pine trees on Ondokuz Mayis University campus. 3 different doses of Ak kobelek (*B. thrugiensis var κurstaki*) preparate (It was obtain from Kazakhstan Research Institute) were used (0,75 g/l; 1,5 g/l ve 3 g/l). Blotting paper were placed in plastic containers with the dimensions of 10x10x10cm and 10 larvae were placed in each container and pine needles were placed as food. The study was conducted in a labratory with 4 repetitions under the conditions of 22±2 oC and 70% humidity. Larvae used in this study were obtained from one colony and they all were the same age. 10 larvae were placed in each container and 5 ml of different doses of the biological preparate was sprayed to the container. This treatment was monitored for 5 days and the dead larvae were noted every day. According to the initial pest number, the daily dead pest number was ratioed to determine the percentage of death. Obtained data were analysed using SPSS 21.0. LD50 and LD90 values were calculated by completing a probit analysis. Also, a variance analysis was completed on the death ratio for each different doses in the same day and the means were compared by completing a Duncan multiple range test ($p<0.05$).

Results and Discussion

The preparate with *Bacillus thrugiensis* was effective on pine processionaries, however there were differences between the doses. As the dose increased after the treatment, the ratio of death due to the dose increased. Particularly after the 3. day, deaths became more significant. At the end of the 5th day on Thaumetpoae pitycompae larvae, the death ratio was 60% with the dose of 0.75 g/l , 75% with the dose of 1.5 g/l, and 90% with the dose of 3 g/l (Figure 1). The performance of a single application of *B. thrugiensis var κurstaki* against T. pityocampa that has been observed in the field (20–85% mortality) is related to a great variability in both the application dose and some population parameters of *T. pityocampa* (Battisti et al., 1998). Isolate *Bacillus thuringiensis* subsp. morrisoni had a promising insecticidal effect on third instar larvae of *T. pityocampa* (up to 70% mortality within 10 days) (Ince et al., 2008). The

bioinsecticides included in *Bacillus thuringiensis subsp. kurstaki* (Btk). The vulnerable performance of a single application has been observed in the field trial of these bioinsecticides with mortality rates ranging from 97 to 99% in Turkey's pine forests (Cebeci et al., 2010). *Thaumetopoea solitaria* of larval high mortality (78%-100%) was attained in the first week after the treatment especially for the first 3 larval stages with the application of the highest 3 concentrations of *Bacillus thuringiensis var. kurstaki* (104, 105, and 106 μg l–1) (Er et al., 2007).

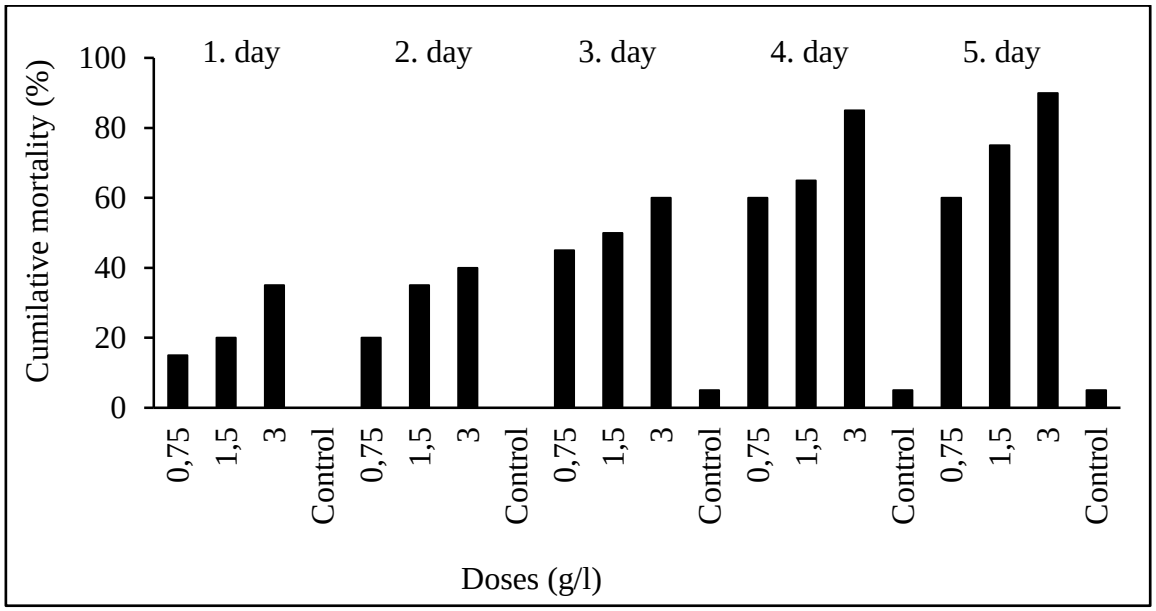

Figure 1. Distribution of death rates of commercial bacteria preparate in different doses by day.

In the study conducted with biopreparate with *Bacillus thrugiensis*, only the LD50 and LD90 values for the 5th day were determined. LD50 values was 0.65 while LD90 was 2.47 (Table 1).

Bacillus thrugiensis is used as an entomopathogen in fighting against several bugs that are harmful for plants. It is used particularly for Lepidoptera larvae (Nikolaos,1998). There are commercial preparates such as Bio-T plus, Foray 76B that includes B. Thrugiensis bacteria that are licensed for pine processionary larvae in Turkey . The Ak Kobelek preparate used in this study is licensed for certain lepidoptera larvae in Kazakhstan (Cotton bollworm, Cabbage butterfly, American white butterfly, Codling moth, Gypsy moth, Grapevine moth).

Table 1. The after treatment of pine processionary with the commercial bacterial preparate.

Days	**Doses (g/l)**	**Death rates (%)**	**LD_{50}**	**LD_{90}**
1.day	0,75	15,00±5,00ab*	4,98	9,80
	1,5	20,00±12,58a		
	3	35,00±8,16ab		
	Control	0,00±0,00b		
2.day	0,75	20,00±8,16a	6,14	14,68
	1,50	35,00±17,08a		
	3	40,00±16,33 a		
	Control	0,00±0,00a		

3.day	0,75	45,00±22,17ab		
	1,50	50,00±17,32ab		
	3	60,00±14,14 a	1,96	4,86
	Control	5,00±5,00 b		
4.day	0,75	60,00±16,33a		
	1,5	65,00±9,57 a		
	3	85,00±9,57 a	1,12	2,92
	Control	5,00± 5,00 b		
5.day	0,75	60,00±15,00a		
	1,5	75,00±5,00 a		
	3	90,00±5,77 a	**0,65**	**2,47**
	Control	5,00± 5,00 b		

*The doses within same day are compared statistically. Same letters in the same line representative of each day show that there is no a statistically significant difference between the doses.

Conclusion

With this study, it was found that the preparate used was also effective on pine processionary larvae. As this study was conducted under labratory conditions, it would be beneficial to conduct the same study in the field. Also, it is important that a comparative study on the effectiveness of commercial preparates used in control against pine processionary in Turkey.

Abstract

Syneresis values of yoghurt samples ranged from 50.00% (with carrageenan 0.25%) to 67.44% (with carrageenan 0.10%). Syneresis level of yoghurt samples with orange were ranged from 60.16% to 64.64%. Viscosity values of samples changed depending on additives. The mineral contents of yoghurt samples were determined by Inductively Coupled Plasma-Atomic Emission Spectroscopy (ICP-AES). Ca contents of yoghurt samples changed from 4155.0 mg/kg (with orange 0.15%) to 6464.64 mg/kg (with carrageenan 0.15 %). K contents of yoghurt samples ranged from 6383.81 mg/kg (with orange with 0.15%) to 10626.32 mg/kg (with carrageenan 0.15%). Generally, mineral contents of liquid phase decreased according to the solid phase of yoghurt samples. While Ca contents of liquid phase change between 274.5 mg/kg (with lemon 0.10%) and 1510.95 mg/kg (with lemon 0.25%), K contents ranged from 406.56 mg/kg (with lemon 0.10%) to 2025.40 mg/kg (with carrageenan 0.25%).

Key words: *pectin, pectin sources, yoghurt production, syneresis, minerals, ICP-AES*

Introduction

Milk has great importance in human nutrition. It is processed to various products with the aim of facilitating its consumption and improving its storability (Çopur *et al.*, 1993). Different stabilizers are used in order to prevent the separation, which is a quality criterion and to give the yoghurt the desired consistency (Hall, 1975; Basset, 1983). Hydrocolloids defined as stabilizers are used to increase consistency, to reduce serum separation and to impartstability tothe lactic acid gel in fermented dairy products like yogurt (Gönç and Gahun, 1980). Agar is a stabilizer other substances used in the production of yogurt (Saldamlı, 1985). In addition, pectin used as stabilizer reduces the amount of cholesterolin the blood at the same time. Pectin that in the form of natural colloidsand methoxylated galacturonic acid in its structure is found in the form of protopectin in plant roots, leaves and fruits (Gönç and Gahun,1980). Pectin is used in yoghurt to preserve the acidity of the products and to increase their shelf life. The primary use of pectin in the food production industry is as a gelling agent (Basset, 1983; Tamime and Robinson, 1985; Tayar *et al.*, 1995). The aim of this study was to inhibit syneresis and to keep minerals in solid phase of yoghurt in yoghurt manufacture by using pectic, carrageenan,and pectin sources like orange, lemon and grapefruit.

Material and methods

Material

In this experiment, cow milk with 9% dry matter was used. Milk was pasteurized in a binary at 85 ^{o}C for 30 min. After heating, it was cooled to the 45^{o}C. Yoghurt culture at the 2% level and stabilizers (orange, lemon, grapefruit, carrageenan, pectin) at 0, 05, 0.10, 0.15, 0.20, and 0.25% concentrations were added in to cooled milk, and then incubated till 4.6 pH. After incubation, yoghurt samples were kept for 1 h in a refrigerator (+4^{o}C) (Tekinşen, 1976).

Determination of Syneresis Level

25 gr of yogurt samples were put into centrifuge tubes (50 mL volume). The samples were centrifuged at 4000 rpm for 15 minutes. Liquid phase of each yogurt sample was transfered into different flask, and weight of liquid phase was measured. Syneresis of yogurts (%) were determined.

Determination of mineral contents

About 0.5 g solid and liquid phase yoghurt samples were digested by using 5ml of 65% HNO_3 and 2 ml of 35% H_2O_2 in a closed microwave system (Cem-MARS Xpress). The volumes of the digested samples were completed to 20 ml with ultra-deionized water and mineral concentrations were determined by inductively coupled plasma-optical emission spectroscopy (ICP-AES; (Varian-Vista, Australia) (Skujins,1998). Working conditions of ICP-AES were given in Table 1.

Statistical analyses

All analyses were carried out three times and the results are mean±standard deviation (MSTAT C) of yoghurt samples (Püskülcü and İkiz, 1989).

Results and discussion

Syneresis level of yogurt samples with orange were ranged from 60.16% to 64.64%. The syneresis level of yoghurt samples with0.1% and 0.15% orange decreased. The yoghurts with added 0.05% orange and 0.05% grapefruit also showed nearly same tendency to syneresis than plain yoghurt whilst increased amount of grapefruit increased syneresis level. The addition of different amounts of pectin caused more syneresis when compared with plain yoghurt. However, change of amount didn't affect syneresis level. Minimum syneresis level was obtained from 0.05% lemon added yogurt whereas syneresis level increased due to raising of amount of lemon. In 0.05% and 0.1% carrageenan added yoghurts more syneresis was observed than plain yoghurt. Scarcely, the increase of carrageenan produced a decrease in syneresis. Maximum syneresis was found in yogurt which contain 0.1% carrageenan. The most appropriate additives and their amounts were found as orange (0.05%, 0.1%, 0.15%), grape fruit (0.05%), lemon (0.05%, 0.2%, 0.25%) (Table 2).

Syneresis and titratable acidity values of yoghurt samples are presented in Table 2. Syneresis values of yoghurt samples ranged from 50.00% (with carrageenan 0.25%) to 67.44% (with carrageenan 0.10%). Generally, syneresis level of yoghurt contained orange skin at the different contentrations were found partly low compared with other samples. In addition, acidity values of most of yoghurt samples were found the same (1%). But acidity values of a few yoghurt samples were found between 1.64% (with carrageenan 0.10%) to 1.76% (with lemon 0.15%). Generallay, syneresis, had not affected to the acidity levels of yoghurt samples. Acidity did not more change depending on syneresis and concentrations.

Viscosity results of yogurt samples are given in Table 3. Viscosity values of samples changed depending on additives. In addition, viscosity values decreaset at increasing rpm levels. Generally, viscosity values of yoghurt with pectin and carrageenan were found higher than those of other samples. These differences can be probably due to using of different fruit materials. It was established the lowest viscosity values in 100 rpm in yoghurt samples. But, viscosity values of yoghurt contained pectin and carrageenan were found partly higher than those of yoghurt contained orange, grapefruit and lemon.

Mineral contents of solid phase of yogurt samples are given in Table 4. Ca, K, Mg, Na, P and S of solid phase of yoghurt samples were found as major elements. Ca contents of yoghurt samples changed from 4155.0 mg/kg (with orange 0.15%) to 6464.64 mg/kg (with carrageenan 0.15 %). K contents of samples ranged from 6383.81 mg/kg (with orange with 0.15%) to 10626.32 mg/kg (with carrageenan 0.15%). Mg contents were found between 603.20 mg/kg (with orange 0.15%) and 911.96 mg/kg (with carageenan 0.15%). While Na

contents of yoghurt samples change between 1377.99 mg/kg (with orange 0.15%) and 2171.10 mg/kg (with carrageenan 0.15%), P contents ranged from 4808.46 mg/kg (with orange 0.15%) to 6844.14 mg/kg (with carrageenan 0.15 %). In addition S content of samples changed between 2953.57 mg/kg (with orange 0.05%) and 5088.97 mg/kg (with carrageen 0.15%). B, Cu, Fe and Zn content of yoghurt samples ranged from 4.02 mg/kg (with pectın 0.05%) to 6.79 mg/kg (with pectin 0.15%), 1.48 mg/kg (with lemon with 0.20%) to 3.51 mg/kg (with orange 0.10%), 15.26 mg/kg (with lemon 0.20%) to 24.76 mg/kg (with carrageenan 0.05%) and 14.61 mg/kg (with orange 0.15%) to 23.72 mg/kg (with petin 0.25%)respectively. Mineral contents of yoghurt samples contained several ingredients were found partly high than that of control group. Generally, mineral contents of yoghurts contained pectin and carrageenan were found higher compared with other ingredients.

Mineral contents of liquid phase of yoghurt samples are summarized in Table 5. Generally, mineral contents of liquid phase decreased according to solid phase of yoghurt samples. While Ca contents of liquid phase change between 274.5 mg/kg (with lemon 0.10%) and 1510.95 mg/kg (with lemon 0.25%), K contents ranged from 406.56 mg/kg (with lemon 0.10%) to 2025.40 mg/kg (with carrageenan 0.25%). Na contents were found between 136.68 mg/kg (with lemon 0.10%) to 593.82 mg/kg (with pectin 0.25%).P contents of liquid phase ranged from 178.08 mg/kg (with lemon 0.10%) to 670.15 mg/kg (with orange 0.10%). S contents of samples were found between 43.05 mg/kg (with lemon 0.10%) and 450.27 mg/kg (with pectin 0.25%). Mg contents of liquid phase ranged from 15.12 mg/kg (with lemon 0.10%) to 115.64 mg/kg (with lemon 0.20%). B, Cu, Fe and Zn contents of liquid phase of yoghurt samples were found between 1.53 mg/kg (with lemon 0.10% and pectin 0.25%) and 3.10 mg/kg (with orange 0.05%), 0.25 mg/kg (with grapefruit 0.15%) and 0.41 mg/kg (with pectin 0.10%), 2.37 mg/kg (with grapefruit 0.25%) and 4.09 mg/kg (with lemon 0.20%) and 0.96 mg/kg (with lemon 0.10%) and 3.89 mg/kg (with orange 0.10%), respectively. Heavy metal contents of liquid phase of yoghurt samples considerably decreased compared with solid phase of yoghurt. Different stabilizers are used in order to prevent the separation which is a quality criterion and to give yoghurt the desired consistency (Çopur *et al.*, 1993). Çopur *et al.*, (1993) reported that titratable acidity values of yoghurt contained pectin at the different concentration (0.01 to 0.50%) were determined between 1.05% and 1.18%. According to the sensorial evaluations, the samples which contain gelatin and gelatin-pectin more preferred. As a result, it has been thought that gelatin and gelatin-pectin can be used as the level of 0.6% and 0.6 +0.05% respectively in yoghurt manufacture (Atasever, 2004). Christensen (1991) reported that the using of pectin with other additive had affected on the structure of yoghurt manufacture.As a result, the use of available stabilizersmay bemore appropriate to prevent to the separation of serum phase in yoghurt production. Thus, minerals penetrated into the serum phase will have been trapped in the solid phase.

Table 1 Working conditions of ICP-AES

Working conditions of ICP-AES:	
Instrument	:ICP-AES (Varian-Vista)
RF Power	: 0.7-1.5 kw (1.2-1.3 kw for Axial)
Plasma gas flow rate (Ar)	: 10.5-15 L/min. (radial) 15 " (Axial)
Auxilary gas flow rate (Ar)	:1.5 "
Viewing height	: 5-12 mm
Copy and reading time	:1-5 s (max.60 s)
Copy time	: 3 s (max. 100 s)

Conclusion

The yoghurts with added 0.05% orange and 0.05% grapefruit also showed nearly same tendency to syneresis than plain yoghurt whilst increased amount of grapefruit increased syneresis level. The addition of different amounts of pectin caused more syneresis when compared with plain yoghurt. Generally, syneresis level of yoghurt contained orange skin at the different contentrations were found partly low compared with other samples. Viscosity values decreaset at increasing rpm levels. Generally, mineral contents of liquid phase decreased according to solid phase of yoghurt samples.

Abstract

Anatolia is one of the centers of the germplasm of nuts and this fruit species is grown in almost every region there. There are a lot of seedling walnut populations with wide genetic variation in Turkey. This provides a very important potential for walnuts breeders. Walnuts are a functional food ingredient rich in nutrients such as protein, vitamins, and minerals. The most important characteristic of walnut oil is the plenty of polyunsaturated (PUFA) fatty acids such as Omega-3 and Omega-6, which makes it a unique food because of the high amount of linoleic acid. Unsaturated fatty acids play an important role in human nutrition, so walnuts become an indispensable part of human nutrition. Therefore, walnut production and consumption in World and Turkey are increasing every year. In this study, some chemical compositions were determined for 14 promising walnut genotypes in Besni and Gölbaşı (Adıyaman Province) in Turkey. The protein rates of walnut genotypes were determined to vary between 13.69% and 19.85%. We have also found that the oil content of these walnut genotypes varies between 49.44% and 60.87%. Oleic acid contents of walnut genotypes ranged from 14.434% to 30.052%. In addition, linoleic and linolenic acids contents of walnut oils were found between 49.647% and 63.534%, and 7.731% and 15.097%, respectively. This study has confirmed the presence of high percentage of oleic, linolenic and linoleic acids in walnut.

Keywords: W*alnut, fat, protein, fatty acids.*

Introduction

Walnut is one of the oldest fruits species cultured both in Turkey and in the world (Şen, 1986). Anatolia stands for also a germplasm of walnut and walnut trees are extremely plenty within almost all regions in Turkey. Walnut trees are cultivated in Turkey mainly for their nutritious nuts, which are used as a food, in the chocolate industry, for baked foods, as well as in the pharmaceutical and cosmetic industry. The trees are also valuable as timber (Ercisli *et al*., 2012). Turkey has significant walnut populations in its distinct ecological regions. These populations are generally composed of seedling trees, but the cultivation of promising walnut genotypes obtained from breeding programs is increased to nut quality standard and quantity in walnut production in Turkey over the last ten years (Koyuncu *et al*., 2004). Walnut is a fruit species well-adapted to the various ecological regions of Turkey. Walnut trees are widely distributed throughout Turkey in the valleys of big rivers and on the hillside. Therefore, Turkey has many promising genotypes cultivated in the various ecological region of Turkey (Muratoglu *et al.,* 2010). The human body basically needs three main nutrients: fats, proteins, and carbohydrates. For healthy life and to maintain it, these three essential nutrients must be taken in a balanced manner. Walnuts are a very rich fruit species of these important nutrient elements. However, the values of these nutrients are different in each of the walnut genotypes. Therefore, it is of utter importance to identify the composition of walnuts and their nutritional values in order to reveal its position in a balanced diet (Beyhan *et al*., 1995). The kernel of a walnut can be considered as a type of concentrated food due to its high rate of fat and protein. In other words, as a hard-shelled fruit, walnut is an excellent untouched and wrapped "food

store". It abounds in two of three basic nutritional elements, which are necessary for humans. Furthermore, it can be kept without losing any nutritional value under relatively bad conditions for more than one year (Şen, 2011; Sutyemez and Kaska, 2005). Fatty acids in the walnut oil are primarily unsaturated. When confronting other hard-shelled fruits containing chiefly monounsaturated fatty acids (MUFA), walnut is pretty rich in terms of polyunsaturated fatty acids (PUFA) such as Omega-6 and Omega-3. Polyunsaturated fatty acids (PUFA) are crucial for human nutrition (Amaral *et al*., 2003; Zwarts *et al*., 1999). In this study, some promising selected walnut genotypes in Besni and Gölbaşı region in Adıyaman were examined in terms of fat, fatty acid and protein contents in their kernels. We were carried out to bring new information on protein, fat, and some fatty acid contents of 14 walnut genotypes from Turkey.

Material and Methods

Mature walnut shelled-nuts of walnut genotypes were harvested from Besni and Gölbaşı, located in the Adıyaman provinces of Turkey. Nut samples of 14 walnut genotypes were randomly selected with three replicates for each tree. Kernels of walnut were analyzed after drying under incubator at 30°C for 24 hours. According to the Kjheldal method, nitrogen was determined and protein ratio was calculated by multiplying the amount of nitrogen determined by 6.25 (Bayraklı, 1987). Walnuts were separated their kernel using nutcracker and after the separation immediately homogenized and oil extraction of kernel powder (25 g) were done using automatic Soxhalet equipment Bligh and Dyer (Bligh and Dyer, 1959). Automatic Soxhlet equipment (Gerhardt Soxtherm) was used for oil extraction with hexane organic solvent. Triplicate analysis was done for each variety. Methylation was done using Boron trifluoride/methanol (AOAC, 1990; Ichihara et al., 1996). The fatty acid analysis was done using a GC (Gas Chromatography)/FID (Flame Ionization Detector) (Perkin Elmer, Clarus 500, USA) equipped with a and SGE column (100 m × 0.32 mm, ID 0.25 μm). As for the GC condition; the oven temperature was held at 140˚C for 5 min, and then increased to 200˚C at a rate of 4˚C min^{-1} and to 220˚C at a rate of 1˚C min^{-1}. FAME mix standard including 37 components were used for fatty acid identification and quantification.

Results and Discussion

In this study, walnut genotypes grown in Adıyaman region were characterized in terms of protein, total fat, and fatty acids. In addition, genotypes were analyzed in terms of Oleic acid, Linoleic acid, and Linolenic acid. Protein contents of the genotypes ranged from 13.69% to 19.85%. The results of the protein values are presented in Table 1. As shown in the table, the lowest protein level (13.69%) was observed in Genotype 1, it was highest (19.85%) in Genotype 15 among the 14 walnut genotypes investigated in the present study. The results of the total fat ratio of the genotypes grown Besni and Gölbaşı were presented in Table 1. Total fat contents of the walnut genotypes ranged from 49.44% (Genotype 14) to 60.87% (Genotype 16). There are different data about fat ratio of walnut kernel, growing in different places. The fat ratio of walnut kernel varied between 49.04% and 78.68% in these studies (Pereira *et al.*, 2008; Yerlikaya *et al.*, 2012; Gharibzahedi *et al.*, 2014*;* Uzunova *et al.*, 2015; Kafkas *et al*., 2017; Matthäus *et al.*, 2018). In our study, fat rates of walnut kernels were lower than those studies. This is probably due to the fact that the walnut genotypes in our study are composed of genotypes that grow naturally and don't have cultural practices. Walnut has all the time been consumed throughout the history owing to its high nutritional value. It is a suitable fruit for healthy diets because it contains fat (50-80%) and protein (12-15%) (Mitrovic *et al.*, 1997). Table 1 showed the fatty acid contents of the walnut kernel samples. As can be seen, oleic acid concentrations changed between 14.434% and 30.052%. In a study conducted in Tunisia, the chemical composition (total oil content, fatty acids) of six walnuts (*Juglans regia* L.) cultivars ('Lauzeronne', 'Franquette', 'Hartley', 'Local pt', 'Local

gd' and 'Parisienne') gathered from Mateur was evaluated. Oleic acid ingredient of these cultivars were found 19.94%, 16.73%, 14.27%, 13.21%, 13.68%, and 16.49%, respectively (Bouabdallah *et al*., 2014). In a study conducted by Zwarts *et al*., (1999), two US commercial cultivars (Tehama and Vina), three European commercial cultivars (Esterhazy, 139, G120) and five New Zealand walnut cultivars (Rex, Dublin's Glory, Meyric, McKinster, and Stanley) were used. The oleic acid content of walnut cultivars varied between 12.7% to 20.4% of the total fatty acids, while 18:2 content varied between 57.0% to 62.5% and the 18:3 content varied between 10.7% to 16.2%. Also in another study, oleic acid values of monounsaturated fatty acids ranged from 14.73% to 24.17% (Beyhan *et al*., 2017). The oleic acid values obtained in our walnut genotypes showed similar results with these studies.

In the present study, the highest linoleic acid was observed in Genotype 13 as 63.534% and the lowest linoleic acid was in Genotype 9 as 49.647%. In addition to, values belonging to other genotypes were included in the intermediate group. In the present study, linolenic contents of these genotypes were determined and the results are given in Table 1. The lowest value of linolenic contents was detected in the Genotype 12 with 7.731% the highest value was in the Genotype 3 with 15.097%. In a recent study, the fatty acid content and antiradical activity of different walnut (*Juglans regia* L.) genotypes grown in Kolyaei region located in Kermanshah Province (Iran) were investigated and it was reported that linoleic acid and linolenic acid contents of the walnut genotypes ranged from 46.9% to 56.8%, and from 10.8% to 13.9% respectively. Also, it is stated that the distinction might have resulted from ecological, nutrition and genetically factors. The variation in the fatty acid composition of the nuts from varied genotypes may affect the end use of the product (Akbari *et al.*, 2015).

The consequence obtained were compared with similar studies in walnut. Its differences could be attributed to the harvesting year and environmental condition, with different temperatures, rainfall, and light, which can affect the chemical composition of fruits (Parcerisa *et al.*, 1995).

Table 1. Protein, fat and fatty acids ratios of walnut genotypes.

Genotypes	Protein (%)	Total Fat (%)	Fatty Acids (%)		
			Oleic acid	Linoleic acid	Linolenic acid
Genotype 1	13.69	55.22	16.806	60.906	11.822
Genotype 2	17.41	51.29	24.308	57.649	7.750
Genotype 3	15.35	58.53	15.382	59.837	15.097
Genotype 5	18.63	54.00	22.540	56.597	10.509
Genotype 6	18.60	56.57	22.056	54.699	11.732
Genotype 8	17.31	57.88	19.897	60.993	9.326
Genotype 9	18.25	56.58	30.052	49.647	8.729
Genotype 10	15.38	60.64	17.242	59.193	11.797
Genotype 12	17.72	52.88	21.407	61.164	7.731
Genotype 13	19.66	57.25	14.434	63.534	11.207
Genotype 14	16.76	49.44	16.689	62.284	11.461
Genotype 15	19.85	51.53	21.122	58.114	10.600
Genotype 16	15.19	60.87	20.108	57.963	10.458
Genotype 17	17.35	50.26	16.041	62.037	10.628

Conclusions

According to the obtained results, 14 walnut genotypes have important values in terms of protein, total fat and some fatty acids content which importance for human health and nutrition are very. Protein and total fat contents of the walnut genotypes varied between 13.69% and 19.85%, from 49.44% to 60.87%, respectively. Oleic acid contents of walnut oils ranged from 14.434% to 30.052%. In addition, linoleic and linolenic acids contents of walnut oils were found between 49.647% and 63.534%, and 7.731% and 15.097%, respectively. This study has confirmed the presence of high percentage of oleic, linolenic and linoleic acids in walnut.

Abstract

The study was carried out in order to determine the effects of weeds on chickpea yield factors such as biological yield, number of main branches, plant length, the first pod height, number of pods per plant, number of seeds per plant, seed yield per plant, harvest index, 100-seed weight. Experiments were created according to randomized block design in Kirsehir Ahi Evran University, Agricultural Practice and Research Center, Turkey between 2015 and 2017 years. In the field experiments, 9 different treatments were included - control, weed free, one-time hoeing, two-time hoeing, three-time hoeing, poste-emergence herbicide application, one-time hoeing with herbicide application, two-time hoeing with herbicide application and three-time hoeing with herbicide application. According to the results, there are significant differences between chickpea yield and yield components depending on different weed control methods. According to results, it was determined yield of 159.7 kg when no weed struggle conditions occurred. On the other hand, three-time hoeing of weed revealed the best yield performance as 847.8 kg per ha?. It has been determined that even the single shearing process increases the yield of chickpea about 2.5 times, 3 hoeing operations increased 6 times according to an average. As the number of chickpea hatchings increased in Kirsehir conditions, the result of the study proved that the yield is positive. As the number of chickpea hoeing increased in Kirsehir conditions, the result of the study proved that the yield is positive.

Keywords: *Kirsehir, Aksu, weeds, yield, yield components*

Introduction

Chickpea is widely grown in East Mediterranean, Africa and Central America. As the case worldwide, it holds an important place in closing the food deficit in Turkey. Its grains are used as human food and its stalk and straw can be used as a valuable animal feed. Turkey ranks fifth after India, Pakistan, Mynmar and Australia in chickpea production (FAO, 2016). Despite some recent setbacks in the area, Turkey still stands its ground as one of the major producers of chickpea. Especially the relatively more successful means of controlling newly developed varieties and weeds contribute to the success in chickpea production.

In a more general sense, the control of weeds for chickpea production is not a common practice in Turkey. Since the plants grow rapidly after the initial growing period and can partially suppress weeds, the producers do not prefer to assume additional expenses to control weeds. However, studies carried out in domestic and other countries have shown that this was not the case and weeds had yield-reducing effects in chickpea production. Ahlawat *et al*. (1981) reported that *Cenepodium album* and *Asphodelus tenouifolius* considerably increased the weed amount in chickpea fields in irrigated or rainy areas. Solh and Pala (1990) stated that the lack of weed control in chickpea growing caused significant losses in yield. Tahabi *et al*. (1994) showed that in chickpea fields with no weed control, the yield loss was 81%.

The study investigates the gains and losses obtained by growing non-irrigated chickpea plants under conditions with weed control and no weed control in the Central Anatolia Region.

Material and Methods

The study was carried out between 2015 and 2017 in the area of Kırşehir Ahi Evran University Research, Turkey. The investigation was conducted to obtain whether weed control is necessary in chickpea growing and if necessary, which method is more successful in weed control. The study was conducted in a randomized block design with three replications. The field was not irrigated and instead, the plants were grown using the natural precipitation occurring during the growing season. The Aksu chickpea variety was used in the experiment. The soil was determined to be clayey, loamy, slightly alkaline (pH:7.8), organic matter-poor (1.26), non-saline, and moderately rich in plant-available phosphorus.

The study were divided into nine treatments:

1) no weed control (control),
2) permanent weed control (weed free),
3) one-time hoeing,
4) two-time hoeing,
5) three-time hoeing,
6) herbicide application after crop emergence,
7) one-time hoeing with herbicide application,
8) two-time hoeing with herbicide application,
9) three-time hoeing with herbicide application,

The application doses and times of the herbicides were determined in accordance to Thomson (1997) and Anonymous (1999). Planting was carried out manually with a row spacing of 30 cm and intra-row spacing of 10 cm.

Diammonium phosphate was distributed to the study area in the amount of 150 kg per hectare. The yield and yield values affecting chickpea were analyzed (count all measured parameters). The SPSS 23V statistical package program was used for the analysis of variance and the Duncan multiple comparison tests ($p<0.05$) of the data.

Results and Discussion

Weeds compete with culture plants for CO_2, O_2, light, and nutrients and some release phytotoxic compounds and negatively affect the growth of plants.

Table 1 shows the differences in the weed control methods with respect to branch number, plant length, first pod height, and number of pods per chickpea plant. The control had the highest branch number (3.11 branches), while the branch number of the weed free treatment, one-time hoeing and the twice-hoed group was considerably low. The treatment that received the herbicide after emergence and the treatment with herbicide+one-time hoeing, herbicide + two-time hoeing and herbicide + three-time hoeing were in the same group. In general, the difference between the branch numbers was around 2 or 3 branches and the variation, albeit statistically significant, was not dramatic. The high rate of branching in the non-controlled area was attributed to the competition with weeds to survive. In a competitive environment, the plants are compelled to develop both their aerial and subsurface parts as much as possible to have access to lighting and nutrients, etc. Mohammadi *et al*. (2005) have reported that competition with weeds occurred in the first three to seven weeks and reduced levels of competition were observed before and after these periods. The results obtained in this study revealed clear signs of competition.

Table 1. Chickpea morphological parameters as a result of different weed control methods

Weed control methods	Chickpea parameters			
	Branch Number	Plant Length (cm)	The First Height (cm)	Number of Pods per Plant
Control	**3.11 a***	40.11 b	17.00 b	14.11 b
Weed free	2.00 b	39.44 bc	21.22 ab	16.33 ab
One-time hoeing	1.88 b	42.55 ab	**25.66 a**	13.11 bc
Two-time hoeing	1.99 b	38.88 bc	20.00 ab	14.66 bc
Three-time hoeing	2.55 ab	39.11 bc	19.22 b	**22.22 a**
Herbicide after emergence	2.55 ab	**45.77 a**	22.44 ab	19.44 ab
Herbicide + one-time hoeing	2.77 ab	44.11 ab	21.22 ab	17.44 ab
herbicide + two-time hoeing	2.44 ab	37.00 c	17.66 b	8.44 c
Herbicide + three-time hoeing	2.88 ab	41.11 bc	18.88 b	14.77 b

* Means in the same column by the same letter are not significantly different to the test of Duncan ($p<0.05$).

The results for the plant lengths showed that the herbicide application after emergence had yielded the longest plants (45.77 cm), followed by the herbicide+one-time hoeing (44.11 cm) and one-time hoeing (42.55 cm) applications. The lowest plant length was obtained in the herbice+two-time hoeing application (37.00 cm).

The results for the first pod height showed that the highest first pod (25.66 cm) was obtained in the one-time hoeing application. The substantial difference in the first pod height values is noteworthy. A difference of about 17.66-25.66 cm indicates that the plants reacted to the applications in an extreme fashion.

The variation in the pods per plant was relatively higher compared with other properties. The highest pods per plant value was 22.22 cm and obtained in the three-time hoeing application, while the lowest pods per plant value was 8.44 cm and obtained in the herbicide+two-time hoeing application.

Table 2 shows the differences in the control methods with respect to yield per plant, biological yield, harvest index, 100-seed weight, and yield. As seen in the Table 2, yield per plant varied between 2.55 g and 7.41 g. This indicates a high variation. The applications had affected the yield per plant. The highest yield per plant was obtained in the herbicide application after emergence and three-time hoeing application.

The highest biological yield was 3.11 kg and obtained in the control group. Considering the high branching rate of the treatment, obtaining a high biological yield was expected. The high rate of branching and a growing habitus increased the biological yield. In the harvest index, the results obtained by the applications, except for the herbicide+two-time hoeing application, were not statistically significant. Although the reason behind the reducing-effect of herbicide+two-time hoeing application on the harvest index was not discerned, the results obtained in this study agree with the results obtained in the study carried out by Mahoney (1981) and Yadav *et al*. (1983) in which the phytotoxic effects of herbicides were determined to reduce the grain yield and yield-affecting characteristics of the chickpea plants.

Table 2. Change of difference between constructed struggle methods according to some characters

Weed control methods	Examined parameters				
	Yield per Plant (g)	Biological Yield (kg)	Harvest Index (%)	100-seed weight (g)	Yield (kg ha^{-1})
Control	5.14 ab*	**3.11 a**	45.72 a	37.23 a	159.7 e
Weed free	5.36 ab	2.00 b	47.19 a	35.89 ab	597.2 c
One-time hoeing	4.38 ab	1.89 b	46.16 a	35.35 ab	395.7 d
Two-time hoeing	4.84 ab	1.99 ab	**49.58 a**	37.58 a	593.5 c
Three-time hoeing	6.89 a	2.56 ab	47.51 a	37.59 a	**847.8 a**
Herbicide after emergence	**7.41 a**	2.56 ab	48.18 a	38.25 a	841.2 a
Herbicide + one-time hoeing	5.54 ab	2.77 ab	45.44 a	35.05 ab	689.7ab
Herbicide + two-time hoeing	2.55 b	2.44 ab	39.72 b	33.36 b	773.8 b
Herbicide + three-time hoeing	5.24 ab	2.88 ab	45.90 a	**38.49 a**	572.3 c

* Means in the same column by the same letter are not significantly different to the test of Duncan ($p<0.05$).

One hundred-seed weight values varied between 33.36 g and 38.49 g but the variation was not high. The results obtained for yield revealed a high variation. The highest yield was 847.8 kg per hectare and obtained in the three-time hoeing application, followed by the herbicide application after emergence with 841.2 kg. The difference between the two groups was determined to be statistically significant. The lowest yield was 159.7 kg and obtained in the application with no weed control, while in the parcels in which weeds were completely removed by constant weed control, a yield of 597.2 kg was obtained, which was below the expected value. In their study carried out under the conditions of Erzurum, Turkey, Kantar *et al*. (1999) determined that, compared with weedy control, herbicide applications increased the chickpea yield at a considerably higher level. The results of this study revealed that only the post-emergence herbicide application resulted in a significantly increased yield and the results obtained with other herbicide applications did not make significant difference between treated and untreated variant. Zimdahl (2004) has stated that the effect of weeds and herbicides on yield depended on the timing of the applications. Application dose and time may reduce the yield.

Conclusions

The herbicide application after emergence and three-time hoeing application were deemed suitable for use in weed control in chickpea cultivation. However, considering the costly nature of three-time hoeing, the herbicide application after emergence is believed to be more appropriate. Surely, the weed-intensive structure of the study area may also have contributed to this effect.

Abstract

The study was carried out in order to determine the effects of weeds on yield factors for Azkan cultivar. In this context biological yield, number of main branches, plant height, the first pod height, number of pods per plant, number of seeds per plant, seed yield per plant, harvest index, 100-seed weight were evaluated. Experiments were created according to randomized block design in Kirsehir Ahi Evran University, Agricultural Practice and Research Center between 2015 and 2017 years. In the field experiments, 9 different applications were given as - control, weed free, one-time hoeing, two-time hoeing, three-time hoeing, poste-emergence herbicide application, one-time hoeing with herbicide application, two-time hoeing with herbicide application and three-time hoeing with herbicide applicationcontinuous weed control, continuous without weed, one-time hoeing, two-time hoeing, three-time hoeing, herbicide application after emergence, one-time hoeing with herbicide application, two-time hoeing with herbicide application and three-time hoeing with herbicide application. According to the results, there are significant differences as statistically between chickpea yield and yield components depending on different weed control methods.
According to results, it was determined when no weed struggle occurred conditions yield 211.3 kg. On the other hand, three times shearing of weed revealed the best yield performance as 1315.1 kg. It has been determined that even the single shearing process increases the yield of chickpea about 4 times according to an average. As the number of chickpea hatchings increased in Kirsehir conditions, the result of the study proved that the yield is positive. As the number of chickpea shearing increased in Kirsehir conditions, the result of the study proved that the yield is positive.

Keywords: *Kirsehir, Azkan, weeds, yield, yield components*

Introduction

Chickpea is an important edible legume grown worldwide. It is especially important because of its cheap and ample availability as a protein source for which the need grows incessantly (Bhan and Kukula, 1986). Turkey is an important chickpea producer. Thus, the studies focusing on the improvement of chickpea growing are intensively carried out but they have yet to reach the desired levels, which is mainly attributable to precipitation and weed control Kantar et al., 19999). The chickpea plant is not only a human food but also a valuable animal feed (Tepe *et al.*, 2011).
Weeds compete with culture plants and negatively affect the available moisture and nutrients in soils and light causing yield losses (Rao, 2000). In addition, some weeds may inhibit the growth of culture plants by releasing phytotoxic compounds, which is known to result in severe yield losses. Therefore, the control of weeds is an absolute necessity.
The study aims to determine the control methods for weeds that are reportedly observed when growing chickpea plants under non-irrigated dry conditions. Determining the control methods will also economically contribute to the minimization of yield losses.

Material and Methods

The study was carried out in Kırşehir, Turkey, between 2015 and 2017 in the lands of Kırşehir Ahi Evran University Research and Application to investigate weed infestation and determine which method is more successful in the control of weeds in chickpea growing.

The study was conducted in a randomized blocks design with three replications. The field was not irrigated and instead, the plants were grown using the natural precipitation occurring during the growing season. The Aksu Azkan chickpea variety was used in the experiment. The soil was determined to be clayey, loamy, slightly alkaline (pH: 7.8), organic matter-poor (1.26), non-saline, and moderately rich in plant-available phosphorus.

The study samples were divided into nine groups as:

1) no weed control (control group),
2) with constant weed control (weed free),
3) one-time hoeing,
4) two-time hoeing,
5) three-time hoeing,
6) herbicide application after emergence,
7) one-time hoeing with herbicide application,
8) two-time hoeing with herbicide application,
9) three-time hoeing with herbicide application,

The application doses and times of the herbicides were determined in accordance with Thomson (1997) and Anonymous (1999). Planting was carried out manually with a row spacing of 30 cm and intra-row spacing of 10 cm.

Diammonium phosphate was applied in experiment according to the calculations made for 150 kg fertilizer per hectare. In the study, the yield and yield values affecting chickpea were analyzed. The SPSS 23V statistical package program was used for the analysis of variance and the Duncan multiple comparison tests ($p<0.05$) of the data.

Results and Discussion

Table 1 shows the differences in the control methods with respect to branch number, plant length, the first pod height, and number of pods per plant. As shown in Table 1, the difference between the branch numbers of the plants was between 1.87- 2.30 branches and it was not significant. In other words, the applications did not have an effect that can change the branch number of the plants.

The plant lengths varied between 30.25 cm and 41.64 cm. The tallest plant (41.64 cm) was obtained in the three-time hoeing application, while the shortest plant was obtained in the application with no weed control. The highest plants lengths were obtained in the herbicide+two-time hoeing (40.21 cm) application and the application with constant weed control (39.68 cm). This indicates that hoeing positively affected the plants growth in length.

Table 1. Change of difference between constructed struggle methods according to some characters

Methods of Struggle	Examined Characters			
	Branch Number	Plant Length (cm)	The First Height (cm)	Number of Pods per Plant
Control	1.87 a	30.25 c	20.62 a	3.00 c
Weed free	**2.68 a**	**39.68 ab**	20.00 a	**22.68 a**
One-time hoeing	2.43 a	37.50 b	22.25 a	11.50 bc
Two-time hoeing	2.21 a	36.00 b	**25.71 a**	8.42 bc
Three-time hoeing	2.58 a	41.64 a	23.52 a	19.47 ab
Herbicide after emergence	1.93 a	31.20 bc	20.60 a	6.60 c
Herbicide + one-time hoeing	2.28 a	36.14 b	22.57 a	11.35 bc
herbicide + two-time hoeing	1.94 a	40.21 ab	20.36 a	16.21 b
Herbicide + three-time hoeing	2.30 a	36.50 b	21.00 a	16.30 b

* Means in the same column by the same letter are not significantly different to the test of Duncan ($p<0.05$).

As the case for branch numbers of the plants, the results for the first pod height revealed statistically not significant differences in the first pod heights of the groups. The first pod height values varied between 20 cm and 25 cm and this variation was deemed not significant. In contrast, the variation in the pods per plant was considerably high. The highest pod number was 22.68 and obtained in the weed control application with no weed, followed by the three-time hoeing (19.47) application. The lowest pod number was 3.00 and obtained in the application with no weed control, followed by the herbicide application after emergence (6.60). The reason behind the reducing effect of the herbicide application after emergence on the pods per plant was not discerned. Although the results obtained by Mahoney (1981) and Yadav *et al*. (1983) who argued that the phytotoxic effects of herbicides resulted in decreases in the grain yield and yield-affecting characteristics of chickpeas are acceptable, they fall short in explaining the degree of the decreases caused by other herbicide applications. However, it can be argued that the herbicide application after emergence negatively affected the plant growth cells. Table 2 shows the differences in the control methods with respect to yield per plant, biological yield, harvest index, 100-seed weight, and yield. As revealed by Table 2, the yield per plant varied between 1.01 g and 7.18 g, which indicates that the variation was high. High variation increased the significance levels. The applications affected the yield per plant values. The highest yield per plant was obtained in the application with constant weed control, while the lowest yield per plant was obtained in the application with no weed control. According to the results, the lack of weed control causes an 85.93% loss in the yield per plant in areas with no weed control compared with the weed-controlled areas. The results obtained for biological yield was similar to those obtained for yield per plant. The highest yield was obtained in the application without weed (15.33 kg), while the lowest yield was obtained in the application with no weed control (2.12 kg). The applications did not have any effect in terms of harvest index. The harvest index values varied between 33.92 and 47.10. Although the variation seems considerably high, it was statistically not significant.

Table 2. Change of difference between constructed struggle methods according to some characters

Methods of Struggle	Examined Characters				
	Yield per Plant (g)	Biological Yield (kg)	Harvest Index (%)	100-seed weight (g)	Yield (kg da^{-1})
Control	1.01 d	2.12 cd	44.48 a	34.53 b	211.3 g
Weed free	**7.18 a**	15.33 a	46.56 a	41.21 a	993.9 c
One-time hoeing	2.90 bc	7.67 bc	39.18 a	34.03 b	884.3 d
Two-time hoeing	2.19 cd	6.32 bc	33.92 a	35.07 b	996.8 c
Three-time hoeing	6.07 ab	**13.82 ab**	43.28 a	38.46 ab	905.7 d
Herbicide after emergence	2.06 c	4.29 c	**47.10 a**	37.45 ab	843.3 e
Herbicide + one-time hoeing	3.21 bc	7.76 bc	41.80 a	34.14 b	781.1 f
Herbicide + two-time hoeing	5.87 ab	12.41 ab	46.96 a	**42.98 a**	1085.2 b
Herbicide + three-time hoeing	5.16 b	11.08 b	46.21 a	36.79 ab	**1315.1 a**

* Means in the same column by the same letter are not significantly different to the test of Duncan ($p<0.05$).

The 100-seed weight of the groups varied between 34.03 g and 42.98 g, which resulted in a statistically significant difference. The highest 100-seed weight value was obtained in the herbicide+two-time hoeing application, while the lowest yield was obtained in the one-time hoeing application.

The results obtained for yield revealed a high variation between the applications. The yield varied between 211.3 kg and 1315.1 kg per hectare. This considerably high variation increased the significance levels. The highest yield was 1315.1 kg per hectare and obtained in the herbicide+three-time hoeing application, followed by the herbicide+two-time hoeing application in which a yield of 1085.2 kg per hectare was obtained. The lowest yield value was 211.3 kg and obtained in the application with no weed control. In the application in which weeds were completely removed by constant weed control, the yield was 993.9 kg and below the expected value. In their study carried out under the conditions of Erzurum, Turkey, Kantar *et al*. (1999) determined that, compared with weedy control, herbicide applications increased the chickpea yield at a considerably higher level. The results of this study revealed that only the herbicide application after emergence resulted in a significantly increased yield and the results obtained with other herbicide applications were not significant. Zimdahl (2004) has stated that the effect of weeds and herbicides on yield depended on the timing of the applications. Application dose and time may reduce the yield.

Conclusion

In conclusion, the herbicide application after emergence and three-time hoeing application were deemed suitable for use in weed control in chickpea growing. However, considering the costly nature of three-time hoeing, the herbicide application after emergence is believed to be more appropriate. Surely, the weed-intensive structure of the study area may also have contributed to this effect.

DETERMINATION OF *PSEUDOMONAS SAVASTANOI* FROM OLEANDER IN TEKIRDAG OF TURKEY

Mustafa MİRİK*, Cansu AYVAZ

Namık Kemal University Department of Plant Protection, Tekirdağ, Turkey
*Corresponding author: mmirik@nku.edu.tr

Abstract

Pseudomonas savatanoi is the causal agent of bacterial knot disease. These bacteria is thought to result from abnormal plant cell multiplication at the infection site in response by the host to large amount of indole-3-acetic acid (IAA) or cytokinin produced by pathogen. Bacterial knot has a lot of host range such as olive, oleander, jasmine, fontanesia, privet, myrtle and pomegranate plants. Bacterial knot disease is one of the most important and common disease. The aim of study was isolation and identification with pathogenicity and biochemical tests of disease agent *Pseudomonas savastanoi* from oleander. So in spring 2017, we obtained some samples of oleander leaves and branches with small ground galls in Tekirdağ province of Turkey. To investigate the variability of *Pseudomonas savastanoi* population, twenty one strains of the bacterium were isolated in Tekirdağ from oleander. The strains were exposed to Gram reaction, levan production on 5% saccharose nutrient agar (SNA), oxidase, pectolytic activity, arginine dihydrolase reaction, hypersensitive reaction on tobacco leaves and pathogenicity test on oleander plant. As result of tests twenety one bacterial strains from oleander produced knots on host species were tested, all strains were pathogenic on oleander plants. They were negative for levan, oxidase, arginine dihydrolase, pectolytic activity and positive for hypersensitive reaction on tobacco leaves. According to results of this study, bacterial knot disease determined and all strains were allocated in the LOPAT 1b with biochemical tests.

Key words: *Nerium oleander, oleander, bacterial knot*

Introduction

Pseudomonas savastanoi pv. *savastanoi* is a pathogenic bacterium inducing galls or knots on stem, twigs, and leaves of several host plants belonging to the family Oleaceae and olive, oleander, jasmine, fontanesia, privet, myrtle and pomegranate plants (Janse, 1981). According to current classification, three different pathovars of *P. savastanoi* denoted savastanoi, nerii and fraxini, elicit hyperplastic growth formations (galls or knots) on young stems and branches of olive (*Olea* spp.), oleander (*Nerium oleander*), and ash (*Fraxinus excelsior*), respectively (Young et al., 1996). The presence of bacterial knot in Turkey was observed on olives growing in the Aegean (Azeri, 1993; Tatli and Benlioglu, 2004) and western Mediterranean (Basim and Ersoy, 2000) regions of the country and on oleander in Sanliurfa (south-eastern Anatolia) (Kavak and Ustun, 2009). Bacteria isolated from different host plants differ in host specificity. Oleander strains infect oleander and plants of Oleaceae, whereas olive strains infect Oleaceae. Strains from ash specifically infect only ash plants (Janse, 1982; Iacobellıs et al., 1998).

The aim of the study was to characterize the population of twenty one *P. savastanoi* pv. *nerii* isolates from leaves and branches of oleander in Tekirdag of Turkey.

Materials and methods

Survey and isolation

In spring 2017, oleander leaves and barnches with small ground galls were collected from different park, garden and roadside in Tekirdag of Turkey. Samples were placed in paper and

transported to the laboratory. Isolations of the pathogen was caried out from diseased branches and leaves. Totaly 21 bacterial strains were isolated fom 53 diseased plants on King's medium B.

Screening bacteria pathogenicity

Hypersensitive reaction on tobacco leaves (HR): Pathogenicity of the obtained isolates were tested on tobacco plants according to Klement (1963). Bacterial suspension of each isolate (10^6 cfu/ml) was infiltrated in tobacco leaf. HR was observed after 24 h.

Pathogenicity tests

Pathogenicity tests were carried out as described by Surico et al. (1984). A total of 21 strains were inoculated into 1-year-old shoots of olive and oleander. Bacterial suspensions (10^8 CFU mL^{-1}) of selected bacterial strains were injected in three replicates into the bark of each test plant using a sterile needle. Swelling at the inoculation sites are evident 20-30 days after inoculation, depending on the plant reaction but virulence assays should last for at least 60 days (Janse, 1982). Sterile distilled water and reference *P. savastanoi* pv. *savastanoi* strain Akçay 9 from olive (provided by Prof.Dr Mustafa Mirik, NKU,TURKEY) were used as negative and positive controls, respectively.

Biochemical and physiological tests

Morphological properties on KB (King et al., 1954) media and biochemical and nutritional tests were used to identify the bacteria. The bacterial cultures were tested for, Gram reaction, levan production on 5% saccharose nutrient agar (SNA), oxidase and pectolytic activity, arginine dehydrolase reaction, and HR test on tobacco leaves (Schaad et al., 2001). All tests were repeated with three replicates. The reference strain Akçay 9 was used as positive control.

Results and discussion

Totaly twenty-one bacterial strains were isolated from fifty three diseased plants on King's medium B in Tekirdag. These strains produced knots on braches of both olive and oleander plants. So twenty one strains were re-isolated and used in identification tests. According to test results, the bacterial cultures were Gram-negative, did not produce levan on SNA, were negative for pectolytic activity, arginin dihydrolase and oxidase, therefore were allocated in the LOPAT 1b group (Lelliott and Stead, 1987).

All samples were collected on oleander plants in Tekirdag. Two different host plants as olive and oleander plants used for Pathogenicity test. The aim of these determined whereas *P. savastanoi* pv. s*avastanoi* or *P. savastanoi* pv. *nerii*. Because olive strains (*P. savastanoi* pv. *savastanoi*) only cause knots in olive plants. Otherwise oleander strains (*P. savastanoi* pv. *nerii*) cause knots on both oleander and olive (Iacobellis et al., 1998).

Conclusion

According to result of this study, bacterial knot disease determined as *P. savastanoi* pv. *nerii* and all strains were allocated in LOPAT 1b group with pathogenicity and biochemical tests.

Abstract

Natural enemies use information cues, mainly plant odors, in their foraging behaviour. The predatory bug *Orius laevigatus* is one of the effective predators against many herbivores in greenhouse vegetables. In mass rearing programs, a diverse variety of natural food stuffs have been employed in artificial diets. For this purpose we analyzed the response of *O. laevigatus* to tomato, carrot, zuchinii and mixed vegetable puree and plum, peach, pear and mixed fruit puree. These products were offered to *O. laevigatus* adult females in 1g quantities in experiments involving a dual choice Y-tube olfactometer. Female predatory bug showed the highest preference for carrot puree to clean air (control) in one replicate (100%). In three replicates female showed high preference for carrot puree (90%), too. *O. laevigatus* did not show a preference in one replicate of zuchinii (30%), but at all replicates preference were 57%. The predatory bug oriented similar preference to tomato puree in three replicates (67%). Mixed vegetable puree attracted *O.laevigatus* in three replicates (83%). However in one replicate predatory bug showed high preference (90%). The predatory bug was attracted to peach, plum, and pear puree 73%, 67%, 40%, respectively. *O. laevigatus* showed high preference (80%) in one replicate for peach and plum puree. Additionally, predatory bug showed 67% preference for mixed fruit puree. However, *O. laevigatus* showed 63% preference when we mixed carrot and peach puree. A better knowledge of the role of olfactory response of predatory bug to different diets will improve the efficiency and utilization of the food in mass rearing programs.

Keywords: *Orius laevigatus, Fruit puree, Vegetable puree, Y-tube olfactometer, Attraction.*

Introduction

The omnivorous predator *Orius laevigatus* (Fieber) (Hemiptera: Anthocoridae) is widely used as a commercial biological control agent in protected cultivation (Chambers *et al*., 1993; Van Lenteren, 2012). This bug feeds on aphids, whiteflies, mites, and thrips, with a distinct preference for the latter group of pests. It can also consume plant food, such as pollen and sap; this alternative diet helps the bug to maintain its population in the absence of protein-rich food (Van de Veire and Tirry, 1999; Saprykin and Pazyuk, 2003). Although *Orius* spp. are effective predators in protected cultivation, they are relatively expensive to mass rear. In commercial mass production systems, this anthocorid is mainly produced on eggs of *Ephestia kuehniella* Zeller (Lepidoptera: Pyralidae), in some cases in a mixture with *Artemia* cysts or eggs of *Sitotroga cerealella* (Olivier) (Lepidoptera: Gelechiidae) (De Clerq *et al*., 2005; Nishimori *et al*., 2016). Several authors have described alternative foods and artificial diets for *Orius* bugs (Bonte and De Clercq, 2008; Riddick, 2009). Several workers proposed artificial moisture sources, and living and oviposition substrates for *Orius* spp. (Richards and Schmidt, 1996; Shapiro and Ferkovich, 2006). However a lot of work is needed on different artificial diet formulation in mass rearing of entomofagous insect.

Fruits and vegetables are an important part of human and animal diet. They provide, not only the major dietary fiber component of food, but also a range of micronutrients, including minerals, vitamins and antioxidant compounds, such as carotenoids and polyphenols (Augspole *et al*., 2014). Tomato juice was found to contain higher levels of 3 sweet/fruity

related aroma compounds: 6-methyl-5-hepten-2-one, linalool, and β-ionone (Zhu *et al*., 2018). When tomatoes undergo thermal treatment, the pectin methylesterase and endopolygalactuonase are inactivated (Hsu, 2008). A total of 148 volatile compounds were identified as plum fruit constituents, esters were by far the dominant volatiles in plum among them (Pıno and Quijano, 2012). More than 300 volatile compounds have been identified in pear fruit (*Pyrus pyrifolia* Nak.) (Rapparini and Predieri, 2003). The possibilities of using olfactory responses of entomophages to various volatile compounds have been actively studied in the recent years with the view of improvement of biological plant protection methods.

The goal of this work was to study the behavioral responses of *O. laevigatus* to vegetable and fruit puree volatiles with the purpose of selecting the most attractive ones.

Material and Methods

Orius laevagatus were purchased from Koppert Biological Systems Company located in Antalya. Carrot, zuchinii, tomato and mixed vegetable puree (carrot 32%, tomato 25%, zucchini 12%, eggplant 3%, onion 4%, pepper 3%) were used in tests (Fig. 1). 1g of puree put in every replicate in jars. Pear, peach, plum and mixed fruit puree (peach+ plum+ pear) and mixed carrot and peach puree were also used in tests (Fig. 2). Olfactometer experiments were carried out by using a Y-tube olfactometer to test whether *O.laevigatus* can discriminate vegetable and fruit puree volatiles versus clean air (control). Females of *O. laevigatus* (1-2 day old) were put in a glass tube and starved for 2 hour. A single female to be tested was introduced into the Y-tube olfactometer and observed until she had walked 5 cm up one of the arms or until 5 minutes had elapsed (Takabayashi and Dicke, 1992; Cakmak et al., 2006). After every 10 insect responses, the Y-tube was cleaned with alcohol and dried. Each experiment was replicated three times.

Statistics: Differences in the proportions of *O. laevigatus* adult' attraction by moving toward one of the puree sources or toward the clean air control were analyzed using the replicated goodness of fit test at a 5% critical level (Sokal and Rohlf, 1995). The null hypothesis was that the predator would exhibit a 1:1 distribution across the two odor sources for each replicate. Insects that did not make a choice were excluded from the statistical analysis.

Figure 1. Vegatable puree in petri dishes (carrot, zucchini, tomato, mix vegetable).

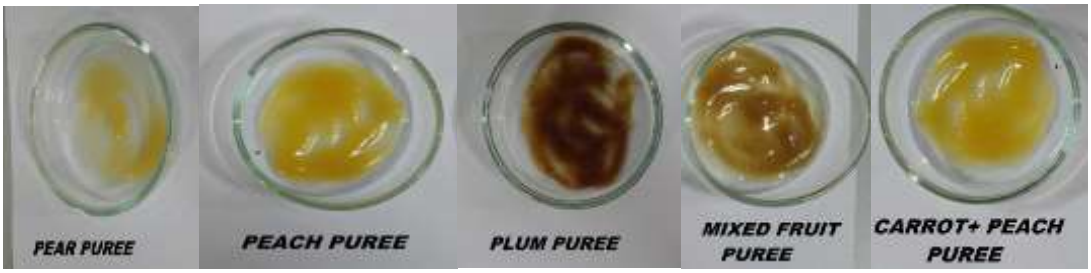

Figure 2. Fruit puree (pear,peach, plum, mixed fruit puree) and mixed carrot and peach puree in petri dishes.

Results and Discussion

The response of *O.laevigatus* to different vegetable and fruit puree and mixed of them were shown in Figure 3. Female predatory bug showed the highest preference for carrot puree to clean air (control) in two replicates (100%, 90%) (P> 0.01, Fig. 3) and one replicate of mixed vegetable puree (90%). In three replicates female show high preference in carrot (90%) and mixed vegetable puree (83%), too. *O. laevigatus* did not show a preference in one replicate of zucchini (30%) and pear puree (20%), but at all replicate preference were 57%, 40%. The predatory bug oriented to tomato and mixed fruit puree similar preference in three replicates (67%). Mixed vegetable puree attracted *O. laevigatus* in three replicates (83%), but in one replicate predatory bug showed high preference (90%) (Fig. 3). The predatory bug attracted to peach and plum puree 73% and 67%, respectively. *O. laevigatus* show high preference (80%) in one replicate for two of them. However, *O. laevigatus* showed 63% preference when we mixed carrot and peach puree. According to these results, the best orientation was found in carrot puree and mixed vegetable puree (Table 1).

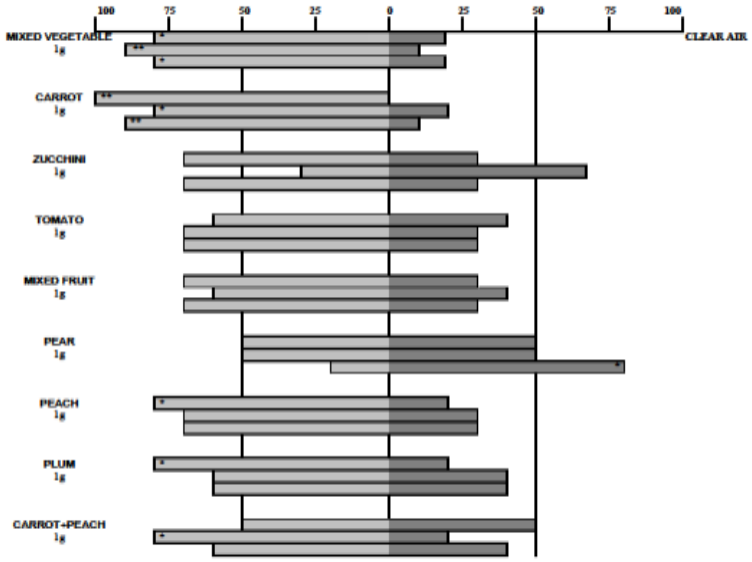

Figure 3. The response of *Orius laevigatus* when offered 1g doses of fruit and vegetable puree; *,**, significant P-values of 0.05 and 0.01, respectively, based on replicated goodness of fit test for G per replicate and GP.

Our results suggest that vegetable and fruit puree volatiles play a role in the attraction of *O. laevigatus*. The best orientation was seen in vegetables. Fruits were in second place with attracting predators. When the best vegetable and fruit puree were mixed together, the attractive effect appears to be falling. Some authors have studied with anthocorid species' orientation to herbivore induced plant volatiles (e.g.: methyl salicylate, methyl isonicotinate) (Lee, 2010; Stephanycheva *et al*., 2014). However, *Orius* predators were also known faculatatively phytophagous (Coll, 1996; Lattin, 1999). For example, *Orius insidiosus* feeds on xylem and mesophyll cells, ingesting water, small amount of sugars, starches and amino acids from the plants (Armer *et al.*, 1998). Also *Orius* species eat pollen (Xu and Enkegaard, 2009). Different

In order to stimulate the use of augmentative biological control, increasing effort is being put into the reduction of production costs. This involves developing economically viable and nutritionally adequate alternative foods or artificial diets (Cohen, 2004; De Clercq, 2008). *O. laevigatus* also can complete its development on certain plant materials, such as fresh sweet pepper pollen (Vacante *et al*., 1997). Additionally, this study showed that carrot puree had significantly more attractiveness for *O.laevigatus*. Besides, comparing to other vegetables, carrots can provide in the human diet significant amount of vitamin A due to the high bioavailability of carrot carotenoids (Van het Hof *et al*., 2000). Also, insects need vitamin for growth and in general they can not synthesize them (Chapman, 1998). Only vitamin A and E are known to be required in insects, where they play a role in the synthesis of pigments and in reproduction, respectively (Chapman, 1998). Carotenoids were reported in many physiological functions, with beneficial effects on survival, growth and immunity (Park *et al*., 2010). Carrot diet decreased developmental time in yellow mealworm, *Tenebrio molitor* L. (Coleoptera:Tenebrionidae) (Oonincx *et al*., 2015). Dhinaut *et al*. (2017) stated that prevention of immunopathology relies on endogenous antioxidant enzymes and the consumption of dietary antioxidants, including carotenoids such as astaxanthin on *T. molitor*. Also mixed vitamin (B6, E, C, etc.) was added in artificial diet (Bonte and De Clerq, 2010). The current study demonstrated that fruit puree was also attractive for *O. laevigatus* females than the control.

Conclusions

In conclusion, we demonstrated that the omnivorous *O. laevigatus* could be reared with vegetable and fruit puree in their artificial diet. A diverse variety of undefined natural foodstuffs, including butter fat, wheat germ, royal jelly, honey, liver extract, yeast products and plant material (pollen, leaf extracts) have been employed for rearing predators. A better knowledge of the role of the different ingredients in these oligidic diets will improve the efficiency and utilisation of the food. More research is needed to develop artificial diets. Also, the attractiveness of the oviposition substrate for the females could be improved by incorporating plant extracts as cues to elicit oviposition behaviour. For instance, Constant *et*

al. (1996) reported that spraying their substrate with leaf extract of *Inula viscosa* (L.) increased oviposition by *Macrolophus caliginosus* Wagner (Heteroptera: Miridae) from 1.2 to 1.6 eggs/female/day. In future we can use carrot puree volatiles to attract predatory bug. The most popular odor sources of *O. laevigatus* can be used by participating in their diets in mass rearing programmes and also these odors can be used to attract predators to their release sites.

Abstract

Drug delivery systems are carriers that allow for the protection of the bioactive compound from physicochemical factors such as oxidation, denaturation, ultraviolet radiation (UV), high temperature, pH, enzymes, and biochemical interactions. Rainbow trout fish (*Oncorhynchus mykiss*) is one of the main commercial fish species widely farmed in Europe. Rainbow trout eggs contain high content of omega-3 polyunsaturated fatty acids in phospholipids form, essential amino acids, vitamins and valuable minerals. A wide variety of encapsulating materials has been used to protect bioactive ingredients. Brilliant blue is a most common food colorant used in food industry. Brilliant blue (BB) can soluble easily in water and gives blue color to food materials. It is hypothesized that BB could be used as an indicator to determine bioactive compound encapsulating capacity of rainbow trout egg. Thus, the aim of this research was to determine water-soluble compound loading capacity of trout fish egg by using BB. BB colorant was selected as a model bioactive compound for loading and encapsulating trial. Among the all concentrations of BB colorant tested, sample BB750 and BB1000 showed the highest bioencapsulating capacity. It resulted that trout fish egg could be successfully used as a bioactive compound carrier vehicle for water-soluble compounds.

Keywords: *Rainbow trout egg, Encapsulating, Brilliant blue colorant, Loading capacity*

Introduction

Rainbow trout fish (*Oncorhynchus mykiss*) is one of the main commercial fish species widely farmed in Europe. Native to the Pacific coast of the United States, it was brought to Europe at the end of the 19 th century and today it is farmed in nearly all European countries (Hardy, 2002) . Fish eggs, commonly referred to as roe, are one of the valuable foodstuff of aquatic sources. Fish roes are obtained as a by-product collected from female fish before spawning time like farmed rainbow trout (Bledsoe, Bledsoe and Rasco, 2003). In recent decades, significant advances in drug delivery systems have enabled more effective drug and bioactive compound administration. To deliver drugs to specific organs, a range of organic systems (e.g., micelles, liposomes, and polymeric nanoparticles) have been designed (Barbe et al., 2004). Contrary to common belief, humans have been developing drug delivery strategies since ancient times, beginning with the chewing of leaves or roots and the inhalation of smoke particles from the burning of medicinal plants. Over centuries, the delivery mechanisms have been refined through the development of more reliable dosage forms, such as tablets and capsules (Lee, Park and Robinson, 2000). In this study, water soluble compound intake capacity of rainbow trout egg was investigated. It is hypothesized that a colorant, brilliant blue (BB), could be used as an indicator to determine bioactive compound encapsulating capacity of rainbow trout egg. BB water soluble food colorant was selected as a model bioactive compound for loading and encapsulating trial.

Material and Methods

Rainbow trout (*Onchorhynchus mykiss*) eggs, with a diameter of 5-7 mm, were freshly obtained from Selina Aquaculture Co. Ltd., Fethiye, Muğla-Turkey and transported in cold chain system to the laboratory. Eggs were washed thoroughly with distilled water and passed to filter paper for 10 min to remove excessive water on surface. Food colorant Brillant Blue was purchased from KRK Gida Ltd. Şti. (İstanbul Turkey).

Bioencapsulating trials

Rainbow trout eggs were divided into seven groups prior to encapsulating trials. Trout fish eggs (10 g) were immersed in BB loading (100 ml) solutions containing 0, 50, 100, 250, 500, 750 and 1000 mg/kg of BB for 30 minutes. After the immersing process, excessive BB solution on eggs surface was removed by the paper towel. Trout eggs containing BB solution were passed to the deep freezer (Dairei Europe, ULTF 80) and stored at -80 ºC for 24 hours. Frozen eggs were dried in a freeze dryer (Telstar, Lyoquest 50) at -50 °C, below 0.4 mbar up to water activity of 0.35±1 (*aw*:0.35)for 30-32 hours.

Color analysis

A CR-400 Minolta chroma meter (Minolta, Osaka, Japan) instrument was used to determine the color of trout egg samples. Four readings on the surface of eggs were done using the CIE Laboratory *L* (*lightness), *a** (redness), *b** (yellowness) system in day light conditions.

LC-MS/MS analysis of Brillant Blue colorant

BB colorant analysis was performed in LC-MS/MS (Thermo TSQ Quantum Access Max LC-MS/MS) according to the instrumental method described by according to the method of (Li, Xia, Ma, Zhao, & Pidatala, 2017) with a slight modification. About 50 mg of egg powder was weighted and transferred to 2 ml tubes. Nine volumes of methanol/water (20:80, v/v) with 10 µM trypan blue was added and mixed thoroughly. The mixture was then sonicated for 10 min at room temperature and centrifuged at 16000g for 10 min at 4 °C. The supernatant was collected and stored at -80 °C until analysis. Chromatographic separation was performed on a Hypersil C18 column (100 mm × 2.1 mm, 1.9 µm). The mobile phase consisted of a gradient of water and methanol, both containing 20 mM ammonium acetate. Extract (10 µl) was injected onto column held at 30 °C for chromatographic separation. All of the samples were kept in an autosampler with the temperature controlled at 4 °C prior to injection during analysis.

Statistical analysis

All experiments were conducted in duplicate, and all analyses were done at least in duplicate. Statistical analysis was conducted according to the statistical analysis software of SAS institute (Statistical Analysis System, Cary, NC, USA). Differences among the mean value of samples were tested by Duncan's Multiple Range Test and significance was defined at $P<0.05$.

Results and Discussion

Color analysis of rainbow trout fish eggs containing brilliant blue colorant

Color analysis of trout egg was performed in daylight and *L*, *a*, *b* values were given in Table 1. *L* value reflects the white-black color of the surface. Highest *L* color value was determined in control group trout fish egg (BB0), whereas lowest was found in BB1000. *L* values of egg samples significantly ($P<0.05$) decreased in parallel with the increase in BB concentration up to the 750 ppm. There was no significant difference *L* values of BB750 and BB1000. *a* value reflects the red-green color of surface. Positive *a* color (redness) value was determined in control group trout fish egg (BB0), whereas negative *a* colors (greenish) were found in BB50-BB1000. It means that the BB solution turned the egg colors from red to greenish. *a* value of egg samples significantly ($P<0.05$) increased in parallel with the increase in BB concentration up to the 1000 ppm. *b* value reflects the yellow-blue color of the surface. Positive *b* color

(yellowness) values were determined in *the* control group (BB0), BB50 and BB100 of trout fish egg, whereas negative *b* colors (bluish) were found in BB250-BB1000. Color alteration from positive *b* values to negative *b* values means that the BB solution turned the egg colors from yellow to a bluish color. Negative *b* values of egg samples significantly ($P<0.05$) decreased in parallel with the increase in BB concentration up to the 1000 ppm.

Table 1. Colour (*L*, *a* and *b*) values of rainbow trout fish egg containing brillant blue.

Samples*	*L (*lightness)	*a* (redness)	*b* (yellowness)
BB0	59.74±2.81	5.47±0.13	21.07±0.41
BB50	31.86±1.23	-9.72±0.92	2.19±0.68
BB100	24.35±2.18	-8.24±0.18	3.00±0.77
BB250	25.20±1.38	-7.92±0.25	-10.08±0.54
BB500	19.06±1.29	-4.01±0.28	-11.95±0.32
BB750	17.72±1.01	-2.57±0.17	-16.42±0.54
BB1000	17.23±1.25	-1.86±0.09	-18.07±0.65

* BB0-BB1000: Eggs immersed in 0-1000 ppm of BB solution.

Optic surface image analysis of rainbow trout fish egg containing brilliant blue colorant

Images of freeze-dried rainbow trout eggs containing brilliant blue colorant were given in Figure 1. As seen in Figure 1, the yellow color of eggs was turned from yellow to blue. Lower concentrations (50 and 100 ppm) of BB solution gave green color to eggs. The color of eggs immersed in 250 ppm BB solution (BB250) were greenish-bluish color. Higher concentrations of immersing solution (500-1000) changed egg colors from light bluish to dark blue. Colors of BB750 and BB1000 samples were almost the same (dark blue).

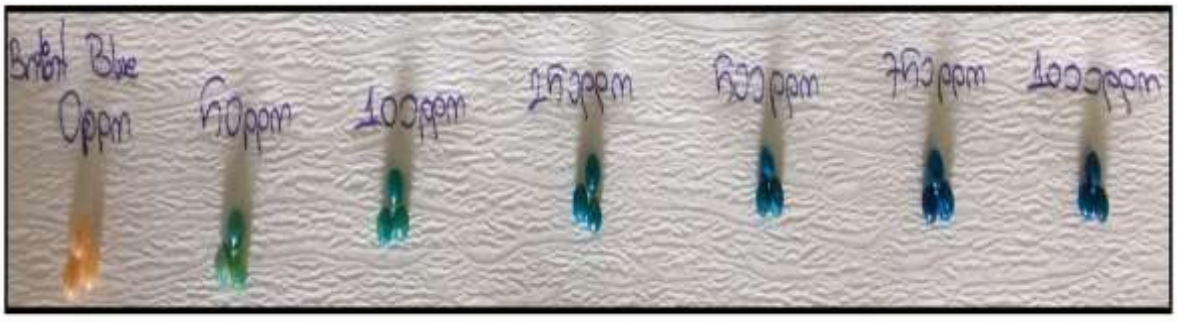

Figure 1. Images of rainbow trout eggs containing brillant blue colorant

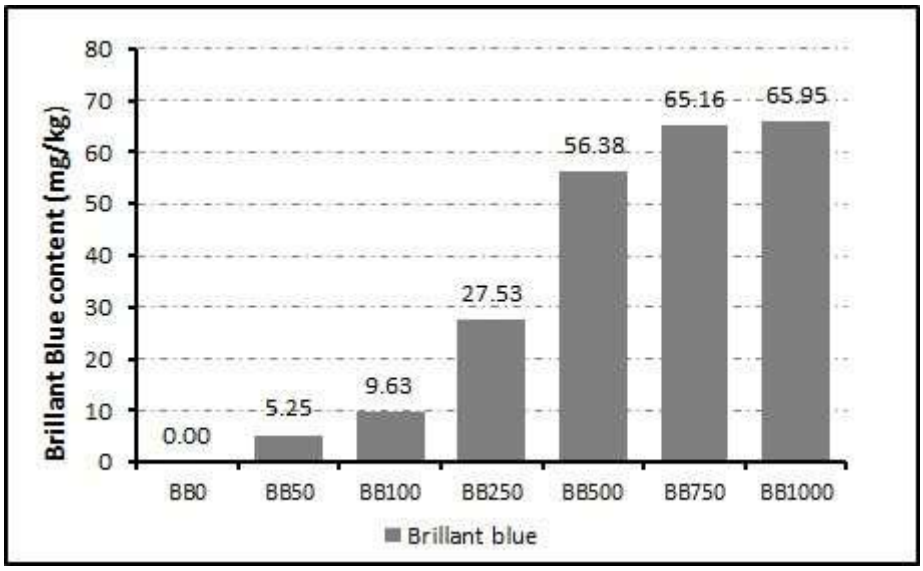
Brilliant blue analysis of freeze-dried rainbow trout fish eggs

The brilliant blue content of freeze-dried rainbow trout fish eggs were given in Figure 2. Producing a bioencapsule for envelopment and protection of bioactive substances starts with the selection of an adequate capsulation material (de Vos et al., 2009). Rainbow trout fish eggs could be delivering vehicle to uptake of bioactive compounds in to body with its bioencapsulation property. Thus brilliant blue, water-soluble food colorant, was selected to determine trout eggs bioencapsulation capacity. As seen in Figure 2, BB content of freeze dried eggs samples significantly ($P<0.05$) increased in parallel with the increase in BB concentration up to the 750 ppm of BB solution (BB750). There was no significant difference between BB contents of BB750 and BB1000. It can be postulated that maximum 65-66 mg/kg BB could be intake into the trout egg. Aquatic organisms such as artemias (Ates et al., 2015),

daphnia (Embregts et al., 2018), rotifers (Manickam et al., 2019) are served as bioencapsulation vehicles for delivering of bioactive compounds.



* BB0-BB1000: Eggs immersed in 0-1000 ppm of BB solution.

Figure 2. Brillant Blue content of rainbow trout fish eggs containing brilliant blue colorant

Conclusions

The results of this study reveal the rainbow trout fish egg could be used in bioencapsulation and delivering of water-soluble bioactive compounds. In this study brilliant blue colorant successfully used as a marker for the determination of bioencapsulation capacity of trout egg. Immersing in trout eggs into the solution containing water-soluble bioactive compound and applying of freeze-drying method to eggs could be a novel method for encapsulating and delivering of bioactive compounds.

Abstract

Diabetes mellitus (DM) is described by World Health Organisation as "Chronic, metabolic disease characterized by elevated levels of blood glucose (or blood sugar), which leads over time to serious damage to the heart, blood vessels, eyes, kidneys, and nerves". Oral antidiabetic agents, insulin, diet and lifestyle changes are conventional therapy in DM. However, patients also prefer complementary therapies including plants. In literature, there are various studies on this subject. Culture, geographic location, religion etc. affect the type of plants commonly used. According to the studies, the most widely used plants are *Nigella sativa, Cinnamomum sp, Prunus Amygdalus amara, Thymus vulgaris,* and *Olea europaea L.* folium. Bioactive compounds (thymoquinone, cinnamaldehyde, catechin, epicatechin, cyaniding, procyanidin etc.) found in these plants have anti-diabetic properties. In vitro and experimental animal studies have shown these plants improve fasting glucose, HbA1c and insulin sensitivity, stimulate insulin secretion, and inhibit carbohydrate digestion. There are also interventional studies indicating the beneficial effects of the folk medicine plants on DM patients but due to the lack of strong research evidence, there is no primary recommendation for usage in the management of diabetes.

Keywords: *Type 2 diabetes mellitus, plants, folk medicine.*

Introduction

Diabetes mellitus (DM) is described by World Health Organisation (WHO) as "Chronic, metabolic disease characterized by elevated levels of blood glucose (or blood sugar), which leads over time to serious damage to the heart, blood vessels, eyes, kidneys, and nerves". According to global report 422 million people have diabetes and 1.6 million people die due to diabetes (WHO, 2018 Treatment of type 2 DM consist of lifestyle intervention (education of patients, nutrition, exercise, self-monitoring of blood glucose and pharmacotherapy (insulin sensitizers with predominant action in the liver, insulin sensitizers with predominant action in peripheral insulin-sensitive tissues, insulin secretagogues, carbohydrate absorption inhibitors, incretin-based therapies, sodium glucose co-transporter 2 inhibitors and insulins) (Dungan, 2016). Treatment failure causes high blood glucose levels. This situation increases the risk of some complications like cardiovascular events, nephropathy (Domingueti et al., 2016).

In recent years, the number of studies on the use of plants in the treatment of diseases has increased. And patients also tend to use natural products. In Turkey, there are various studies on this issue. Prevalence of using folk medicine is 26.9-88.1%. The most widely used plants are *Nigella sativa, Cinnamomum sp, Prunus Amygdalus amara, Thymus vulgaris*, and *Olea europaea L.* Folium (Candar et al., 2018; Ceylan et al., 2009; Ilhan et al., 2016). The aim of this review is to provide detailed information about folk medicine used in diabetes mellitus.

Material and Methods

The paper is based on an extended review of "*Nigella sativa, Cinnamomum s.p, Prunus Amygdalus amara, Thymus vulgaris*, and *Olea europaea L.* folium and type 2 DM". The literature search was done in the PubMed database. The search terms were the following combination of keywords: "*Nigella sativa*" AND "Type 2 diabetes mellitus", "C*innamomum*

sp" AND "Type 2 diabetes mellitus", *"Prunus Amygdalus amara*" AND "Type 2 diabetes mellitus", "*Thymus vulgaris*" AND "Type 2 diabetes mellitus" and "*Olea europaea L.* folium" AND "Type 2 diabetes mellitus". The data search was restricted to the last 10 years from 2008 to 2018.

Results and Discussion

***Nigella sativa* (black seed or black cumin):** It belongs to the Ranunculacea family. Black seeds and their oil have been used for more than 2000 years especially in the Indian and the Arabian civilizations for treatment of a variety of diseases in the respiratory system, digestive tract, kidney, liver cardiovascular system, and immune system (Tavakkoli et al.,2017). Hazrat Rasool Allah (PBUH) said, "Let all the black seed upon you, these contain cure of all diseases except death" Chemical composition of *Nigella sativa*: 32-40% fixed oil, 0.4-0.45% volatile oil, 16-19.9% protein, 33.9% carbohydrates, 5.5% fiber, 6% water and 1.79-3.74% minerals (Ijaz et al., 2017).

Nigella sativa contains many active compounds: nigellicine, nigellidine, thymoquinone (TQ), dithymoquinone, thymol, and carvacrol (Gholamnezhad et al., 2016). According to Table 1, 2 g/day *Nigella sativa* supplementation with anti-diabetic medication has improved fasting blood glucose, HbAlC etc. in type 2 DM patients. And in the studies, no adverse effects were recorded.

It has been determined that TQ has the main role to improve glucose metabolism in type 2 DM. The possible mechanisms of TQ and other active compounds on type 2 DM: improves body antioxidant defense, increases insulin secretion, decreases gluconeogenesis, and reduces glucose absorption and body weight (Heshmati and Namazi, 2015).

Cinnamomum sp: Cinnamon has been used as both a spice and a flavoring agent. In Asian countries, it has had popularity as an herbal medicine for the treatment of DM (Necyk and Zubach-Cassano, 2017). There are main varieties; *Cinnamomum zeylanicum and Cinnamon cassia* (also known as *Cinnamomum aromaticum*/Chinese cinnamon). *Cinnamomum zeylanicum* is also known as Ceylon cinnamon (the source of its Latin name, zeylanicum) or 'true cinnamon'. One important difference between Cinnamon cassia and *Cinnamomum zeylanicum* is their coumarin content. The levels of coumarins in *Cinnamon cassia* appear to be very high and pose health risks when consumed regularly in higher quantities. Coumarins are secondary phytochemicals with strong anticoagulant, carcinogenic and hepato-toxic properties. And it has been reported *Cinnamomum zeylanicum* contains 'hardly any' coumarin (Ranasinghe et al., 2013). The European Food Safety Authority advocates against the regular, long-term use of *Cinnamon cassia* as a supplement due to its coumarin content (EFSA, 2008). Cinnamaldehyde, cinnamic acid, eugenol, coumarin, and procyanidins are major components of cinnamon (Azimi, Ghiasvand, Feizi, Hariri, & Abbasi, 2014). Cinnamon polyphenols display insulin-like properties and stimulate glucose uptake in skeletal muscle and adipose tissue (Akilen et al., 2012). According to Table 2, clinical studies on Cinnamomum sp. and Type 2 diabetes mellitus do not have standard features (sample size, dosage, duration etc.). And results are conflicting. When 120 mg/day and 1 g/day cinnamon supplementation have improved HbAlC and fasting blood glucose, 3 g/day cinnamon supplementation has shown no beneficial effect. In the Cochrane review, it has been reported there is insufficient evidence to support the use of cinnamon for type 1 or type 2 DM (Leach and Kumar, 2012).

***Prunus Amygdalus amara (*bitter almond):** Almonds are the good dietary source of unsaturated fatty acids, fiber, vegetable protein, α-tocopherol, manganese, magnesium, copper, phosphorus. Almonds also contain an array of phytonutrients including phenolic acids, phytosterols, and polyphenolic compounds such as flavonoids and proanthocyanidins (Kamil and Chen, 2012). Clinical studies about bitter almond and type 2 DM are limited. However, almond supplementation (20% of energy intake) during 12-24 weeks has improved

glycemic control and lipid profiles in patients with type 2 DM (Gulati et al., 2017; Li et al., 2011). Incorporation of almonds in a well-balanced healthy diet could lead to beneficial effects in patients with type 2 DM.

***Thymus vulgaris* (thyme):** It is commonly used as a culinary herb and different medicinal purposes (treatment of disorders affecting the respiratory, digestive, cardiovascular, and nervous systems) (Salehi et al., 2018). It has been reported thyme has the antioxidative activity which better than α-tocopherol and BHA. Thyme is rich in phenolic acids and flavonoids (Roby, Sarhan, Selim, & Khalel, 2013). However, clinical studies about thyme and type 2 DM are limited.

***Olea europaea L. folium*:** *Olea europaea* is a traditional Mediterranean plant and its fruit and oil are frequently consumed for the healthy diet. It's also known as the symbol of abundance, glory, and peace. Olive oil contains monounsaturated fatty acids, phenolic compounds etc., so most people prefer to consume it (Uylaser and Yildiz, 2014). Oleuropein is the most abundant bioactive component and its quantity can reach up to 60-90 mg per gram of dry olive leaf (Ghanbari et al., 2012; Sahin and Bilgin, 2018). In a clinical study with type 2 DM patients, it has been shown 500 mg oral olive leaf extract supplementation during 14 weeks improved HbA1c and fasting plasma insulin levels. According to the results obtained from the study of experimental animals olive leaf extract without olive leaf reduced digestion and absorption of starch(Wainstein et al., 2012).

Table 1. Clinical studies on Nigella *sativa* and Type 2 diabetes mellitus

Participants	Intervention duration/Doses	Control	Outcomes	Adverse Effect	Reference
94 patients with type 2 DM treated with anti-diabetic medication	3 months Group 1: 1 g/day Group 2: 2 g/day Group 3: 3 g/day *Nigella sativa* capsule	-	<u>In group 2</u> Fasting blood glucose↓ HbAlC↓ Insulin resistance B-cell function↑ <u>In group 1 and 3</u> No significance improvement	No record of any side effect	(A. O. Bamosa, Kaatabi, Lebdaa, Elq, & Al-Sultanb, 2010)
114 patients with type 2 DM treated with anti-diabetic medication	3 months (n:57) 2 g/day *Nigella sativa* capsule	3 months (n:57) activated charcoal	<u>In intervention group</u> Fasting blood glucose↓ HbAlC↓	No record of any side effect	(Kaatabi et al., 2015)
60 patients with type 2 DM treated with standard oral hypoglycemic drugs	12 months (n:30) 2 g/day *Nigella sativa* capsule	12 months (n:30) activated charcoal	<u>In intervention group</u> HbAlC↓	No record of any side effect	(A. Bamosa et al., 2015)

Table 2. Clinical studies on Cinnamomum sp and Type 2 diabetes mellitus

Participants	Intervention duration/Doses	Control	Outcomes	Adverse Effect	Reference
59 patients with type 2 DM	3 months 1.2 g/day cinnamon capsules	Microcrystalline cellulose	Compared to control and baseline no improvement in fasting blood glucose HbA1c	No information	(Wainstein, Stern, Heller, & Boaz, 2011)
66 patients with type 2 DM treated with oral hypoglycemic agents	3 months Group 1: 120 mg/day Group 2: 360 g/day cinnamon tablets	Placebo tablets	Compared to baseline in group 1 and 2 HbAlC↓ fasting blood glucose↓	No record of any side effect	(Lu et al., 2012)
105 patients with type 2 DM treated with oral hypoglycemic agents	3 months Group 1: 1 g/day cinnamon capsules Group 2: 1 g/day whortleberry capsules	Starch	In group 1 HbAlC↓ Body mass index↓	No information	(Mirfeizi et al., 2016)
44 patients with type 2 DM treated with oral hypoglycemic agents	2 months 3 g/day *Cinnamomum zeylanicum* capsules	Microcrystalline cellulose	No improvement in fasting blood glucose HbA1c HOMA-IR carboxymethyl lysine levels	No record of any side effect	(Talaei et al., 2017)

Conclusions

There are interventional studies indicating beneficial effects of the folk medicine plants on DM patients but lack of strong research evidence of herbal medicines on diabetes outcomes does not allow for their inclusion by American Diabetes Association as the primary recommendation in the management of diabetes (ADA, 2018). It is the right approach to ensure and encourage compliance with medical treatment, diet, and exercise for diabetic patients.

Abstract

Green shield bug (*Palomena prasina* L., Hemiptera: Pentatomidae) is a quite common pest species in Turkish hazelnut orchards. *P. prasina* causes severe loss of yield by damaging quality and quantity in the edible parts of the hazelnut. Usually, chemical control methods are applied against this pest. Due to the adverse effects of insecticides on the environment and human health, alternative control methods are gaining importance, and microbial control methods are taking importance in field control actions. For this purpose, four different entomopathogenic bacterium isolates 271a (*Bacillus thuringiensis*), Akçakoca2 (*Bacillus megaterium*), HMA5 *(Bacillus megaterium*), FPN2 (*Pseudomonas putida*) were applied against nymphs and adults of *P. prasina* under laboratory conditions (24° C, 70% humidity). The study was conducted in two iterations and three replications, and each replication was composed of 5 individuals of the same age and was observed for 12 days. All isolates were used at 10^8cells ml $^{-1}$ concentration. Per cent effects were calculated via the Abbott formula. In the study, Akçakoca2 and FPM2 isolates were found to be 100% effective, followed by HMA5 isolate at 96% and 271a isolate at 73%. When the effects of entomopathogenic bacterial isolates against the adults were examined, it was found that Akçakoca2 isolate was 75% effective, followed by 271a isolate at 70%, FPM2 isolate at 50%, and HMA5 isolate at 41%. As a result, Akçakoca2 isolate was identified as the most effective against both adults and nymphs of *P. prasina*, having an effectiveness close of that of the chemical. All of the isolates used were found to be more active on nymphs than on adults.

Keywords: *Biological control, Palomena prasina, Bacillus thuringiensis, Bacillus megaterium, Pseudomonas putida*

Introduction

With its 600,000 hectares of production area and approximately 600,000 tons/year production, hazelnut is one of Turkey's most important export products that sums an annual average exchange input of about 2,5 billion dollars. Turkey covers 65-75% of world hazelnut production and 70-75% of total exports. There are about 400,000 families, in other words, about 2 million persons, who takes an income from hazelnuts production (Bozoğlu, 2001; Anonymous, 2006). Some of the insect species that are harmful to hazelnuts indirectly affect the product by harming different plant tissues, while others have a more direct effect like feeding on the fruits. Species belonging to the Pentatomidae (Hemiptera) are also included in the fruit-damaging group. These pests cause the total yield and product quality to decrease by feeding on nuts (Kurt, 1975; Tuncer et al., 2002). The green shield bug [*Palomena prasina* L. (Heteroptera: Pentatomidae)] is the most critical fruit-damaging species, and it dramatically surpasses other pests because the damage level that inflicts in all hazelnut orchards. (Işık et al., 1987; Tuncer et al., 2005). Feeding on the fruit's early stages causes empty shells, deformed fruits and shedding while feeding on the fruit after its inner bonding period causes spotting. The spotting damage is sometimes up to 20% in hazelnuts and creates significant problems in export (Tuncer et al., 2005). The green shield bug is reported as the most harmful hazelnut pest in Italy also, where it builds-up high populations (Tavella et al., 2002). *P. prasina* is a polyphagous species and is found in many regions in Turkey, especially in

hazelnut production areas. Its harm to other plants is insignificant and has 1 generation per year (Lodos, 1982; Saruhan, 2004).

Biological methods can be an alternative in the control of *P. prasina*. Several antagonist microorganisms have been successfully used to control pests in agricultural areas, as *Bacillus thuringiensis, B. megaterium and Lysinibacillus sphaericus*. *Bacillus megaterium* is considered an important entomopathogen in the control of insects (Aksoy ve Ozman-Sullivan 2008) also because of its extensive habitat (Gu et al. 2007, Patricia et al. 2007). Although bacteria are used by many researchers in the biological control against many pests (Sezen et al., 2004, Bursova et al., 2006, Gökçe et al. 2010, Özşahin et al. 2014), the application against *P. prasina* if overlooked. Four different isolates of *B. megaterium* were used against *P. prasina* and at the end of day 12, some of the isolates were found to be 98% effective (Aksoy et al., 2018).

This study was conducted to determine the effect of some bacterial isolates on *P. prasina* adults and nymphs, in laboratory conditions.

Material and Methods

Palomena prasina adults and nymphs used in the experiment were collected from different hazelnut production areas of Samsun province and breeding were managed in the laboratory on fresh beans. The four isolates of the bacteria used in the experiment were obtained from the bacteriology laboratory in the Plant Protection Department of the Faculty of Agriculture in Ondokuz Mayis University (Table 1).

Table 1. Isolates of entomopathogenic bacteria used in this study.

Isolate denomination	**Entomopathogenic bacteria isolates**
271a	*Bacillus thuringiensis*
Akcakoca2	*Bacillus megaterium*
HMA5	*Bacillus megaterium*
Fpin2	*Pseudomonas putida*

The study was carried out in laboratory conditions (24°C, 70% humidity) and in 10x10x10 cm plastic containers, making sure that the nymphs and adults used in the study were of the same age. The study was conducted in 3 iterations and repeated twice. Each iteration contained five insects. These insects were fed with fresh beans. The study was carried out by spraying suspensions (2 ml) prepared from entomopathogenic bacterial isolates at a dose of 10^8 cells/ml. Containers in which only water was sprayed were considered as the control group. The study was checked daily for 12 days, and mortality numbers were noted.

Results And Discussion

When Akçakoca2 and Fpin2 isolates were applied against *Palomena prasina* nymphs in the study, mortality started from the second day and reached 100% at the end of day 12. HMA5 isolate followed Akçakoca2 and Fpin2 efficacy, at 96.67%. The less effective isolate against nymphs was 271, summing a 73.3% mortality. All isolates used against the *P. prasina* nymphs in laboratory conditions were found to be highly effective (Figure 1).

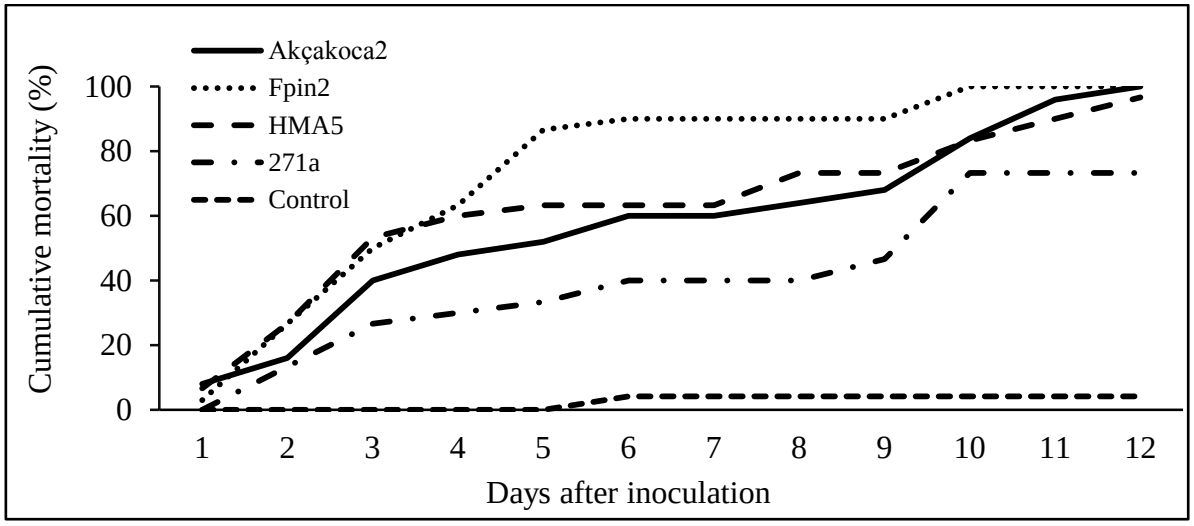

Figure 1. Cumulative mortality of nymph of *Palomena prasina* after inoculation with different isolates of entomopathogenic bacterial isolates.

Several studies have been carried out on the insecticidal and nematocidal effects of *B. megaterium*. Khyami-Horani et al. (1999) reported that *B. megaterium* populations were highly toxic to the 4th instar larvae of *Culiseta longiareolata* (Diptera: Culicidae). Aksoy and Ozman-Sullivan (2008) reported that *B. megaterium* isolates were effective against *Aphis pomi* (Hemiptera: Sternorrhyncha: Aphididae) causing 92% -100% mortality five days after application. This bacterium has also been used against nematodes. In another study, *B. megaterium* SAkc-2 isolate was shown to be highly pathogenic for the 4th period nymphs of *P. prasina.* SAkc-2 isolate showed 98% efficacy after 12 days of application (Aksoy et al. 2018).

The same isolates were tested against the adults of *P. prasina* and had a lower effect than on the nymphs. At the end of day 12, the highest effect was observed with Akçakoca2 isolation at 75%, followed by 271a isolate at 70.83%, Fpin2 isolate at 50.00% and HMA5 isolate at 41.67% (Figure 2).

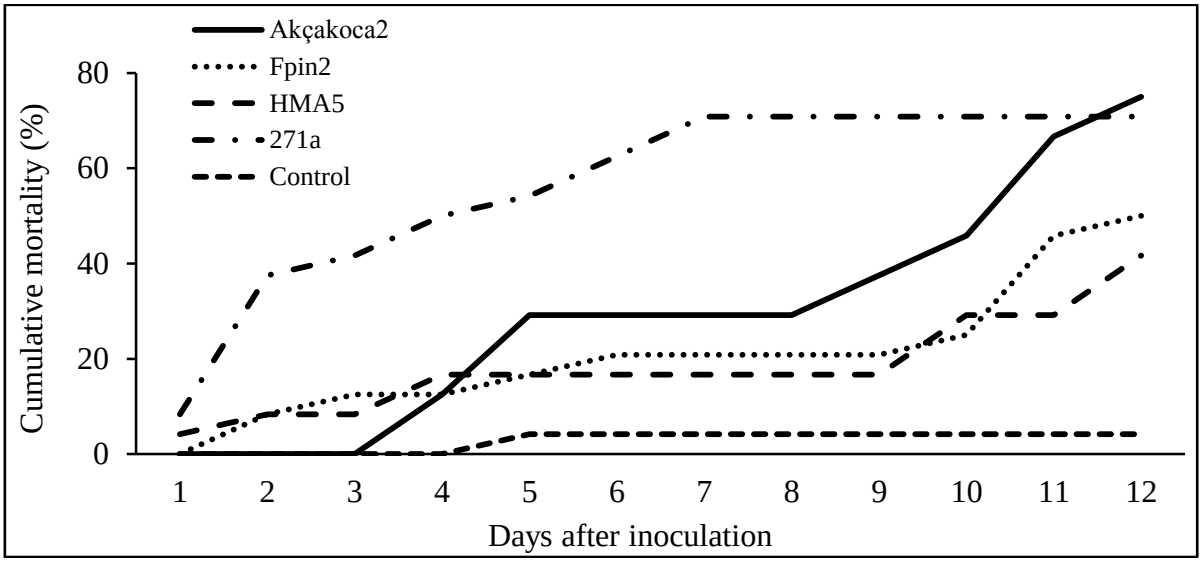

Figure 2. Cumulative mortality of adults of *Palomena prasina* after inoculation with different isolates of entomopathogenic bacterial isolates.

Conclusions

Our results are consistent with the effect of some *B. megaterium* isolates used as entomopathogenic bacteria against different insects and nematodes (Padgham, Sikora 2007; Aksoy and Ozman-Sullivan 2008; Huang et al. 2010). We suggest that Akçakoca2 isolate will be a potential biocontrol agent against the adults and nymphs of *P. prasina*. However, isolates Fpin2 and HMA5 have been identified as a potential biological control agent in the control of pest nymphs.

Acknowledgement

I would like to thank Hasan Murat Aksoy for his help in collecting, reproducing, and applying the isolates.

Abstract

Tropinota (*Epicometis*) *hirta* Poda (Coleoptera: Scarabaeidae) damages reproductive parts of flowers of several fruit trees, some vegetables, and many ornamental bushes. The hairy beetle overwinters as larvae and ecloses in soil. Adult beetles emerge in time for spring fruit trees blooming. This beetle is active during the day, concealing near soil to overnight. The control of hairy beetle is complicated, and insecticides cannot be used due to the impact on the honeybees, pollinators, and other beneficial insects. Traps, as chromotropic traps, alone or in combination with a pheromone lure, are a method for the control of hairy beetles while adult. We used picasso blue (#0000FF) traps lured by pheromone in several combinations: 1) clear/no pheromone; pheromone clear; colour/no pheromone, and) and colour/pheromone. Each traps were assembled with a 22 cm wide funnel, eventually painted with Picasso blue, connected with the neck of a 5-litre colourless plastic bottles filled with water (1 litre). The combination of Picasso blue funnel + pheromone lure was the most effective in hairy beetle control. Total caught hairy beetle counts: 351.33 for Picasso blue + pheromone treatment, 282.67 for Picasso blue treatment, 13.67 for pheromone treatment and 2.33 for the control. The maximum of hairy beetle catching was in the fifth week (17-24.04.2017); number of hairy beetles caught between 3rd and sixth weeks was high. Use of the funnel traps is an important method of harmful keep under control.

Keywords: *Apple, Konya, Blue, Attractant trap, Biotechnical control.*

Introduction

Turkey is among the world's leading fruit producers with a total of 20.321.777 tons (TUIK, 2016). Because Turkey has different climate and soil characteristics, fruit production is performed in almost all regions. According to the data from 2016, annual fruit production in Konya, where the study was conducted is about 314.873 tons. Apple takes the most significant production tonnage (101.081 tons) compared to other fruits (TUIK, 2016). In Konya, although fruit growing is an essential agricultural production sector, the producers have problems with cultivar selection, irrigation, harvesting, preservation, and marketing. In addition to these factors, many plant diseases and pests also affect production negatively (Eşitken et al., 2012)

Scarabaeids is a significant group of insects that contain many pests. Adults of many species are phytophagous and fed with leaves, flowers and roots of cultivated plants (Hurpin 1962). *Tropinota hirta* Poda is a member of this group and is one of the most important pests causing yield loss by feeding with flower parts of plants. This beetle damage the reproductive parts of flowers of several fruit trees, some vegetables, and many ornamental bushes (Endrödi, 1956; Homonnay and Homonnayne-Csehi, 1990). In a study conducted in Hungary, it was determined that *T. hirta* adults cause significant yield losses by feeding with flowers (Rackskō et al., 2007). The pest also causes damage to forest trees and cereals. (Hurpin, 1962; Zashev, Keremedchiev, 1968**).** Hairy beetle survives to overwinter as larvae and matures under the soil. Hairy beetle caterpillars usually live alone, and in this period they are fed with wood,

dead leaves and annual plant roots **(**Demir, 2005). Arslan and Aslan (2015) found that the population density of *Epicometis hirta* adults increased from the end of March to the middle of April in the almond trees of Kahramanmaraş province. Mature beetles emerge with the bloom of fruit trees in spring. Adult hairy beetles cause the most damage to plants at the end of the spring (Özbek et al., 1998; Özbek, 2008).

Adults of the beetle begin to come out of the soil in the spring and are fed by the flowers of fruit trees, ornamental plants, grains, and forest trees. They feed with male and female organs of flowers, and the damaged flowers cannot produce fruit. As a result of a study in the cherry garden in Bulgaria, adult hairy beetles were found to be fed with flowers of cherry trees and cause significant crop loss (Kutinkova and Andreev, 2004). Control of the hairy beetle is complicated, and insecticides cannot be used due to the damage on honeybees and other beneficial insects. In a study which determines the density of hairy beetle in peach, apple, cherry and apricot orchards in Çanakkale, blue funnel, pit traps, sticky plates, and cinnamyl alcohol + trans-anethole (1:1) mixture were used. As a result of the study, the most number of hairy beetle adults were caught in traps where the blue bowl + attractant was used (Gezer and Özpınar, 2015).

Toth et al. (2003; 2009), used an attractive mixture (cinnamyl alcohol and anethole) with blue and white colour traps in their study. As a result of the study, adult hairy beetles were caught in the cinnamyl alcohol and anethol traps. However, Kara (1995), reported that it was challenging to control this pest because it damages the flower. In such cases chemical control can be used.

In the study conducted on the apple and cherry gardens in the Sultandağı district of Afyonkarahisar province; it was determined that the pest could be kept under control mostly when the blue funnel and the attractant were used over the flowering period of the plants (Sağdaş, 2010). The catch rate of adult hairy beetles seemed to increase with white traps before and after blooming and with blue traps during blooming (Aydın, 2011). A study was conducted in Bulgaria to determine the seasonal population change of *Tropinata hirta*. A colour tone similar to the Picasso blue was used in the study (VARb3k). As a result of this study, it has been demonstrated that this colour is a method to control adult hairy beetles (Mitko et al., 2011). Uysal (2011), used Picasso blue as a trap in a study on plum and apricot trees in Isparta and reported the colour to be a critical biotechnical control to catch adult hairy beetles.

This study was conducted to determine the rate of hairy beetle adult catching using blue funnels and pheromone traps.

Material and Methods

This study was carried out on fruit orchard of Braeburn apple cultivar grafted on M9 and MM106 clonal rootstocks at Research and Application Orchard of Department of Horticulture, Faculty of Agriculture at Selçuk University in 2017. In the study, Picasso blue and pheromone (against hairy beetles) were used as traps. Funnels (14 cm top-wide, 9 cm height, 3 cm hole-wide) were painted with Picasso blue and placed on 5-litre colourless bottles with water inside. Large holes were opened in the bottle to prevent water from overflowing in case of rain and loss of beetles caught. The pheromones used in the study were connected to the funnels by wire and placed in the middle of the funnel. The pheromones in the trap have regularly been changed on a monthly basis. The bottles were checked once a week. The adult hairy beetles in the water were removed from the water using a strainer and counted. Then captured adult hairy beetles were removed from the orchard.

The study was set up according to randomised complete blocks trial design with three replications. In the study, control (no colour, no pheromone), pheromone (no colour), Picasso blue (no pheromone) and Picasso blue + pheromone treatments were tested. The experimental

data were collected and subjected to analysis of variance (ANOVA) using SPSS v.20 (IBM Corp. 2011. Armonk, NY) statistical software. The means were separated by Duncan's multiple test at $p \leq 0.05$ level.

Results and Discussion

Traps in the study were established at Selçuk University apple orchard on 13.03.2017. Traps were checked regularly, once a week. The first hairy beetle adults were caught on 23.03.2017. The study showed that blue + pheromone traps are more catching over the whole week than other traps. During all weeks, a total of 1950 hairy beetles were caught. 1054 of this number were caught in traps where blue + pheromone was used. Toth et al. (2003) reported that the number of captured hairy beetle adults increased significantly in traps used with attractant. Besides, Vuts et al. (2009) reported that the attractant they used (trans-anethole) had a remarkable effect in catching adult hairy beetles. In the study; a small number of hairy beetles were caught in all treatments in the first weeks. Climatic conditions have a relevant influence on the emergence of this situation. Because studies have shown that the population density of hairy beetle adults decreases during rain, low temperature or closed weather (Kara, 1995). After that, most of the adults were caught in traps where only blue colour was used (848 hairy beetle adults). This shows that adult hairy beetles can be caught using blue traps without using any attractors. The maximum number of hairy beetle was caught in the fifth week (17-24.04.2017) in all treatments. The number of hairy beetles caught between 3rd and sixth weeks was the highest and beetle caught in other weeks can be ignored. It is thought that most of the beetles were caught in this period because the apples had the most bloom. Also, in the control groups, the number of hairy beetles caught in all weeks of the study was less than the other traps. It has been determined that the differences in the number of beetles caught between the practices be statistically significant up to the 10th week ($p \leq 0,05$). At weeks 11 and 12, the difference between treatments at all traps was insignificant he low catches rate over the last weeks may be due to a limited number of flowers in apple trees (Table 1.).

Total	2,33 ± 2,31c	13,67 ± 5,51c	282,67 ± 12,74b	351,33 ± 14,84a	0,000

In the present study, the number of adult hairy beetles started to appear towards the end of March, reaching the highest level in the middle of April. In other studies, these months were

the period when the hairy beetle population was at the highest level (Hurpin,1962). There were significant differences between treatments in the 4th and fifth weeks. As we already mentioned, this situation is thought to be due to plants being in the flowering period. Compared with other treatments (Control, Pheromone, Picasso blue), many adults in traps when blue + pheromone used was at the highest level in the mentioned weeks. There has been a decrease in the adult population after the 6th week. Moreover, the 11th and 12th weeks, the population of adults was at a level that can be ignored (Fig.1.).

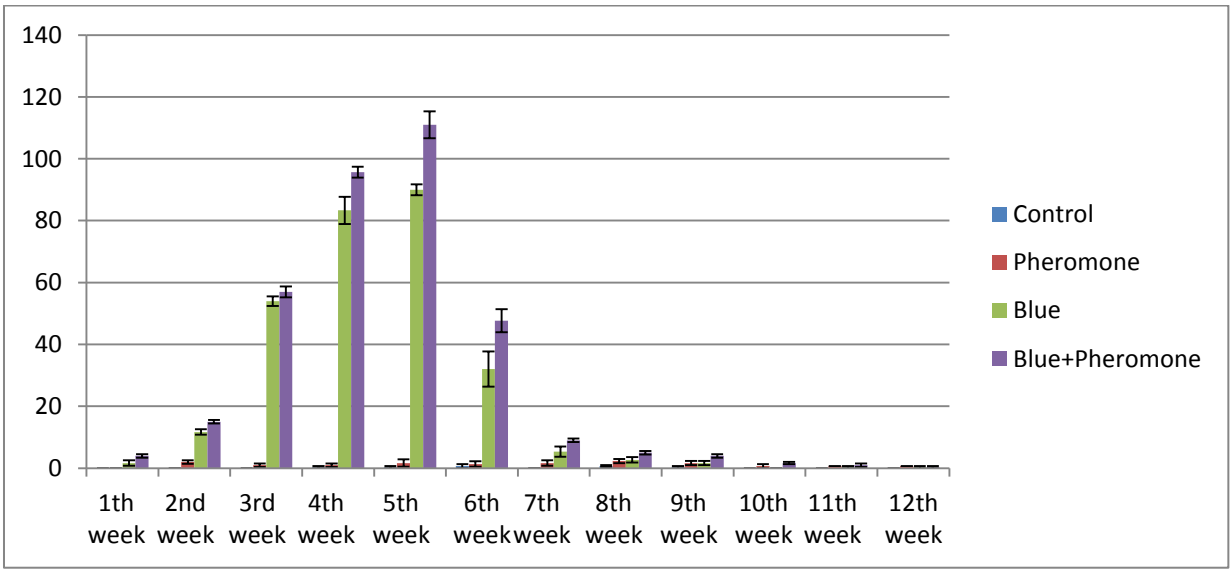

Fig.1. Number of adult *T. hirta* captured in traps

Uysal (2011) also used an attractant with a bottle filled with water and a blue funnel in his work in Isparta. He has reported that the use of attractant with blue colour is an effective method of catching adult hairy beetles. Similarly, Sağdaş (2010) has also used a blue colour (parliament blue) and attractant in his work and reported that this method is useful in insect catching. The blue colour used in these studies is a colour close to the colour we used. In this study, the most significant number of adult hairy beetles were caught in blue color+pheromone treatment as in the other studies mentioned above.

Mitko et al. (2011), used the colour referred to as 'deep royal blue' to study the seasonal fluctuation of *Epicometis hirta* Poda in Bulgaria, which is similar to the colour we used in this study. They reported that the colours they used were an effective method for catching pest. Also, Aydin (2011) used different tones of blue in his study to capture the pests. As a result of the study, 6,57 individuals in 'dark blue' trap and 10,53 individuals in 'light steel blue' trap were caught. However, the dark blue colour, which is the closest colour to Picasso blue in the -study mentioned above, caught less adult hairy beetles.

Conclusions

In this study, blue color+pheromone treatments were found to be more effective in catching adult hairy beetles compared to all other treatments (Blue, Control, Pheromone). Besides, it has been determined that only blue colour treatments have more effective results than control.

In the present study has shown that blue traps are an effective biotechnical method in the control of adult hairy beetles. According to the results obtained, it is possible to keep the adult hairy beetles under pressure by using only blue color without using any attractant or any chemical material. Thus the natural balance would be preserved.

PROSPECTIVE USE OF BACTERIOPHAGE ISOLATES AS AGENTS OF PHAGE THERAPY AND PLANT PROTECTION FROM PHYTOPATHOGENIC BACTERIA

Andrew GUPALO*, Taras KOMPANETS, Ganna KOROTYEYEVA, Olena ANDRIYCHUK

Department of Virology, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine

Abstract

Bacteriophages, as natural antagonists, have considerable potential for developing methodological approaches to control the spread of bacterial pathogens. Bacteriophages have a number of advantages over other control: they are highly specific to host bacteria, non-toxic to macro organisms, non-pathogenic for common microflora of plants and soil. Therefore, the main objective of the study was to isolate and identify bacteriophages that were specific to phytopathogenic bacteria. Samples of beets, potatoes, apples, garlic and mandarins with symptoms of rot were selected from vegetable storehouses. The main symptoms of bacterial lesions observed in fruits were areas of mild decay, softening of the tissues, and the extraction of the exudate. As a result of this work we isolated phages specific to Pseudomonas syringae lachrymans 7591, P. fluorescens 8573, P. savastanoi pv. *phaseolicola* 4013 and Serratia marcescens sp. Bacteriophages led to the formation of negative colonies which were separated into three groups based on plaque size: large (6 mm), medium (3 mm) and small (1 mm). To identify host range specificity of isolated phages, spectrum of lytic activity was studied against 9 strains of phytopathogenic bacteria. Our research revealed that among 14 phage isolates, five expressed lytic activity against different strains of phytopathogenic bacteria. Obtained data indicate that isolates with a broad spectrum of lytic activity can be used as promising biological agents in control of bacteriosis. Consequently, isolated bacteriophages can be considered as phage therapeutic agents.

Keywords: *plant pathogenic bacteria, morphological features, bacteriophages.*

Introduction

Bacteriophages, the viruses of bacteria, have received increased research interest in recent years as a genuine environmentally friendly means of controlling bacterial diseases. Phage biocontrol possesses advantages over chemical controls since tailor-made phage cocktails can be adapted to target specific disease-causing bacteria (Buttimer et al., 2017). They show specificity and affect only certain groups of bacteria, preventing the spread of infectious diseases in plants. It is possible to apply phage-based product at bacteriophage concentration from 10^6 to 10^8 pfu/ml. The introduction of a new ecologically sound system in plant protection is an important scientific task that will allow obtaining competitive agricultural products without residues of pesticides in it. Therefore, the main objective of the study was to isolate and identify bacteriophages specific to phytopathogenic bacteria in order to develop basics for reduction of pathogen populations below the economic threshold levels (Sovinska et al., 2015).

Materials and Methods

Samples of plants with symptoms of bacterial lesions were investigated. In our research we used test bacteria: *Pseudomonas syringae lachrymans* 7591, *P. fluoresc*ens 8573, *P. savastanoi pv. phaseolicola* 4013 and *Serratia marcescens* sp. Phages were isolated by direct seeding. Phage titers were determined as plaque forming units (pfu/ml) using the standard double layer agar plate method. Pure bacteriophage lines were acquired by 6-times passaging

with subsequent accumulation on sensitive bacteria cultivated in commercial nutritional broth with additional aeration at 25ºC. The morphological features of viral particles were studied using electron microscope JEOL-1400 (Japan) (Faidiuk et al., 2015).

Results and Discussion

Plant diseases caused by bacteria are a serious problem in the cultivation and storage of agricultural products. Among such pathogens the most important are bacteria related to the *Pseudomonas* and *Serratia* genera (Sovinska et al., 2017). Using these species as test bacteria, the selection of specific phages was carried out. The selected phages possessed a wide range of lytic activity against these bacterial species and virtually eliminated them. That is why one of the alternative approaches for controlling bacterial diseases is the application of bacteriophages as natural bacterial antagonists (Clokie et al., 2011). Due to the high specificity of phages against host bacteria, such therapy will destroy pathogenic bacteria without affecting useful microorganisms. In addition, the ability of phages to self-replicate indicates that low doses of phage preparations can be used to protect plants. Thus, the use of phages led to a reduction of peach morbidity caused by *Xanthomonas pruni* at 86 – 100%. In the US, a grant was received in order to patent the right to produce phage-based antimicrobials to control legume disease caused by *Pseudomonas syringae* (Kutter et al., 2004; Ramos et al., 2011). For our research samples of beets, potatoes, apples, garlic and mandarins with symptoms of rot were selected from vegetable storehouses. The main symptoms of bacterial lesions observed in fruits were areas of mild decay, softening of the tissues, and the extraction of the exudate. After selection of vegetable samples with symptoms of bacterial lesion bacteriophages specific to phytopathogenic bacteria were obtained. As a result of this work we isolated phages specific to Pseudomonas syringae lachrymans 7591, P. fluorescens 8573, P. savastanoi pv. ***phaseolicola*** 4013 and Serratia marcescens sp. All selected phages were reproduced with the same efficiency on the bacteria strains used in this study. Bacteriophages led to the formation of negative colonies with large (6 mm), medium (3 mm) and small (1 mm) sizes depending on the test bacterium (fig.1).

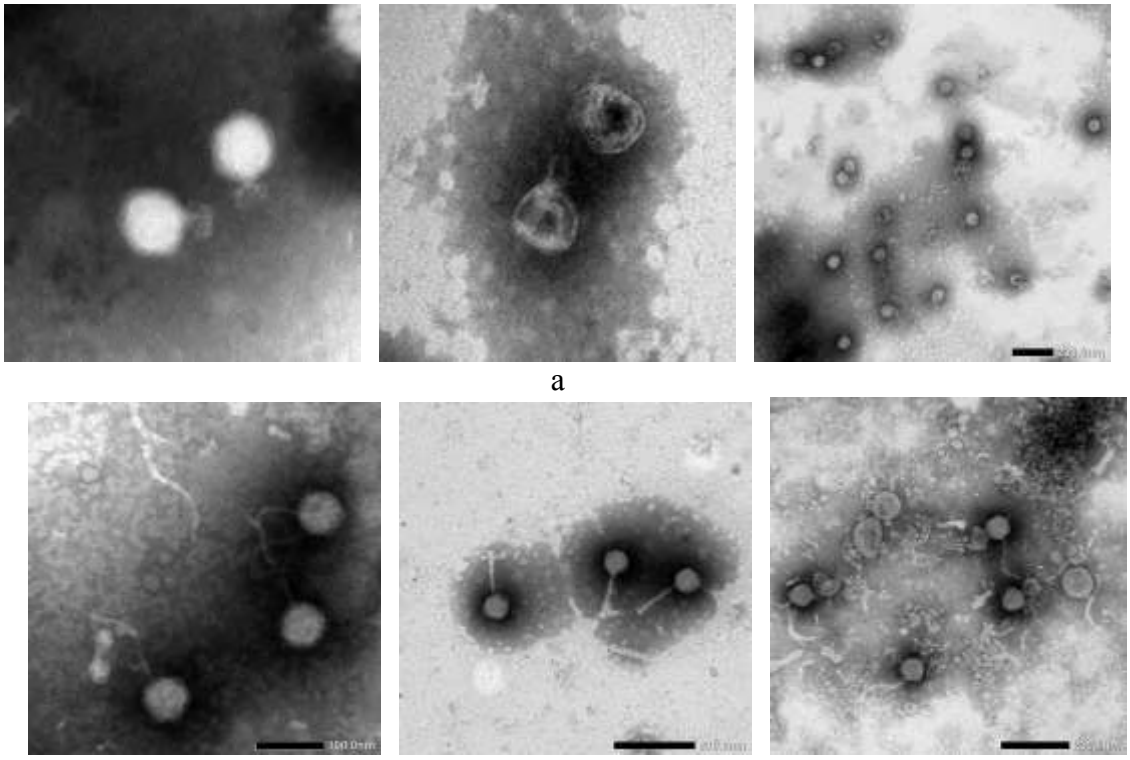
Fig. 1. Phage plaque morphology on test culture *Serratia marcescens sp.* (plaques diameter = 3 mm)

To identify host range specificity of isolated phages spectrum of lytic activity was studied against 9 strains of phytopathogenic bacteria. Our research revealed that among 14 phage samples five expressed lytic activity against different strains of phytopathogenic bacteria. It shows that the selected phages possessed a wide range of lytic activity (i.e., polyvalent bacteriophages) and could be used as perspective biologic agents in control of bacterial diseases.

a b

Fig. 2. The spectrum of phages' lytic activity against test bacteria: a - *Pseudomonas fluorescens 8573*, b - *Serratia marcescens sp.*

Analysis of electron microscopic observations showed that investigated bacteriophages had different morphology and size. Phage particles revealed short-tailed icosahedral structures with a head of approximately 43±1 nm in diameter and a short tail of 1 ± 0,5 nm in length, confirming them as belonging to the morphotype C1 of family *Podoviridae* of *Caudovirales* order. Beside these, electron microscopy analysis showed another group of bacteriophage particles with typical features of *Siphoviridae* family, *Caudovirales* order (icosahedral head with long tail, size – head diameter 67±2 nm, tail length 120±3 nm) (fig. 3).



a

b

Fig.3. Electron microscopy images of phage isolates: a – virions of phages belonging to the family *Podoviridae*, b – virions of phages belonging to the family *Siphoviridae*

Activity of selected phages indicated that they can be used as a biological plant protection product in disease management against phytopathogenic bacteria. This product had a selective effect on phytopathogenic bacteria, did not pollute the environment, increased profitability of

production and provided environmentally friendly agricultural production. Its application could reduce the exposure of toxic chemicals on food products. Biologically active preparation was designed for protection against bacterial infections of sugar beet plants and reduction of rot during the storage of agricultural products. The active ingredients of the preparation were naturally occurring bacteriophages that selectively and specifically killed only certain strains of microorganisms.

Conclusions

The results of this research create possibility for developing biologically active product based on specific bacterial viruses (bacteriophages). Laboratory tests in order to preliminary assess efficacy of plant protection product are used for making selection of agents which will be used as biological product in order to manage bacterial diseases in plants. These products are proven to be nontoxic, environmentally safe and effective for significantly reducing or eliminating plant pathogenic bacteria.

FIRST RECORD OF THE BROWN-BANDED COCKROACHES, *SUPELLA LONGIPALPA* (F.) IN NEW VALLEY, EGYPT

Ahmed El-TOKHY*

New valley University, Faculty of Agriculture, plant protection department, El-kharga, New Valley government, Egypt
*Corresponding author: a.el-tokhei@aun.edu.eg.

Abstract

The tropical cockroach, *Supella longipalpa* (Fabricius) (Blattodea: Ectobiidae) was detected as pest for the first time in El-Kharga, New Valley, Egypt. The city is the capital of the New Valley Governorate and located in the south-west of the western desert in Egypt (24°32'44" N, 27°10'24" E, altitude 32 m) and has a hot desert climate with annual average relative humidity 37.9%. These special conditions in this region are very suitable for proliferation the brown-banded cockroach, *Supella longipalpa*. The complaint led to the inspection of infested houses, using glue traps and the brown-banded cockroaches were found in every room where they showed a preference for high places, often around furniture and sometimes in the kitchen. In addition, they were found in subsequent surveys, confirming the establishment of this species in this region. The brown-banded cockroaches lately have invaded the houses, restaurants and hospitals in this region. Many of adults, nymphs and oothecae were obtained after their rearing under room conditions. The aim of this study was to recognize current information gaps about this pest in the New Valley area to acquire more knowledge about health-related effects and prospective management of *Supella longipalpa* in Egypt. This paper reports the first detection of tropical roach, *S. longipalpa*, as an urban pest in New Valley, Egypt. For enhanced management of *S. longipalpa* an intelligent pest management program is required. Sanitation, harborage removal, glue traps and insecticide baits are advised to be used in an integrated manner.

Keywords: *Blattodea, Furniture roach, Tropical roach, urban pest, Egypt*

Introduction

Cockroaches are primitive tropical and subtropical insects that have existed for over 200 million years. There are approximately 4600 species of cockroaches that have been identified worldwide, divided into eight families: Cryptocercidae, Blattidae, Blattellidae (Ectobiidae), Blaberidae, Polyphagidae, Nocticolidae, Tryonicidae and Lamproblattidae and about 445 genera (Wu *et al.*, 2014). Originally, all cockroaches were creatures of the outdoors. They lived in trees and vegetation in a region where warm temperatures favoured their development. Some species (about 1 %) of these roaches adapted to take the food, water, warmth and shelter related to man's lifestyle. The association with man has improved at different rates within the numerous species of cockroaches considered to be pests. Some cockroaches are thought to be pests because they invade houses, hospitals, hotels and food institutions (Kassiri *et al.*, 2014; Pomes and Arruda, 2014). They contaminate food and food preparation areas with their saliva, faces and body parts that play a role as allergens and vectors of organisms causing food poisoning and infectious illnesses (Rivault *et al.*, 1993; Kopanic *et al.*, 1994). *Supella longipalpa* is considered as one of the important sources of diseases in carrying many different microorganisms such as *Bacillus cereus, Escherichia coli, Salmonella typhimurium, Shigella dysenteriae* (Vazirianzadeh *et al.*, 2014), eggs of *Ascaris lumbricoides*, cysts of *Entamoeba coli*, cysts of *Entamoeba histolytica*, and eggs of *Taenia* spp. (Illgen-Wilcke *et al.*, 1992; Kinfu and Erko, 2008). Also, its cast skins and excrement have been reported as a source of allergens (Gore and Schal, 2007; Wirtz, 1980).

Material and Methods

On 23 July 2016, some females, males and nymphs of brown-banded cockroaches were collected in some houses in the city of El-Kharga, New Valley, Egypt and reared under room conditions (average temperature 29.5 °C ± 2 °C and relative humidity 29% ± 3%), using the method of Gilbert (1964). The cockroaches were reared in a glass cage (30 × 25 × 20 cm) of which the top was greased with medical, petroleum jelly, 2.5 cm width, to prevent the escape of cockroaches. Small wood boxes were supplied for shelter. The diet consisted of dry bread and rabbit-food pellets. All food was treated with heat before use to control a white mite, *Caloglyphus* sp. The water was supplied with a small water bottle (Piquett and Fales, 1952), with twisted medical cotton wool to provide a moist surface. The cages were covered with screen net (18 mesh) for ventilation and were cleaned every week. Sticky traps were used as a tool for surveillance cockroach.

Results and Discussion

This paper reports the first detection of the tropical roach, *S. longipalpa*, as an urban pest in the New Valley, Egypt. Adults, nymphs and oothecae of the cockroach were identified using the cockroach dichotomous key based on morphological characters (Choate, 2013). They were found to belong to the species *S. longipalpa*. The presence of two light-coloured pale stripes across the middle of the nymph body and the two cross bands on the closed wings of the adults are characteristic (Fig. 1). The most common pest cockroaches in Egypt are *Blattella germanica* (German cockroach or croton bug) followed by *Periplaneta americana* L. (American cockroach) and *Blatta orientalis* (Oriental or shad cockroach) (William 2005). *Supella longipalpa* is usually referred to by its common names of brown-banded cockroach, spotted cockroach, furniture cockroach, TV cockroach and the tropical cockroach. (Houseman 2004, Schal 2011). It was known previously as *S. supellectilium* (Serv.) (Gurney 1970). Tsai and Chi (2007) suggested that the origin of the brown-banded cockroach is the Nile Valley region of Africa. Rehn (1945) also indicated that *S. longipalpa* is native to Africa. A few overviews indicate that the distribution range and abundance of this species is declining. Kinfu and Erko (2008) led a study in Ethiopia, which is believed to be the root territory of *S. longipalpa* but did not collect specimens of this species among 2 240 cockroaches gathered in Addis Ababa. Furthermore, it represented only 10% of the 4,240 cockroaches collected in Ziway. The brown-banded cockroach is associated with human residences and prefers to live in a dry area with the favourite places being under tables, electrical devices, inside television sets and behind the pictures in rooms. This wide range of suitable habitats results in *S. longipalpa* being distributed through various zones of apartments and structures, which makes their control difficult (Hassan 2016).

The present works expands knowledge of brown-banded, *S. longipalpa* that is the first record for the brown-banded cockroach, as a pest in New Valley, Egypt in July 2016, a new species to the Egyptian fauna as urban pests in areas at relatively high temperature, where they have found a suitable environment due to for living and spreading in this region.

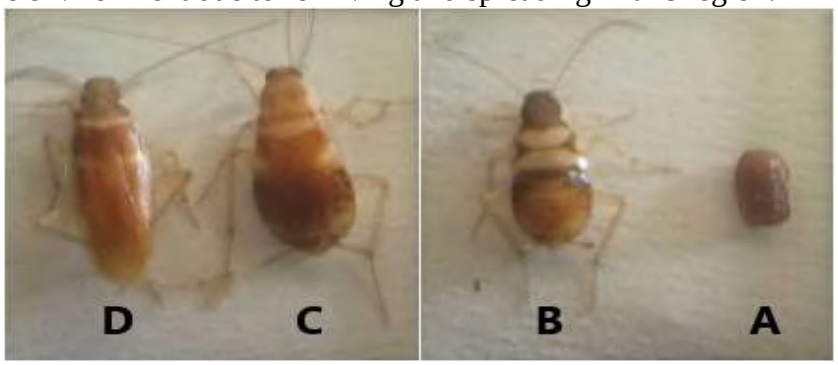

Fig. 1. The morphological characters of *Supella longipalpa* stages
(A) Oothecae (B) Nymph (C) Female (D) Male

Conclusion

New detection of brown-banded cockroach, *Supella longipalpa* in El-kharga, New Valley Governorate, Egypt is reported. This region has a special climate with dry conditions which is very suitable for this species that adapted to these conditions more than other cockroaches. *Supella longipalpa* is known as the spreader of foodborne diseases, and our report documents a new distribution region of this species in Egypt which may be a future problem in the field of public health.

THE MICROBIOLOGY OF GREEK/CYPRUS TRAHANAS AND OF TURKISH TARHANA: A PRESENTATION OF SOME LITERATURE DATA

Aikaterini GEORGALA

Laboratory of Dairy Research, Agricultural University of Athens, 75 Iera Odos Str., 11855, Votanikos, Athens, Greece
*Corresponding author: georgala@aua.gr

Abstract

Greek and Cyprus Trahanas are the most popular fermented milk-cereal products of Greece and Cyprus, and are produced during summer from fresh ewes', goats' milk or a mixture of them. Broken wheat is then added to the fermented milk and heated to cook the mixture and then a thick paste is left to cool and cut into small pieces and left to dry (sun or oven drying). In Greek trahanas, fermentation of the lactic acid bacteria *Streptococcus lactis, Streptococcus diacetylactis, Leuconostoc cremoris, Lactobacillus lactis, Lactobacillus casei, Lactobacillus bulgaricus* and *Lactobacillus acidophilus* plays the major acid- and aroma -producing roles. A great biodiversity of microorganisms was observed during Cyprus trahanas fermentation. Lactic acid bacteria (LAB) were the predominant group, followed by yeasts. *Lactococcus*, *Lactobacillus*, and yeast species contribute greatly to its fermentation. Turkish Tarhana is the dry form of yoghurt-cereal mixture that is produced by mixing cereal flour, yoghurt, baker's yeast (*Saccharomyces cerevisiae*) and cooked vegetables, salt and spices followed by fermentation for one to seven days. The fermented slurry is then air-dried and used in soup making. LAB species found in Tarhana fermentation vary depending on the raw materials, fermentation time and techniques used for its production and play an important role in lactic acid and aromatic compounds formation. *Lactococcuslactis* spp. *lactis, Leuconostoc mesenteroides, Lactobacillus acidophilus, Enterococcus durans, Pediococcus* spp., *Lactobacillus delbrueckii* ssp. *lactis* and *Lactobacillus paracasei* bacteria played a role during the fermentation of Tarhana dough. Yeasts were mainly represented by *S. cerevisiae*.

Keywords: *Trahanas, Tarhana, Microbiology.*

Introduction

Fermented foods are an important part of diets in many parts of the world and are known from ancient times. Traditional fermented cereal foods are widely used in the diet of people in the Middle East, Asia, Africa and some parts of Europe. 'Trahanas' in Cyprus and Greece and 'Tarhana' in Turkey are two of the oldest traditional fermented milk/cereal foods and very nutritive foods due to the nutritional properties of wheat and milk/ yogurt. These products have also interesting organoleptic characteristics. There are similar products with different names such as 'Kishk' in Egypt, Syria, Lebanon and Jordan, 'Kushuk' in Iraq, 'Tarhonya/Talkuna' in Hungary and Finland. Methods for preparation of such products vary from place to place but cereals and fermented milk are always the major components.

Trahanas is one of the most popular fermented milk-cereal products of Greece which is produced during summer mainly from whole fresh ewes', goats' milk or a mixture of them. Sometimes instead of milk, a pulp of vegetables is used and then the product taken is called 'nistisimos trahanas'. For trahanas making, fresh milk is allowed to acidified for some days' either spontaneously or by adding a culture of yogurt while it is stirred every day until it reaches the desired acidity. Broken wheat is then added to the fermented milk and heated to cook the mixture and the thick paste formed is left to cool down and cut into small pieces (finger-sized pieces) which subsequently are left to dry (sun or oven drying). When trahanas is dry enough, it is stored in a cool place. Sometimes eggs are also added in the production of

trahanas and the final product is called 'sour trahanas with eggs'. The ratio of milk to wheat used in trahanas production is usually 3:1 or 4:1. Sometimes instead of sour milk, fresh milk is used for trahanas production and then the product is called 'sweet trahanas'. Greek 'Trahanas' is a very nutritive food as it is a good source of proteins, minerals etc. and is used largely for feeding people and elderly people.

Tarhana is the dry form of a yogurt-cereal mixture and is one of the oldest and most popular fermented cereal foods of Turkey representing an important part of the diets of many Turkish people. Production method and recipe of tarhana may differ from place to place to place. Tarhana has an acidic and sour taste with a yeasty flavor and is mainly used for soup making. It can also be consumed as a snack after being dried to thin layer or nugget, not to be ground. Tarhana is produced by mixing cereal flour (mainly wheat flour), yogurt, baker's yeast (*Saccharomyces cerevisiae*) and a variety of cooked vegetables (tomatoes, onions, green peppers and red peppers), salt and spices (mint, thyme, dill, tarhana herb etc.) followed by lactic and alcoholic fermentation for one to seven days. The fermented slurry is then air-dried and used in soup making, giving a product with high nutritional contents of proteins, vitamins etc. making tarhana healthy for children, the elderly and medical patients.

Results and Discussion

This work is a review on some literature data on the microbiology of the Greek/Cyprus fermented milk/cereal product named 'Trahanas' and of the Turkish fermented milk/cereal food named 'Tarhana'.

Lazos et al (1993) studied the microbiological changes that occur during the fermentation period of Greek Trahanas (a milk-wheat flour combination prepared in Greece) made with or without prior boiling of milk. Both boiled and un-boiled milk was fermented for 35 hours, a time that is required for the curd separation. Afterward, the curd-wheat flour mixtures were fermented for 15 hours. In a fermentation time longer than 15 hours the microbial population grew in sufficient numbers in order to convert milk into a fermented product. In un-boiled milk preparation (MAF) the microorganisms *Streptococcus* reached their maximum values at the 23 hours of fermentation. However, it was observed that from 30 hours of fermentation and afterward their growth was limited as pH value dropped to 4.36 and acidity expressed as the lactic acid was 0.82%. In the case of boiled milk preparation (MBF) the microorganisms *Streptococcus* reached their maximum values after 30 hours of fermentation while their numbers were lowered as the pH failed to 4.42 and the acidity was 0.72% (expressed as lactic acid). Total counts of microorganisms and Lactobacillus counts increased continuously with the fermentation time while streptococci increased up to 23 hours of fermentation and reduced thereafter as the pH value dropped to values lower than 5.0-4.5. Similar behavior showed the coliform bacteria which were found in lower counts. The yeasts and molds counts were low and their amount remained constant during fermentation and increased only if enough acid (0.4-0.7% lactic acid, pH 4.4-5.5) was produced. In unboiled milk preparation (MAF preparation) the microorganisms *S. lactis* and *S. diacetylactis* predominated among all streptococci. In comparison, *S. cremoris* was found in low counts. Initially, in the fermentation process, cultures of the microorganisms *Lactobacillus casei* and *Lactobacillus lactis* were predominated while later on cultures of *Lactobacillus acidophilus* and *Lactobacillus bulgaricus* were isolated. When the numbers of *L. bulgaricus* increased, the numbers of *L. acidophilus* dropped. In comparison to unboiled milk preparation (MAF), no counts of the microorganisms *Streptococcus faecalis*, *Leuconostoc cremoris,* and *Lactobacillus acidophilus* were found in the boiled milk preparation (MBF). *L. casei* and *L. bulgaricus* were the only lactobacilli isolated, while *S. lactis* and *S. diacetylactis* were the major cocci found. The main aroma producing microorganisms isolated during trahanas fermentation were *Streptococcus diacetylactis* and *Leuconostoc cremoris*. Also, the main acid

producing microorganisms were *Streptococcus lactis*, *Lactobacillus casei* and *Lactobacillus bulgaricus*. Concluding, Lazos et al. (1993) refer that the fermentation process that takes place in the production of Greek Trahanas food is a lactic acid bacterial fermentation that last about 50 hours and in which *Streptococcus lactis*, *Streptococcus diacetylactis*, *Leuconostoc cremoris*, *Lactobacillus lactis*, *Lactobacillus casei*, *Lactobacillus bulgaricus* and *Lactobacillus acidophilus* paly the major acid and aroma producing role.

Bozoudi et al. (2017) studied the microbiological characteristics of Cypriot Trahanas, a traditional fermented ewe's milk product. A great biodiversity of the authentic microbiota of the traditional Cypriot Trahanas was found. Lactic acid bacteria (LAB) were the predominant group of microorganisms, followed by yeasts. During a 5-day fermentation period lactococci, lactobacilli and yeasts were found to be the predominant species that contribute greatly to the completion of the fermentation stage. *Lactococcus lactis* and *Lactococcus* spp. displayed their higher numbers on the 3rd day of fermentation time. However, there were not found any *Lactococcus* species at the end of fermentation time (day 5) probably due to the acidic conditions formed in fermented milk (pH 3.8 at day 5) and the cell lysis. Concerning *Lactobacillus* species there were found in low numbers during the first two days but they highly increased at the 5th day (end) of the fermentation period. Yeasts were found throughout the fermentation period with *Saccharomyces unisporus* to be the predominant one from the start to the end of the fermentation time. Also, *Lactobacillus* spp. seemed to predominate throughout the fermentation period. LAB on MRS agar (pH 6.2) and LAB on M-17 agar reached their higher numbers on day 4 of the fermentation process. Also, total aerobic counts and LAB on MRS agar (pH 5.7) reached their higher numbers on day 3 of fermentation. A significant decrease in their population was observed at the end of fermentation time due to the acidic environment created by the significant reduction of pH that NSLAB cause. However, LAB on M-17 agar and yeasts were found in high levels until the end of fermentation time.

Ibanoglu et al. (1999) studied the effect of different ingredients on the fermentation activity of tarhana. Three different tarhana formulations were prepared: a) tarhana with a yoghurt to wheat flour ratio of 0.5 with 80.0 g salt kg^{-1} wheat flour used (standard tarhana, named S1), b) tarhana with a yoghurt to wheat flour ratio of 1.0 with 80.0 g salt kg^{-1} wheat flour used (tarhana named S2) and c) tarhana with a yoghurt to wheat flour ratio of 0.5 without salt (tarhana named S3). The total and lactic acid bacteria count of tarhana made with increased yogurt was higher than that of the rest tarhana samples as more yogurt was added to the sample. At the end of fermentation period, the tarhana sample without salt had a higher lactic acid bacteria count than the rest two tarhana samples. So, it is shown that the addition of salt before fermentation resulted in a lower fermentation activity and lactic acid concentration. The increase of yeasts number showed that yeast fermentation was involved in tarhana fermentation. The microbial populations of all tarhana samples increased significantly during the first day of fermentation and decreased gradually thereafter.

Erbas et al. (2005) studied and compared the microbiological properties of wet and dry tarhana during a storage period of 6 months. Also, the changes of some microbiological properties of tarhana dough at its fermentation stage of production were studied. The *Lactobacillus* spp. the count was decreased from 6.47 to 5.44 $\log_{10}$ CFU/g during tarhana fermentation and the total mesophilic aerobic bacteria decreased from 6.43 to 5.95 $\log_{10}$ CFU/g with the increase of tarhana acid content. The reduction of the above microorganisms continued through the storage period of tarhana product. The TMAB, LAB and yeasts and molds counts were approximately equal at the beginning of tarhana fermentation. TMAB and LAB increased on the first day of fermentation but decreased thereafter as a result of the increase of the acid content. The yeasts and molds populations decreased continuously during the tarhana fermentation period. No coliforms were detected in any of the tarhana samples

during the whole fermentation and storage periods. This showed no contamination either from the environment or from the raw materials.

Sengun et al. (2009) studied for the first time by molecular-based methods the predominant lactic acid bacteria (LAB) isolated during the processing of Tarhana. Tarhana samples were collected from eight different regions of turkey. By using the molecular-based methods the bacteria Pediococcus acidilactici was found to be the 27% of the microbial isolates while 19% of the microbial isolates were identified as *Streptococcus thermophilus*, 19% as *Lactobacillus fermentum*, 12% as *Enterococcus faecium*, 7% as *Pediococcus pentosaceus*, 5% as *Leuconostoc pseudomesenteroides*, 4% as *Weissella cibaria*, 2% as *Lactobacillus plantarum*, 2% as *Lactobacillus delbrueckii* spp. *bulgaricus*, 2% as *Leuconostoc citreum*, 1% as *Lactobacillus paraplantarum* and 0.5% as *Lactobacillus casei*. The bacteria *P. acidilactici* and *Streptococcus thermophilus* were found to be isolated from the majority of the Tarhana samples examined. Yoghurt added for tarhana production was found to be the main source of the bacteria P. acidilactici and S. thermophiles. One hundred and fifty Gram-positive, catalase negative isolates were obtained from different steps of Tarhana dough. However, 16 isolates were taken from dried tarhana samples. From yoghurt and broken wheat that were added for tarhana production, 50 isolates and 10 isolates were obtained, respectively.

Settanni et al. (2011) studied the evolution of lactic acid bacteria (LAB) and yeasts during the fermentation of tarhana that was produced with some pasteurized ingredients and carried out at 30^0C and 40^0C. During tarhana fermentation LAB and yeasts were found to be in the range of 10^7-10^8 colony forming units (CFU)g^{-1}. However, there were not detected any coliform bacteria. The lactic acid bacteria that were isolated during tarhana fermentation were grouped according to their phenotypic and polymorphic characteristics and the species identified were the Pediococcus acidilactici, Lactobacillus plantarum, and Lactobacillus brevis. The pasteurization that was applied to the tarhana vegetable ingredients (except wheta flour) improved the hygienic conditions of tarhana while it did not influence the common LAB evolution during fermentation. Concerning the LAB counts, no statistically significant differences were found between the two tarhana production that took place under 30^0C or 40^0C fermentation temperature.

Kivanc and Funda (2016) studied the changes in bacteria and yeast number during the fermentation period of Tarhana dough. At the initial part of fermentation, the number of yeasts, molds, TMAB (total mesophilic aerobe bacteria), LAB (lactic acid bacteria) were found to be similar. The lactic acid bacteria (LAB) and yeasts which are responsible for the flavor and taste of tarhana as they produce lactic acid, ethanol, carbon dioxide, increased within the 5 days of fermentation. The lactic acid bacteria increased from $1.32x10^2$ to $4.20 x10^4$ CFU/g and the yeasts content increased from $3.45x10^1$ to $2.40x10^5$ CFU/g in the content of tarhana dough. The TMAB count increased rapidly within 3 days of fermentation. A total of 640 bacteria were isolated through tarhana dough fermentation and from them 623 were identified as lactic acid bacteria. Also, a total of 540 yeasts were isolated. The bacteria *Lactococcus lactis* spp. *lactis, Leuconostoc mesenteroides, Lactobacillus acidophilus, Enterococcus durans, Pediococcus* spp., *Lactobacillus delbrueckii* ssp. *lactis* and *Lactobacillus paracasei* bacteria were found to play a role during the fermentation of Tarhana dough. Also, the yeasts *Kluyveromyces marxianus, Yarrowia lipolytica, Pichia membranaefaciens, Pichia mexicana, Pichia angusta, Debaryomyces hansenii, Candida sorboxylosa, Candida fluviatilis, Saccharomyces cerevisiae* were identified during the Tarhana fermentation. The various strains of yeasts determined and the lactic acid bacteria (LAB) were the dominating strains found in the natural Tarhana fermentation. The microorganisms *E. durans, L. plantarum, S. cerevisiae, K.marxianus* and *Y. lipolytica* dominated at the final stages of tarhana fermentation.

Conclusion

A great biodiversity of microorganisms was observed during the fermentation period of the two fermented milk/cereal products, the Greek/Cyprus Trahanas and the Turkish Tarhana.

Abstract

Entomophagous fauna – predators in the region of East Sarajevo (Republic of Srpska, Bosnia and Herzegovina) was examined in 2011 and 2012 in intensive orchards in the locations Vojkovići and Kula, in semi-intensive orchards in locations, Tilava and Petrovići, and in the extensive orchard in the location Kasindo. Sampling by direct trees scrutiny, branches shaking, the collection of infested plants organs, and the collection of predators adults and juveniles weekly and biweekly during vegetation season by entomological nets and meshes, aspirators & collecting vacs restituted the predators and instars which lived freely on the infested and free parts of the plants. In the area of East Sarajevo, in orchards of pears, in 2011 and 2012 year, eight predators species were found. Larvae and imaginal stages of these insects were reared from colonies of aphids (*Dysaphis pyri* Boyer de Fonscolombe, *Aphis pomi* De Geer) and psyllid species (*Cacopsylla pyri* Linne, *Cacopsylla pyrisuga* Forster, *Cacopsylla pyricola* Forster). Examinations revealed the presence the following predators species: *Anthocoris nemorum* Linne (Hemiptera: Anthocoridae), *Adalia bipunctata* Linnaeus, *Coccinella septempunctata* Linnaeus, *Harmonia axyridis* Pallas (Coleoptera: Coccinellidae), *Episyrphus balteatus* DeGeer, *Syrphus ribesii* Linne (Diptera: Syrphidae), *Chrysoperla carnea* Stephens and *Chrysopa septempunctata* Wesmael (Neuroptera: Chrysopidae).

Keywords: Beneficial insects, Pears, City of East Sarajevo.

Introduction

In addition to harmful species, many beneficial insects live on pear; the predators represent the most important regulators of pest populations. During their life and all stages of development (Mihajlović, 2008), they can kill a significant number of preys. Among predators of pear insect pests, there are many available species from different orders: Hemiptera, Dermaptera, Neuroptera, Coleoptera and Diptera (Maceljski 2002; Almaši et al., 2004).

Predators from the order Hemiptera - the most significant order - belong to Anthocoridae, Miridae and Nabidae and feed on aphids and scale insects, psyllid and miners caterpillars. From family Anthocoridae the most important are *Anthocoris nemoralis* (F.), *A. nemorum* (L), *Orius majusculus* Reuter, *O. minutus* (L.), *O. vicinus* (Ribaut) (Staubli et al., 1992; Beers et al. , 1993; Horton et al., 1997; Solomon et al., 2000). Particularly significant is *Anthocoris nemoralis* F. which is regularly present in the demes of psyllid species (*C. pyri, C. pyrisuga and C. bidens*) and aphids (Souliotis, 1999; Shaltiel and Coll, 2004).

Predators from the order Neuroptera - that are well-known predators of aphids, scale insects, psyllid species, and smaller caterpillars in orchards, comprehend the Family Chrysopidae with a large number of species in Genus *Chrysopa: perla* Linnaeus, *Ch. septempunctata* Wesmael, *Ch. ventralis* Curtis, *Ch. nigricostata* Brauer, *Chrysoperla carnea* Stephens, *Hemerobius micans* Olivier (Vuković, 1986). Adults feed pollen or honeydew, despite adul*ts of Ch. perla* can also prey leaf aphids (Hodek and Honek, 1988) and psyllid species (*C. pyri, C. pyrisuga and C. pyricola)* (Vilajeliu et al., 1998; Souliotis, 1999; Jerinić-Prodanović, 2010), is considered among the most efficient species (Vuković, 1986).

Coleoptera predators belong to Coccinellidae with a number of species that feed on leaf aphids, scale insects and psyllid species: *Adalia bipunctata* Linnaeus, *Coccinella septempunctata* Linnaeus, *Adonia variegata* Goeze, *Propylea quatuordecimpunctata* Linnaeus, *Synharmonia conglobata* Linnaeus and *Hippodamia tredecimpunctata* Linnaeus (Vuković, 1990), and in recent years *Harmonia axyridis*, which was found in the area of East Sarajevo (Tešanović et al., 2011).

Predators from the order Diptera are common antagonists of aphids and psyllid, belonging to Syrphidae or Cecidomyiidae. Females lay eggs on plants infested with aphids, and their larvae feed on haemolymph from aphids body (Nijveldt, 1988). The most important species are: *Episyrphus balteatus* De Geer, *Syrphus ribesii* Linnaeus, *Metasyrphus colorae* Fabricius, *Sphaeroforia scripta* Linnaeus, *S. menthastri* Linnaeus (Vuković, 1990). In the area of East Sarajevo, the most common from Syrphidae was *Episyrphus balteatus* and *Aphidoletes aphidimyza* (Tešanović et al., 2011) from Cecidomyiidae.

Material and Methods

The scrutiny was realised in 2011 and 2012 in the orchards (locations Vojkovići, Kula, Tilava, Petrovići, Kasindo) and the laboratory of the Faculty of Agricultural in East Sarajevo. Visual examination of randomly selected trees restituted presence of insects and their number. Observing 10 (Kula and Kasindo) or 20 (Petrovići, Tilava and Vojkovići) trees weekly or biweekly during host plant growing season restituted collection data on all instars of insects free-living on plant organs by shaking branches, using entomological nets and aspirators meshes and vac.

Sampling refereed 100 different plant organs (leaf and flower buds, leaves) within a randomly selected tree. All sampled infested plant material with predators was scrutinised in the laboratory. All collected eggs, larvae and pupa of entomophagous insects, were reared in the laboratory to adult in plastic flax or Petri dishes with prey-infested plant parts. Collected and reared insects were fixed in 70% alcohol; some of them were mouted, in slide or different preparations for microscopy or pinned/carded and labelled for preservation in the collection. Adults & juveniles morphology comparison by keys and appropriate entomological literature (Balachowsky 1966) allowed the identification to species level.

Results and Discussion

In pear orchards, eight entomophagous species of insects - predators were collected. Larvae and adult instars of these antagonists were identified in demes of aphids and psyllid. The following species were found: *Anthocoris nemorum* Linne (Hemiptera: Anthocoridae), *Adalia bipunctata* Linne, *Coccinella septempunctata* Linne, *Harmonia axyridis* Pallas (Coleoptera: Coccinellidae), *Episyrphus balteatus* DeGeer, *Syrphus ribesii* Linne (Diptera: Syrphidae), *Chrysoperla carnea* Stephens and *Chrysopa septempunctata* Wesmael (Neuroptera: Chrysopidae). Table 1 summarises their presence.

Table 1. Findings of insect predators in the area of East Sarajevo, 2011 and 2012

	Order	Familia	Species of insects	Locations				
				Vojkovići	Kula	Tilava	Petrovići	Kasinso
1.	HEMI-PTERA	Anthocoridae	*Anthocoris nemorum*	+	-	-	-	-
2.	COLEO - PTERA	Coccinellidae	*Adalia bipunctata*	+	+	+	+	+
3.			*Coccinella septempunctata*	+	+	+	+	-
4.			*Harmonia axyridis*	+	+	+	+	+
5.	DIP-TERA	Syrphidae	*Episyrphus balteatus*	+	+	+	-	-
6.			*Syrphus ribesii*	+	-	+	-	-
7.	NEURO - PTERA	Chrysopidae	*Chrysoperla carnea*	+	+	+	+	-
8.			*Chrysopa septempunctata*	+	+	+	+	-
			Total number of insects	**8**	**6**	**7**	**5**	**2**

Intensive orchards in Vojkovići host eight species of predators. Two species, *A. bipunctata* and *H. axyridis*, were found in all locations. Three species of predators, *Coccinella septempunctata*, *Chrysoperla carnea* and *Chrysopa septempunctata* were present in all pear orchards, except in extensive orchards in Kasindo which host two species *only: A. bipunctata* and *H. axyridis. E. balteatus* was identified both in Vojkovići and Kula intensive orchards, and semi-intensive Tilava orchard, while the *S. ribesii* was found in Vojkovići intensive and Tilava semi-intensive orchards. *A. nemorum* was present only in the Vojkovići intensive orchard. Our data sustain the literature (Maceljski, 2002, Almaši et al., 2004; Jerinić-Prodanović, 2010; Tamaš, 2012;), that describe an abundant predatory guild, build-up by Hemiptera, Neuroptera, Dermaptera, Coleoptera and Diptera that are devoted to controlling invasive insects pests. During our examination, we identified predatory species from the same orders. Order Coleoptera and fam. Coccinellidae contributes with *Adalia bipunctata* L. and *Coccinella septempunctata* L. both psyllid-oriented predators (Jerinić- Prodanović, 2010), and *Harmonia axyridis* Palla, reared from *Dysaphis pyri* Boyer de Fonscolombe demes, as also reported by Vuković (1990). All these species have already been identified in the area of East Sarajevo as predators of aphids on apple (Tešanović et al., 2010). Besides these species, from order Neuroptera and fam. Chrysopidae, two species were found: *Chrysoperla carnea* Stephens and *Chrysopa septempunctata* Westmael as predators of aphids and psyllid species, in all locations except the Kasindo, also by Vuković (1986, cit. Tamaš, 2012). The critical predatory species are from Diptera and fam. Syrphidae (*Episyrphus balteatus* De Geer, *Syrphus ribesii* L., *Metasyrphus colorae* Fabricius, *Sphaeroforia scripta* L., *S. menthastri* L., *Scaeva pyrastri* L., *Syrphus latifasciatus* Macquart (Vuković, 1990). Our examination showed the presence of *E. balteatus and S. ribesii* in Vojkovići and Tilava, while E. balteatus only *exists* in Kula. Their larvae were feeding on *D. pyri* demes, as also observed by Vuković (1990) and Tamaš (2012). In Vojkovići also the Hemipteran *Anthocoris nemorum* L., exists and is one of the most relevant species, feeding on *C. pyri* and *C. pyrisuga*, as reported by Jerinić-Prodanović (2010).

Conclusion

In the area of East Sarajevo, during 2011 and 2012 and in intensive, semi-intensive and extensive orchards of pears, eight antagonists species were found: *Anthocoris nemorum, Chrysoperla carnea, Chrysopa septempunctata, Adalia bipunctata, Coccinella septempunctata, Harmonia axyridis, Episirphus balteatus* and *Syrphus ribesii.* Entomophagous species were most numerous in the intensive orchard in Vojkovići, that may depend by the of selective insecticides with a minor side-effect on the predatory guild. The lowest number of predatory exists in Kasindo extensive orchards.

Abstract

The current study evaluated the potential use of two widely available agricultural wastes at local level: chicken manure (chic) and banana wastes (ban) in the production of *Agaricus bisporus* mushroom in order to assess the possibility of alternating the traditionally imported substrate (based on horse manure). Therefore, the trial consisted on growing the mushroom on substrates formed by several mixtures of both wastes subjected to composting and mixed in various proportions (0%, 30%, 50%, 70% and 100% at volume basis) compared to a control substrate (based totally on horse manure). Fruit formation in the substrate chic-ban:100-0 was earlier by 1 to 3 days compared to remaining substrates. Average yield was the highest (350.9 g/box) in control substrate and the lowest in substrates based totally on chicken manure or banana wastes composts. Individual mushroom weight ranged between a minimum of 36.8 g in chic-ban:0-100 and a maximum of 58.5 g in control substrate. In the substrates chic-ban:70-30 and chic-ban:50-50 yields were comparable to control (283.9 g/box and 294.2 g/box respectively). Fruit number did not vary significantly among all substrates. Cap diameter was the highest in chic-ban: 50-50 (6 cm), stipe diameter was the highest in control (2.25 cm), and mushroom length was superior in both substrates compared to others. All substrates produced marketable fruits except chic-ban:0-100. Consequently, it was possible to totally substitute the traditional compost by the mixtures chic-ban:70-30 and chic-ban: 50-50 making of this type of cultivation a less expensive one at the level of Lebanon.

Keywords: *A. bisporus, agricultural wastes, composting, substrate, yield.*

Introduction

Innovation in managing agricultural wastes or biomass is a continuous challenge and recent trends favor the utilization of this biomass for value added purposes (Rosentrater *et al.,* 2009). Mushroom cultivation is a direct utilization of their ecological role in the bioconversion of solid wastes generated from agriculture into edible biomass (Savoie *et al.,* 2011). Button mushroom (*Agaricus bisporus* (Lange) Sing.) is one of the most commonly consumed mushrooms in the world (Manzi *et al.,* 2001). It is highly nutritious and it is being traditionally grown on a substrate based on composted horse manure and wheat straw. Physical and chemical properties of substrates are prerequisite for providing essential nutritive compounds and adequate texture for mycelia growth (Chang and Miles, 2004).

In Lebanon, mushroom sector could promote the economic and social development of rural areas (Karam *et al.,* 2010), however the scarcity of horse manure has been obliging local growers to import the traditional compost at a high cost from foreign countries. Consequently, there is a need to find alternative compost mixtures based on more available resources (Sassine *et al.,* 2005). Millions of wastes are generated each year from agricultural activities (El Zein *et al.,* 2015). Previous local trials have recommended the utilization of various waste types such as chicken manure (Sebaaly *et al.,* 2018a) and winery wastes (Sebaaly *et al.,* 2018b) as additives for the traditional compost during button mushroom production. Additionally, the banana cultivation sector is also generating huge amounts of wastes that are

normally unutilized or burned. In fact, banana cultivated areas are in continuous expansion mainly in Southern Lebanon (Kamthan and Tiwari, 2017). The potential use of banana wastes was earlier reported on *Pleurotus* spp. (Sturion, 1994). Moreover, chicken is one of the most produced livestock products (USDA, 2016) and chicken manure generated by local farms is being used as soil amendments. It is well known that properties of agricultural wastes differ globally due to variation in agricultural activities, animal feed and climate conditions. Consequently, the current work investigated the potential use of local types of wastes as a method to provide easily available and less expensive substrates for *A. bisporus* production in Lebanon. Therefore, deep litter chicken manure was mixed with composted banana wastes in different ratios aiming to compare the productivity of the various formulations formed to the one of the traditional compost.

Materials and methods

Composting and pasteurization

The experiment started by preparing three types of composts: the first was based on straw-bedded horse manure, the second on deep litter chicken manure and the third on banana leaves and pseudo-stems (Table 1). It was an outdoor process where composts were turned and wetted until they turned dark-brown and consistent. Nitrogen-rich supplements like urea, ammonium nitrate and protein supplements were added to the compost pile for accelerating the composting process. This phase was achieved in 45 days after obtaining an odorless product and a compost temperature of 50°C (Demirer *et al.,* 2005). It was followed by 8 days of pasteurization (Peker *et al.,* 2007) which consisted on steam pasteurization for the preparation of pathogen-free and selective compost with zero ammonia level.

Table 1: Composition of compost formulations based on agricultural wastes

Amounts of components added to 400 Kg of each waste type	Straw-bedded horse manure	Deep litter chicken manure	Banana wastes (leaves and pseudo-stems)
Wheat straw (Kg)	200	200	200
Urea (Kg)	1.2	1.7	2.3
Ammonium nitrate (Kg)	1.2	1.5	2.5
Gypsum (Kg)	2	2	5
Protein supplements (Kg)	-	-	5

Treatments

Chicken and banana composts were mixed in various percentages based on volume (0 %, 30 %, 50 %, 70 % and 100 %) to form five different substrates: chic-ban:100-0, chic-ban:70-30, chic-ban:50-50, chic-ban:30-70 and chic-ban:0-100. Control consisted on the traditional compost totally based on horse manure. The Table 2 shows the physical and chemical properties of the various tested substrates.

Table 2: Properties of various substrates used for growing *A.bisporus*

	control	chic-ban (100-0)	chic-ban (70-30)	chic-ban (50-50)	chic-ban (30-70)	chic-ban (0-100)
M.C (%)	54.8	62.7	65.9	66.7	69.8	72.4
O.M (% d.w)	65.5	54.7	62.8	70.1	76.8	80.9

M.C: moisture content, O.M: organic matter content, N: nitrogen, C: carbon

Spawning

"Agaricus A15" strain was imported from Sylvan farm Hungary. Ten boxes were used for each substrate. One kilogram of spawn was used per substrate type, thus 100 g per box. A layer of 5 cm of casing soil (peat) was added at the surface of spawned composts. Inside the growing room, temperature was maintained at around 25°C and relative humidity at 90 %. Regulations of air temperature, compost temperature and watering were adopted from Le Lion (1998). Compost scratching was done five days after spawning. In day seven, CO_2 was liberated through ventilation and room temperature was decreased to 16°C as triggers for pin head formation. Mushrooms were harvested in three consecutive flushes over a period of 30-36 days depending on substrate type.

Measured indicators

Number and fresh weight of mushrooms were recorded daily in order to determine the average yield per box relative to each mixture. In addition, mushroom length (considering the stipe length and cap thickness), cap diameter and stipe diameter were measured on harvested fruits using a sliding caliper. Timing of fruit flushes was recorded as soon as mushrooms became well-developed and was expressed as number of days after spawning. For the evaluation of shelf-life, three representative mushrooms of each substrate were subjected to bagging (paper bags) and/or refrigeration as follows: First group was kept at ambient temperature (23°C) with no paper bags; second group was kept at ambient temperature (23°C) in paper bags; third group was refrigerated (4°C) with no paper bags and fourth group was refrigerated (4°C) after being disposed in paper bags.

Experimental design and statistical analysis

A Complete Randomized Design (CRD) with 6 treatments and 10 replications (10 boxes per treatment) was used. Analysis of variance (ANOVA) was adopted for evaluating the effect of substrates on tested indicators and consisted of means ± SE compared by Fishers' least-significant differences test (LSD). Statistical analysis was done using STATISTICA10 program.

Results and discussion

Substrate effect on mushroom production

The type of substrate has variously affected the timing of fruit formation (Table 3). The earliest first flush of mushrooms was obtained in chic-ban:100-0 and the latest in chic-ban:30-70 and chic-ban:0-100. All substrates produced mushrooms over three consecutive flushes with different frequencies. The whole cropping cycle was achieved first in chic-ban:100-0 and the last in chic-ban:30-70.

Table 3: Timing of mushroom flushes in experimental substrates

Mixtures	**Flush 1**	**Flush 2**	**Flush 3**
Control	19 DAS	26 DAS	31 DAS
chic-ban:100-0	18 DAS	24 DAS	30 DAS
chic-ban:70-30	19 DAS	26 DAS	33 DAS
chic-ban:50-50	20 DAS	26 DAS	35 DAS
chic-ban:30-70	21 DAS	28 DAS	37 DAS
chic-ban:0-100	21 DAS	27 DAS	36 DAS

On the other hand, substrate effect was statistically significant on averages of mushroom weight (P_{value}=0.00) and yield (P_{value}=0.00) while it was not significant (P_{value}=0.19) on average mushroom number per box.

Average mushroom number (Fig. 1a) ranged between a minimum of 3.4 mushrooms per box in chic-ban:0-100 and a maximum of 6 mushrooms per box in control. Average mushroom weight (Fig. 1b) was significantly higher in control compared to remaining substrates except chic-ban:50-50 (58.5 g in control and 55.5 g in chic-ban:50-50). It did not differ significantly between the substrates chic-ban:100-0 and chic-ban: 30-70 (46.8 g and 45.4 g respectively) and was the lowest in chic-ban:0-100 (36.8 g). Average yield (Fig. 1c) was significantly higher in control substrate compared to chic-ban:100-0, chic-ban:30-70 and chic-ban:0-100 (350.9 g/box compared to 187.5 g/box, 190.7 g/box and 125.2 g/box respectively). Substrates based totally on composted chicken manure or banana wastes had a lower productivity compared to the traditional substrate based on horse manure (chic-ban:100-0: 1.3 Kg/m^2 and chic-ban:0-100: 0.8 Kg/m^2 compared to control: 2.3 Kg/m^2). However, average yield, thus productivity in chic-ban:70-30 and chic-ban:50-50 were comparable to control (1.9 Kg/m^2 and 2 Kg/m^2 respectively compared to 2.3 Kg/m^2).

Substrate effect on mushroom characteristics

There was a significant effect of the substrate type on averages of mushroom length (P_{value}=0.00), cap diameter (P_{value}=0.00) and stipe diameter (P_{value}= 0.00). Average mushroom length (Fig. 1d) was not significantly different in the mixtures chic-ban:50-50 and control where it was around 6.7 cm. On the other hand, it was significantly higher in control, chic-ban:70-30 and chic-ban:50-50 compared to chic-ban:100-0, chic-ban:30-70 and chic-ban:0-100 (6.7 cm, 6 cm, 6.7 cm compared to 5.5 cm, 5.2 cm and 4.3 cm respectively). Average cap diameter (Fig. 1e) was not significantly different among control, chic-ban:50-50 and chic-ban:70-30 (5.9 cm, 5.7 cm and 5.5 cm respectively) as well as between chic-ban:100-0 and chic-ban:30-70 (5 cm in both substrates). The lowest average of this indicator was recorded in chic-ban:0-100 (3.7 cm). Moreover, the addition of composted banana wastes in proportions of 30 % or 50 % has induced the formation of mushrooms with higher stipe diameter (Fig. 1f) compared to higher proportions (70 % and 100 %).

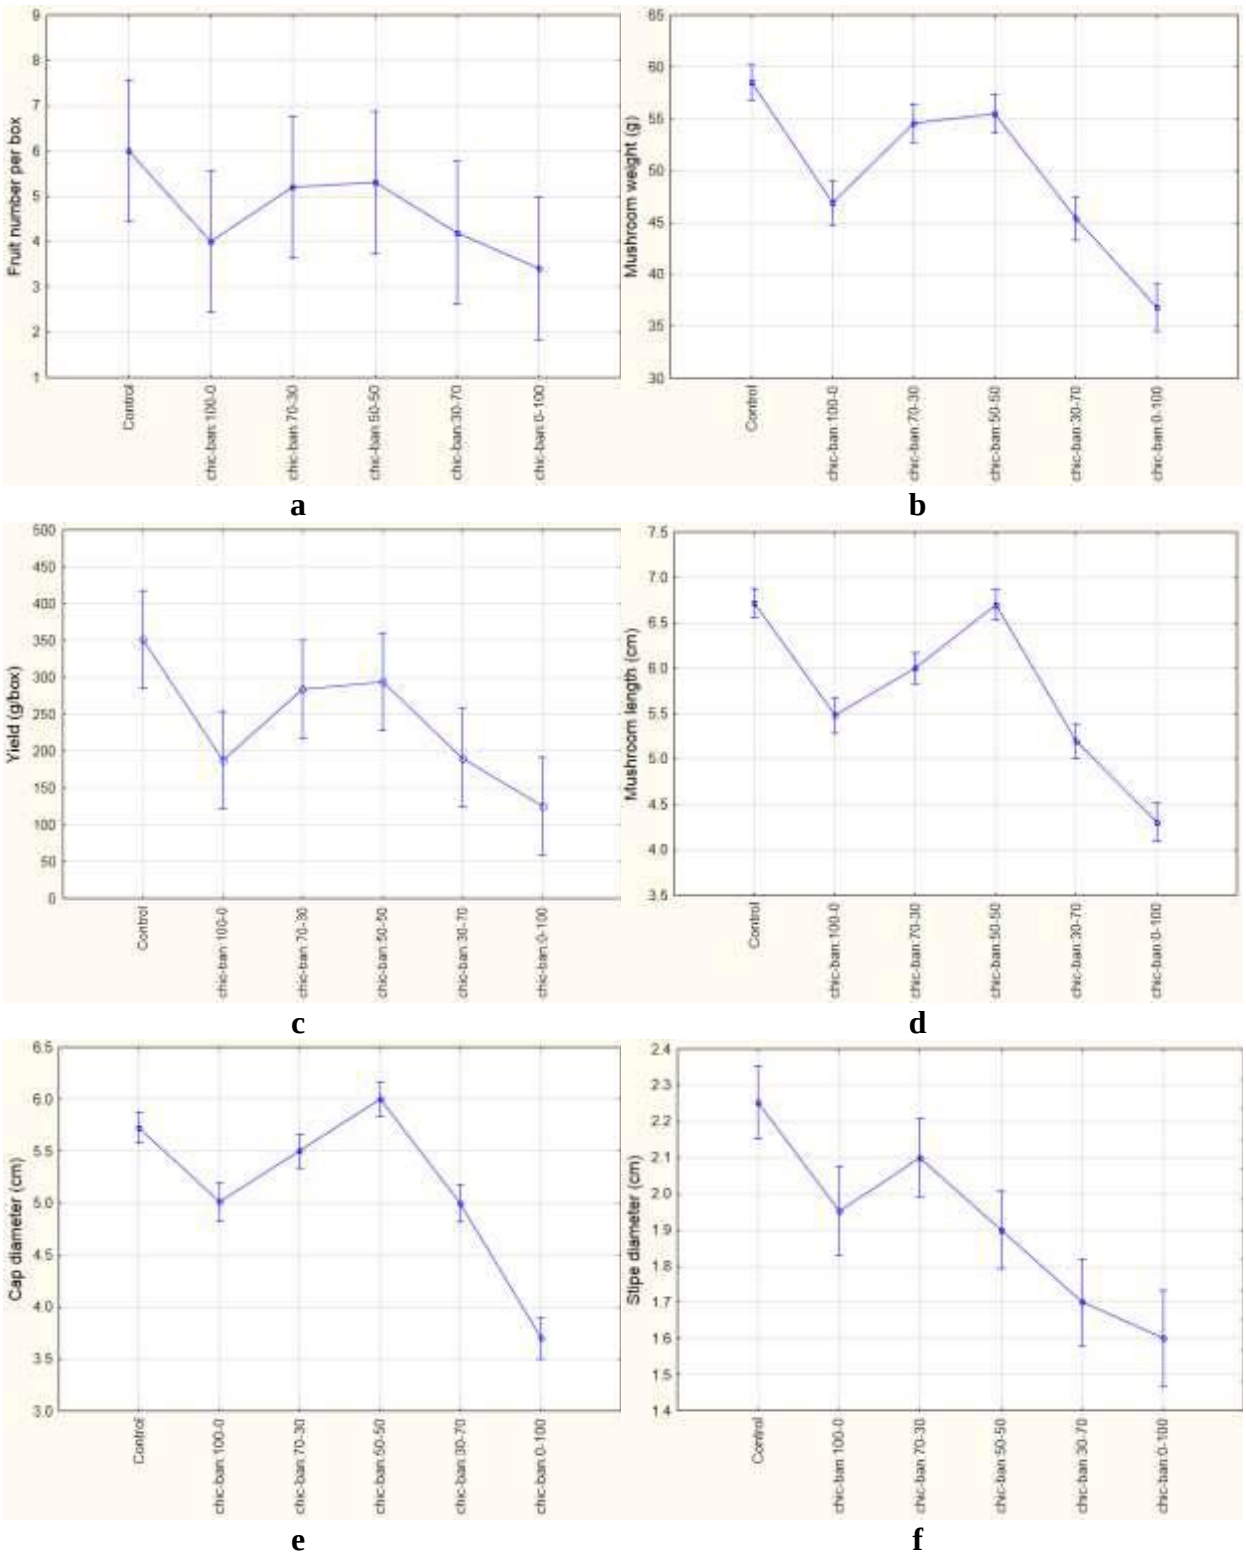

Figure 1: Averages (middle markers) and their 95% limits of confidence (±2 x standard Error: SE) (vertical bars) of indicators

Mushroom shelf-life

Despite the effect of post-harvest treatments (no bagging, no refrigeration), mushrooms of the substrate based totally on composted banana wastes had the longest shelf-life (Fig. 2). With no post-harvest treatments shelf-life was extended with increasing proportions of banana wastes in substrates. It was also extended by bagging and refrigeration. For instance, shelf-life of non-bagged mushrooms kept at room temperature ranged between 1.5 to 3 post-harvest days, while the one of bagged and refrigerated mushrooms ranged between a minimum of 7 post-harvest days in control substrate and a maximum of 10 post-harvest days in chic-ban:0-100.

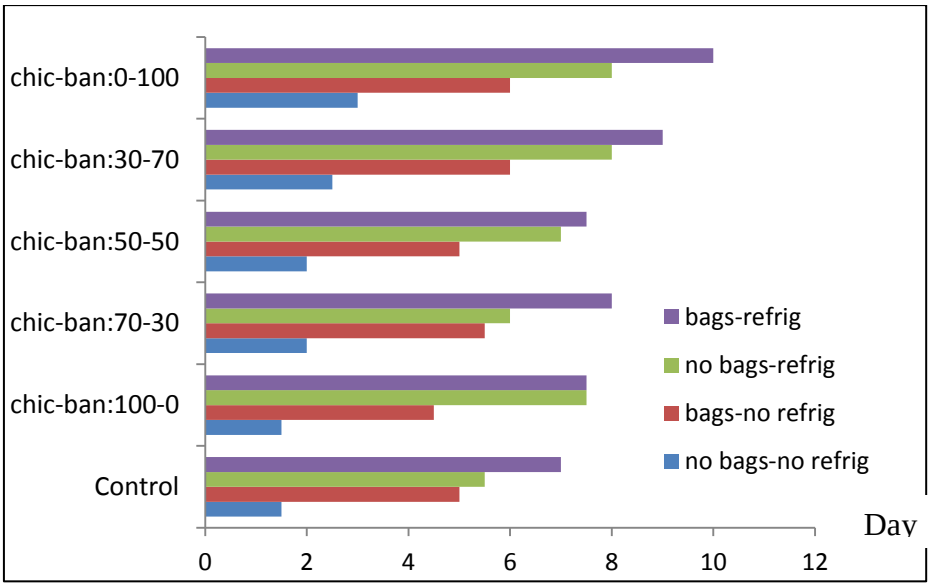

Figure 2: **S**helf-life (number of days after harvest) of mushrooms collected from experimental substrates

Under the specific experimental conditions, it was possible to grow *A. bisporus* on composted banana wastes and composted chicken manure although productivity of both substrates was low compared to that of the traditional compost. On the other hand, when chicken manure compost was dominant in the substrate (chic-ban:70-30) or equally mixed to banana wastes compost (chic-ban:50-50) productivity was comparable to that of traditional substrate.

The amount of nitrogen in the compost is directly related to mushroom growth ensuring an energy supply for the micro-organisms (Baar and Paradi, 2004). Normal nitrogen concentration in the compost is approximately of 1.5 % (Chang and Miles, 2004). Sözbir *et al.* (2015) found that the highest *A. bisporus* yield was obtained from substrates containing maximum nitrogen amounts. Our results showed that mushroom yield was high with nitrogen concentrations ranging between 1.9-2.2 % and was negatively affected by lower or higher N concentrations. In addition, the earliest primordial initiation, thus the earlier first flush was observed in the substrate chic-ban:100-0 due to the high nitrogen content (2.3 %) which has induced the shortest pre-harvest time (mycelia growth rate, spawn running time and primordial initiation). On the other hand, according to Huang *et al.* (2010) and Carmona *et al.* (2012) a nitrogen content exceeding 2 % affects negatively mushroom production which explains the low productivity of the substrate chic-ban:100-0. In general, when N is high in the substrate the compost temperature increases due to high mycelia growth, however, high compost temperature may damage the mycelium and eliminates the possibility of maximum productivity (Royce and Beelman, 2007). Moreover, variations in substrates productivity can

be attributed their C:N ratios. Best yields were obtained from substrates with C:N ratios of 18:1 and 20:1. They were in confirmation with findings of Zhen *et al.* (1995). In addition, C:N ratios higher or lower than those values (17:1, 22:1 and 24:1) have negatively affected yield with the lowest productivity obtained at C:N ratio of 24:1 in the substrate chic-ban:0-100. Huang *et al.* (2010) and Carmona *et al.* (2012) have noted earlier that a high C:N ratio affects negatively mushroom growth and Sözbir *et al*. (2015) have observed that low C:N ratio increased yield with best results obtained at C:N ratio of 19 and 22.

The presence of banana wastes in the mixtures has increased their organic matter content, thus their C:N ratios. Banana wastes are rich in cellulosic materials (Mahalakshmi and Linnett Naveena, 2016) and leaves are a good source of lignin, which is higher than in banana pseudo-stems (Mohapatra *et al.,* 2010). Edible mushrooms are known to be a good agent in the degradation of cellulose (Padam *et al.*, 2014). However, the longer growth cycle reached when banana wastes were present in the mixture in proportions higher than 30 % may be attributed to the more complex structure of banana wastes compared to chicken manure requiring longer time for degradation by mycelia. In fact, organic matter in banana compost was greatly higher than that of chicken manure compost. Cellulose and lignin contained in such substrates could have played an important role deciding yield. According to Sivaprakasam (1980) mushroom yield was positively related with cellulose content and negatively related with lignin content of the substrate. Mushroom physical characteristics were influenced by the various substrates confirming the findings of Sözbir *et al*. (2015). In general, mushrooms obtained from all substrates were marketable except those produced by the mixture chic-ban:0-100. They had a cap diameter falling in the range determined by EC (2002) and FAO (2004): 2.5-7 cm together with a normal stem length/cap diameter ratio (EC, 2002). Furthermore, the positive effect of increasing proportions of banana wastes in the mixture on mushroom shelf-life could be attributed to the lower water content in mushrooms grown in such substrates. In general, the short shelf-life of mushrooms is due to their high water content (Marshall and Nair, 2009) and according to Maheshwari (2013) storing mushrooms in paper bags or subjecting them to cold refrigeration prevents moisture loss.

Conclusion

The traditional substrate could be supplemented by banana wastes when extended mushroom shelf-life and fresh market are targeted or by chicken manure when an earlier cropping is seeked. In addition, the total substitution of traditional compost is possible through the use of substrates chic-ban:50-50 or chic-ban: 70-30, the use of which has maintained quantity and quality of the product. Since both types of agricultural wastes are widely available in Lebanon, mushroom growers could benefit from a reduced substrate cost. Finally, in order to optimize the benefits from banana wastes, composting for more than one year is recommended prior to their utilization in mushroom production.

Abstract

The aim of study was to determine the influence of different nitrogen concentrations (75, 140 and 205 mg L^{-1} NH_4NO_3) on the bioactive compounds content in New Zealand spinach (*Tetragonia tetragonoides* (Pall.) O. Kuntze syn. (*Tetragonia expansa*)) grown in floating hydroponic systems. Also, under the same conditions spinach (*Spinacia oleracea* L.) was grown and mentioned species were compared. Spinach as well as New Zealand spinach are nutritionally valuable leafy vegetables with high vitamin and mineral content. Both species are specific for the tendency of nitrogen accumulation, so it is necessary to be careful when consuming and processing it. New Zealand spinach is less known and mostly un-researched species in our region. By comparing the analyzed species significantly higher content of vitamin C (46 100 g^{-1} FW), phenols (108.04 mg L^{-1} FW), flavonoids (70.77 mg L^{-1} FW), non-flavonoids (37.27 mg L^{-1} FW), total chlorophyll (0.88 mg g^{-1} FW), carotenoid (0.17 mg g^{-1} FW) and antioxidant capacity (2172.63 μmol TE L^{-1}) were determined in spinach compared to New Zealand spinach. In spinach, nitrogen had a significant negative impact on the bioactive compounds content significantly reduced vitamin C content for 36.35 %, total phenols for 23.38 %, flavonoids for 26.08 %, non-flavonoids for 47.84 % and pigment compounds. In New Zealand spinach, with an increase of nitrogen in nutrient solution the opposite trend was determined. Namely, by increasing the nitrogen concentration significantly higher amounts of vitamin C even twice and total phenols for 5 % was determined in New Zealand spinach, while content of pigment compounds did not significantly change.

Keywords: *Floating Hydroponics, Leafy Vegetables, Vitamin C, Total Phenol, Antioxidant Activity.*

Introduction

Leafy vegetables become an important part of nutrition due to high nutritional and low energy value (Fatema *et al.*, 2013). To ensure the continuous production of leafy vegetables for the market throughout the year hydroponic techniques suitable for the production of vegetables with a short vegetation cycle are used (Nicola *et al.*, 2006; Toth *et al.*, 2012). The most widely used hydroponic techniques suitable for leafy vegetables cultivation are Nutrient Film Technique (NFT) and floating hydroponics. In order to achieve a higher yield and quality for each vegetable species it is necessary to determine the optimum composition of nutrient solution, the sowing density and choose appropriate cultivars depending on the cultivation period and purpose (Toth *et al.*, 2012). In floating system, cultivation of spinach (*Spinacia oleracea* L.) is already well developed, while possibilities of hydroponics cultivation of New Zealand spinach (*Tetragonia tetragonoides* (Pall.) o. Kuntze syn. (*Tetragonia expansa*)) are still being researched. Both mentioned leafy vegetables species have tendency to accumulate higher levels of nitrates (nitrophilic plants) which can potentially become harmful for human health because of nitrification process transferring to nitrites. Except nitrates and nitrites,

leaves of both mentioned species also contains oxalates, therewith scientific studies cites that accumulation of mentioned compounds is less in New Zealand spinach leaves compared to spinach (Kawashima *et al.*, 2003; Jaworska, 2005a; Jaworska, 2005b). Mentioned leafy vegetables species are rich in nutritional composition containing a numerous antioxidants such as vitamin C, E, minerals, polyphenols, chlorophylls and carotenoids (Jaworska *et al.*, 2001; Barzegar *et al.*, 2007). The aim of study was to determine the influence of different nitrogen concentrations (75, 140 and 205 mg L^{-1} NH_4NO_3) on the bioactive compounds content in New Zealand spinach (*Tetragonia tetragonoides* (Pall.) O. Kuntze syn. (*Tetragonia expansa*)) and spinach (*Spinacia oleracea* L.) grown in floating hydroponic system..

Material and Methods

Plant material

Experiment was conducted at experiment station of Department of Vegetables Crops (University of Zagreb Faculty of Agriculture, NW Croatia, Zagreb, 45°49'N, 16°02E). New Zealand spinach 'Nuova zelanda' and spinach 'Matador' were grown in heated greenhouse in floating system. The floating system consisted of 4 pools dimensions 70 cm width x 115 cm length. The sowing of New Zealand spinach was carried out on October 17, 2017, and spinach on October 30, 2017. Prior to sowing, New Zealand spinach seeds were treated with potassium nitrate (KNO_3, 4.000 ppm) solution for 24 hours in in order to achieve better germination. Polystyrene containers (30 cm width x 50 cm length) with 40 pots filled with seedling substrate (Potgrond H Klasman) were used for cultivation. During the production cycle minimum (min. 16 °C) and maximum air temperature (max. 27 °C) and air humidity (min. 42%; max. 70%) were recorded. Spinach harvest was carried out on December 19, while New Zealand spinach harvest on January 22. Immediately after harvest fresh vegetable leaves were transported to the Department of Agricultural Technology, Storage and Transport (University of Zagreb Faculty of Agriculture) where healthy, undamaged leaves were separated for further analysis.

Nutrient solutions for cultivation of leafy vegetables were prepared with 4 different concentrations of ammonium nitrate (NH_4NO_3). As control solution (samples Sk and Nzk), the nutrient solution adjusted for spinach cultivation following composition was used (Cukrov *et al.*, 2017): 46.6 g $Ca(NO_3)_2$, 56.70 g KNO_3, 30.08 g KH_2PO_4, 13.61 g NH_4NO_3, 10.23 g K_2SO_4, 3.36 g $MgSO_4$, 1.008 g Fe-EDDHA, 0.045 g H_3BO_4, 0.1561 g $MnSO_4$, 0.0112 g $CuSO_4$ and 0.0056 g Na_2MoO_4 prepared in total volume of 70 L. In the next three treatments concentrations of NH_4NO_3 were: 75 mg L^{-1} (samples SN 1, NzN 1), 140 mg L^{-1} (samples SN 2, NzN 2) and 205 mg L^{-1} (samples SN 3, NzN 3). pH, EC value and amount of dissolved oxygen of nutrient solutions were measured daily for each pool and amounted average: pH value 5.98 (1. pool), 6.33 (2. pool), 6.00 (3. pool), 6.24 (4. pool); EC values 2.69 dS m^{-1} (1. pool), 2.76 dS m^{-1} (2. pool), 3.09 dS m^{-1} (3. pool) and 3.42 dS m^{-1} (4. pool) while amount of total dissolved oxygen varied daily and ranged from 3.7 mg L^{-1} to 11.4 mg L^{-1}.

Determination of chemical composition and antioxidant capacity by ABTS method

The basic chemical composition of fresh leaves was carried out by standard methods (AOAC, 1995) and included: total dry matter content (%), total acid content (%) and pH value. The content of following biologically active compounds was also analyzed: vitamin C (mg 100 g^{-1} FW) (AOAC, 2002), total phenols (flavonoids and non-flavonoids) (mg L^{-1}) according to Ough & Amerine (1988) and pigment compounds, total chlorophylls and carotenoids content by Holm (1954) and Wettstein (1957). The absorbance of pigment extracts was measured spectrophotometrically (Shimadzu UV 1650 PC) at 662, 644 and 440 nm with acetone (p.a.) as a blank probe. The absorbance values were recalculated according to the Holm-Wettstein equations (mg L^{-1}) while the final result of the pigment content was expressed in mg g^{-1}:

(1)
$$chlorophyll\ a = 9.784\ \times A_{662} - 0.990\ \times A_{644}[mg\ L^{-1}],$$
$$chlorophyll\ b = 21.426\ \times A_{644} - 4.65\ \times A_{662}[mg\ L^{-1}],$$
$$chlorophyll\ a+b = 5.134\ \times A_{662} + 20.436\ \times A_{644}[mg\ L^{-1}\ ],$$
$$carotenoids = 4.695 \times A_{440} - 0.268 \times (klorofil\ a+b)[mg\ L^{-1}].$$

Antioxidant capacity by ABTS assay was performed according to Miller et al. (1993). ABTS, potassium persulfate and standard Trolox were obtained from Sigma-Aldrich. As stock standard Trolox (2.5 mM) was prepared in ethanol (80 %). To prepare ABTS radical solution (ABTS•1) the 5 mL of ABTS solution (7 mM) and 88 mL of potassium persulfate (140 mM) solution were mixed and allowed to stand in the dark at room temperature for 16 h. On the day of analysis 1 % ABTS•1 solution (in 96 % ethanol) was prepared. Ethanol extract prepared for the purposes of total phenol content was used. A total of 160 µL of ethanol extract were directly injected in the cuvette and mixed with 2 mL 1 % ABTS•1, while absorbance at 734 nm was measured (Shimadzu 1650 PC, Germany). The final results was calculated based on calibration curve and expressed as mmol TE L^{-1}.

Statistical analysis

Statistical analysis was performed using the SAS (2010). The experiment was set as randomized block design with two containers of each vegetable species in each pool. The experiments were performed in triplicate. Data were subjected to the one-way analysis of variance (ANOVA). Mean values were compared by the t-test (LSD) and were considered significantly different at $p \leq 0.0001$. In tables different letters indicate significant differences between mean values within each column. Also standard deviation (±SD) was expressed.

Results and Discussion

Bioactive compounds content of spinach and New Zealand spinach grown in floating

Significant statistical differences for all analyzed bioactive compounds and antioxidant capacity of spinach and New Zealand spinach between treatments were determined (Tab 1). In spinach cultivated in control solution (Sk) the highest vitamin C content (46.70 mg 100 g^{-1} FW) was determined, while the lowest vitamin C content (28.67 mg 100 g^{-1} FW) was determined in treatment with 75 mg L^{-1} NH_4NO_3 (SN 1). The vitamin C content in New Zealand spinach leaves varied from 10.19 mg 100 g^{-1} FW (NzN 1; 104 mg L^{-1} NH_4NO_3) to 22.44 mg 100 g^{-1} FW (NzN 3; 205 mg L^{-1} NH_4NO_3). According to the obtained results, in New Zealand spinach leaves even twice lower vitamin C content was determined compared with spinach regardless of the treatment. Also, in spinach, vitamin C content significantly decreases due to the increase of NH_4NO_3 concentration during which in treatment SN 3 (205 mg L^{-1} NH_4NO_3) even 36% less vitamin C was determined compared to the control treatment (Sk). But in New Zealand spinach samples such trend was not determined, respectively the increase of NH_4NO_3 concentration stimulated the increase of vitamin C content. Numerous scientific data cites that increased nitrogen concentration negatively affects on the vitamin C content (Mozafar, 1993; Radman et al., 2015). Except vitamins, significant bioactive compounds are also phenols. In spinach cultivated in control solution (Sk) the highest total phenol content (108.04 mg L^{-1}) were determined while the lowest content (87.57 mg L^{-1}) in treatment SN 3 (205 mg L^{-1} NH_4NO_3). In New Zealand spinach samples the opposite results were obtained, i. e., the the highest NH_4NO_3 concentration (NzN 3) resulted with the highest total phenol content (43.91 mg L^{-1}). Cultivation of New Zealand spinach in solutions with lower NH_4NO_3 concentrations (NzN 2, NzN 1) and in control solution (Nzk) resulted with significantly lower total phenol content. Stowe & Osborn (1980) and Radman et al. (2015) cite that by increase of nitrogen concentration content of phenolic compounds are significantly reduced. The main reason for the opposite effect of higher nitrogen concentration on bioactive compounds content in samples of New Zealand spinach might be due to the

lower tendency of nitrates, nitrites and oxalates accumulation in New Zealand spinach compared to the spinach (Jaworska and Kmiecik, 1999). But also the content of bioactive compounds depends on the plant part (Jaworska, 2005). Significantly higher values, average 29%, of antioxidant capacity were determined in spinach compared to the New Zealand spinach regardless of the treatment. Obtained results are expected given that significantly higher values of bioactive compounds were determined in spinach leaves. Also, given that higher NH_4NO_3 concentrations affected on the reduction of bioactive compounds in spinach leaves, lower antioxidant capacity were determined in treatments SN 1, SN 2 and SN 3. Contrary, in New Zealand spinach treatment with the highest NH_4NO_3 concentration (NzN 3) the highest antioxidant capacity was determined.

Pigment compounds of spinach and New Zealand spinach grown in floating

The presence of nitrogen in the soil and chlorophylls in plants is directly related, whereby the content of chlorophyll increases by increasing the nitrogen concentration (Jones et al., 2007; Nemadodzi et al., 2017). However, the results of total chlorophyll content (Tab 2) obtained in this research are not in agreement with above mentioned. In both researched species the lower total chlorophyll content was determined due to the increase of NH_4NO_3 concentration in nutrient solution. The same trend was also determined for total carotenoids which content decreased by increasing NH_4NO_3 concentration, whereby the negative effect was less pronounced in New Zealand spinach treatments (NzN 1, NzN 2, NzN 3). Also, in spinach, higher values of pigment compounds content was determined compared to the New Zealand spinach, in average 59% more of total chlorophylls and 48% more of total carotenoids.

CHa- chlorophyll a; CHb- chlorophyll b; TCH- total chlorophyll content; TC- total carotenoid content; SN 1- spinach 75 mg L^{-1} NH_4NO_3; SN 2- spinach 140 mg L^{-1} NH_4NO_3; SN 3- spinach 205 mg L^{-1} NH_4NO_3; NzSk- New Zealand spinach control solution; NzN 1- New Zealand spinach 75 mg L^{-1} NH_4NO_3; NzN 2- New Zealand spinach 140 mg L^{-1} NH_4NO_3; NzN 3- New Zealand spinach 205 mg L^{-1} NH_4NO_3. Different letters indicate significant differences between mean values within each column.

Conclusions

Based on the obtained results can be concluded that increase of the NH_4NO_3 concentration in nutrient solution in spinach cultivation significantly reduces the content of analysed bioactive compounds (vitamin C, total phenols, chlorophylls and carotenoids and also antioxidant capacity). In samples of New Zealand spinach opposite trend was determined. Also, it is important to emphasize that both tested leafy vegetable species cultivated in floating system are rich in nutritional composition and further studies in optimization of cultivation by hydroponics techniques especially of New Zealand spinach are necessary.

Abstract

Millipedes are common pests of cassava and often cause serious economic losses. Pesticide application remains the first option that farmers choose to minimize the damage caused by the myriapods. The result is high health risk, increased cost of production and also environmental pollution. A field experiment involving false horn plantain (Apantu) as component crop, an improved cassava (Ampong) and landrace cassava (Afia Abaayaa), base crop was conducted on farm at two hot spot areas in 2015 and 2016. Plantain based intercrops and sole cassava were tested for their ability to reduce the population and damage caused by millipedes to cassava and the effect on root yield of cassava. The results followed a similar pattern in both locations. Plantain intercropped with both improved and local cassava proved the most effective intercrops. In these two intercrops, the incidence of the millipedes and the extent of damage to cassava roots were the lowest ($P<0.05$). The intercropping could not influence the yield of cassava however, the yield of plantain was negatively affected ($P< 0.05$) in the intercrop plots recording 50% low yields compared to the sole plantain. A total of 44 contact farmers were sensitized on using intercropping as a strategy to manage the activity of millipedes in cassava cultivation.

Introduction

Cassava *(Manihot esculenta* Crantz) is the fifth largest food crop after maize, rice, wheat and potato in the world (FAO, 2014). It provides the main source of carbohydrates to a large proportion of the population of the tropics, especially the inhabitants of the wetter tropics, including the western region of Ghana. It can be grown on a variety of soils and generally requires or receives little inputs. Cassava is therefore relatively cheap to produce. Again the potential yields are not realized because of a myriad of pest problems. The Research Extension-Farmer Linkage Committee (RELC), a body set up as a link between researchers and farmers in their report for 2010-2011 identified millipede infestation as a major contributing factor to low root yield of cassava and other root and tuber crops in the Western Region of Ghana. Accordingly, the estimated annual average for cassava production in metric tons decreased from 722,162 in 2003 to 707,894 in 2008 (MoFA 2008). Millipede infestation in January 2012 caused a panic situation for officials of the national agricultural ministry, researchers and politicians. Reconnaissance survey to the area by a team of research scientists from CRI identified three hot spots in Wassa Amenfi East, Prestea-Huni Valley and Wassa East districts. Their pest status has been documented (Fening *et al.*, 2016).

Millipedes normally live in and feed on rotten leaves and wood and other kinds of moist decaying plant matter and are therefore useful as scavengers. However, when conditions are favourable they develop high populations and invade farms and dwellings (Baker, 1979). There are reports that millipedes cause economic damage to several crops in Ghana (Peters, 2000; Fening *et al*., 2014) and elsewhere (Atukunda *et al*., 2003; Ebregt *et al*., 2004; Epidi and Njoku, 2010). These include root and tubers such as cassava, sweet potato, cocoyam and yam. Other affected crops are guinea corn, cotton, millet, groundnut, watermelon and

cabbage. With the current world population increasing by an estimated 97 million per year (Saravi and Shokrzadeh, 2011) the implication is that many more mouths would have to be fed. This therefore necessitates a growing need for increased agricultural production. Cultivation of arable crops to maximize crop productivity has attained the simplified status of monocropping resulting in artificial ecosystems. Most arable, cash and plantation crops such as rice, maize, pineapple, cassava and plantain are currently produced in monocultures worldwide. Consequently, this system has resulted to increased vulnerability of such crops to pests and diseases pressure and ultimately leading to agro pesticide approach of managing these biotic stresses. Besides the heavy investments in agro chemicals coupled with its varied effects on food poisoning and environmental pollution, crop losses due to pests currently stand at an average of 35% globally (Oerke, 2006). About 3 billion kilograms of pesticides is applied globally each year with an annual spending of nearly $38 billion (Pan-Germany, 2012). Environmental and social costs associated with current level of pesticide use have been estimated at $10 billion per year (Pimentel, 2005). According to Carriger *et al*. (2006), only about 0.1% of the pesticides reach the target organisms and the bulk of the remnant contaminates the surrounding (Kumar *et al*., 2015). Annually, cases of pesticide poisoning affects 5 million people, most of them in developing countries and accounts for 20,000 unintentional deaths (WHO, 2004). Although Africa accounts for less than 4% of global agrochemical use, its farmers face the greatest barriers in equipping themselves against pesticide hazards (Williamson, 2003). As a result, the continent which uses the least of world agro chemicals, suffers over 90% of pesticide effects (Eddleston *et al.,* 2002).

An alternative approach based on sound ecological principles which conforms to indigenous farming practice to ensure efficiency and sustainability must be adopted. This is needed to take advantage of the immense benefits of diversifying crop ecosystems and can be achieved by promoting polycultures such as mixed cropping and intercropping. Intercropping is a common phenomenon in Ghana's indigenous agriculture but mostly recognized as insurance against crop failures. Intercropping of cassava with plantain in field trials has been found to reduce the population of millipedes (Braimah *et al*., 2012). In general, Intercropping with cassava is vital in weed, pest and disease reduction (Wolfe, 2000). Ibeawuchi (2004) also reported that intercropping effects through its diverse crop species and morphology, keeps low its attack and destructive tendencies since some of the intercrop species may be resistant to the pest and or disease. The objectives of the study therefore were; to evaluate the incidence of millipedes and their damage in plantain based intercropping system in comparison with sole crops of cassava and to sensitize and train farmers on impact of intercropping on millipedes.

Materials and Methods

Experimental site description

Field experiments were conducted on-farm in June 2015 to October 2016 in two communities of two districts of the Western region of Ghana. These are Nsuopun (5.862°N, 1.985°W) within an elevation of 181m above sea level (a.s.l) in the Amenfi East District and Tebe (5.391°N, 2.033°W) at an elevation of 91m (a.s.l) in Prestea-Huni Valley district identified as endemic areas of millipede infestation of root and tuber crops in the Western region. The area falls within the high forest vegetation zone and lies in the equatorial climate zone that is characterized by moderate temperatures and receives bimodal pattern of high rainfall with an average of 1,600mm per annum. Dominant crops cultivated in the area include cassava, cocoyam, plantain, cocoa, oil palm rubber and vegetables.

Intercropping treatments and field layout: A land space of 35 x 31 m^2 (1.09 ha) was prepared by slashing and burning and marked out into plots of 6m x 9m. Treatments comprised; Sole Plantain (SP), Plantain + improved cassava (PCI) Sole improved cassava (SCI), Plantain +

local cassava (PCL) and Sole local cassava (SCL). The cassava varieties were improved variety (Ampong) and a landrace (Afia Abaayaa). The Apantu variety of plantain was used. The treatments were arranged in a Randomized Complete Block Design (RCBD) and replicated thrice. Weeding was done at 3, 6, and 9 months after planting.

Data collection: Parameters measured included number of millipedes per plant, number of roots damaged by the millipedes per plant, number of holes per plant and yield in tons per hectare. Data were collected at 6 months after planting and at harvest. During sampling, 5 cassava plants were uprooted in the inner rows and 5kg of soil was scooped and assessed for soil arthropods on all plots. Roots were also counted, visually assessed for damage holes and weighed

Selection of contact farmers for sensitization and training exercise: Purposive sampling procedure was used to select participating contact farmers. Farmers who have cropped cassava for 5 years continuously and were ready to participate were selected from the two millipede endemic communities. In all 44 farmers comprising 16 from Nsuopun and 38 from Tebe registered. They were made up of 17 and 27 females and males respectively. All husbandry activities were carried out with the contact framers. On each activity day farmers were sensitized on intercropping as a measure to manage millipedes on cassava fields.

Data analysis: To test the effects of the cropping system (sole cropping and intercropping) on millipede population, root damage and yield, the field data collected was subjected to analysis of variance (ANOVA). The significance of differences in mean values was analyzed by Tukey's Studentized Range (HSD) Test method of SAS (Proc GLIMMIX, SAS 9.3; Cary, North Carolina, USA). Quantitative data recorded for beneficiary farmers' sensitization was analyzed with descriptive statistics.

Results and discussion

Assessment of intercropping effects on millipede incidence and damage 6MAP

Intercropping plantain with cassava significantly affected millipede population 6 MAP in both locations (Table 1). However, no damage to roots was recorded 6 months after planting. In both locations, the intercrop of the landrace harboured significantly higher millipede population than any of the intercrop and sole cropping. Generally, millipedes' population was higher at Tebe compared to Nsuopun. Lower millipede population was recorded for sole plantain at Tebe but in sole cassava (improved) at Nsuopun.

Table 1. Mean number of millipedes at 6 months after planting (MAP), Nsuopun and Tebe 2015

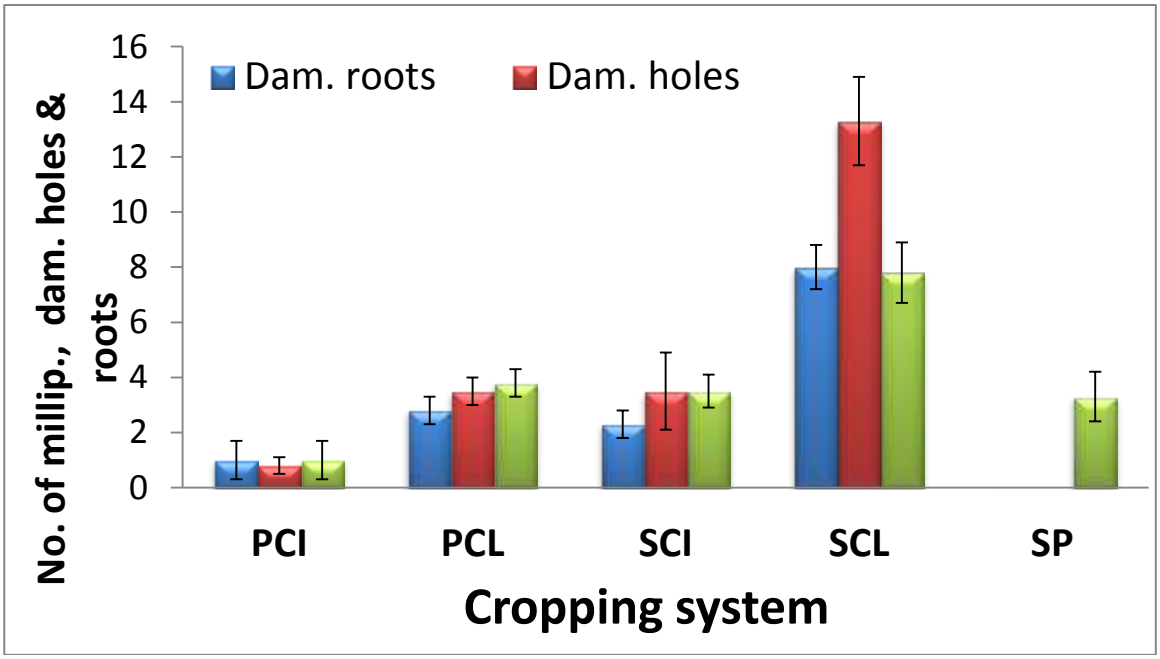

Figure 1. Effect of intercropping plantain with cassava on millipede population and damage at Tebe, 2016

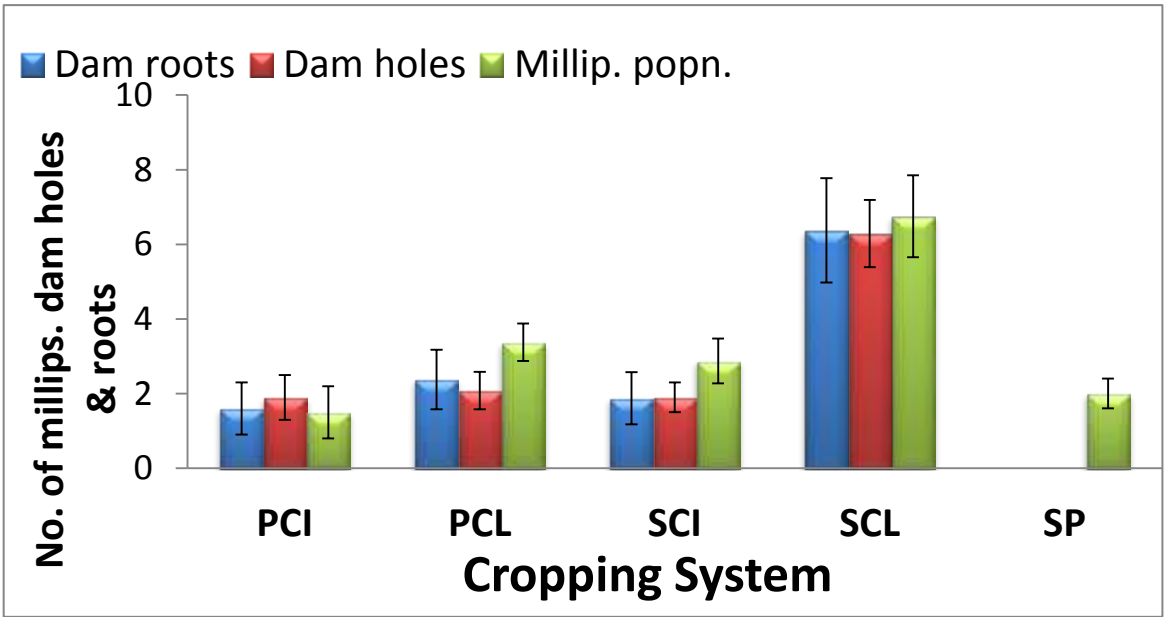

Figure 2. Effect of intercropping plantain with cassava on millipede population and damage at Nsuopun, 2016

Assessment of intercropping effects on millipede incidence and damage at harvest: At harvest, the population and damage records followed a similar pattern at both locations with intercropping plots recording lower population and damage levels compared to sole plots (Figure 1). At Tebe more millipedes as well as their damage were recorded than at Nsuopun. Millipedes showed some preference for local cassava than the improved materials. The plantain and improved cassava intercrop recorded significantly low number of millipedes as well as their damage among all the treatments. No differences ($P<0.05$) were shown in plantain and local cassava as well as sole cropping of improved cassava. Millipede population and damage was significantly highest in the landrace as sole crop

Assessment of intercropping effects by millipede incidence and damage on yield: The intercropping could not significantly affect yield of cassava figure 2(a). The result is expected as improved variety significantly (P< 0.05) out-yielded the landrace. On plantains however, there were significant differences in yield with the intercropping of improved cassava recording 4 tons/ha while local cassava intercrop recorded about 6 tons/ha. Yields of plantain in the intercropping system was 50% lower than the sole plantain.

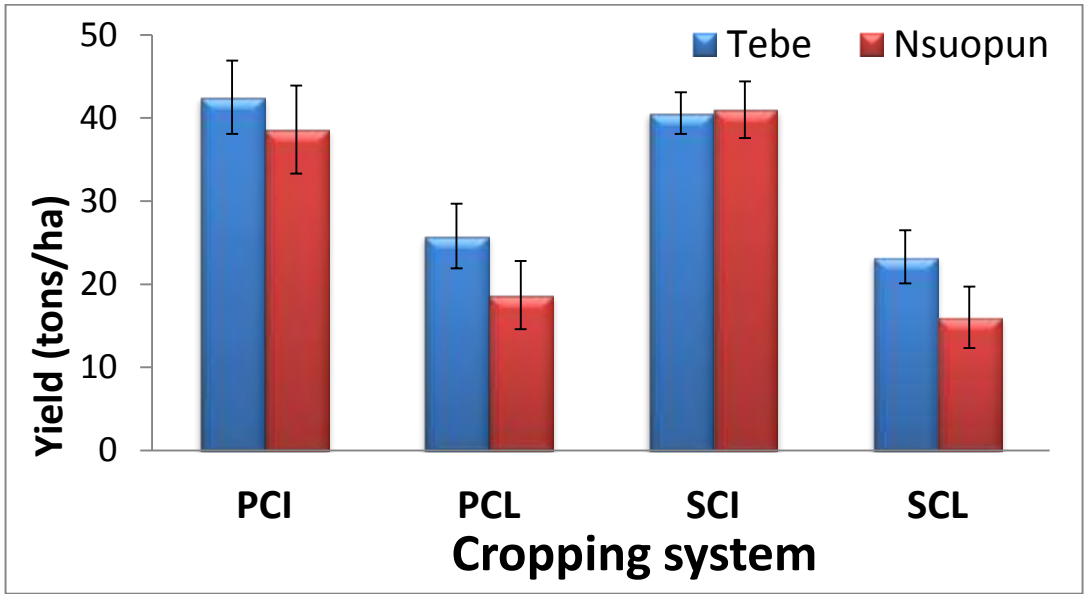

Figure 3. Yield of cassava in plantain based cassava intercrop at Tebe and Nsuopun, 2016

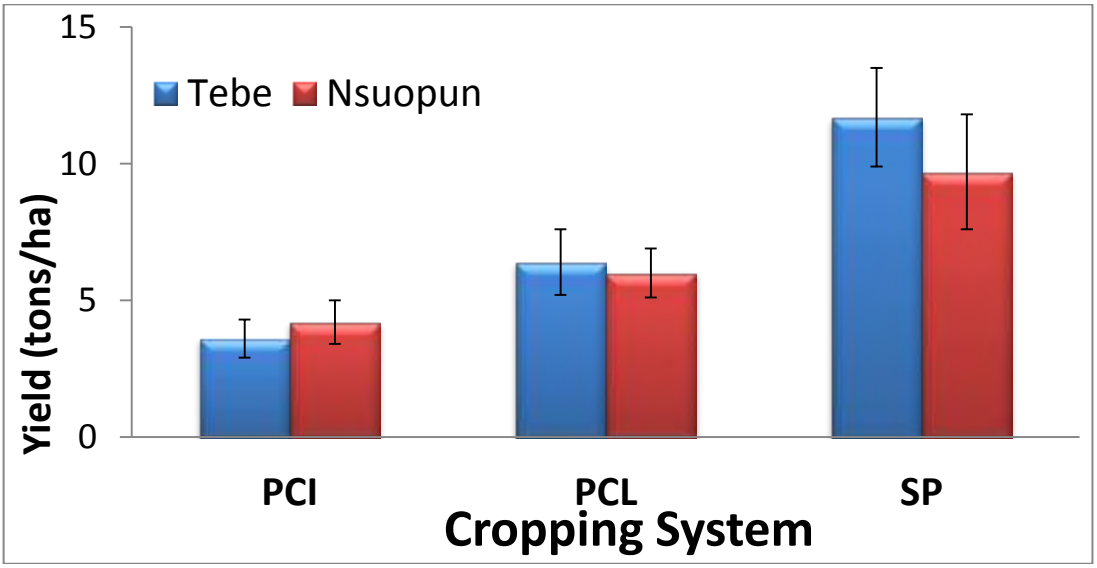

Figure 4. Yield of plantain in plantain based cassava intercrop at Tebe and Nsuopun, 2016

Beneficiary farmer sensitization on effects of intercropping to manage millipedes

Table 2. shows details of contact farmers sensitized on how to use intercropping technology to mitigate the deleterious effects of millipedes on cassava fields. In total, 44 farmers were sensitized 28 of which were from Tebe. Females constitute 39% much the same for youthful farmers.

Table 2. Beneficiary farmers sensitized on effects of intercropping plantain with cassava at Nsuopun and Tebe 2016

Location	**Estimated Area (Ha)**	**Beneficiaries**			**Youth *(up to 35yrs)***	**% Youth**
		Male	Female	Total		
Nsuopun	0.2ha	10	6	16	5	31
Tebe	0.2ha	17	11	28	12	43
Total	0.4ha	27	17	44	17	39

The ever increasing scarcity of cultivable land in the developing world necessitates the practice of intercropping. Plantain and cassava intercrop is commonly practiced in Africa (Dowiya *et al*., 2009; Akinyemi *et al*., 2010; Ngeleza *et al*., 2011). Plantain and cassava intercrop is advocated from this study to manage the deleterious effect of millipedes in cassava fields. This assertion falls in line with Ennin *et al.*, (2002) who stated that the practice of intercropping increase efficiency of resource utilization. Assessment at 6 MAP showed millipede presence in intercrops and sole cropping fields of plantain and cassava as observed by Fening *et al*. (2016). The millipede presence however did not manifest any damage on the developing tuberous roots probably due to their low numbers or the short dry spell experienced around the time of assessment which could have reduced millipede activities. The higher millipede numbers recorded at Tebe as compared to Nsuopun support the findings of Fening *et al*., 2016 which could probably be as a result of the high elevation of Nsuopun. Lowest millipede population recorded in sole plantain at Tebe was expected since plantain was found to be unattractive to millipedes (Braimah *et al*., 2012)

At harvest, the trend was not different. Activities of millipedes were minimal in the intercropping plots as compared to the sole plots. The unattractiveness of plantain to millipedes coupled with the non preference of improved cassava varieties was exhibited in this study and corroborates the findings of (Braimah *et al.*, 2012; Fening *et al.* 2016). This resulted in the least millipede populations and damage to roots in the intercropping of the improved cassava. The performance of plantain and local cassava as well as sole improved cassava was similar, controlled millipede population and damage lower than sole local cassava. Sole local cassava therefore recorded very high millipede population and damage which confirms the assertion of Fening *et al*. (2016) that millipedes have particular preference for local cassava and highly susceptible to pests and diseases (Okechukwu and Dixon, 2000).

The yield of cassava in both intercrop and sole cropping were not influenced by intercropping, this corroborate the findings of (Prabhakar and Nair, 1992) noting that neither spatial arrangement of cassava nor change in plant density of intercropped groundnut had any substantial effect on tuber yield of cassava. Yields of intercrops were generally reduced as compared to the potential of individual crops but the reduction is often compensated by utilization of resources such as weeds smothering, reduction in runoff and soil losses, additional income to farmers, provision of food security and reduction in pests' population and their damage (Ennin *et al.*, 2002; Akinyemi *et al*., 2010). Reduction in yield of plantain in intercropping as against the sole crop is supported by (Karikari, 1981; Adetiloye, 2003) and could probably be due to the high nutrient requirements of cassava.

The approach of sensitizing farmers by use of evidence-based interventions in formulating training according to Ssekyewa (2005), Mariyono (2007) and Pophiwa (2012) ensure success by promoting results oriented innovations which are visible and significant enough to convince farmers to try the new practice themselves. Training of farmers to improve their knowledge of new technologies and increase their level of productivity **(**Rosegrant and Cline,

2003). Forty per cent of farmers who participated in the sensitization exercise belong to the youthful bracket, an indication that the innovation could be practiced for a long time and adopted by many farmers in future.

Conclusion

We conclude that for effective and sustainable management of millipedes as pests of root crops, plantains intercropped with improved cassava is best although yields of plantains could be compromised and sensitizing farmers to try a new practice on their own ensures sustainability of the innovation.

Abstract

The peach trunk aphid is an important insect pest attacking stone fruits in Jordan and worldwide. It attacks almond, cherry, apricot and peach. Insecticides represent the main solution to control this insect pest, but they proved to pose many environmental problems and cause toxicity to human. In addition, many insects developed resistance to insecticides that lead farmers to raise their application rates and increase their frequency. So, it is not recommended to use these chemicals to control this insect particularly at home gardens. Using botanical insecticides proved to have success in controlling insect pests. The purpose of this research project was to test the aphicidal activity of the aqueous extracts of *Ephidra sinica* medicinal plant on the peach trunk aphid using the shoot-cut bioassay technique and different concentrations prepared to determine the Median Lethal Concentration rate (LC_{50}) of the plant extract. Results revealed that high concentration of aqueous extract of *Ephidra sinica* medicinal was toxic as Imidacloprid to the peach trunk aphid, *Pterochloroides persicae.*

Key words: *Botanical insecticide, Peach trunk aphid, Integrated pest management, Botanical insecticide.*

Introduction

Stone fruits are grown in Jordan both commercially and as part of home gardens (Ateyyat, 2008). In 2014, about 91671 dunums were under productive stone fruit cultivation in Jordan that produced 117,326 tons (Statistical Year Book, 2014). Stone fruits in Jordan are attacked by several insects including *Capnodis* spp., ***Zeuzera Pyrina, Scolytus rugulosus*** and different aphids that threaten their produce (Mustafa & Al-Momany, 2007) . Three aphid species are recorded to colonize stone fruits in Jordan from which peach trunk aphid, *Pterochloroides persicae* represent the most destructive one (Ateyyat, 2008). Sever infestations result in branch decline due to aphid colonies sucking that may induce tree decline if infestation continued to a few years. As other aphids, it excretes huge amount of honeydew which encourage sooty mold growth on upper plant parts and affect physiological operations (Ateyyat, 2008). Mustafa (1991) studied the reproductive biology of the peach trunk aphid in Jordan. Also, Ateyyat (2008) evaluated the efficacy of three insecticides and two insect growth regulators against this insect pest. Farmers mainly depend on chemicals to control this insect; the chemical insecticides pose negative effects on environment and human health particularly when using them in home gardens. Botanical insecticides proved to provide an alternative safe control methods for aphids (Ateyyat, 2009; Ateyyat et al., 2012a; Ateyyat et al., 2012b; Ateyyat et al., 2012c; Ateyyat and Abu Darwish, 2009; Al-Mazra'awi and Ateyyat, 2009; Hakimi et al., 2015).

Ephedra plants are members of the Ephedraceae family. They have medicinal properties as they are used as part of the tradition medicine to treat hay fever and common cold (Janet et al., 2003). Methanolic Extracts of *Ephedra pachyclada* showed to have an antimicrobial

Activity on Some Enteric Gram-Negative Bacteria that known to cause Nosocomial Infections (Sadeghi Dosari et al., 2016). Many negative impacts were recorded because of the extensive and misuse of chemical insecticides application. These include; environmental pollution, acute and chronic toxicity to agricultural workers and consumers, development of resistance, resurgence and outbreaks in insect pests. The present research project provides an alternative safe solution to reduce these negative impacts as botanicals could be use as part of the integrated pest programs and/or organic agriculture. The insecticidal activity of Ephidra was not tested as far as the data bases show.

So, the purpose of this study is to study the aphicidal activity of the aqueous extracts of the leaves of *Ephidra sinica* against the peach trunk aphid.

Materials and method

Plant extract

Ephedra leaves will be collected from Al-Tafila city (220 km south of Amman) in Jordan. Leaves will be thoroughly washed with tap water to avoid unwanted materials accumulated on the leaves then they will be left to air-dry under shade at room temperature. Powder will be prepared from the dried material using an electrical home grinder. Ten grams of the powdered material will be dissolved in 90 ml of distilled water and will be kept in a reciprocating shaker for continuous agitation for 24 h for thorough mixing. After that, filtration for the extract will be made using vacuum pressure pump. The resulted amount will be completed to 100 ml by adding extra distilled water to get a stock solution of 10 000 mg/L concentration. More concentrations (dilutions) will be prepared as required.

Bioassay

The aqueous extract of Ephidra leaves will be tested against the peach trunk aphid. Insects will be collected from infested stone fruit trees and the excised cut-shoot bioassay technique will be used in which about 25 adults or immatures will be moved to 10-cm long shoot of healthy stone fruit. After ensuring that the insects settle on the healthy shoots, they will be exposed to the required treatment. Two controls will be used, the negative control in which distilled water will be used and the positive control in which imidacloprid insecticide will used at the lower recommended rate of application. Each treatment will be replicated at least three times. Treatments will be applied using aerosol sprayers (Preval, Chicago Aerosol, Coal City, Illinois) under a fume hood. Mortalities will be recorded after 24, 48 and 72 hr of treatment applications.

Statistical Analysis

For calculating the Median Lethal Dose (LC_{50}) and the Lethal Concentration 90 % (LC_{90}), mortalities will be corrected using Handerson-Tilton's formula, after which SAS (2014) will be used to get the LC_{50} and LC_{90} of the extract. Also, the same program will be used to obtain the one-way ANOVA and mean separation to compare the best tested concentration of the aqueous extract of Ephidra with both negative and positive controls at the three recorded times.

Results and discussion

About 15, 37 and 96 grams per liter of *Ephidra sinica* aqueous extracts are required to achieve the thirty lethal dose (LC30), the median lethal dose (LC_{50}) and the ninety lethal dose (LC_{90}), respectively (Table. 1).

Table 1. Concentration-mortality data for peach trunk aphid treated with *Ephidra sinica* aqueous extracts

Slope ±SE	LC_{30} (gm/l)	95% CL	LC_{50} (gm/l)	95% CL	LC_{90} (gm/l)	95% CL
0.0373± 0.0103	14.555	-25.802 – 47.292	37.274	11.338- 10.1763	96.189	58.137 – 292.531

Using Ephidra at high concentration of 100 grams per liter gave high mortalities to PTA immatures, which is not significantly different with that obtained using the positive control treatment through the use of imidacloprid insecticide after one day, two days and three days of applications (Figs 1,2,3). Decreasing the concentration of Ephidra to 10 g/l resulted in 85% mortality after 72 days of application (Fig. 3) though it was 58 % after 24 h of treatment (Fig. 1). Even though all the tested concentrations of aqueous extracts of Ephidra gave significant mortalities to PTA compared with negative control, but its use at 1 g/l and below resulted in mortalities below 40 % after 24 h of application (Fig. 1).

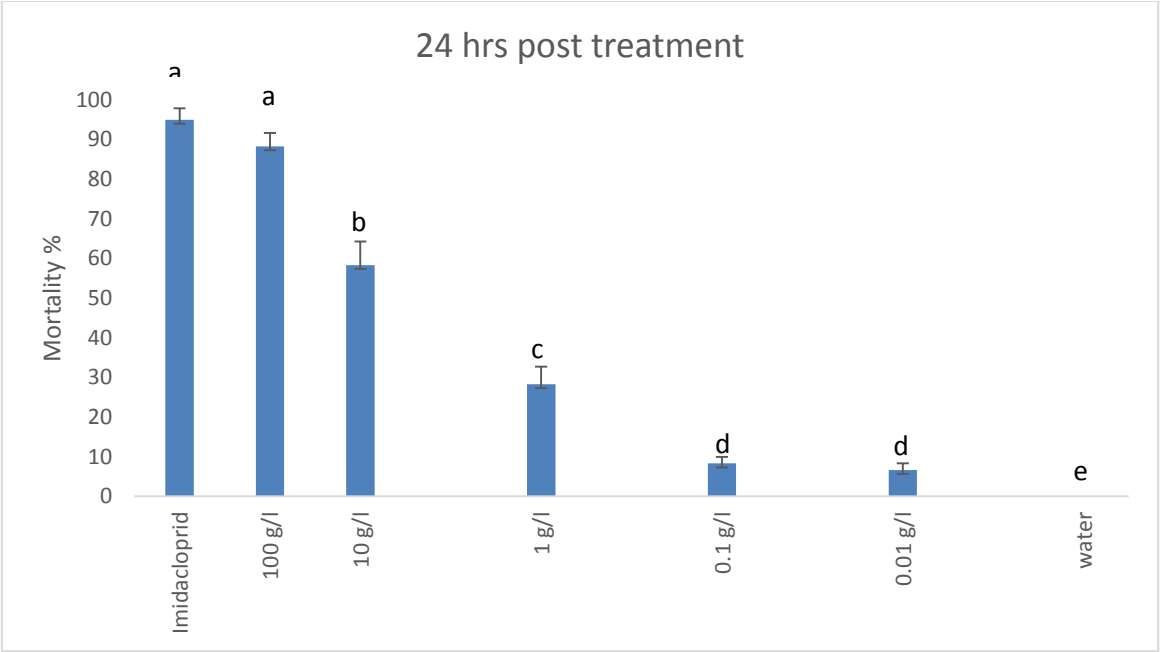

Figure 1. Percentages of mortality of peach trunk aphid exposed to different concentrations of *Ephidra sinica* aqueous extracts 24 hrs post treatment. Means with different letters are not significantly different using LSD at 95% CL after arcsine transformation.

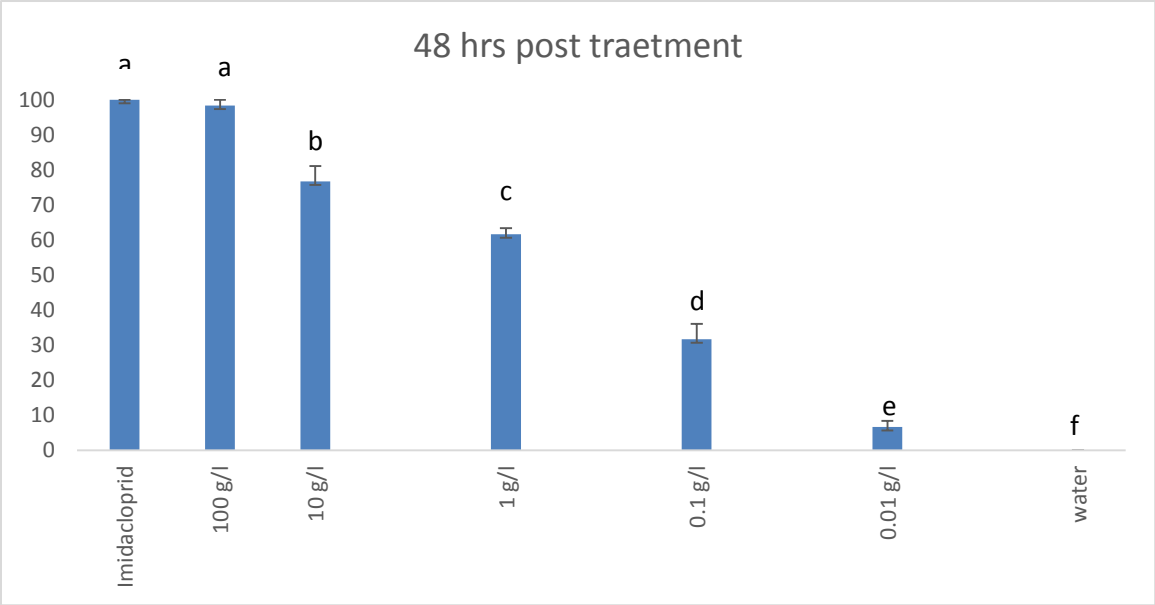

Figure 2: Percentages of mortality of peach trunk aphid exposed to different concentrations of *Ephidra sinica* aqueous extracts 48 hrs post treatment. Means with different letters are not significantly different using LSD at 95% CL after arcsine transformation.

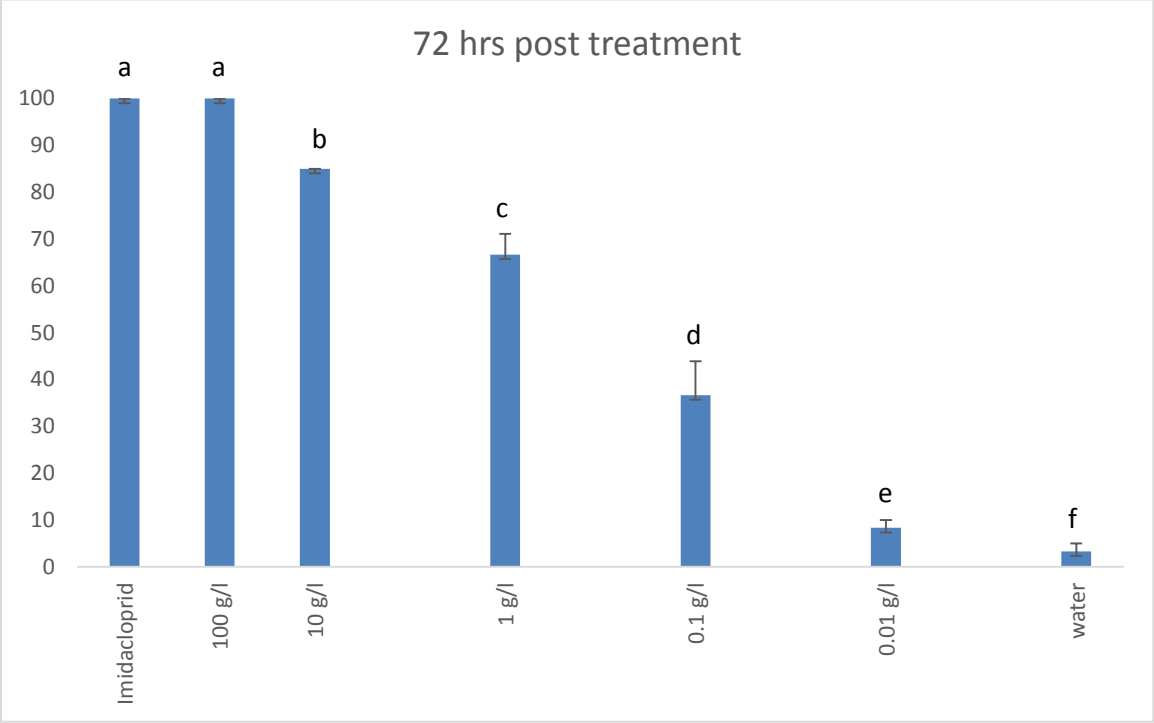

Figure 3: Percentages of mortality of peach trunk aphid exposed to different concentrations of *Ephidra sinica* aqueous extracts 72 hrs post treatment. Means with different letters are not significantly different using LSD at 95% CL after arcsine transformation.

Results show the requirement of huge amounts of Ephidra plants to be extracted to achieve a valuable control of PTA that may be related to the large size of this insect pest. This decrease its chance to use plant as botanical insecticide. However, the case may be different with other insects or pests. No studies on the insecticidal activity of this plant are available as far as databases show. Therefore, its mode of action on insects is not available, but Gurley et al. (1998) identified various alkaloid and non-alkaloid compounds, particularly ephedrine-type

alkaloids (ephedrine, pseudoephedrine, norephedrine, and methylephedrine). Mortality of PTA may be ascribed to these alkaloids.

Conclusion

Though ephedra used as a medicinal plant but the FDA in 2003 recommended consumers stop using ephedrine-alkaloids' products (FDA, 2007) due to registered cases of severe disability or sudden cardiac death caused by ephedra use (Haller, 2000). This opens the door for extended research to divert the attention of using this plant from medicinal plant to botanical insecticide as part of integrated pest management programs.

Abstract

Every year a lot of crop damage is caused by various diseases and among them fungal diseases are very common. The fungistatic and fungicidal effect of aqueous plant extracts were evaluated on several phytopathogenic fungi (*Fusarium oxysporum, Rhizoctonia solani, Alternaria alternata, Botrytis cinerea* and *Plasmopara viticola).* Fresh aerial parts of *Pinus nigra* J. F. Arnold, *Pinus sylvestris* L and *Juniperus communis* L. were collected for the preparation of aqueous extracts. The poisoned food method was used in the preliminary screening of aqueous extracts for their antifungal properties evaluation (for 20 and 10% of aqueous extracts of each plant), and broth-microdilution method was used to determine the minimal inhibitory concentrations (MICs) and the minimal fungicidal concentrations (MFCs) of the extracts (with 10% of starting test concentrations of aqueous extracts of each plant). This study showed that all the aqueous extracts obtained from the aerial parts of the tested plants had strong fungistatic and fungicidal activities against the phytopathogenic fungi. Anyway, the extract from *Juniperus communis* L. showed the strongest activity against *Alternaria alternata* with MICs of 2.5% and MFCs of 5%, and *Alternaria alternata* was shown as most sensitive fungus against tested plant extracts. The antifungal properties of *Pinus nigra* J.F. Arnold, *Pinus sylvestris* L and *Juniperus communis* L. make these plants of potential interest for the control of fungi affecting plant yield and safety. These preliminary results, obtained from *in vitro* experiments, may be supplemented by other more comprehensive studies *in vivo*, both in controlled greenhouse conditions and in open field to practically evaluate the use of these extracts.

Key words: *plant extracts, phytopathogenic fungi, poisoned food method, broth-microdilution method.*

Introduction

More than 800 million people in developing countries do not have adequate food supplies and at least 10% of food is lost due to plant diseases (Strange and Scott, 2005). In a hungry world with an increasing population, efforts are made at reducing crop loss due to pathogen fungi. Compared to other plant parasites, fungi cause the greatest impact with regard to diseases and crop production losses. In recent time, the application of synthetic fungicide proved effective in inhibiting growth of plant-pathogenic fungi and this increases the use tremendously, thereby causing a lot of harmful effects such as health and environmental problems. In the attempt to combat this, many countries have made rules and regulations in the use of fungicides. The uses of phytochemicals in the treatment of plant microbes have been found to be the better alternative. Increased public concern about the accumulation of pesticide residues in the biosphere and the development of resistance among pathogens against conventional antibiotics has led scientists toward the development of alternative strategies for plant disease suppression. Also, recently, public pressure to reduce the use of synthetic fungicides in agriculture has significantly increased (Shafique et al., 2007).

Biological control is a nature friendly approach that uses different bioactive compounds produced by other organisms that may act as suppressors or/and inhibitors in the

developments of phytopathogens. Natural product-based fungicides have the ability to decompose rapidly, reducing risk to the environment with the added advantage in that they have both unique modes of action and low mammalian toxicity (Duke et al., 2003; Ortiz et al., 2008). Plants have the ability to synthesize secondary metabolites highly active against the pathogen. These metabolites show antimicrobial effect and serves as plant defense mechanisms against pathogenic microorganisms.

Exploitation of naturally available chemicals from plants, which retards the reproduction of undesirable microorganisms, would be a more realistic and ecologically sound method for plant protection and will have a prominent role in the development of future commercial pesticides for crop protection strategies, with special reference to the management of plant diseases (Varma and Dubey, 1999; Gottlieb et al., 2002).

Considering these, in this work, we reported the *in vitro* antifungal activity of extracts from three plants against five important phytopathogenic fungi.

Materials and methods

Plant material

The needles of 50 year old *Pinus nigra* J.F. Arnold, *Pinus sylvestris* L. and *Juniperus communis* L. were collected during October 2013 (autumn season) from Berovo region in Macedomia. The needles from lower third of crown of ca. 30 randomly selected trees in each of the populations were collected. The plant parts were air-dried at room temperature for three weeks in dark conditions. The dried plant parts were milled to a fine powder in a mill.

Preparation of the plant aqueous extracts

First, stock aqueous extracts were obtained by soaking 20 and 40 g of air-dried and milled plant material in 100ml of distilled water (20% and 40% w/v) at room temperature (20 ± 2^0C) for 24 hours with occasional shaking. Then, the mixtures were filtered through two layers of cheesecloth and centrifuged for 20 min at 5.000 rpm to remove particulate materials. Finally, the extracts were stored in the refrigerator at 4^0C to be used in the future.

Test organisms

The target fungi were chosen to represent potential pathogenic fungi causing plant diseases. The fungi samples, *Botrytis cinerea* FNS- FCC 23, *Fusarium oxysporum* FNS- FCC 103, *Plasmopara viticola* FNS- FCC 65, *Alternaria alternata* FNS- FCC 624, *Rhizoctonia solani* FNS- FCC 218 were provided from the Culture Collection of the Department of Microbiology and Microbial Biotechnology, Faculty of Natural Sciences and Mathematics, Skopje, Macedonia. Fungal cultures of phytopathogenic strains were kept on Sabouraud Dextrose Agar (SDA) at 4^0C.

Inoculum disc

Seven days old culture of the test fungi were used for the preparation of inoculum disc of 5 mm in diameter.

The poisoned food method

This technique involves the poisoning of the fungal growth medium using antifungal agent and then measuring the reduction of growth of the organism on the medium. The decrease in mycelial growth indicates the inhibition of fungal growth by the antifungal substance (Ali-Shtayeh and Abu Ghdeib, 1999; Mukherjee and Raghu, 1997; Kumar et al., 2013). The extracts were incorporated into the molten Sabouraud Dextrose agar at a desired final concentration (20 and 10% of aqueous extracts of each plant) and mixed well. Then, the medium was poured into Petri dishes. After overnight pre-incubation, the inoculation was by a mycelia disc of 5 mm, which was deposited in the center of the plate. After further incubation under suitable conditions for the fungal strain tested (25 ± 1°C/ five days) the diameters of fungal growth in control and sample plates were measured, and the antifungal effect was estimated by the following formula:

$$\text{Antifungal activity}(\%)=((Dc-Ds)/Dc)\times 100$$

Where Dc was the diameter of growth in control plate and Ds was the diameter of growth in the plate containing tested antifungal agent.
Five replications were maintained for each isolate and the mean values were calculated.

Broth-microdilution assays

Antimicrobial activity was tested using broth microdilution method, where minimum inhibitory concentrations (MIC) determination was performed by a serial dilution method in 96 well microtitre plates. Cultures of fungal species were maintained on Sabouraud Dextrose agar at appropriate optimal temperature.
After 5 days of cultivation, fungal suspensions were made in Sabouraud Dextrose broth and their turbidity was standardized using McFarland 0.5. Each well contained the final fungal concentration of 10^6 CFU/mL.
Stock solutions of the extracts was 20% (w/v) and than serially diluted. The tested concentrations of extracts were within 10- 0.078125% (w/v). After making dilutions of the extracts, the inoculum was added to all wells and the plates were incubated at 25±1°C for seven days. To ensure medium sterility, each plate contained one non-inoculated well without extract. Experiments were performed in triplicate against each fungus. MIC was defined as the lowest concentration of extracts at which microorganisms showed no visible growth after seven days. Determination of minimal fungicidal concentrations (MFC) was performed by inoculation of broth taken from all clear wells on Sabouraud Dextrose agar, which were further incubated for seven days at 25±1°C. The MFC was defined as the lowest concentrations of the extracts at which inoculated microorganisms were killed.

Results and discussion

Phytopathogenic fungi are the most problematic pests of agricultural crops worldwide (Savary et al., 2006). *Aspergillus flavus*, *Alternaria alternata* and *Botrytis cinerea* are among the prevalent pathogens causing diseases in many economic crop species.
Plants produce many kinds of low-molecular-mass secondary metabolites that are generally non-essential for the basic metabolic processes of the plant.
In the current study, we evaluated the antifungal activity of plant extracts on some phytopathogenic fungi. The effect of 20 and 10% of aqueous extracts of each plant (*Pinus nigra* J. F. Arnold, *Pinus sylvestris* L and *Juniperus communis* L.) on the radial growth rate of the tested fungal species is presented in Table 1.

Table 1. Fungal growth inhibition (in percentage) by the extracts of the tested plants on phytopathogenic fungi.

		Botrytis cinerea FNS- FCC 23	*Fusarium oxysporum* FNS- FCC 103	*Plasmopara viticola* FNS- FCC 65	*Alternaria alternata* FNS- FCC 624	*Rhizoctonia solani* FNS- FCC 218
Pinus nigra J. F. Arnold	10%	68.2	70.4	45.4	72.1	54.5
	20%	78.5	74.6	54.9	84.3	62.3
Pinus sylvestris L	10%	66.3	69.1	52.2	76.3	65.9
	20%	74.2	77.3	61.9	84.8	72.1
Juniperus communis L.	10%	75.9	78.3	63.3	87.3	75.8
	20%	81.2	82.0	71.5	97.8	88.4

This study showed that all the aqueous extracts obtained from the needles of *Pinus nigra* J.F. Arnold, *Pinus sylvestris* L. and *Juniperus communis* L. have antimicrobial properties. All the

extracts showed inhibition effects on the growth of the test fungui (Table 1). Among the tested plant species, *Juniperus communis* L. markedly inhibited the fungus growth even at a 10% of concentration. The inhibition of the mycelial growth of the test fungi was found to be 63.3 to 97.8 percent by the extract of *Juniperus communis* L.; 52.2 to 84.8 percent by the extracts of *Pinus sylvestris* L; and 45.4 to 84.3 percent by the extracts of *Pinus nigra* J. F. Arnold at the concentration of 10 and 20%. The extracts of *Juniperus communis* L. was found to be most effective for the control of the test fungi.

The inhibition in the radial growth rate was concentration dependent, and *Alternaria alternata* FNS- FCC 624 was shown as most sensitive fungus against tested plant extracts, with growth inhibition of 97.8% by 20% of extract from *Juniperus communis* L.

The MICs of aqueous extracts of plants were determined using a broth dilution micromethod in 96-well round-bottomed polystyrene microtiter plates. Broth- microdilution method is the most appropriate one for the de termination of MIC values, since the method offer the possibility to estimate the concentration of the tested antimicrobial agent or extract in each well in 96-well microtitration plate. Microbial growth was determined by visual readings and the MIC was considered as the lowest concentration of each extract at which there was no microbial growth after seven days of incubation.

Table 2. Minimal inhibitory concentrations (MIC) and minimal fungicidal concentrations (MFC) of tested plant extracts against phytopathogenic fungi.

		Pinus sylvestris L.	*Juniperus communis* L.	*Pinus nigra* J.F. Arnold
Alternaria alternata FNS- FCC 624	MIC	2.5%	2.5%	5%
	MFC	10%	5%	10%
Fusarium oxysporum FNS- FCC 103	MIC	5%	5%	5%
	MFC	10%	10%	10%
Botrytis cinerea FNS- FCC 23	MIC	5%	2.5%	5%
	MFC	10%	10%	10%
Plasmopara viticola FNS- FCC 65	MIC	5%	5%	5%
	MFC	10%	10%	10%
Rhizoctonia solani FNS- FCC 218	MIC	5%	5%	5%
	MFC	10%	10%	10%

The *in vitro* evaluation for antifungal activity of aqueous extracts of tested plants at different concentrations revealed that 10% concentration completely killed all tested phytopathogenic fungi, and 5% concentration inhibited the growth of fungi. The results from Table 2 showed that *Alternaria alternata* FNS- FCC 624 with MICs of 2.5% and MFCs of 5% was most sensitive fungus against tested plant extracts and the extract from *Juniperus communis* L. showed the highest antifungal activity among all three plants. The fungitoxic effects of the extracts indicate the potential of these plant species as a natural source of fungicidal material.

Ortiz et al. (2007) found that the ethanolic extracts from the aerial parts of *Juniperus lucayana* Britton exhibited antifungal activity against *Botrytis cinerea*. This fungus is a serious pathogen that attacks economically important crops (Aleu et al., 2001; Daoubi et al., 2005). *Juniperus* species have been extensively investigated as a source of natural products with potential antimicrobial, acaricidal and insecticidal activities (Karaman et al., 2003; Schmidt, 2004; Barrero et al., 2005).

Also, reports are available on antifungal activity of pine (*Pinus sylvestris* L.) and spruce (*Picea abies* L.) extracts and essential oils against a wide range of fungi: Fusarium culmorum, F. poae, F. solani (Krauze-Baranowska et al., 2002). Natural substances of plant origin, like plant extracts and essential oils may be promising, because plant extracts are effective against phytopathogens (Albouvette et al., 2006; Koul et al., 2008), their extraction is not complicated and time-consuming and extracts do not pollute the environment (Zarins et al., 2009).

Conclusion

The aqueous extracts obtained from the needles of *Pinus nigra* J.F. Arnold, *Pinus sylvestris* L. and *Juniperus communis* L. exhibited good antifungal activities and were capable of reducing growth of tested phytopathogenic fungi. The tested plant aqueous extracts could serve promising and potential raw materials in industry for producing natural antifungal agents with potential applications in agriculture for controlling the pathogenic fungi.

These preliminary results, obtained from *in vitro* experiments, may be supplemented by other more comprehensive studies *in vivo*, both in controlled greenhouse conditions and in open field to practically evaluate the use of these extract in the frame of an Integrated Pest Management System. Also, it is of great interest to deepen our knowledge about the molecular mechanisms of action of plant aqueous extracts not only against microorganisms, but even on plant biology.

Abstract

The use of plant protection products has been the most effective way to protect crops against pests. The basic aim of the spraying operation is to achieve the highest possible effectiveness in combating pests. This effectiveness, as well as the level of pesticide consumption and safety during the treatment, depends largely on the quality of spraying usable liquid. One of the three determinants of the quality of the treatment is the degree of coverage of the sprayed objects. The quality of the treatment is influenced by many technical and technological factors, among them nozzles used. This study about the degree of coverage on sprayed objects using selected nozzles assessed which of the tested sprays had the best properties in terms of covering both horizontal and vertical surfaces on sprayed plants. The tests were carried out in laboratory conditions. The object was an artificial plant, to which water-sensitive papers were attached vertical and horizontally and sprayed surfaces were determined. After the experiment, the probes were subjected to computer image analysis. On the basis of the analysis of the obtained test results, it was found, that the characteristic feature for tested nozzles was the range in the degree of coverage of surfaces marked as vertical and horizontal.

Keywords: *degree of coverage, nozzle, quality of spraying*

Introduction

Users of sprayers have a problem to find appropriate nozzles for the spraying procedure. The right choice of nozzles such as the type and size determines a highly effective spraying. On the basis of the research, it was shown that the nozzles have a direct influence on the quality of the treatment (Nuyttens et al. 2009; Őzkan 2008; Szewczyk et al. 2013). It is also important to adopt the appropriate technical and technological parameters in order to achieve a successful treatment. One of the three indicators to assess the quality of the procedure is the degree of coverage (Abbaspour-Fard et al. 2008, Cunha i in. 2012, Fox i in. 2003, Lipiński, Lipiński 2009, Thomson, Lyn 2011). The authors emphasized in their work that it is a practical and accurate method.

Therefore, at the Institute of Agricultural Engineering of the University of Environmental and Life Sciences in Wrocław, tests were carried out to assess the degree of coverage when spraying with double-stream nozzles.

Materials and methods

The experiments were executed in 2018 in real conditions. Coverage tests were carried out on a test stand, which scheme is presented on Figure 1.

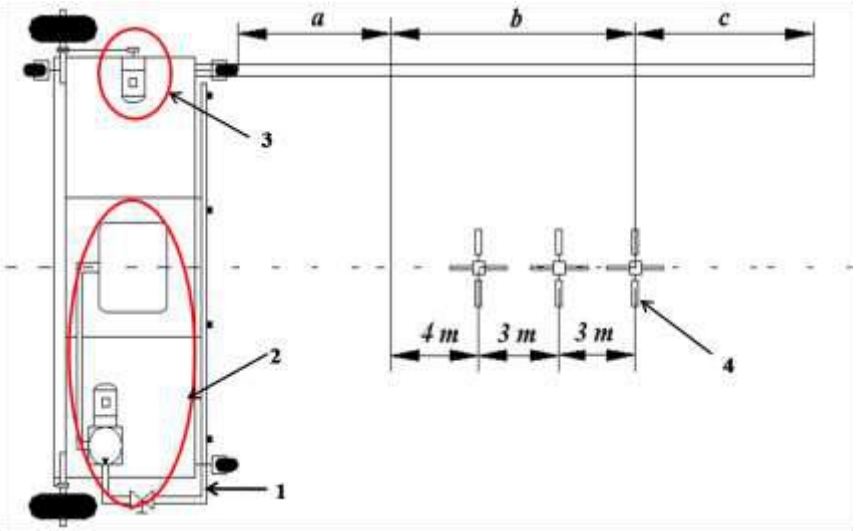

Fig. 1. Scheme of the test position for the degree of coverage for the sprayed objects a – acceleration section, b – measurement section, c – final section 1 –carrier nozzles, 2 – driving system of carrier nozzles, 3 – liquid system of carrier nozzles 4 – artificial plant

The primary element measurement stand was a nozzle carrier, which is equipped with both driving and liquid spraying systems. The carrier nozzles was moved in a straight line on the designated route. The road that the carrier traveled was divided into three parts, the run-up section, on which the carrier obtained the set speed, the measuring section, and the ending section, where the carrier lost speed and stopped. Three artificial plants were placed in the measurement section, to which water-sensitive papers were attached on horizontal (top and bottom) and vertical (approach and leaving) surfaces (fig. 2).

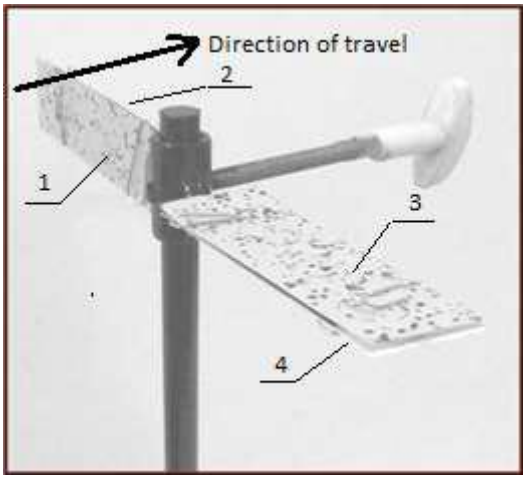

Fig. 2. Water sensitive papers were attached to four collector plant zones: 1 - the vertical transverse approach surface, 2 - the vertical transverse leaving surface, 3 - the horizontal upper level surface, 4 - the horizontal bottom level surface

The research involved the use of ejector double-stream nozzles, which differ in the way of liquid emission, asymmetrical AI 3070 11003, symmetrical AITTJ 60 11003 and TTI 60 11003 (Fig. 3).

AI 3070 11003 AITTJ 60 11003 TTI 60 11003

Fig. 3. Nozzles used in research

The following parameters and working conditions of the sprayers were adopted for the tests:
• Set speed - 6 km · h^{-1}
• Liquid pressure - 0.2; 0.3; 0.4 MPa.
During the tests, the wind speed was approx. 2 m · s^{-1}. In order to assess the degree of coverage, water-sensitive papers subjected to computer image analysis. Three fragments with a surface area of 1 cm^2 were randomly selected on the scanned paper, randomly sized and the surface covered with working liquid was read in Adobe PhotoShop®. The degree of coverage was determined as the ratio of the surface of the paper covered with working liquid to the total surface area tested (1 cm^2).

Results and discussion

The test results are presented in figures 4 - 6. During the measurements there were no traces of coverage of the horizontal lower objects, therefore there are only shown the results of the three remaining surfaces. Raising the working pressure of the nozzles resulted in an coverage of individual surfaces. In all analyzed cases, the highest cover value was noted for the TTI 60 nozzle with symmetrical spray angles, and the lowest for the AI3070 nozzle with asymmetrical spray angles. Taking into account the vertical surfaces, it should be stated that the highest values of the driveway surface were obtained for the TTI60 nozzle, while the lowest for the AITTJ60 nozzle. However, in the case of covering the leaving surfaces, it can be noticed that similar values were noted for the TTI60 and AI3070 nozzle, while slightly lower values were obtained for the AITTJ60 nozzle.

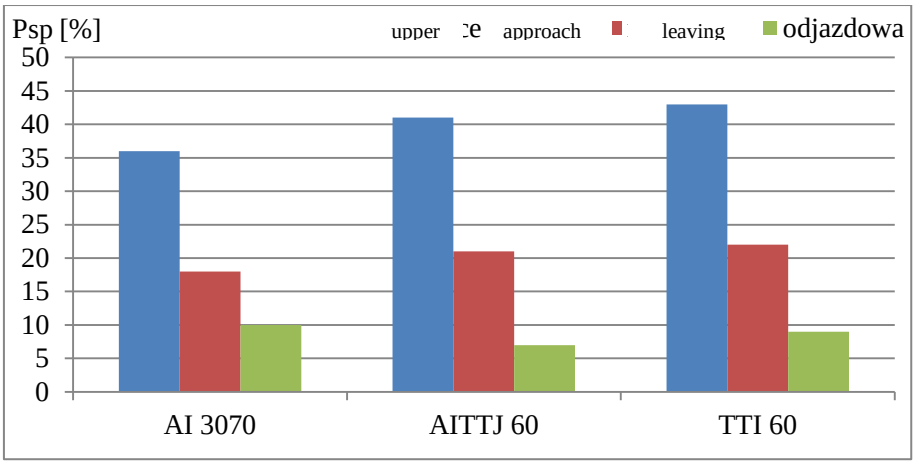

Fig. 4. The value of coverage degree of sprayed objects during spraying with selected nozzles at a pressure of 0.2 MPa
upper

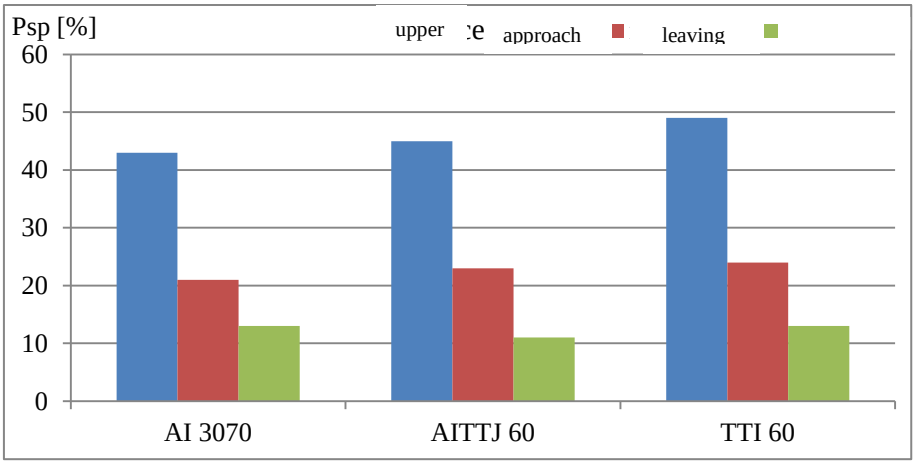

Fig. 5. The value of coverage degree of sprayed objects during spraying with selected nozzles at a pressure of 0.3 Mpa

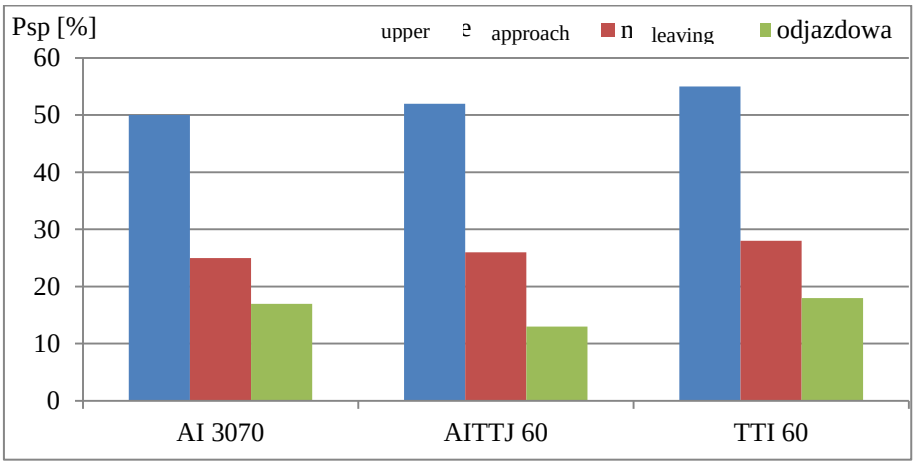

Fig. 6. The value of coverage degree of sprayed objects during spraying with selected nozzles at a pressure of 0.4 MPa

Interpretation of the obtained results is in line with what many researchers emphasize in their publications in relation to the importance of selecting the right nozzle for spraying as an important factor of work quality performed during plant protection treatments (Guler et. al. 2007).

Conclusions

On the basis of the conducted experiments and their analysis, the following conclusions were formulated:

1. The increase in pressure caused an increase in coverage of the analyzed surfaces.
2. The highest values of the degree of coverage on of the upper horizontal surface were obtained with the use of the ejector nozzle TTI 60, with symmetrical spray angles.
3. The highest values of degree of coverage of vertical surfaces were noted for the asymmetrical atomizer AI3070, with asymmetrical spray angles.
4. No traces of coverage were found on the horizontal bottom surface.

Abstract

Examination of pesticidal effect of essential oil in agriculture is increasingly important due to tendency to reduce use of synthetic pesticides. The aim of this study is to determine allelopathic effect of *Cannabis sativa* L. essential oil on the initial development of selected vegetable species. Applied concentrations are 200□l/l, 400□l/l, 600□l/l i 800□l/l. Used vegetable species are *Allium cepa* L., *Solanum lycopersicum* L. and *Daucus carota* L., while observed parameters are length of hypocotyl and epicotil. Experiment was carried out in laboratory conditions, each variant of experiment had two repetitions, control variant used distilled water. By processing data, all applied concentrations attach inhibitory effect to monitored parameters. Highest inhibitory effect on average length of hypocotyl *A. cepa* L. of 2,73mm had highest applied concentration of essential oil of 800□l/l, as opposed to 9,97mm in control. Length of epicotil *A. cepa* was 13,6mm in control, while the highest inhibitory effect gave the highest concentration of essential oil with a length of 2,4mm. Length of hypocotyl *S. lycopersicum* L. was 30mm in control while in variant with 600□l/l it recorded the highest inhibitory effect with a length of 10,67mm. Length of epicotil *S. lycopersicum* L. in control was 13,03mm while in variant with 600□l/l was 3,2mm. Length of hypocotyl *D. carota* L. in control was 8,73mm while concentraion of 200□l/l gave the highest inhibitory effect with length of 5,97mm. Length of epicotil *D. carota* was 16,3mm in control but varianth with 200□l/l gave the highest inhibitory effect with 11,07mm.

Key words: *essential oil, Cannabis sativa L., Allium cepa L., Solanum lycopersicum L., Daucus carota L.*

Introduction

According to some estimates, weeds can reduce the yield of world production by 10-15%, which amounts to about 300 milion tons of food annually (Kojić i Janjić, 1994). In addition to unwashed weed plants that cause losses to agricultural production and certain cultivated plants in other crops, they can significantly reduce the yield of crops grown (Kojić et al., 1996). *Cannabis sativa* L. except that the cultivated species can also be found on roderal habitats, on arable land in crops, perennial fodder plants, orchards, but also in vegetable crops (Vrbničanin, 2015). Among the many negative effects that the weed species have on cultivated crop, they can cause allelopathic effects with their secondary metabolites. Allelopathy refers to the relationship between the two organisms where one organism influences positively or negatively on another with its secondary metabolites (Farooq et all, 2013). Tests of allelopathic relations between weeds and cultivated plants are very important for sustainable agricultural production (Marinov-Serafimov, 2010). Plant species in which allelopathic effects have been shown to a large number of cultivated species are: *Ambrosia artemisiifolia* L., *Avena* sp., *Amaranthus retroflexus* L., *Cyperus esculentus* L., *Chenopodium*

album L., *Helianthus tuberosus* L., *Rumex crispus* L., *Sorghum halepense* (L.) Pers., *Xantium strumarium* L. (Šćepanović et al., 2007). The repellant and pesticidal effects of certain *Cannabis sativa* L. compound (McPartland, 1997) have also been reported, and since it can also be reported as crop in crops, it is necessary to determine its allelopathic effect on cultivated plants. For the examination of allelopathic effects, biotests derived in laboratory conditions were used, since they are of high sensitivity and are performed in a relatively short time (Mahmoodzaden et all, 2015).

The aim of this paper is to determine the allelopathic effect of *Cannabis sativa* L. essentia oil on the initial development of vegetable species: *Allium cepa* L., *Solanum lycopersicum* L. and *Daucus carota* L. in laboratory conditions.

Material and method

An overgrown part of the plants, stems, leaves, fruits of *Cannabis sativa* L. harvested during the period of ripening in 2016, was collected. Work in the laboratoryws carried out during 2017, with the plant material being first crushed by a blender. In the process of hydro-distillation, 60g of ground plant material was boiled in 800ml distilled water for 2h and 30min. *Cannabis sativa* L. essential oil obtained by this process was used to treat seeds of examined vegetable species in concentrations of □□□□l/l, □□□□l/l, □□□□l/l i □□□□l/l (Rahimi et all, 2013). Fifteen seeds of vegetable species (*Allium cepa* L., *Solanum lycopersicum* L., *Daucus carota* L.) were placed in Petri dishes (diameter 6cm) with filter paper in two repetitions. Then dishes were packed with 5ml of dilution from each concentration of essential oil while distilled water was used in control (Rahimi et all, 2013). Upon completion of the experiment, the length of hypocotyl and epicotilles of seeds in each Petri dish were measured.

Results and discussion

Influence of *Cannabis sativa* L. essential oil on *Allium cepa* L.

Inhibitory effect of esential oil was observed when monitoring perameters of initial development of plant species *Allium cepa* L.. Increasing concentration of essential oil increased inhibitory effect on length of hypocotile and length of epicotile. Control variant yielded an average length of hypocotil of 9,97mm while variation with a concentration of essential oil of 800□l/l was 2,73mm. The smallest inhibitory effect was in appplication of 400□l/l where average length was 7,03mm. Average length of epicotill of *Allium cepa* L. also indicates inhibitory effect of essential oil. Average length of epicotill of 2,4mm was recorded in a variant with the use of 800□l/l of essential oil as opposed to control in which was 13,6mm. The weakest inhibitory effect was recorded by variant with use of 400□l/l essential oil where an average length of 8,3 was recorded. Average length of hypocotyl and epicotil *A. cepa* L. in different variant experiment are shown in Table

Table 1. Average length of hypocotyl and epicotil (expressed in mm) of *Allium cepa* L., *Solanum lycopersicum* L. and *Daucus carota* L. depending on concentration of *Cannabis sativa* L. essential oil used.

Plant species	Length of hypocotyl					Length of epicotyl				
	□□l/l	□□□□l/l	□□□□ l/l	□□□□ l/l	□□□□ l/l	□□ l/l	□□□□l/l	□□□□l/l	□□□□l/l	□□□□l/l
Allium cepa L.	9,97	6,13	7,03	3,23	2,73	13,6	7,2	8,37	3,67	2,4
Solanum lycopersicum L.	30	16,83	18,97	10,67	18,63	13,03	7,43	6,4	3,2	5,7
Daucus carota L.	8,73	7,27	8,3	6,27	5,97	16,3	12,27	14,1	11,1	11,07

Pavlovski et al. (2013) examined effect of essential oil of plant species *Schinus lentiscifolius* March. on germination and initial development of *A. cepa* L. and showed an inhibitory effect on parameters monitored.

Influence of Cannabis sativa L. essential oil on *Solanum lycopersicum* L.

Essential oil in all variants showed an inhibitory effect on *Solanum lycopersicum* L.. The greatest inhibitory effect was observed in variation in which 600□l/l was applied were average length of hypocotile was 10,67mm while in control was 30mm. The smallest inhibitory effect had a variant with 400□l/l with an average length of hypocotil of 18,97mm. Average length of epicotile *S. lycopersicum* L. in control variant was 13,03mm, while in variant with 600□l/l of essential oil it was 3,2mm. The smallest inhibitory effect was observed in variant with use of 200□l/l essential oil and amounted to 7,43mm. Average length of hypocotil and epicotile of *S. lycopersicum* L. in different variant experiment are shown in Table 1..

Ali and all (2016) investigated effect of *Rosmarinus officinalis* L., *Thymus vulgaris* L. and *Pimpinella anisum* L on *S. lycopersicum* L. essential oils and conclude that different allelopathic effects on tested germination parameters and initial development of investigated species.

Influence of *Cannabis sativa* L. essential oil on *Daucus carota* L.

Applied concentrations of *Cannabis sativa* L. essential oil to *Daucus carota* L. showed an inhibitory effect on both of investigated initial development parameters. Average length of hypocotil *D. carota* L. in control was 8,73mm while the lowest concentration of essential oil produced the strongest inhibitory effect, with average lengthin that case of 5,97mm. The weakest inhibitory effect was the concentration of essential oil of 600□l/l and length of hypocotil in that variant was 8,3mm. The same effect was observed when monitoring second parameter, length of epicotile. Average length of epicotil in control variant treated with distilled water was 16,3mm, while in variant with 200□l/l was the strongest inhibitory effect and length of 11,07mm. The weakest inhibitory effect on average length of epicotil *D. carota* L. in different variant experiment are shown in Table 1..

In 2014, Aslani and all proved inhibitory effect of the methanol extract of *Tinospora tuberculata* L. on *Daucus carota* L..

Conclusion

Based on conducted experiment, inhibitory allelopathic effect of *Cannabis sativa* L. essential oil on initial development of selected vegetable species is clearly observed. All ivestigated concentrations led to inhibition of growth of hypocotil and epicotill. Obtained results indicate ability of *C. sativa* L. species to reduce development of examined vegetable species *Allium cepa* L., *Solanum lycopersicum* L. and *Daucus carota* L. with their secondary metabolites if they are found in their crop as a weed. The results of the experiment should also be taken into account when organizing crop, if *C. sativa* L. sowing is planned and the vegetable species tested on the same plot.

Abstract

The aim of this study was to identify isolates within the pathogenic species of *Leptosphaeria maculans* and *Leptosphaeria biglobosa*, based on the pathogenicity and phytotoxin production. The fungus cultures were isolated from rapeseed plants showing the symptoms of stem canker. They were collected from nine locations in rapeseed growing region of northern Serbia. In the study were used 119 local isolates from Serbia and two reference isolates from the Center for Agricultural Research, Rothamsted, Great Britain, (L. m. for *Leptosphaeria maculans*, and L. b. for *Leptosphaeria biglobosa*). The pathogenicity of the isolates was examined on the Westar, Glacier and Quinta rapeseed cultivars. Eight isolates caused small necrotic spots on cotyledons in all tested cultivars, while 111 caused large necrotic spots in which the formation of pycnidia was observed. Four local isolates (K-113, C-3, St-5 and S-11) and reference isolate L.m. were used for the extraction and isolation of phytotoxins, based on their morphological and pathogenic characteristics. Isolates C-3, St-5, S-11 and L. m. did not produce a yellow brown pigment in the Czapek medium but produced sirodesmin PL while the K-113 isolate produced a yellow brown pigment and did not produce sirodesmin PL.

Keywords: *Leptosphaeria maculans*, *Leptosphaeria biglobosa*, rapeseed, phytotoxin**.**

Introduction

Leptosphaeria maculans (Desm.) Ces and De Not (anamorph: *Phoma lingam* (Tode ex Fr.) Desm.) cause dry (black leg) on oil rapeseed worldwide. Desease is economically very important in Europe, Australia and Canada (West *et al.*, 2001). The appearance of the disease to a greater or lesser intensity depends on climatic factors, cultural practices and varieties resistance (Howlett, 2004; Aubertot *et al.*, 2006; The population of *L.maculans* can be divided into at least two subgroups,which are termed as virulent or avirulent (McGee & Petrie 1978 Koch *et al.*, 1989 Badawy & Hoppe 1989),Tox^{+} or Tox^{0} (Balesdent *et al.*, 1992),A or B (Johnson and Lewis 1994). Aggressive isolates (group A or Tox^{+}) induce grey-green,sporulating lesions on leaves and destructive stem canker while non-aggressive isolates (group B or Tox^{0}) cause leaf spot and superficial stem lesions (Koch *et al.*, 1989; Badawy *et al.*, 1991; Williams, 1992; Thürwächter *et al.*, 1999). Brun *et al.*, (1997) and Williams and Fitt (1999) indicated that group A is highly virulent, while group B is slightly virulent. Koch *et al.*, (1991), Mengistu *et al.*, (1991) & Kutcher *et al.*, (1993) have studied the virulence of different isolates of *L. maculans* on three varieties of oil rapeseed (Westar, Quinta and Glacier) and classified them into four pathogenic groups. Group B was then isolated and identified as a new species called *Leptosphaeria biglobosa* (Shoemaker and Brun, 2001). A number of plant pathogens produce secondary metabolites (toxins) in order to obtain nutrients from plant cells. In some fungi, the toxins have potential toxicity or carcinogenic properties that could endanger the health of humans, animals and plants.(Bohnert *et al.*, 2010) In some cases, toxins cause death of plant cells to release nutrients or disrupt plant metabolism in favour of the pathogenic fungi. (Howlett, 2006). Many selective toxins play a role in the virulence of pathogenic fungi(Howlett, 2006; Wolpert, 2002) The role of non-selective toxin

in virulence is complex and the production of toxins is not always correlated with virulence (Elliott *et al.,* 2007). Sirodesmin PL, the product of the pathogenic fungus *Leptosphaeria maculans*, belongs to the class of epipolythiodioxopiperazines (ETPs), and is characterized by the presence of disulphide bridges (Gardiner *et al.,* 2004; Gardiner *et al.,* 2005) The diketopiperazine ring originates from cyclic dipeptides and sulphur bridges are responsible for all the known toxic effects of these molecules (Mullbacher *et al.,* 1986). Gardner *et al.,* (2005) stated that disulphide bridges are a key structural element for the creation of a variety of reactive forms of oxygen and for connection with the cysteine residues of proteins. It is assumed that the toxicity of ETPs could be explained by these reactions. Sirodesmin PL is a non-selective toxin that causes chlorosis and necrosis, inhibits root growth and leads to the extinction of plant cells (Badawy *et al.,* 1989; Fox and Howlet, 2008). In addition, these compounds have antibacterial and antiviral properties. (Rouxel *et al.,* 1988). The aim of this study was to identify isolates within the pathogenic species of *Leptosphaeria maculans* and *Leptosphaeria biglobosa*, based on the pathogenicity test and to perform crude separation of fungal toxins using preparative TLC on silica-gel plates, and to identify individual toxins using HPLC cupled with a tandem mass-spectrometric detector (LC–MS–MS).

Materials and Methods

Isolation of fungi and obtaining monospore culture

Infected plants of oilseed rape were collected during 2009/10 in the region of Vojvodina, Serbia. Diseased plant organs (root, basal and upper stem, leaf, flower, pod and seed) with clearly defined symptoms of the disease were used for the isolation of the fungi. Diseased tissue fragments were soaked in a 3 % solution of sodium hypochlorite for 5–10 min and then washed with sterile water and naturally dried under controlled conditions. After drying, the fragments of diseased tissue were applied to the culture medium of potato dextrose agar (PDA) (Difco, Detroit, USA) that had previously been poured into petri plates. To prevent bacterial growth in the medium, 50 mg of streptomycin sulphate (Galenika, Belgrade, Serbia) was added per litre. The inoculated petri plates were incubated at 25±1°C. After 5 to 10 days, the formation of pycnidia and pycnidiospores was observed under a stereo microscope. Pure cultures were obtained by the following procedure: pycnidiospores, which were released from pycnidia serving as a single droplet originating from the culture media, were transferred with the tip of a spear needle into plastic tubes to which 2 mL of sterile water had previously been added. The prepared suspension of conidia was applied onto the aqueous agar medium, which had previously been poured into petri plates. After 48 h, germination of the conidia was observed under a stereo microscope. The germinated conidia, together with fragments of the substrate, were transferred onto PDA medium in petri plates and placed in an incubator at 25°C in order to develop monospore fungal isolates. In this way, 119 isolates of fungi were obtained. All isolates were analysed at the morphological and molecular level. Based on morphological(colony appearance, shape, size and colour of the pycnidia and picnospores (Punithalingam and Holliday, 1972; Fitt *et al.,* 2006) and molecular characteristics (Polymerase Chain Reaction – Restriction Fragment Lenght Polymorphism, PCR–RFLP Balesdent *et al.,* 1998) it was determined that 111 isolates belonged to *L. maculans* and 8 to *L. biglobosa* (data not shown). Using the method of random selection, four isolates (three of L. maculans, St-5, C-3 and S-11, and one of *L. biglobosa*, K-113) were taken for further research.

Phytopathogenic test

The pathogenicity of the isolates (total of 119 iolates from serbia and two isolates from the Centre for Agricultural Research, Rothamsted, UK designated L.m. - *Leptosphaeri maculans* and L.b - *Leptosphaeri biglobosa*) hes been examined by the method of Koch *et al.,* (1991), Chen and Fernando (2006). Seeds were disinfected by dipping in 3% solution of sodium-

hipohlorite (NaOCl) for 3 to 5 min. and then washed with tap water and dried at room temperature under controlled conditions. The success of disinfection was tested on PDA nutrient medium. Disinfected seeds of varieties Westar, Quinta and Glacier were applied in two Petri dishes, and not disinfected seeds of listed varieties were used as controls. In each box was placed 5 seeds. Thus prepared Petri dishes were placed in a thermostat at 25°C ± 1°C in the dark. After 15 days was carried out visual and microscopic examination of the seeds and substrate, after which the seeds were placed in a germination chamber. Germinated seeds were sown in plastic containers with a diameter of cells 4 × 5 cm, which were previously filled with sterile substrate. Each cell was seeded by one germinated seed. After germination (6-7 days), when the cotyledons separated, inoculation was performed as follows: sterile needle was used to injure one cotyledon, while the other cotyledon was not injured. Injured part was inflicted by micropipette with 5 μl (10^6) suspension of pycnospores. After inoculation, plants were transferred to controlled conditions at a temperature of 20ºC, 95% RH and 12 h photoperiod. After 48 h the plants were placed in greenhouse conditions. During follow-up of symptoms true leaves were removed several times. Symptoms were rated after 15 days. using the scale – (no symptoms), + (slight lesions), ++ (moderate lesions), +++ (severe lesions). As a negative control, a variety of glacier was used where distilled water was applied to cotyledons.

Extraction and isolation of phytotoxins

Four isolates of L. maculans were used for the extraction and isolation of the phytotoxins. Three isolates (C-3, St-5 and S-11) originated from Vojvodina and the fourth, designated L.m. (*L. maculans*) and serving as the reference isolate, was received from the Centre for Agricultural Research, Rothamsted, UK. In addition, an *L. biglobosa* culture (designated K113) was prepared as a known negative. All five isolates were sown in Czapek liquid medium, 16 which had previously been poured into tubes. The tubes were placed in a climate chamber at 20°C with 12 h photo period. After 30 days, the cultures were filtered to separate the fungus mycelium from the liquid medium.Culture extracts were prepared and purified according to previously published procedures, (Koch *et al.*, 1989, Pedras and Bisesenthal, 2001) using a thin layer chromatography (TLC) fractionation, with double elution. The culture filtrate was first extracted with ethyl acetate (6 mL of ethyl acetate per 5 mL of filtrate). The organic extract was dried with anhydrous sodium sulphate. After removal of sodium sulphate by filtration through a qualitative filter paper, the samples were evaporated under a stream of nitrogen. The residue was redissolved in 100 μL of chloroform at room temperature. The chloroform solution was applied on an analytical TLC plate (Macherey-Nagel, Silicalgel G-25 UV_{254}, glass plates, 20 × 20 cm × 0.25 mm) using a glass capillary and the plate was developed using ethyl-acetate : chloroform (1:1) as the eluent. After drying, the plate was examined under UV light et 254 nm (Mitrović et al., 2012). According to the literature data, (Koch *et al.*, 1989, Badawy and Hoppe, 1989) spots that can be visually observed under the UV light at 254 nm, are unambiguously identified as phytotoxins Based on the preliminary results, a larger-scale experiment (with a greater amount of media) was set up with the purpose of preparative isolation of the observed phytotoxins (for the analysis of their chemical properties and phytotoxicity.). The final chloroform solution of the dry extract was applied to a preparative (prep.) TLC plate: (Macherey-Nagel, Silicagel G-200 UV254, glass plates, 20 × 20 cm × 2 mm), and the plate was developed in the binary eluent system, ethyl-acetate : chloroform (1:1). Three spots were identified under UV light at 254 nm, and designated as 1 (with retention time, Rf = 0.15), 2 (with retention time, Rf = 0.44) and 3 (with retention time, Rf = 0.60). The spots were removed from the TLC plate by scratching the silica gel layer, and individually extracted in absolute ethanol (20 mL) at room temperature with viguorously shaking for 2 h. The extract of TLC spot, designated as 2, was evaporated under a nitrogen stream, and then again applied on a preparative TLC plateand eluted,

according to the above mentioned procedure, yielding fractions 2a (Rf = 0.49), 2b (Rf = 0.40), 2c (Rf = 0.32) and 2d (Rf = 0.22). Spots were removed and ectracted according to the same procedure as described earlier. All subsequent extracts are were purified on a Sephadex column (SPE Bakerbond Sephadex G-25) previously conditioned with 10 mL of ethanol. The collected ethanolic filtrate was evaporated under a nitrogen-stream, and the dry residue was used in the identification of phytotoxins using the LC–MS–MS method.

LC–MS–MS characterization of phytotoxins

Chemical composition of isolated fractions was determined by reversed-phase high-performance liquid chromatography (Agilent Technologies Series 1200 Rapid Resolution liquid chromatograph) coupled with tandem mass spectrometric detection (Agilent Technologies Series 6410A Triple-Quad mass spectrometer with an electrospray ion source). 1 µl of undiluted sample was injected into the system. The components were separated using a Zorbax Eclipse XDB-C18 rapid resolution column 50 mm × 4.6 mm, 1.8 µm (Agilent Technologies), held at 40 °C. The samples were eluted using the gradient mode: 0 min 30 % B, 7–10 min 100 % B (phase A being 0.1 % aqueous formic acid and phase B – 0.1 % formic acid in acetonitrile) with a post time of 2.5 min. The mobile phase flow was 1 mL min^{-1}. The eluent was forwarded into the electrospray ion source (ESI) without flow splitting. The ESI parameters were as follows: nebulizer pressure 40 psi, drying gas temperature 350°C, drying gas flow 9 L min^{-1}, capillary voltage 4000 V and fragmentor voltage 100 V. All samples were analyzed in the MS2Scan mode (MS1 experiment), using positive polarity, in the m/z range 150–900. Afterwards, the representative sample (St-5/2b) was analyzed in the Product Ion Scan mode (MS2 experiment), using [M+H]+ of suspected sirodesmins peaks as precursor ions, and a collision voltage of 0–30 V (in 10 V increments). All the acquired data were processed using MassHunter Workstation-Qualitative Analysis software, ver. B.03.01 (Agilent Technologies).

Results and Discussion

Isolates of L.m, St-5 and S-11 were caused by chlorotic spot (+ slight phytotoxicity) after 5 days, while no change in cotyledones was observed in the K-113 isolates compared to the control variant. After 10 days, isolates L.m, St-5 and S-11 showed moderate phytotoxicity (++) except for K-113. After 15 days, isolates of L.m, St-5, S-11 caused the most severe lesions (+++) on cotiledons while K-113 was assessed as slight virulent (+) compared to the control variant (Figure 1). Expressed aggressiveness of the isolates in the conducted studies indicates that L.m, St-5 S-11 belong to the species *L.maculans* while K-113 *L.boglobosa* (Fitt et al 2006, West et al. 2001, Brun et al. (1997)

Figure 1. Pathogenicity of isolates on varieties Westar, Glacier and Qiunta

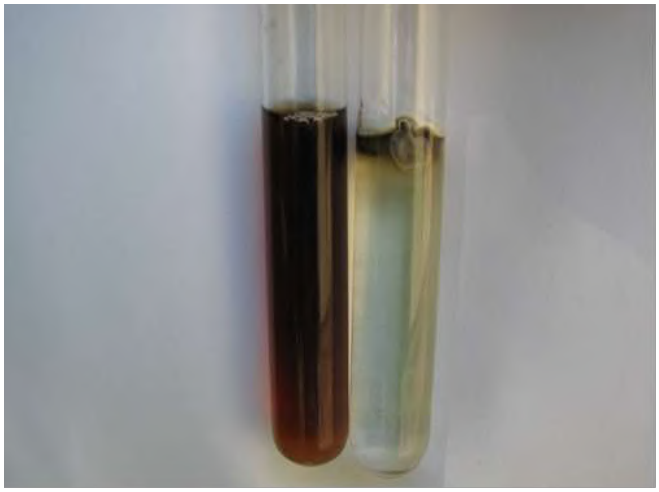

Figure 2: Production of pigment in Liquid Czapek medium

Isolates L.m., St-5, C-3, S-11 do not produce yellow pigment in Czapek liquid medium, compared to K-113 (Figure 2) The absence of yellow pigments in the examined isolates (L.m., St-5, C-3, S-11) classified them as a group of virulent (aggressive) isolates relative to K-113 which form pigments, which is in line with allegations (Williams & Fitt, 1999).

Chemical profile of L. maculans extracts

Since reference standards for sirodesmins were not available, the absolute concentrations of the detected compounds in the samples could not be determined. However, it was possible to compare the differences in content of each compound throughout the fractions. It was observed that the bulk of the identified sirodesmins were contained within the fraction (according to the spot from preparative TLC) designated 2b (Mitrović *et al.*, 2012). For the majority of compounds, only a small percentage was present in fractions 2a and 2c, with the exception of compounds with the strongest signals (sirodesmin PL, sirodesmin C and P444), that diffused into 2c spot to a greater extent. Another exception is P318 (phomamide), which occurs exclusively in fraction 1. Fractions 2d and 3 were practically devoid of sirodesmins (Figure 3, Table 2).

Due to differences in the response factors, which are to be expected when using ESI-MS, the peak areas (given in Table 1) can only be treated as a rough approximation of relative abundances within a sample. However, in our opinion, it is safe to assume the protonation constants of the sirodesmin congeners are sufficiently comparable to be able to state that the dominant ETP components of the investigated L. maculans cultures were sirodesmins PL and C, and their deacetylated derivatives, which is in agreement with previous results (Badawy and Hoppe, 1989b), and also supported by our results obtained by analyzing TLC plates (Mitrović *et al.*, 2012).

While it is known that a polysulphide bridge in the diketopiperazine ring is responsible for the observed toxic effects (while the nature of side groups does not affect toxicity), and the reduction thereof leads to complete loss of activity, the exact mechanism of toxicity is still a matter of debate(Gardiner *et al.*, 2004; Gardiner *et al.*, 2005).

Regardless of the mechanism (or a combination thereof) that is responsible for the phytotoxic effects of ETPs, activity could be expected for all detected polysulphide-bridge containing

sirodesmins, although it is likely that only the dominant components contribute significantly, as indicated by Badawy and Hoppe, (1989b).
Referring to our previously published results (Mitrović *et. al.*, 2012), we came to the conclusion that there was no significant difference between investigated *L. maculans* extracts. No sirodesmins were found in the reference extract K113 prepared from an *L. biglobosa* culture (Mitrović *et. al.*, 2012). This indicates that sirodesmins could be employed as markers for the differentiation of two species – *L. maculans* and *L. biglobosa*.

Conclusions

The results obtained by the phytopathogenic test, developed in the liquid Czapek medium, show that the investigated isolates of St-5, S-11 and C-3 originate from Serbia, cause severe symptoms in cotyledones in all varieties (Westar Glacier, Quinta) and do not form yellow-brown pigments while K-113 isolate forms a yellow-brown pigment and causes slight virulence.Isolates C-3,St-5, S-11 in thin-layer chromatography and high-performance liquid chromatography with mass spectrometric detection demonstrated the presence of sirodesmins except for K-113. It was found that the dominant epipolythiodioxopiperazines in the investigated L. maculans isolates were sirodesmin PL, sirodesmin C, and their deacetylated derivatives.Based on the conducted studies, the isolates C-3, St-5, S-11 belong to the species *Leptosphaeria maculans* while the K-113 type of *Leptosphaeria biglobosa.*

Abstract

The Mediterranean fruit fly (Medfly), *Ceratitis capitata* (Wiedemann) (Diptera: Tephritidae) is one of the important pests of citrus in Turkey. The Medfly is a polyphagous tropical fruit fly which attacks more than three hundred and fifty botanical species from sixty five different families. The females puncture the fruits and lay eggs below the skin of the host fruits, which are destroyed by larval feeding. The study was conducted to control of *Ceratitis capitata* (Wiedemann) (Diptera: Tephritidae) with mass trapping on washington orange in Antalya province of Turkey. Fourty Eostrap® invaginada traps baited with 95% trimedlure impregnated in a polymeric plug-type dispenser were used in both years. After two years of the study, the average number of the catches per trap varied in the sampling period. In the first year, a total of 894 adults were caught by traps the average number of the catches per trap was recorded between 1 and 2 percent. The highest number of catches per trap was recorded on 1st November, followed by 6th September and 15th November 2016. In the second year, a total of 408 adults were caught by traps. The average number of the catches per trap was recorded between 1 and 2 percent. The highest number of catches per trap were recorded on 11th October, followed by 13th September, and 6th September 2017.

Keywords: *Ceratitis capitata, Washington orange, pheromone traps, Antalya province.*

Introduction

The washington orange, *Citrus sinensis* (L.) Osbeck (Rutaceae: Sapindales) is one of the main cultivated *Citrus* variety in Turkey. The washington orange production is consisting of approximately 375.435 ha with a total produce of 1.358.100 tons of fruit per annum in Turkey, and Antalya province's share is 100.912 ha and 410.035 tons (Anonymous, 2016). The Mediterranean fruit fly (Medfly), *Ceratitis capitata* (Wiedemann) (Diptera: Tephritidae) is the most destructive pest among economically important fruit fly species (IAEA, 2003; Thomas *et al.*, 2007). The medfly is a highly adaptive polyphagous tropical fruit fly attacking more than three hundred and fifty plant species (Weems, 1981; Liquido *et al*., 1991). The female flies lay eggs below the skin of fruits which are destroyed by larval feeding (Christenson and Foote, 1960). Protein bait sprays mixed with malathion or low toxicity insecticides, spinosad, lambda-cyhalothrin are successfully used to control medfly populations (McQuate *et al.*, 2005; Urbaneja *et al*., 2009). Traps baited with trimedlure are important tools for detection, monitoring and controlling of the medfly (IAEA, 2003). The mass trapping has proved to be effective in suppression of the Medfly and advantage of reduced environmental impact when comparing with toxic bait sprays (Navarro-Llopis *et al.*, 2008; Martinez-Ferrer *et al.*, 2010). In addition, mass trapping has been developed in several countries using traps baited with trimedlure, hydrolysed proteins or food-based attractants (Epsky *et al.*, 1999; Katsoyannos *et al*., 1999; Cohen and Yuval, 2000; Miranda *et al*., 2001; Heath *et al*., 2004; Ortu *et al.*, 2005; Alemany *et a*l., 2006). This method has been conducted on different fruit trees like peach (Sastre, 1999], cherimoya (Ros *et al*., 2000), citrus (Miranda *et al.*, 2001; Alonso Muñoz *et al*., 1999; Llorens *et al*., 2004), fig (Escudero *et al*., 2005), persimmon and coffee (McQuate *et al.*, 2005) and apple (Ortu and Prota, 1988). The purpose of the current

study was to evaluate mass trapping for the control of Medfly in washington orange in Antalya province of Turkey.

Material and Methods

The study was conducted in 2016-2017 at washington orange orchard in Antalya province of Turkey. The study was carried out using the Eostrap® invaginada traps (Sanidad Agricola Econex, Santomera, Murcia, Spain) baited with 95% Trimedlure, (formulated in a polymeric plug-type dispenser) (Sanidad Agricola Econex, Santomera, Murcia, Spain) and dichlorvos or 2.2- dichlorovinyl dimethyl phosphate (DDVP) tablet (Sanidad Agricola Econex, Santomera, Murcia, Spain). In the first year, the study was conducted with 40 traps/1.8 ha and placed in the experimental site from 26 July to 15 November. In the second year, the study was carried out with 40 traps/1.8 ha and placed in the same site from 17 August to 22 November. The traps were placed 1.5 m above ground and checked weekly, trapped medfly adults were counted and removed from the traps. The trimedlure and DDVP tablet in traps were replaced with the new ones in every 90 days.

Results and Discussion

The population density of *C. capitata* varied in each of the sampling year. In the first year, the mass trapping was conducted with 40 traps/1.8 ha in washington orange orchard and a total of 894 medfly adults were caught by traps (Figure 1). The first adults were caught by the traps on 2 August, and the population density of this pest was gradually low during the sampling periods. The largest mean of catches per trap were recorded on 1 November (1.75), followed by 6 September (1.70), 15 November (1.68) and 18 October (1.63).

In the second year, the mass trapping was conducted with 40 traps/ha at the same orchard and a total of 408 medfly adults were caught by traps (Figure 2). The population density of medfly was very low comparing with previous year. The first adults were caught by the traps on 24 August, and the population density of this pest was significantly low during the sampling periods. The largest mean of catches per traps were recorded on 11 October (1.33), followed by 13 September (1.20), 6 September (1.08) and 8 November (0.95).

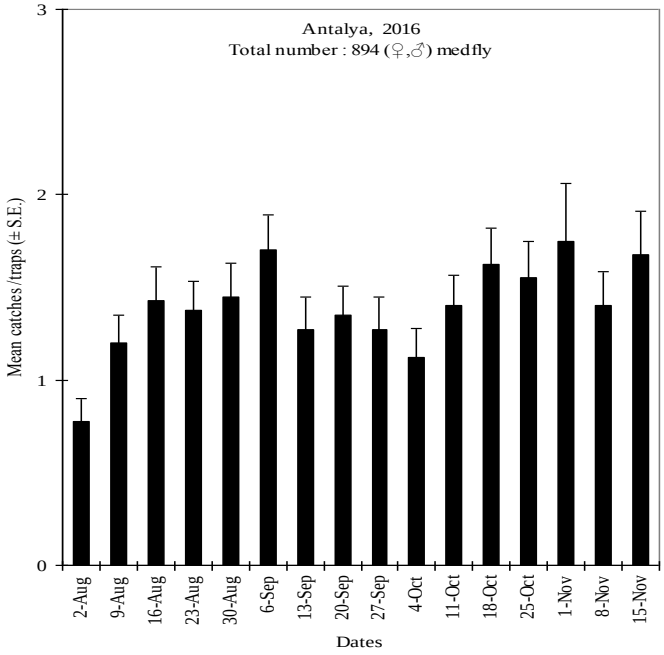

Figure 1. Mean (±SE) catches of medfly adults in traps baited with trimedlure (26 July to 15 November) at washington orange orchard in Antalya province.

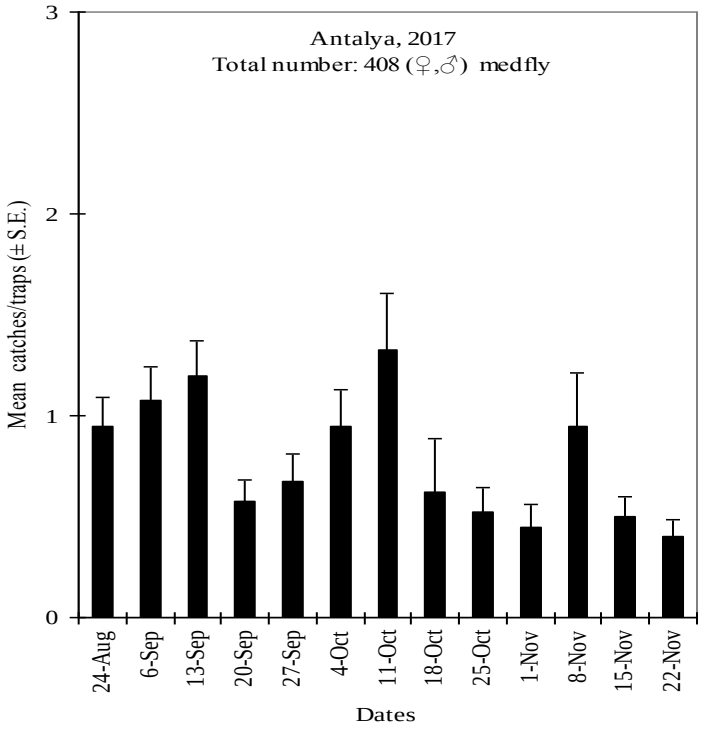

Figure 2. Mean (±SE) catches of medfly adults in traps baited with trimedlure (17 August to 22 November) at washington orange orchard in Antalya province.

The mass trapping has shown significantly effective pest management tool for the Medfly and developed in several countries using traps baited with trimedlure, hydrolysed proteins or food-based attractants (IAEA, 2003; McQuate *et al.,* 2005; Navarro-Llopis *et al*., 2008; Katsoyannos *et al.,* 1999; Cohen and Yuval, 2000; Miranda *et al*., 2001; Heath *et al.,* 2004; Ortu *et al.,* 2005; Alemany *et al*., 2006; Avery *et al*., 1994; Sastre *et al.,* 1999; Ros *et al*., 2000; Garcia *et al*., 2003; Jemâa *et al.,* 2010; Ros *et al*., 1997).

A various number of traps were used with mass trapping to control medfly on different host plants. Martinez-Ferrer *et al.* (2010) suggested that 25 trap per ha (Maxitrap Model baited with Ferag. CC D TM® attractant) can be a good stand-alone control method against the Medfly in citrus groves in Spain. In addition, IAEA (2003) suggested that 20-25 traps per ha density was required by using a mass trapping technique for medfly. Martinez-Ferrer *et al.* (2010] reported that for the Clemenules variety, a 25 traps per ha were enough to capture adults flying within the grove and attract the foraging medflies, as low percentage of fruits were attacked. A number of researchers reported that if the population density of medfly increase, the number of trap per ha will be increased. Therefore, during September-October Medfly population is high, a 50 trap per ha density has been widely accepted as appropriate for citrus orchards (Navarro-Llopis *et al.,* 2008; Primo, 2004; Navarro-Llopis *et al.,* 2004; Leza *et al*., 2008; Martinez-Ferrer *et al.,* 2012; Martınez-Ferrer *et al.,* 2006). Martinez-Ferrer *et al.* (2010) reported that for the early-season varieties, 50 traps per ha captured as many adults as did 75 and 100 traps per ha, but not enough to diminish the adult medflies foraging in the grove under accepted levels. The percentage of the total caught over this period varied for each of the sampling month in both years. The distribution of the total caught of this pest according to the months as percentages were 27.85 (August), 25.05 (September), 25.50 (October) and 21.59 (November) in 2016 (Figure 3). These percentages were 9.31 (August), 34.56 (September), 33.58 (October) and 22.55 (November) in 2017 (Figure 4).

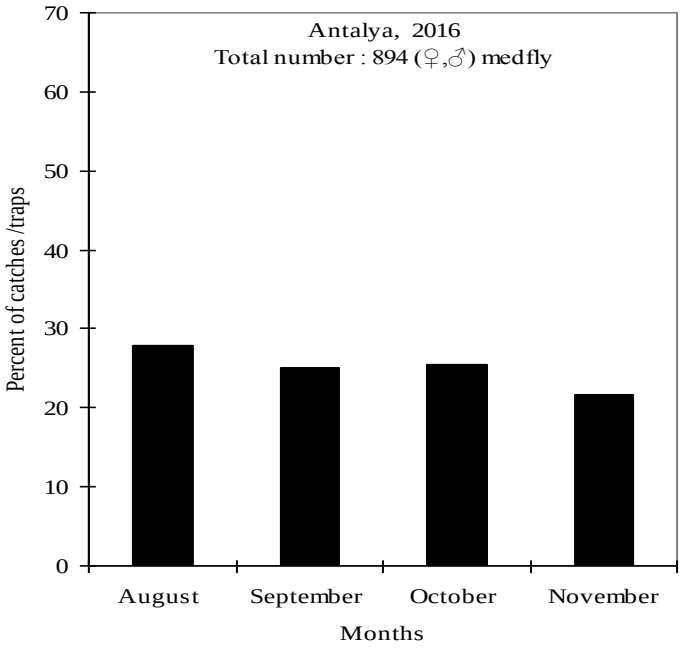

Figure 3. Percentage of the total medfly adults caught over the sampling period at washington orange orchard in Antalya province.

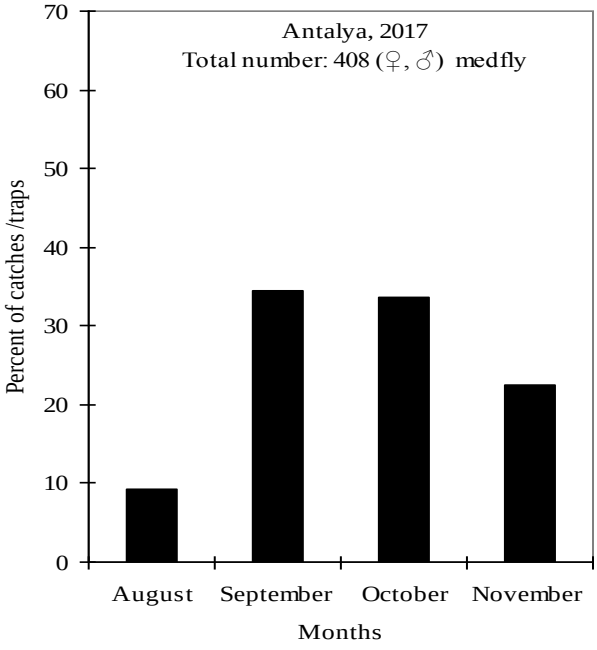

Figure 4. Percentage of the total medfly adults caught over the sampling period at washington orange orchard in Antalya province.

Several studies were conducted by many researchers to evaluate the population density of medfly on various host plants. The population density of medfly was significantly high in September and October due to high temperatures in citrus- producing area (Martinez-Ferrer *et al.,* 2010; Martınez-Ferrer *et al.,* 2007; Boulahia-Kheder *et al.,* 2012). The present results indicated that the population density of medfly was high in August in 2016 and September and October in 2017.

Conclusions

The present study was conducted by traps baited with trimedlure to evaluate of mass trapping for the control of Medfly in washington orange in Antalya province of Turkey. As a result of two-year investigations, the population density of this pest varied in each of the sampling year. In the first year, 40 trap per 1.8 ha were used with mass trapping to control of the medfly. A significant number of medfly were caught by traps, keeping population density under 2 mean catches per traps during the sampling periods. In the second year, 40 trap per 1.8 ha were used with mass trapping to control of this pest. The population density of medfly was signifacantly low comparing with that of the previous year.

Abstract

The grape berry moth, *Lobesia botrana* (Denis & Schiffermüller) (Lepidoptera: Tortricidae), is one of the important pests of vineyards in Hatay province of Turkey. The current study was conducted to determine the population density of grape berry moth at the different varieties of vineyards in Hatay province of Turkey. The study was carried out in 2016-2017 at ten varieties: Arra 4, Arra 13, Arra 15, Arra 16, Arra 18, Arra 19, Arra 30, Redglop, Vitroblack 25, and Crimson varieties, located in Reyhanlı district of Hatay province. The grape berry moth pheromone (10 mg, (E, Z) -7,9-dodecadienyl acetate) with delta type traps were used in this study. One pheromone trap was placed in each of the vineyard. The pheromone traps were weekly checked and captured grape berry moth adults were counted and then traps were cleaned. Pheromones in the delta traps were replaced with the new ones in every 40 days. After two years of the study, the average number of the catches per trap varied in the sampling period. In the first year, the highest number of the the grape berry moth were recorded in June, followed by July, May, August and April. In the second year, the highest number of the grape berry moth were recorded in June, followed by July, May and August.

Keywords: *Grape berry moth, Lobesia botrana, vineyards, pheromone traps, Hatay*

Introduction

The grape berry moth, *Lobesia botrana* (Denis & Schiffermüller) (Lepidoptera: Tortricidae), is one of the most important pest of grapevine in Turkey. The grape berry moth is a major pest of grapevines responsible for great economic losses and frequent insecticide applications. The grape berry moth is a polyvoltine species (Bovey, 1966; Roehrich and Boller, 1991) and adaptive polyphagous attacking many plant species (Savopoulou-Soultani *et al*., 1990, Stavridis and Savopoulou-Soultani, 1998). The grape berry moth larvae cause damage to grapes by feeding on fruit, resulting in direct damage and secondary infection indirect damage caused by increased susceptibility of the berries to gray mold, *Botrytis cinerea* (Bovey, 1966; Roehrich and Boller, 1991; Fermaud and Le Menn, 1989). The main sex pheromone component of *L. botrana*, (E)-7,(Z)-9-dodecadienyl acetate (E7,Z9-12:Ac), was identified three decades ago (Roelofs *et al*., 1973; Buser *et al*., 1974). The main pheromone component has been used to monitor the flight activity and population dynamics (Anshelevich *et al*., 1994), as in mating disruption for pest control (Arn *et al*., 1988; Sauer and Karg, 1998, Charmillot and Pasquier, 2004; Kast, 2001; Varner *et al*., 2001; Ioriatti *et al*., 2005). The purpose of the current study was to evaluate the population density of grape berry moth at the different varieties of vineyards in Hatay province of Turkey.

Material and Methods

The study was conducted in 2016-2017 in Reyhanlı district of Hatay province. In the first year, the study was conducted from 20 April to 24 August 2016 at ten vineyards consiting of Arra 4, Arra 13, Arra 15, Arra 16, Arra 18, Arra 19, Arra 30, Redglop, Vitroblack 25, and Crimson varieties. In the second year, the study was conducted from 28 April to 4 August

2017 at ten vineyards consiting of Arra 4, Arra 13, Arra 15, Arra 16, Arra 18, Arra 19, Arra 30, Redglop, Crimson and Vitroblack 25 varieties. In both studies, the grape berry moth pheromone (10 mg, (E, Z) -7,9-dodecadienyl acetate) with delta type traps were used. One pheromone trap was placed 1.5 m above ground grapes, checked weekly and captured grape berry moth were counted and cleaned. Pheromones in the delta traps were replaced with the new ones in every 40 days.

Results and Discussion

The population density of *L. botrana* varied in each of the sampling year. In the first year, the pheromone trapping was conducted at ten different vineyards and a total of 595 grape berry moth were caught by pheromone traps (Figure 1). The first moth was caught by the traps on 27 April, and the population density of this pest was gradually varied during the sampling periods. The largest mean of catches per trap were recorded on 6 July (5.8), followed by 1 June (5.50), and 29 June (5.30). The highest number of *L. botrana* moth were recorded in June (235), followed by July (169), May (116), August (49) and April (26).

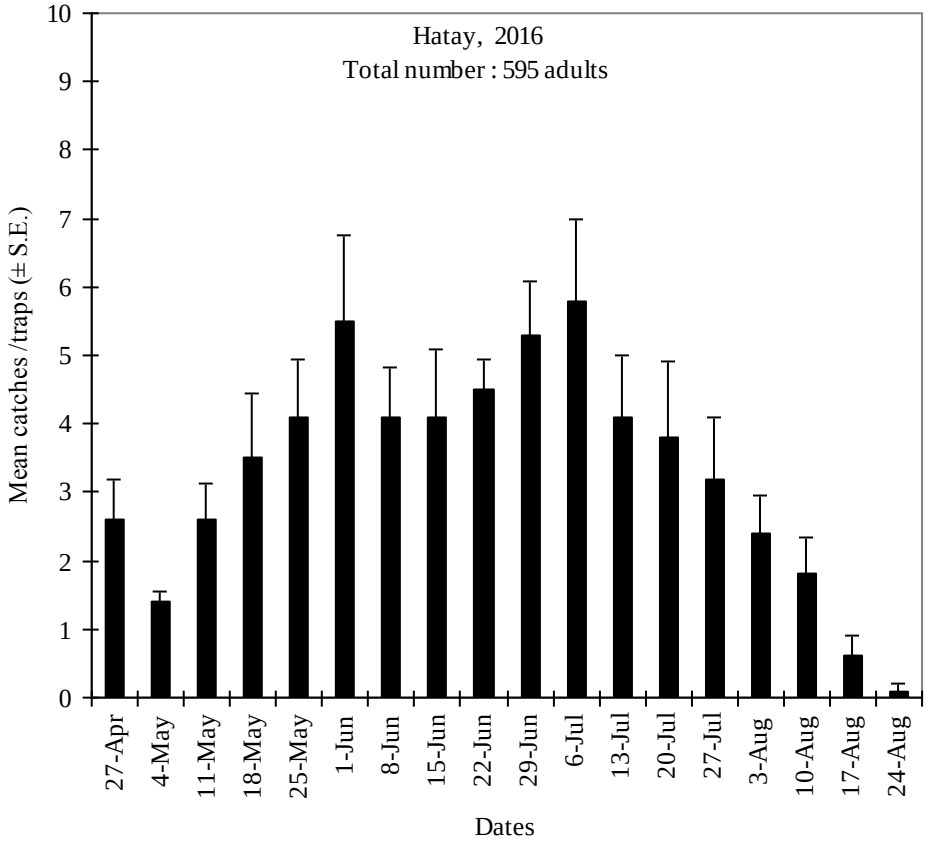

Figure 1. Mean (±SE) catches of grape berry moth in traps baited with pheromone (20 April to 24 August 2016) at ten vineyards in Hatay province.

In the second year, the pheromone trapping was conducted at ten different vineyards and a total of 401 grape berry moth were caught by pheromone traps (Figure 2). The first moth was caught by the traps on 5 May, and the population density of this pest was gradually varied during the sampling periods. The largest mean of catches per trap were recorded on 23 June (5.20), followed by 16 June (4.60), and 30 June (4.50). The highest number of *L.botrana* moth were recorded in June (221), followed by July (95), May (82), and August (3).

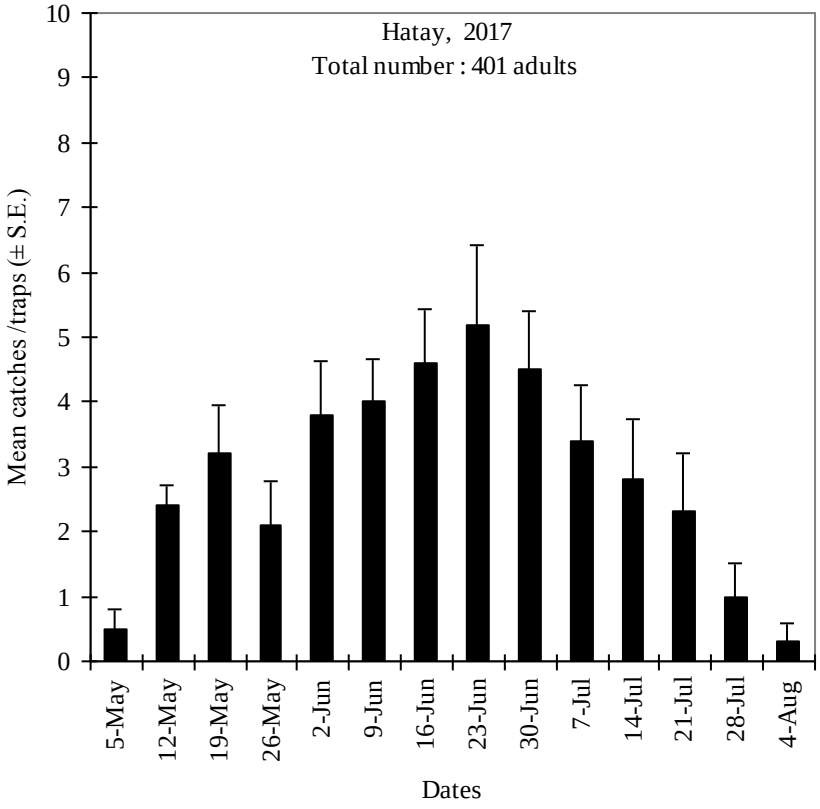

Figure 2. Mean (±SE) catches of grape berry moth in traps baited with pheromone (28 April to 4 August 2017) at ten vineyards in Hatay province.

Karabulut and Demirel (2014) reported that population density of the grape berry moth differed for sampling locations and years. In the first year, a total of 844 grape berry moth adults were caught by the pheremone traps. The first adults were caught on 27th May. The highest number of adults caught was on 15th July, followed by 22nd and 29th July. The ratios of the grape berry moth adults caught by the pheremone traps were, in descending order, 49.4% in July, 22.39 % in June, 17.65 % in August, 6.99% in September and 3.55 % in May. In addtion, in the second year, a total of 846 grape berry moth adults were caught by the pheremone traps. The first adults were caught on 26th May. The highest number of adults caught was on 28th July, followed by 2nd June and 7th July. The ratios of the grape berry moth adults caught by the pheremone traps were, in descending order, 39.83% in July, 31.56 % in June, 19.26 % in August, 5.31 % in September and 4.01% in May.

Conclusions

The present study was conducted by traps baited with pheromone to evaluate the population density of grape berry moth at the different varieties of vineyards in Hatay province of Turkey. As a result of two-year investigations, the population density of this pest varied in each of the sampling year. In the first year, a total of 595 grape berry moth were caught by pheromone traps. The largest mean of catches per trap were recorded on 6 July, followed by 1-29 June. The highest number of *L.botrana* moth were recorded in June, followed by July, May, August and April. In the second year, a total of 401 grape berry moth were caught by pheromone traps. The largest mean of catches per trap were recorded on 23 June, followed by 16-30 June. The highest number of *L.botrana* moth were recorded in June, followed by July, May and August.

Abstract

The grape berry moth, *Lobesia botrana* (Denis & Schiffermüller) (Lepidoptera: Tortricidae), is one of the important pests on wine vineyards in Hatay province of Turkey. The study was conducted to determine the population density of grape berry moth on the wine vineyards in Hatay province (Turkey). The study was carried out at four different wine vineyards located in Belen district of Hatay province. The wine vineyard contained Syrah, Sangiovese, Cabetnet sauvignon and Barbari varieties. The grape berry moth pheromone (10 mg, (E, Z) -7,9-dodecadienyl acetate) with delta type traps were used in this study. Two pheromone traps were placed in each of the wine vineyards. The pheromone traps were weekly checked and captured grape berry moth adults counted, and then the traps were cleaned. Pheromones in the delta traps were replaced with the new ones every 40 days. A total of 1786 grape berry moth adults were caught by the pheromone traps. The number of captured grape berry moth adults was changed during the sampling period. The highest number of the grape berry moth adults captured by pheromone traps was in 11 July, following in 25 July, 18 July, the lowest number of the grape berry moth adults caught by pheromone traps was on 15 August.

Introduction

The grape berry moth, *Lobesia botrana* (Denis & Schiffermüller) (Lepidoptera: Tortricidae), is one of the most important pest of grapevine in Turkey. The grape berry moth is a polyvoltine species (Bovey, 1966) and adaptive polyphagous attacking many plant species (Savopoulou-Soultani *et al*., 1990). The grape berry moth larvae cause damage to grapes by feeding on fruit, resulting in direct damage and secondary infection indirect damage caused by increased susceptibility of the berries to gray mold, *Botrytis cinerea* (Bovey, 1966; Roehrich and Boller, 1991). The main sex pheromone component of *L. botrana*, (E)-7,(Z)-9-dodecadienyl acetate (E7,Z9-12:Ac), was identified three decades ago (Roelofs *et al*., 1973). The main pheromone component has been used to monitor the flight activity and population dynamics (Anshelevich *et al*., 1994). The purpose of the current study was to evaluate the population density of grape berry moth at the different varieties of wine vineyards in Hatay province of Turkey.

Material and Methods

The study was conducted in 2017 in Reyhanlı district of Hatay province. In the first year, the study was conducted from 04 July to 15 August 2017 at five wine vineyards consiting of Syrah, Sangiovese, Cabetnet sauvignon and Barbari varieties. The grape berry moth pheromone (10 mg, (E, Z) -7,9-dodecadienyl acetate) with delta type traps were used. Three pheromone traps for Syrah, Sangiovese + Syrah varieties, two pheromone traps for Sangiovese, Barbari varieties and one pheromone trap for Cabernet sauvignon variety were placed 1 m above ground on grapes. All pheromones traps were checked weekly and captured grape berry moth were counted and cleaned . Pheromones in the delta traps were replaced with the new ones in every 40 days.

Results and Discussion

The pheromone trapping was conducted at Syrah variety and and a total of 791 grape berry moth were caught by pheromone traps (Figure 1). The population density of this pest was gradually varied during the sampling periods. The largest number of catches per trap were recorded on 11 July (560), followed by 25 July (117), 18 July (65), 1 August (35), 8 August (11) and 15 August (3).

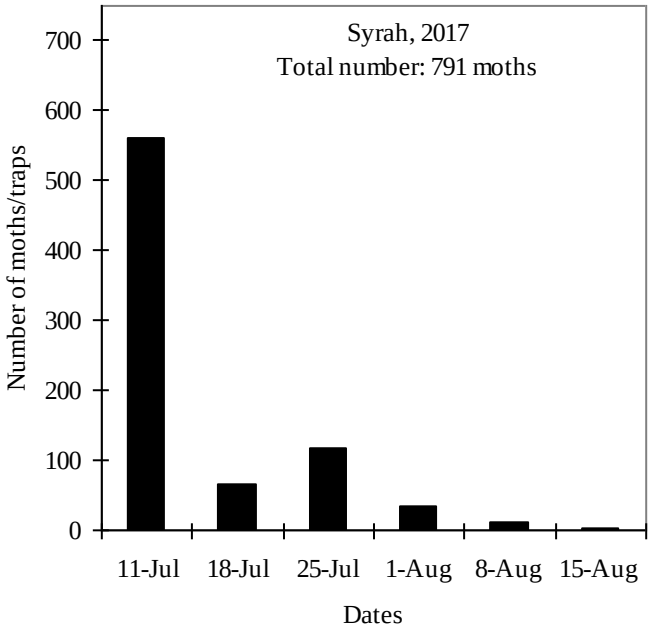

Figure 1. Number of catches of grape berry moth in traps baited with pheromone (04 July to 15 August 2017) at Syrah wine vineyards in Hatay province.

The pheromone trapping was conducted at Sangiovese+Syrah varieties and and a total of 427 grape berry moth were caught by pheromone traps (Figure 2). The population density of this pest was gradually varied during the sampling periods. The largest number of catches per trap were recorded on 11 July (312), followed by 25 July (82), 1 August (16), 8 August (8), 18 July (7) and 15 August (2).

The pheromone trapping was conducted at Sangiovese variety and and a total of 119 grape berry moth were caught by pheromone traps (Figure 3). The population density of this pest was gradually varied during the sampling periods. The largest number of catches per trap were recorded on 11 July (78), followed by 25 July (24), 18 July (13), 1 August (4), 8 August (0) and 15 August (0).

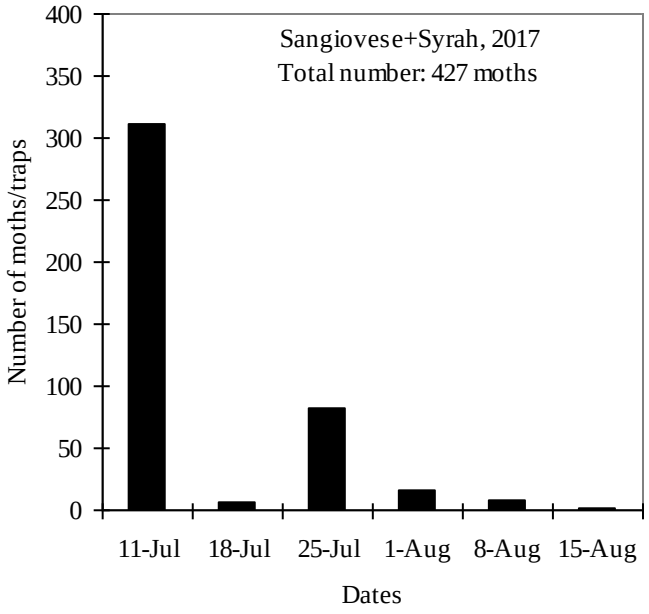

Figure 2. Number of catches of grape berry moth in traps baited with pheromone (04 July to 15 August 2017) at Sangiovese + Syrah wine vineyards in Hatay province.

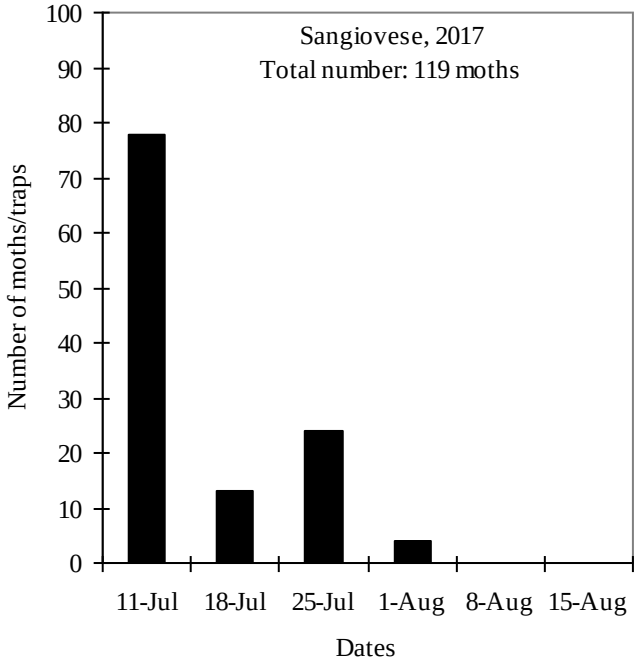

Figure 3. Number of catches of grape berry moth in traps baited with pheromone (04 July to 15 August 2017) at Sangiovese wine vineyards in Hatay province.

The pheromone trapping was conducted at Cabernet sauvignon variety and and a total of 403 grape berry moth were caught by pheromone trap (Figure 4). The population density of this pest was gradually varied during the sampling periods. The largest number of catches per trap were recorded on 11 July (285), followed by 25 July (87), 18 July (16), 1 August (10), 8 August (4) and 15 August (1).

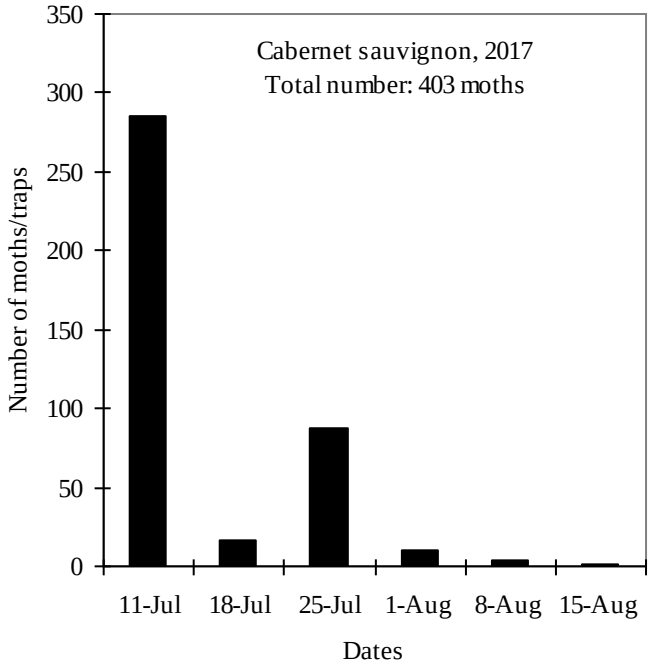

Figure 4. Number of catches of grape berry moth in traps baited with pheromone (04 July to 15 August 2017) at Cabernet sauvignon wine vineyards in Hatay province.

The pheromone trapping was conducted at Barbari variety and and a total of 46 grape berry moth were caught by pheromone traps (Figure 5). The population density of this pest was gradually varied during the sampling periods. The largest number of catches per trap were recorded on 11 July (29), followed by 1 August (7), 25 July (3), 18 July (3), 8 August (3) and 15 August (1).

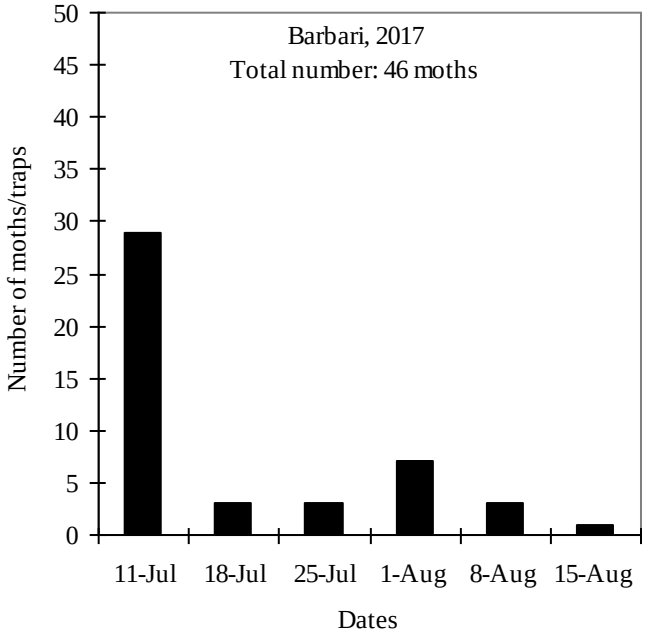

Figure 5. Number of catches of grape berry moth in traps baited with pheromone (04 July to 15 August 2017) at Barbari wine vineyards in Hatay province.

Karabulut and Demirel (2014) reported that population density of the grape berry moth differed for sampling locations and years. In the first year, a total of 844 grape berry moth

adults were caught by the pheremone traps. The first adults were caught on 27th May. The highest number of adults caught was on 15th July, followed by 22nd and 29th July. In the second year, a total of 846 grape berry moth adults were caught by the pheremone traps. The first adults were caught on 26th May. The highest number of adults caught was on 28th July, followed by 2nd June and 7th July.

Conclusions

The present study was conducted by traps baited with pheromone to evaluate the population density of grape berry moth at the different varieties of wine vineyards in Hatay province of Turkey. As a result of investigations, the population density of this pest varied in each of the sampling varieties. The highest number of the grape berry moth adults captured by pheromone traps was in 11 July, following in 25 July, 18 July, the lowest number of the grape berry moth adults caught by pheromone traps was on 15 August.

Abstract

Meat and meat products are commonly consumed foods around the world due to their high nutrients availability. However, these foods also provide a suitable environment for growth of pathogenic and spoilage microorganisms. In addition, lipid oxidation causes a reduction in the nutritional value and the formation of undesirable flavor, color, odor and toxic compounds in the meat and meat products. Therefore, some natural or synthetic food additives are used in meat and meat products. However, the effectiveness of these additives which are added to the products by using traditional application methods decreased over time and the meat industry suffers some problems in maintaining product quality. In addition, nowadays consumers demand high quality foods with an extended shelf life and without chemical additives. Edible films and coatings obtained from vegetable or animal sources and applied to the food surfaces by various methods to improve the quality characteristics of food and extend the shelf life. Besides, edible films and coatings can prevent the undesirable color formation, lipid oxidation and microbiological deterioration when they are combined with antioxidant and antimicrobial compounds. Edible films and coatings applied to meat and meat products have some advantages such as the reduction of moisture losses during the storage period, the confinement of water in ready-to-eat meat, the limitation of lipid and myoglobin oxidation, the elimination of spoilage and pathogenic microorganism contamination, the reduction of volatile flavor loss and the prevention of undesirable taste and odor formation. In this review study, research about edible films and coatings prepared with antioxidant and antimicrobial compounds are reviewed.

Keywords: *Edible films and coatings, antimicrobial, antioxidant, meat and meat products.*

Introduction

Adequate and balanced diet is one of the most important contributing factors for achieving or maintaining a good state of health. It is generally accepted that balanced diets of meat and plant food are most effective for human nutrition. Meat and meat products are widely distributed and consumed around the world due to their high nutrients availability. Meat and meat products are better sources of protein than plant foods (except soy bean products). In meat, the essential amino acids are available in well-balanced proportions and concentrations. As well, meat and meat products have B12 deposits for children and particularly rich in iron to prevent anemia. However, they are highly perishable products due to their high moisture contents, nitrogenous nutrients, minerals, fermentable carbohydrates, suitable pH and other growth factors, therefore they can be possibly dangerous to health through microbial growth and chemical changes (Sanchez-Ortega et al., 2014).

Lipid oxidation is reduced the nutritional value of the meat and meat products as far as the development of undesirable taste, color, smell and toxic compounds (Vital et al., 2016; Noor et al., 2018). On the other hand, microorganisms that grow in meat products may cause changes in appearance, flavor, odor, and other features of the meat products. Also, they can threaten human health by causing food infections and intoxications (Ozbay-Dogu and Saricoban, 2014). Many strategies are implemented in meat industry to prevent lipid

oxidation, inhibit undesirable changes, increase shelf life and protect human health (Mor-Mur and Yuste, 2010). Use of edible films and coatings that among these protection methods has increasing trend. Edible films and coatings obtained from vegetable or animal sources and applied to the food surfaces by various methods improve the quality characteristics of food and extend the shelf life. Besides, edible films and coatings can prevent the undesirable color formation, lipid oxidation and microbiological deterioration when they are combined with antioxidant and antimicrobial compounds (Umaraw and Verma, 2017).

Edible Films and Coatings

Edible films and coatings are defined as a non-synthetic materials produced by vegetable or animal origin natural resources (polysaccharide, protein and lipid) alone or in combination. They form a thin layer on the surface of food or between food components and can be consumed with food (Pavlath and Orts, 2009). Edible films and coatings have been used for centuries to prevent loss of moisture during storage and transportation. First recorded use of biopolymer was in China around twelfth century where citrus fruits were preserved by coating them with wax. Later in the sixteenth century, in England larding (coating with lard) was practiced to prolong shelf-life of meat (Ortiz et al., 2014). Currently, edible films and coatings are used for various purposes such as protecting the food against chemical and microbiological deterioration and increasing the shelf life of products (Hassan et al., 2018). Packing material is defined as an "edible" packaging when it is an integral part of the food and can be consumed with together. Coatings are a particular form of films directly applied to the surface of materials and are regarded as a part of the final product. On the other hand, edible films are obtained from food suspensions that are usually cast over an inert surface, which after drying can be placed in contact with food surfaces (Salgado et al., 2015). Edible films and coatings are an alternative to extend the shelf life of foods by acting as barriers to water vapor, oxygen, and carbon dioxide and as a carrier of substances to inhibit pathogenic and spoilage microorganisms. In addition, these films and coatings prevent food from physical changes by providing mechanical protection during transportation and storage (Temiz, 2006). In addition, they provide brighter and smoother product appearance (Salgado et al., 2015). These films are generally biodegradable in nature making it an eco-friendly packaging approach. Thus, they contribute to the protection of the environment (Song and Zheng, 2014). Edible films and coatings act as a barrier between muscle foods and the surrounding environment to enhance the quality of products protecting them from physical, chemical and microbiological deterioration. Additionally, they may provide moisture loss reduction during storage of fresh or frozen meats and a decrease in lipid and myoglobin oxidation of the meat (Oguzhan Yildiz and Yangilar, 2016).

Components of Edible Films and Coatings

Edible films and coatings vary in the vast range of hydrophilic and hydrophobic boundaries. Additionally, they need a suitable solvent in order to prepare a film or coating forming the dispersion. Mostly water or alcohol are used as a solvents according to natural solubility characteristics of film forming materials. In addition, functional additives are used to improve protective properties of edible films and coatings.

The main components which are used in the preparation of edible films and coatings are polysaccharides, proteins (hydrophilic) and lipids (hydrophobic) (Salgado et al., 2015). Polysaccharides are hydrocolloids of high molecular weight which in water form intensive hydrogen bonds to form gel. The hydrophilic polysaccharide components are found to have good mechanical properties but the edible films and coatings made up of these components have greater permeability for water vapour and gasses. Among polysaccharides, chitosan derivatives, cellulose, alginate, pectin derivatives, seaweed extract and starch are most

commonly used in the preparation of edible films and coatings (Mellinas et al., 2015). Proteins inherently have interactive forces that provide cohesiveness which is essential for film/coating formation. Protein based edible films and coatings exhibit excellent gas barrier but poor moisture barrier properties. This gas barrier property can be used in preventing oxidative rancidity, enzymatic browning and flavor loss in meat and meat products (Cutter, 2006). Various types of protein such as gelatin, casein, whey protein, corn zein, wheat gluten, soy protein, mung bean protein and peanut protein have been used as edible films (Umaraw and Verma, 2017). Lipids are hydrophobic substances which have excellent moisture barrier property, were the very first kind of coating used on fresh meats as "Larding" in sixteenth century. Nowadays beeswax, paraffin, mineral and vegetable oils are also used (Mellinas et al., 2015). Lipid based edible films and coatings are brittle and have poor strength and elasticity (Dursun and Erkan, 2009). Thus, better form of lipids is composite films/coatings with hydrocolloids or proteins (Umaraw and Verma, 2017). Composite films and coatings can be formed of polysaccharides, proteins and/or lipids. All substances have been combined to create composite barriers with desired mechanical strength and low permeability (Umaraw and Verma, 2017). Renewable agricultural resources or industrial by-products can be used as a main component in the production of edible films and coatings. Starch, cellulose, chitosan, carrageenan, whey protein, gelatin, and keratin are materials that can be used as an alternative in the preparation of edible films and coatings (Reddy et al., 2013). Water or ethanol is usually used as a solvent in the preparation of edible films and coatings to preserve the consumption of the food (Ustunol, 2009). Plasticizers, which are small molecules such as glycerol, propylene glycol, or polyethylene glycol, are used to control the viscosity of the liquid formulation, add flexibility and tensile strength and control surface tension (Dursun and Erkan, 2009; Ustunol 2009). Antioxidants and antimicrobials, emulsifiers, antifungal and flavoring agents, colorants and other functional substances may be added into edible films and coatings for improving the quality of food and protecting consumer health (Oussalah et al., 2004; Quintavalla and Vicini, 2002).

Production Techniques of Edible Films and Coatings

Edible coatings can be obtained by dipping the product into, or by brushing or spraying it with a solution, so as to the film directly on food surface. Edible films can be obtained by creating a standalone film from a solution for the subsequent covering of food surface (Ortiz et al., 2014).

Use of Edible Films and Coatings in Meat and Meat Products

Red Meat and Meat Products

The use of edible films and coatings containing antioxidant and antimicrobial compounds could improve the oxidative and antimicrobial stability of meat. For this reason, their use in meat and meat products has been attracting an interest in recent years and various research on this area has been conducted. In Table 1, some examples of the use of edible films and coatings in red meat and meat products are presented. Previous studies indicated that the application of protein and carbohydrate based edible films and coatings delayed lipid oxidation, inhibited the growth of microorganisms and increased the shelf life of the products during storage of raw or cooked red meats. For example, Shin et al. (2017) studied the effect of apple peel powder based edible films containing tartaric acid on the raw or cooked beef meatball. The authors concluded that the use of edible films prevent lipid oxidation and growth of microorganisms and the process does not affect the sensory properties of raw or cooked beef meatball.

Table 1. Application of edible films and coatings for red meat and meat products preservation

Products Used	Major Component	Additives	Storage Conditions	Effects	References
Ham slices frankfurter	Sodium alginate	Distilled ethanol Tsipouro Raki, Ouzo	4 and 10 ^{0}C 40, 52, 81 d	Reduced *L. Monocytogenes* population	Kapetanakou et al. (2016)
Ground beef	Zein	2% or 3% *Zataria multiflora* essential oil 1% monolaurin	4 ^{0}C 3 d	High phenolic content Increased antioxidant activity Effective in controlling *E. coli* O157:H7 and *L. monocytogenes* growth	Moradi et al. (2016)
Raw or cooked beef meatball	Apple peel powder	0.75% (w/v) Tartaric acid	4 ^{0}C 10 d	Prevented lipid oxidation and microbial growth Enhanced shelf life	Shin et al. (2017)
Bovine meat	*Plantago major* seed mucilage	0%, 0.5%, 1%, 1.5% dill essential oil	4 ^{0}C 18 d	Reduced lipid oxidation Antimicrobial effect	Behbahani et al. (2017)
Cooked beef meatbal	Whey protein isolate	2%, 4% laurel and sage extracts	18 ^{0}C 60 d	Retarded oxidative changes; Enhanced shelf life	Akcan et al. (2017)

Poultry Meat and Meat Products

Various research on the use of edible films and coatings was conducted in the poultry meat and meat products. In Table 2, some studies on these products are presented. These studies stated that antioxidant edible films and coatings could prevent lipid oxidation, the development of off-flavors, and nutritional losses, whereas antimicrobials could prevent spoilage from food-borne bacteria and organoleptic deterioration. For example, Tosati et al. (2017) studied the quality and extension of the shelf life of fresh frankfurter sausage with turmeric starch residue and gelatin based edible coatings. They determined that the edible coatings reduce growth of microorganisms during the storage period. Also, researchers found that the physicochemical properties such as pH, texture, humidity and color remain stable and these coatings may be an alternative substitution for synthetic casing in sausages.

Table 2. Application of edible films and coatings for poultry meat and meat products preservation

Products Used	Major Component	Additives	Storage Conditions	Effects	References
Chicken breast fillets	Whey protein isolate	10 and 20 g/kg oregano or clove essential oil	4 ^{0}C 13 d	Reduced total mesophilic aerobic, *Pseudomonas* spp. and the count of lactic acid bacteria Enhanced shelf life	Fernandez-Pan et al. (2014)
Fresh chicken breast	0.2% c-carragenan, 2% kitosan	Allil izotiyosiyanat Oriental mustard extract EDTA	4 ^{0}C 21 d	Reduced Salmonella level Decreased lactic acid bacteria and the count of aerobic bacteria.	Olaimat and Holley (2015)
Refrigerated chicken fillet	2% chitosan	1%, 2% propolis extract	4 ^{0}C 12 d	Prevented growth of bacteria Inhibited increase of peroxide values, TBA and total volatile nitrogen: Enhanced shelf life and quality	Jafari et al. (2017)
Fresh frankfurter sausage	Turmeric starch residue and gelatin	-	5 ^{0}C and 10 ^{0}C 30 d	Prevented microbial growth pH, texture, humidity and color stability; Substitution of synthetic casing	Tosati et al. (2017)
Chicken breast fillets	Sodium caseinate nanoemulsion	6% ginger essential oil	4 ^{0}C 12 d	Reduced total aerobic psychrophilic bacteria, mold and yeast ; Weak antioxidant potential Strong antimicrobial activity	Noori et al. (2018)

Seafood

The quality of seafood is quickly deteriorated during storage due to chemical and enzymatic reactions. For these reasons, the main objective of using edible films and coatings in seafoods is to prevent the growth of microorganisms and lipid oxidation. The edible film and coating studies about seafoods are presented in Table 3. Previous studies revealed that the application of edible films and coatings not only inhibit the microbial spoilage but also prevent lipid oxidation and total volatile bases during storage of seafood. For example, Jasour et al. (2015) studied the effect of chitosan based edible coating containing lactoperoxidase to enhance quality and shelf life of rainbow trout. The results indicated that the edible coatings have significantly lower numbers of *Shewanella putrefaciens*, *Pseudomonas fluorescens*, and psychrotrophic and mesophilic bacteria. Researchers also concluded that the coating application extend the shelf life of trout fillets by at least 4 days.

Table 3. Application of edible films and coatings for seafood preservation

Products Used	Major Component	Additives	Storage Conditions	Effects	References
Rainbow trout	Chitosan	Lactoperoxidase	4 ^{0}C 16 d	Reduced *Shewanella putrefaciens, Pseudomonas fluorescens* and psychrotrophic and mesophilic bacteria Lower TBA values Enhanced shelf life Improved sensory properties	Jasour et al. (2015)
Fish sausage	Chitosan-gelatin	Shrimp concentrate	4 ^{0}C 45 d	Extended lag phase and prevented to the growth of microorganisms Decreased total volatile bases and pH values	Aleman et al. (2016)
Silver carp fillet	Sodium alginate-carboxymethylcellulose	0%-0.5% *Ziziphora clinopodioides* essential oil 0%-1% apple peel extract 0%-0.5% zinc oxide nanoparticle	4 ^{0}C 14 d	Enhanced shelf life Prevented growth of *L.monocytogenes*	Rezaei and Shahbazi (2018)

Conclusions

The use of edible films and coatings are a very common application in the meat industry and the number of researches on this area has increasing trend. Especially, the use of edible films and coatings prepared with natural antioxidant and antimicrobial materials has been becoming popular due to the consumer awareness. It is believed that the use of this technology reduces the amount of waste and prevents the environmental pollution. However, there are some shortcomings in these studies and they are not commercially viable and acceptable. For this reason, more studies are required about the choice of suitable edible film and coating materials, optimization of the process, provide for industrial suitability and development of low-cost applications for enhancing to the availability of this technology.

Abstract

Total phenolics, phenolic acid composition and antioxidant capacity of immature rice grains which were stabilized at 1200 W (8.0 and 10.1 min), 1400 W (7.0 min), and 1600 W (4.4 and 5.0 min) with medium wave and 1200 W (10.1 min), 1400 W (6.2 and 7.1 min) and 1600 W (5.0 min) with short wave infrared emitters were investigated and compared with unprocessed immature grains. Although a decrease in the content of phenolics and antioxidant capacity was observed in some stabilized grains, it was concluded that these decreases might not be directly related with stabilization conditions since they are not consistent with radiation intensity or process time. Furthermore, the content of the phenolics and antioxidant capacity were higher in some stabilized grains when compared to unprocessed immature grains. Instead, the variations were attributed to random error. In conclusion, it was found that infrared radiation can be used to stabilize immature rice grains without negatively affecting the content of phenolic compounds and antioxidant capacity.

Keywords: *Rice bran, infrared, stabilization, phenolics, antioxidants.*

Introduction

The phytochemical profile of whole grain rice has been widely studied and found that it includes notable amount of bioactive compounds such as γ-oryzanol, tocopherols, tocotrienols, and phenolics compounds (Guafo and Trindade, 2017). However, there is lacking information related to immature rice grains. Immature rice grains are defined as either thin, chalky kernels or kernels which have green seed coat. Besides, rice grains that have a moisture content exceeding 22% (before harvest) are also considered as immature (Buggenhout et al., 2013).

Immature rice grains are generally utilized as feed since they are susceptible to rancidity and rapidly deteriorates immediately after milling. In a recent study, it has been shown that free fatty acid content of unprocessed immature rice grains increased from 5.49 % to 35.71 % in 3 months of storage at room temperature (Yılmaz et al., 2018). Although it has been widely applied in thermal operations, the use of infrared (IR) radiation in food industry is more recent. However, it has been used in dehydration, baking, frying, pasteurization and sterilization (Krishnamurthy et al., 2008). Recently, Yılmaz et al. (2014a) have shown that IR radiation can be used for stabilization, in other words enzyme inactivation, of rice bran.

The aim of this study was to determine the effects of IR radiation on phenolics and antioxidants of immature rice grains at selected IR stabilization conditions which have already been proven to be effective in terms of retarding free fatty acid increase.

Materials and Methods

Material

Immature rice grains (variety of Osmancık-97), which were yellow-green in color, were provided by a local rice milling factory (Özer Gıda) in Çanakkale, Turkey immediately after milling. Broken grains and foreign matters were separated from the immature grains using a

laboratory-scale trieur (CRM-1252T, Yaşar Makina, Samsun, Turkey) and the cleaned grains were used for stabilization.

Infrared Stabilization

The laboratory-type IR stabilization system was explained in previous studies (Yılmaz et al., 2014a; Yılmaz et al., 2014b). Before stabilization, 500 g of cleaned immature grain was soaked in water for 10 min and allowed to drain for 5 min. Samples were placed on a conveyor system with a Teflon belt (20 cm width and 110 cm length) as a single layer and stabilized using either medium wave (Item no: 09755054) or short wave (Item No: 09751741) IR emitters (Heraeus Noblelight, Hanau, Germany). Distance between the emitters and the sample (belt) was maintained constant at 15 cm throughout the experiments. Stabilization was carried out at IR powers ranging from 800 W to 2200 W for varying process times. As a result of the preliminary analyses, 10 stabilization conditions which were successful in terms of stabilization (retarding the increase in free fatty acid) were selected. These conditions were 1200 W (8.0 and 10.1 min), 1400 W (7.0 min), and 1600 W (4.4 and 5.0 min) for medium wave and 1200 W (10.1 min), 1400 W (6.2 and 7.1 min) and 1600 W (5.0 min) for short wave IR emitters. The effect of these conditions on the phenolics and antioxidants of immature rice grains were investigated.

Extraction of phenolics and antioxidants

Extraction of free and bound phenolics and antioxidants was carried out using the method specified by Tuncel and Yılmaz (2011).

Determination of total phenolic content

Total phenolic content was analyzed spectrophotometrically according to Folin-Ciocalteau assay. Briefly, 100 µL of sample extract was mixed with 900 µL of deionized water, 5 mL of 0.2 N Folin Ciocalteau reagent and 4 mL of sodium carbonate (75 g/ L). The content was incubated in the dark for 2 h and the absorbance was measured at 765 nm with UV-VIS spectrophotometer (Agilent, Waldbronn, Germany). The results were expressed as mg ferulic acid equivalents per gram immature rice seed.

Determination of phenolic acid composition

Phenolic acid composition was determined by reverse phase liquid chromatography according to the method outlined in our previous study (Tuncel and Yılmaz, 2011). Gallic acid (GA), protocathechuic acid (proto-CA), *p*-hydroxybenzoic acid (*p*-hydBA), vanillic acid (VA), caffeic acid (CA), chlorogenic acid (ChA), syringic acid (SA), *p*-coumaric acid (*p*-COU) ferulic acid (FA), *o*-coumaric acid (*o*-COU), rosemarinic acid (RA) and trans-cinnamic acid (tr-CIN) were analyzed in either free or bound form extracts. The mobile phase was consisting of solvent A (methanol: water: formic acid, 10: 88: 2, v / v) and solvent B (methanol: water: formic acid, 90: 8: 2, v / v). Initial condition was 100 % A; 0 -20 min, changed to 80 % A; 25 - 50 min, to 50 % A; 50 - 54 min, followed by isocratic elutions of 50 % A; 54 - 63 min, 0 % A; and 63 - 70 min, 100 %A. Stationary phase was an Agilent Zorbax Eclipse XDB C18 column (150 mm x 4.6 mm x 5 µm) which was operated at 23 ºC. The flow rate was 1 mL/min throughout the analysis and the injection volume was 5 µL. Quantitation was based on external calibration curves built for each of the phenolic acids and the results were expressed as µg/g.

Determination of antioxidant capacity

Trolox equivalent antioxidant capacity (TEAC)

Trolox antioxidant capacity of the immature rice grains was determined according to Re et al. (1999). ABTS stock solution (7mM) was reacted with 2.45 mM potassium persulfate for 14 h at room temperature in a dark cabinet to generate ABTS radical cation. The radical solution was diluted with phosphate buffer saline to an absorbance between 0.680 and 0.720. Three different concentrations of extracts were added to 1 mL of diluted ABTS radical and the percentage inhibition of the radical was monitored for 6 min at 734 nm. All measurements

were performed with three dilutions per extract and in duplicate. The results were expressed as milimolar equivalents of Trolox per gram immature rice grain.

2,2-Diphenyl-1-picrylhydrazyl (DPPH) radical scavenging capacity

DPPH radical scavenging capacity of the extracts was measured according to the method reported by Yılmaz and Tuncel (2015). Briefly, 600 µL of 1 mM methanolic DPPH solution was mixed with three different concentrations of sample extract and brought to 6 mL volume using methanol. Absorbance of the content was measured at 517 nm using UV-VIS spectrophotometer (Agilent, Waldbronn, Germany) after incubation in the dark for 15 min. Percentage inhibitions were plotted against concentration and the results were expressed as EC_{50} values, the efficient concentration (mg) at which 50 % inhibition occurred.

Statistical analysis

Due to the unequal number of observations, one-way ANOVA was carried out to understand the effect of IR stabilization conditions on phenolics and antioxidants of immature rice grain using MINITAB. When significant effects were observed, Tukey's test was used for multiple comparisons. Results were presented as mean ± standard error and means were the average of 3 replicates.

Results and Discussion

Total phenolics content

Total phenol contents of unprocessed and IR stabilized immature rice grains were presented on Table 1. The results of the phenolics acids were presented as ferulic acid equivalents (FAE) since it is one of the most abundant phenolics acid in cereals. It was found that the content of the free phenolics was higher than that of the bound ones. Similarly, Tuncel and Yılmaz (2011) reported higher free phenolics content in rice milling fractions such as immature rice, rice bran, brown rice, unpolished rice, white rice, and chalky rice compared to bound phenolics. Although the effect of IR stabilization conditions was found statistically significant ($p<0.05$) on total phenolics content, it was observed that the results were very close mathematically and the variations might be attributed to random error. Free, bound, and total phenolics content of the IR stabilized samples were ranged between 0.37-0.55 mg FAE/g, 0.06-0.10 mg FAE/g, and 0.48-0.66 mg FAE/g, respectively. On the other hand, free, bound, and total phenolics content of the unprocessed immature rice grains were 0.52, 0.13, and 0.65 mg FAE/g, respectively (Table 1).

Table 1. Total phenol content of unprocessed and infrared stabilized immature rice grains

Wave lenght	Process time (min)	IR Power (W)	Total phenol (mg FAE/g)

*Within each column, means followed by different letters are significantly different by Tukey (P <0.05) **MW (Medium wave), SW (Short wave)
*** GA: Gallic acid, proto-CA: proto-catechuic acid, *p*-COU: *para*-coumaric acid, FA: ferulic acid, *o*-COU: *ortho*-coumaric acid, *tr*-CIN: *trans* -cinnamic acid, *p*-HBA: *p*-hydroxybenzoic acid, VA: vanillic acid, CA: caffeic acid, ChA: chlorogenic acid, SA: syringic acid, *p*-COU: *para*-coumaric acid

Phenolic acids

Among the analyzed 12 phenolic acids, gallic, proto-catechuic, *p*-coumaric, ferulic, *o*-coumaric and *tr*-cinnamic acids were identified in free, while gallic, *p*-hydroxy benzoic, vanillic, caffeic, chlorogenic, syringic, *p*-coumaric and ferulic acids were detected in bound phenolic extracts (Table 2, Table 3). Gallic, *p*-coumaric and ferulic acids were found either in free or bound form extracts. However, the amounts of *p*-coumaric and ferulic acids were 1.79 and 1.87 µg/g in free and 71.28 and 150.90 µg/g in bound form extracts, which clearly explains the requirement of bound phenolics extraction (acid / alkali hydrolysis) for cereals to understand the real phenolic acid composition.

The effect of IR stabilization conditions was statistically insignificant on the content of all free phenolic acids excluding *o*-coumaric acid ($p>0.05$). *O*-coumaric acid content of immature rice grain significantly decreased with IR stabilization ($p<0.05$). The lowest *o*-coumaric acid content was observed in immature rice grains which were stabilized at 1600 W for 5.02 min using short wave IR emitters. Among the bound phenolics acids, the effect of IR stabilization conditions was significant on the content of vanillic, caffeic, chlorogenic, p-coumaric and ferulic acids ($p<0.05$). The highest bound vanillic acid content was observed in unprocessed immature rice grain while no clear decreasing trend was observed for the other bound phenolics with regard to IR stabilization conditions (Table 3).

Antioxidants

Trolox equivalent antioxidant capacity (TEAC) and DPPH scavenging activity assays were employed to measure antioxidant capacity of either free or bound form extracts and the results were presented on Table 4. DPPH scavenging assay results were expressed as EC_{50} values, the efficient concentration (mg) at which 50 % DPPH radical inhibition occurred. Therefore, higher EC_{50} values correspond to lower antioxidant capacity. In this manner, the results of the 2 assays were compatible. The effect of IR stabilization was insignificant on either TEAC or DPPH scavenging capacity of the free form extracts ($p>0.05$). However, it was significant on bound form antioxidants with respect to both antioxidant capacity assays ($p<0.05$). Nevertheless, variation in antioxidant capacity of the bound form extracts was not consistent with the IR stabilization conditions and therefore could not be related with the power of IR emitters or the duration of the stabilization process.

Table 4. Antioxidant capacities of unprocessed and infrared stabilized immature rice grains

SW	5.02	1600	5.82 ± 0.15	8.84 ± 0.04^{B}	79.73 ± 5.06	136.94 ± 9.44^{AB}

*Within each column, means followed by different letters are significantly different by Tukey (P <0.05) **MW (Medium wave), SW (Short wave)

Conclusion

In conclusion, it was found that IR radiation can be used to stabilize immature rice grains without negatively affecting the content of phenolic compounds and antioxidant capacity**.**

Abstract

The vegetable oil sector is an industrial sector that brings raw materials from agriculture to more durable and ready-to-use conditions through various preparation, processing, preservation and packaging techniques. Values such as monounsaturated fatty acids, polyunsaturated fatty acids, saturated fatty acids, smoke point are of great importance for use in the food industry and industrial vegetable oils. Stability and nutritional characteristics of oils are the most important factors in food technology. There is no pure oil with high functional and nutritional properties and high oxidative stability. For this reason, blended oils are prepared to improve commercial applications and functional properties of vegetable oils. New specific products with desired nutritional properties can be created. Blending oils lead to improved industrial applications. The economic, high nutritional value and strong stability properties of blended oils, which are offered at a more affordable price to the market, have become quite common in recent years. Blended oils have advantages such as low cost, reduced complexity of varieties, ideal and desired performance for applications, high smoke point, helping to establish omega 6/3 balance. The disadvantages are; unfavorable oils and unfavorable blends may cause undesirable results in taste, odor, color and function. In this study, a literature review about blended oils was presented and samples from domestic and foreign markets were showed. The commercial examples of oil blends in the market are generally comprising of olive, canola, sunflower, hazelnut, soybean and grape seed oils, while scientific research are more focused on blends containing palm oil and some specialty oils with functional properties such as rice bran oil, black cumin oil etc. In the future, there will also be many economical and health reasons for the production of new oil blends using new and conventional oil sources to be introduced to the market.

Keywords: *Edible oils, Oil blends, Vegetable oil sector.*

Introduction

Thanks to technological developments and increased production, the vegetable oil sector has also improved considerably. The types of vegetable oil produced have rised and the product variety advanced (Arıoğlu, 2010). Consumers prefer vegetable oil consumption by looking at factors such as taste, price and nutritional characteristics. Without sacrificing nutritional values, tasty and affordable oil consumption is a desire for everyone. In the modern world, it is a difficult and important responsibility to select and consume the oils that are beneficial to health among the many options available. Variety of mono- polyunsaturated and saturated fatty acids and controlling they amount in the vegetable oil of the diet, play a key role in regulating many physiological processes in the body. Studies have suggested that oil consumption provides 20% energy per day of normal nutrition, with 8-10% of saturated fatty acids and 10-12% of polyunsaturated fatty acids. The World Health Organization (WHO) recommends a total oil consumption of 30-35%, with saturated fatty acid <10%, polyunsaturated fatty acid 6-11%, and monounsaturated fatty acid 10-14%. The consumption of 2 or 3 tablespoon per day of vegetable oils with this fatty acid formulation completes a

healthy and balance diet. Polyunsaturated fatty acids contain omega-3 ALA (α-linolenic acid) and omega-6 LA (linoleic acid). These fatty acids are essential and are taken only by diet.
Because of the health effects of the fatty acid composition, blended oils have gained popularity by providing more stable and healthy consumption of vegetable oils. Blending vegetable oils is a viable method for regulating fatty acid composition. Blending two or more oils with different properties is one of the simplest procedures to produce a new specific product (blended oil). Blended oil production not only regulates fatty acid composition but also contributes to high oxidative stability and prolong shelf life, affordability and more nutritional elements (Srikanth and Rajaveni, 2014). Some companies in the vegetable oil sector are only interested in the economy, using the cheap oil, rather than looking at the nutritional quality and fatty acid composition in preparing the blend (Taşan and Geçgel, 2007). Polyunsaturated fatty acids are vegetable oils used for baking and frying. For example, soybean oil is considered superior to many vegetable oils. However, it exhibits low thermal stability and low oxidative stability. To overcome the problem of low oxidative stability of soybean oil, methods such as modifying the fatty acid composition and increasing natural antioxidants are used. For this purpose, blends of soybean oil with hydrogenated soybean oil and high oleic sunflower oil have been tried (Abdulkarim et al., 2010).

Vegetable Oil Production and Consumption Values in the World

34% of global crude oil production and 61% of exports are made by Indonesia and Malaysia, while 64% of crude oil production comes from palm and soybean oil. In the production of olive oil, the EU countries (mainly Spain, Italy, Greece) are in the top 75% share. Turkey, in the crude vegetable oil from oilseeds production is far behind in the world ranking. But olive oil is a big producer and is ranked 5th in the world with 4.7% share (Öztürk, 2016) .

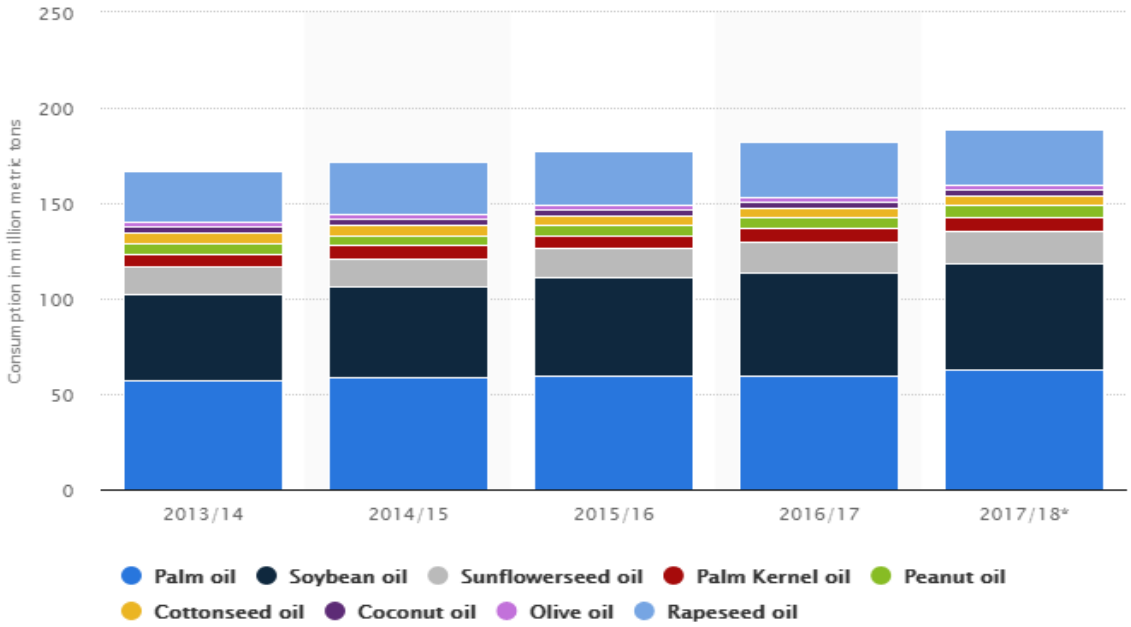

Figure 1. Consumption of vegetable oils worldwide from 2013/14 to 2017/2018, by oil type (in million metric tons)

In 2016/17, sunflower oil consumption amounted to 16.52 million metric tons worldwide. The global vegetable oil production amounted to around 182 million metric tons in 2016/2017. When the global oil consumption is examined, most consumption has been in the palm oil with 64%. This was followed by soybean oil with 53%, rapeseed oil with 27% and sunflower oil with 15%. Olive oil consumption in the EU countries which ranks first, followed by the United States and Turkey (Anonymous, 2018).

Literature On Issue

Food products is based on the frying process throughout the world. For this reason, oxidative stability in fats is an important point. Synthetic antioxidants are used to minimize rancidness and extend shelf life. Adding natural antioxidants rich oils to edible frying oils is an easy process to increase stability. For example, the stability of sunflower oil has been strengthened with the addition of black cumin oil, rich in tocoferol and thymoquinone (Kıralan et al., 2017). Linseed oil is one of the most important oils because of the high amount of α-linolenic acid (ALA, omega-3), which is an essential fatty acid. At the same time, linseed oil is very prone to oxidation. To improve the oxidation stability, flaxseed oil is blended with other vegetable oils rich in bioactive and antioxidant components. For this process, 80:20 cold pressed *Nigella sativa* oil and sesame oil were added to linseed oil. As a result of the study, the total amount of phenolic components increased in the blended oil samples compared to individual oil. Radical scavenging activity has increased by 10-20%. The results show that the blending of vegetable oils containing strong antioxidant ingredients such as cold pressed *Nigella sativa* seed oil and sesame oil into linseed oil significantly enhances the oxidation stability and that the blended oil technique is a simple and effective alternative to the use of synthetic antioxidants (Hamed and Abo-Elwafa, 2012).

Increase in oleic acid in vegetable oils, an important goal to raise the quality of fat. Because, as the amount of oleic acid in vegetable oils rises, cardiovascular diseases decrease, resistance to oxidation enhances. Sunflower oil with a high oleic acid content can be used alone or blended with soya and canola oils to reduce the linolenic acid content to 2-3%. In addition, sunflower oil is blended with canola and palm oils which are rich in monounsaturated fatty acids in order to extend its shelf life (Duru and Bozdoğan Konuşkan, 2014).

Yalçın et al. (2017) in the study extra virgin olive oil and sesame seed oil were blended in varying proportions and stored for 90 days in room conditions. Oxidation parameters varying during storage have been examined. Extra virgin olive oil is more susceptible to oxidation compared to sesame oil, but the formation of oxidation products is observed to decrease in the oil blend. The results show that extra virgin olive oil can be blended with sesame oil containing strong antioxidants and stored for a long time.

Olive oil and palm olein oil were blended at various ratios to observe the effect of saturated / unsaturated fatty acid ratio on physicochemical properties. The high oil content of palm olein has been reported to show strong chemical stability in frying processes. As a result, the increase of the saturated fatty acid ratio in the blended oil affected the stability of the oil (Naghshineh et al., 2010). A variety of blend oil combinations have been established to strengthen oxidative stability. One of them is the investigation of the effect of grape seed oil addition to sunflower oil on the quality, physicochemical properties and radical scavenging activity. As a result, as grape seed oil ratio in sunflower oil increased, properties such as refractive index, iodine value, peroxide value, saponification value and acid value decreased and radical scavenging activity enhanced. It is also stated that the oxidative stability of the blended oils can be increased by raising the grape seed oil ratio (Codină et al., 2015). In another study where sunflower oil was used, cold pressed tiger nut oil and sunflower oil were formed at 0/100 and 100/0 range. In the prepared samples, degradation in the frying process decreased and oxidative stability increased (El-Anany et al., 2012). It has been found that the blend of olive pomace oil-refined olive pomace oil (50:50) used in frying processes is exposed to lower levels of degradation reactions according to sunflower oil (Yaşdağ and Tekin, 2017) because of the low amount of unsaturated fatty acids. In a study of frying performance, Marco et al. (2007) compared sunflower and palm oil blend to palm oil alone. The free fatty acid value of the sunflower/ palm oil 65/35 (w: w) blend was lower. In the frying process, it has been determined that the oxidative stability is higher than the use of palm oil alone, although it is stated that some oxidation indices appear faster in the blend oil.

Ramadan et al. (2011) investigated the effects of corn oil, black cumin oil and coriander oil additions on functionality, stability and radical scavenging activity; the polyunsaturated fatty acids decreased as the blend ratio increased, while the monounsaturated fatty acids ascended. The oxidative stability of oil blends is higher than that of pure corn oil. The effect of coconut oil addition on vegetable oil blends on fat, fatty acid composition, oxidative stability and radical scavenging activity was investigated in a study using palm, rice bran, sesame, mustard, sunflower, peanut, safflower and soybean oil (Bhatnagar et al., 2009). The resulting seven blends were improved in terms of mono- and polyunsaturated fatty acids, total tocopherols and radical scavenging activity. In addition, reductions in peroxide formation were observed. It has been stated that the oxidative stability of these blends is higher.

Lipidium sativum L. rich in omega-3 ALA (α-linolenic acid) oil and blends of this oil with vegetable oils were used in the feeding of experimental rats to investigate antioxidant enzyme status in their body. Sunflower oil, rice bran oil, sesame oil are used for preparation blended vegetable oils and added to the diets of rats for 60 days. As a result, the percentage of tocopherol was increased in the body of rats fed blend oil compared to the experimental rats fed with the native fat. The activity of antioxidant enzymes (catalase, glutathione, peroxidase) in their body was improved but in some liver enzymes not change (Umesha et al., 2002).

Khan et al. (2010) conducted a serum lipid profile and retinol assay in experimental rats fed a micronutrient rich, edible vegetable oil blend, used mustard oil and palm olein oil. Experimental rats, which fed with fat containing 1% cholesterol before the study, were fed micronutrient-rich fat in the amount of 10% of their diets during the 1 or 6-month period and significant changes were recorded in their serum lipid profiles. It is expressed that the maximum benefit is obtained if the oils are used in blend. It has also been found that when used as a blend, it has a mitigating effect on diseases such as coronary heart diseases, diabetes, obesity, hypertension.

Conclusion

Depending on the previously published studies, the blend oils have superior properties compared to the individual oils. Blended oils contribute to the functional and nutritional properties of vegetable oils consumed in household use. In industrial use, it has advantages such as increasing the commercial potential of the oil, lowering the cost, strengthening the stability. It regulates the fatty acid content of vegetable oils, which are susceptible to oxidation, and prolongs the shelf life. It provides chemical stability of fats in frying processes and storage after frying. Enriched with vegetable oils containing essential fatty acids, provides functional oils to be produced. Blended oils enables the consumer to obtain tasty and healthy oil at a more affordable price. The household use of blended oils is not common because of fraud in vegetable oils. This fraud is most commonly in the form of canola, safflower and soybean oil added olive oil or sunflower oil. Consumers have a negative attitude towards professionally prepared blended oils due to illegally prepared vegetable oil blends.

In blended oil samples; to increase omega-3 ratio sunflower oil is blended with canola oil, and addition of palm super olein oil to sunflower oil to improve frying performance. "A cheap alternative instead of 100% natural extra virgin olive oil" to the market with the slogan of the oil blend is used in varying proportions. There are soya, canola and olive oil blends to ensure omega-3/6 balance. In the same way to increase nutritional value and omega-3 ratio; sunflower oil with high oleic content, natural rapeseed oil, extra virgin olive oil, natural Camelina sativa seed oil, natural sesame oil blends are prepared. In order to benefit from the antioxidant properties, combinations of grape seed, avacado and tiger nut oil with other vegetable oils are produced.

Abstract

An in vitro propagation protocol was developed for the production of Teleki 8B, 140 Ruggeri, 110 Richter, Kober 5BB, 99 Richter and SO4 (Selection Oppenheim 4) grapevine rootstocks through meristem tip culture. These plants will be used in nematode virus transmission baits. Meristem tissues were isolated from apical shoot-tips with 5-10 mm in length collected from plants maintained at greenhouse and grown on liquid and solid Murashige Skoog Medium (MS) supplemented with 1 mg/L^{-1} 6-Benzylaminopurine (BAP). The tubes and petri dishes with meristematic tissues were incubated in growth chamber at 24°C during a 16 h light period 8 h dark period. After eight weeks, newly emerged shoots were transferred into MS medium and stored in growth chamber for further growth. At final stage adequate grown shoot were transferred into MS medium with 1 mg/r L^{-1} Indole Butyric Acid (IBA) for root formation and growth. When root formation and growth were completed, all plantlets were transferred to 8 cm pots filled with peat and soil. Total of 153 plants were propagated with this method from 6 grapevine rootstocks.

Keywords: *Meristem tip culture, Grapevine rootstocks, Murashige and Skoog Medium*

Introduction

Grapevine is one of the most widely cultivated fruit crop in Turkey covering an area of 6,9 million hectares. It is grown in varied climatic conditions ranging from temperate to semi tropic and tropics. Turkey is known as one of the mother lands of grapevine and ranks sixth in world grape production. Having favorable ecological conditions and good soils, more than 1250 grape varieties can be grown in almost every part of the country. Approximately 40% of grape product is consumed for raisin, 35% is consumed as fresh and 3% is processed to wine. Various factors are responsible for decrease of agricultural productivity in Turkey. Viruses, viroids, bacteria, fungi, constitute pathogens that some were reported as very problematic in various crop plants in Turkey (Argun et al., 2002; Çığşar et. al., 2002, 2003; Öztemiz et al., 2005; Akbaş et. al., 2007; Uygun et al., 2010; Buzkan et.al., 2010; Yıldırım, 2014; Buzkan et al., 2015; Gazel et al., 2016). Grapevine pathogens can distributed by several ways. Infected plant materials are main reason of higher epidemics. For example once pathogen infected grapevine seedling is planted to non infected vineyard rapid spread to healthy plant is possible due to presence of several nematode and insect vectors. Becides there is no chemical treatment to eradicate virus, bacteria and some fungi infections from infected vine. Establishing vineyards with healthy plants is obvious method for restriction of disease distribution. In vitro meristem tip culture is an efficient method for obtaining disease free material from grapevines. The main reason for use of the meristem culture is most pathogens fail to invade the meristematic region of shoot tips since the multiplication of meristem cells is faster than replication of pathogen. Successful regeneration of healthy plants can be achieved by culturing only disease free apical meristems isolated from infected grapevines.

Meristem culture allows higher genetic stability of regenerated plants with low somaclonal variations (Milosevic et al., 2011).

This method have been efficiently applied to several plant species including dahlia, freesia, geranium, lily, chrysanthemum, citrus to eliminate pathogens (Milosevic et al., 2012). In a laboratory study *Impatiens hawkerii* Bull. was totally eradicated from *Tomato spotted wilt virus* (TSWV) and *Cucumber mosaic virus* free chrysanthemum plants were micro propagated via meristem tip culture (Verma et. al., 2004; Milosevic et.al., 2011). Furthermore *Grapevine Leafroll Associated Virus* 1 and *Grapevine Fanleaf Virus* free grapevines were obtained from the optimum 0.5 mm size of meristem tips (Fayek et al., 2009). On the other hand this method shown to be effective for elimination of *Rhizobium vitis* (Sim and Golino 2010). Meristem tip culture allows multiplication of plant that do not produce seeds and could not be vegetatively propagated. In addition this method is not season and climate dependant. Insitu meristem culture under controlled sterile conditions with healthy tissue from plants allows rapid propagation of a large number of plants in a short time (Khan et al., 2015).

Most of the vineyards in Turkey are infested by phylloxera (*Viteus vitifolii*). Gall formation by feeding of higher population of this pests in grapevine roots results in poor growth and death of the vine. The European grape *Vitis vinifera* is highly susceptible to phylloxera and to overcome damage grafting on resistant American rootstocks is recommended in most parts of the country (Sengel et.al., 2012).

Within existing American rootstocks Teleki 8B, 140 Ruggeri, 110 Richter, Kober 5BB, 99 Richter and SO4 (Selection Oppenheim 4) are mostly preferred in Northwestern Marmara Region due to phylloxera resistance, well adaptation and good growth in local soil and climate conditions. *Grapevne Fanleaf Virus*, *Grapevine Leafroll Associated Virus* and Rhizobium vitis are problematic among production materials in Turkey and were detected in mother plants of Kober 5BB, SO4 (Selection Oppenheim 4) and Teleki 8B rootstocks from which cuttings is collected for new rootstock production. Meristem tip culture is recommended for production of virus free plants of these rootstocks. On this purpose a study was carried out forin vitro propagation of Teleki 8B, 140 Ruggeri, 110 Richter, Kober 5BB, 99 Richter and SO4 (Selection Oppenheim 4) grapevine rootstocks through meristem tip culture.

Material and Method

Meristem cultures of Teleki 8B, 140 Ruggeri, 110 Richter, Kober 5BB, 99 Richter and SO4 (Selection Oppenheim 4) were isolated mid June till the end of August from shoots of actively growing vines grown in greenhouse established in Viticulture Research Institute. Apical shoots 5 to 10 cm long, were collected from vines, larger leaves removed, sterilized by immersing for 10 minutes in 10% sodium hypochlorite and rinsed three times in sterile distilled water (Figure 1). Apical meristem tips no longer than 0.5 mm long were excised under a binocular stereomicroscope in a laminar flow cabinet using flame sterilized needle.

Shoot Proliferation

Meristematic tissues were grown on solid Murashige Skoog Medium (Murashige and Skoog, 1962) (MS) supplemented with 3% sucrose, 1.9 gr/lt KNO_3 and 1 mg/L^{-1} 6-Benzylaminopurine (BAP) and 7 gr Agar- Agar (Table 1). The medium was adjusted with 1N KOH to pH 5.8 sterilized by autoclaving for 15 min at 120 ^{o}C. Culture tubes (30x120 mm) and 60 mm glass petri dishes were used in the culturing process. The tubes and petri dishes with meristematic tissues were incubated in growth chamber at 24°C during a 16 h light period 8 h dark period. After eight weeks, newly emerged shoots were transferred into MS medium and stored in growth chamber for further growth and this process was repeated till obtaining shoots with length suitable for rooting.

Table 1**.** MS media formulation used for meristem culture of grapevine rootstocks

Ingredients	**gr/100 ml**	**Ingredients**	**gr/100 ml**
NH_4NO_3	16.5	$Na_2Mo_4.2H_2O$	0.125
$CaCl_2.2H_2O$	4.4	$CuSO_4.6H_2O$	0.125
$MgSO_4.7H_2O$	3.7	$CoCl_2.6H_2O$	0.125
KH_2PO_4	1.7	$FeSO_4$.7H2O	1.114
$MnSO_4.H_2O$	0.223	Na2EDTA.$2H_2O$	1.49
H_3BO_3	0.062	Thiamine-HCl	0.01
ZnSO4.4H2O	0.086	Pyridoxin-HCl	0.05
KI	0.415	Nicotinic acid	0.05

Figure 1**.** Apical shoots and actively invitro grown meristematic tissues of rootstocks

Root proliferation

At final stage adequate grown non contaminated shoots of 5 cm in length with small leaves were cut from mother plants and transferred into new culture tubes (30x 200mm) containing MS rooting medium with 3% sucrose and 1 mg/L^{-1} Indole Butyric Acid (IBA) which promote root formation and elongation.

When root formation and growth were completed, all plantlets were transferred to viols filled with peat. Before transplanting plantlet roots were soaked to fungicide to prevent fungal soil borne diseases. These viols were covered with nylon to achieve sufficient ex-situ conditions for sustaining plant growth without any loss (Figure 2). This young plants were covered for two weeks and then viols were uncovered everyday for a few hours. After plantlets complete aclimatization period they were transferred to 8 lt pots filled with sterile peat and soil.

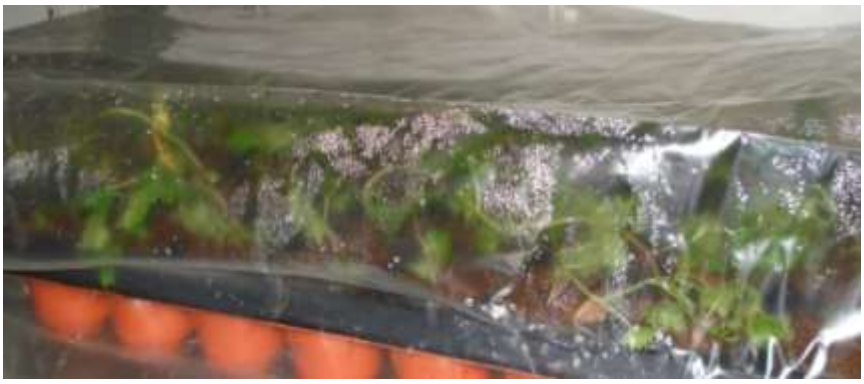

Figure 2. Ex-situ acclimatized new plantlets grown in climate room.

Results and Discussion

Approximatelly 432 meristematic tissues were isolated from Teleki 8B, 140 Ruggeri, 110 Richter, 5BB, 99 Richter and SO4 (Selection Oppenheim 4) rootstocks during two months period. Within these meristem some of them lost due to browning without regeneration. In addition *Aspergillus* and *Penicillium* contaminations were observed in some test tubes and they were discarded. In some cases meristems remained dark brown for a period but later green tissues started to grow and form new shoots. As these shoots reached adequate height they were transferred to new MS medium for further elongation. At the end of rooting process 153 plants were transferred to pots and maintained in climate room at 24ºC 16 h light 8 h dark period (Table 2).

Table 2.Number of plants produced by meristem tip culture

Rootstocks	**Plants transferred to pots**
SO4 (Selection Oppenheim 4)	27
Kober 5BB	43
140 Ruggeri	13
110 Richter	32
99 Richter	21
Teleki 8B	17

The period of axillary shoot collection from mother plant also affect meristem growth. Better meristem isolation and growth was observed when collected at the end of June till mid July. Most of the meristems established at the end of August did not survive.

The effect of culture medium mineral composition and hormones on the micropropagated grapevines has been stated by different authors (Troncoso et.al, 1990;. Balance of hormone amount and medium composition was considered essential to achieve higher meristem regeneration and shoot growth. Experiments of Sarker et. al. (2015) indicated that Citrus micropropagation performance declined parallel to BAP concentration increase or decrease from the optimum dose.

Several researchers also reveal that BAP concentration higher than 1 mg L^{-1} increase the number of vitrified shoots (Subotić et al., 2008; Milosevic, 2011). In addition pale and stunted shoots in some crop plant such as Alocasia higher concentrations observed in higher BAB concentration. In our study meristem tissue growth was promoted by addition of 0.01 gr BAP into 1 liter MS medium. This amount was found sufficient regaring regeneration of new buds and good growth of shoots was achieved. Vitrification, stunting was not observed.

As invitro propagated shoots transferred to rooting medium they produce good roots. The IBA dose was determined adequate for rooting of all rootstock shoots. On the other hand new plantlets of up to 180 cm height was obtained in five months period at rooting medium.

Conclusion

We carried out a study to invitro micropropagate plantlets of Teleki 8B, 140 Ruggeri, 110 Richter, Kober 5BB, 99 Richter and SO4 (Selection Oppenheim 4). Meristem tip culture is effective method to produce plants free of diseases when meristematic tissues less than 0.5 cm excised. Otherwise diseases will be transmitted. In our study we tried to establish culture with meristematic dome and we took small pieces. In miicropropagation process we used standard MS medium with BAP and IBA hormones. After 6 months we achieved to propagate 153 new plantlets.

Abstract

Diseases in agricultural areas cause significant losses regarding quality and yield. To reduce these losses, intensive pesticides are used. Extreme pesticides use causes many problems. For this reason, alternative control methods have become necessary. This study was conducted to determine the antifungal effect of *Origanum onites* L. essential oil against *Sclerotinia sclerotiorum* (Lib.) de Bary, *Alternaria solani*, *Verticillium dahliae* and *Fusarium oxysporum* f. sp. *lycopersici*. Essential oils were applied by impregnation with a micropipette on filter paper adhered to the covers of petri dishes.In the antifungal study 0 (control), 0.5, 0.7, 1, 1.5, 2 and 4 µlpetri^{-1} dish doses were used. In the antifungal study, mycelium diameters in the petri dishes were measured by automatic caliper at the end of the 7th day of incubation period. As a result, essential oil of *O. onites* was inhibited mycelial growth in *A. solani*, FOL, *S. sclerotiorum* and *V. dahliae* at a dose of 1.5 µlpetri^{-1} dish by 100%. It was found that 1.5 µlpetri^{-1} dose of *O. onites* essential oil inhibited the mycelium growth of *S. sclerotiorum* by 13.33%. The essential oil of *O. onites* inhibited the mycelium growth in *A. solani, S. sclerotiorum*, FOL and *V. dahliae* at a dose of 4 µlpetri^{-1} dish by 100%. These findings showed that the *O. onites* essential oil has high antifungal activity. This result showed that *O. onites* essential oil had a potential to replace synthetic pesticides.

Keywords: *Origanum onites, antifungal, essential oil.*

Introduction

Origanum genus (Labiatae) is represented by 22 species or 32 taxa in Turkey. Of these species, 21 were endemic, while the endemism rate is 65.2% (Aydin *et al.,* 1998; Dundar *et al.,* 2008). The favorable climatic conditions for the growth of Origanum species are warm-temperate southwestern Eurasia and Mediterranean regions (Kokani, 1997). Among culinary spices, thyme plays a primary role in world trade. It has been produced in particularly in Europe, including France, Greece, Spain and Turkey, as well as in America, including Chile, Mexico and Peru (Olivier, 1996; Barreyro *et al*, 2005). In Turkey, numerous species of thyme have been exported, which are: *Origanum onites, O. minutiflorum, O. majorana, O. syriacum* var. *bevanii, O. vulgare* (Baser *et al*, 1993; Kirimer *et al*., 2003; Toncer *et al*., 2009). Among these species, *O. onites* is the most exported species in the world (Yaldız *et al*., 2005).

Due to the antimicrobial substances they contain, essential oils have an alternative potential against infecting organisms. It is acknowledged by the entire world that herbal products are less toxic to the environment and human health in controlling diseases (Lee *et al*., 2007). In particular, it has been reported that essential oils exhibit favorable antifungal activities against various pathogens, both *in vitro* and *in vivo* conditions (Baruah *et al*., 1996). Origanum essential oil was reported to exhibit anti-bacterial, anti-oxidant, anti-fungal cytotoxic and insecticidal activity (Vagi *et al*., 2005; Tepe *et al*.,2004; Muller *et al*., 1995; Wilson *et al*., 1997; Traboulsi et al., 2002). Once again, in a similar study, the antifungal activity of the Lamiaceae family members on *Verticillium dahliae* pathogens was reported (Rus *et al*., 2015).

In this study, the antifungal activity of *Origanum onites* essential oil on the plant pathogens, including *Verticillium dahliae, Alternaria solani, Sclerotinia sclerotiorum* and *Fusarium oxysporum* f. sp. *lycopersici* was investigated.

Material and Methods

Plant Material and Extraction of Essential Oils: *Origanum onites* plants collected during the flowering phase of Mersin province in 2017 vegetation period. By using Neo-clevenger aparate and hydro-distillation method, the essential oils were obtained from the plants dried in the shade. The essential oils obtained were stored at +4°C until the activity studies.

Fungus Cultures: The fungi of plant pathogen used in the study (*Verticillium dahliae* (Vd), *Alternaria solani* (As), *Sclerotinia sclerotiorum* (Ss) and *Fusarium oxysporum* f. sp. *lycopersici* (Fol) were obtained from the stock cultures in Phytopathology laboratories of Department of Plant protection, Faculty of agriculture, Ahi Evran University.

Antifungal tests: The prepared PDAs, 10 ml per each, were poured into 60 mm plastic petri dish. Sterile drying papers were adhered to the covers of petri dishes and the drying papers were impregnated with essential oils at the determined doses (0.5, 0.7, 1, 1.5, 2, 4) by the help of a micropipette. As a control group, 8 µl sterile distilled water was impregnated onto the drying paper. The surroundings of the petri dishes were covered with parafilm and left to incubate at 25 °C. Seven days after treatment, mycelial growth of the diseases was measured with digital calipers. The treatments were carried out 3 times with 2 repetitions. The inhibition rate of essential oils (%) is calculated according to the following formula.

I:100x(dc-dt)/dc

I: Mycelium growth inhibition rate (%)

dc: Mycelium growth in control

dt: Mycelium growth in treatment (Pandey *et al*., 1982)

Statistical Analysis

The analysis of variance (ANOVA) was used to determine the significance levels of differences between the experimental treatments, and the means were compared by using the DUNCAN test. Statistical analyses were carried out using the SPSS software.

Results and Discussion

The results of the antifungal effects of *Origanum onites* essential oil on *Verticillium dahliae, Alternaria solani, Sclerotinia sclerotiorum* and *Fusarium oxysporum* f.sp. *lycopersici* (Fol) are given in Table 1 and Figure 1.

It was determined that *O. onites* essential oil has statistically significant antifungal activity on the tested plant pathogenic fungi. The negative effect of fungi on mycelium growth has changed due to the pathogen and increased dose. *O. onites* essential oil reduced the mycelial growth of Fol compared to the control and stopped it completely at a dose of 1.5 µl/petri. Similar results were also found in *V. dahliae* and *A. solani* pathogens. It was determined that *S. sclerotiorum* was the most tolerant pathogen to *O. onites* essential oil and it prevented the mycelium growth of the pathogen only at the highest dose (Table 1).

O. onites essential oil inhibited the mycelium growth of *V. dahliae, A. solani* and *Fol* by 100% at a dose of 1.5 µl/petri. However, *O. onites* essential oil inhibited the *S. sclerotiorum* mycelium growth by 100% only at the highest dose (4 µl/petri dish) (Figure 1).

Table 1. The antifungal effects of *Origanum onites* essential oil on plant pathogen fungi

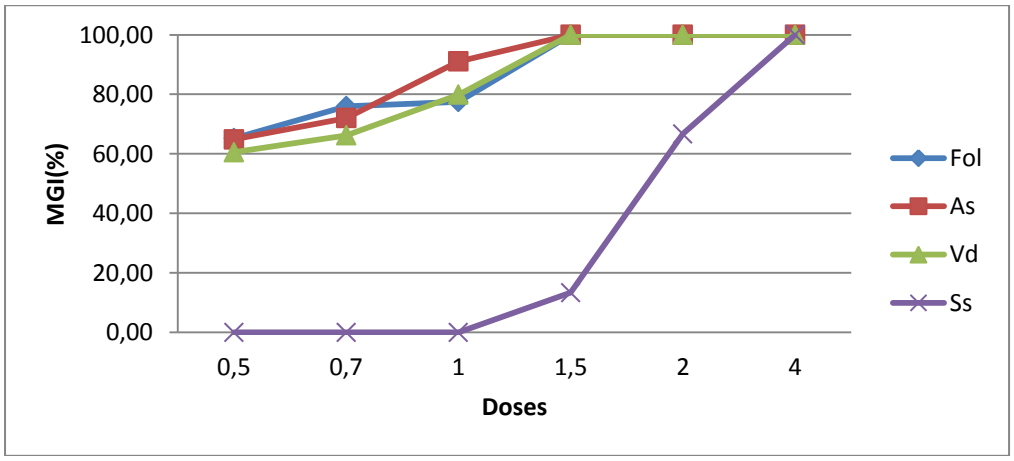

Figure 1. % Mycelium growth inhibition rate(MGI) of *Origanum onites* essential oil on plant pathogen fungi

Similar studies were carried out by different investigators on *Fusarium oxysporum* f. sp. *lycopersici*, *V. dahliae* and other plant pathogenic fungi and antifungal effects of plant essential oils were reported in these studies. It was reported that *Salvia officinalis*, *S. cryptantha* and *S. tomentosa* plant essential oils and extracts have an antifungal activity on the mycelium growth of *Fusarium oxysporum f. sp. radicis-lycopersici* depending on the doses, extracts and essential oils (Yilar and Kadioglu, 2016). Yilar *et al*. (2016) reported that *Vitex agnus-castus* L. and *Myrtus communis* L. essential oils inhibited the mycelium growth of *Fusarium oxysporum f. sp.radicis-lycopersici* and *Verticillium dahliae* by 70.70%-100% and 93.00%-100%, respectively compared to the control. Likewise, in a similar study *Heracleum platytaenium* Boiss. essential oil inhibited the mycelium growth of *V. dahliae* and *Fusarium oxysporum f. sp.radicis-lycopersici* by 73.25% and 100%, respectively at 10 µl dose (Bayan *et al*., 2016). *O. onites* and *T.spicata* essential oils exhibited the strongest antifungal activity against *A. alternata* (Soylu and Kose, 2015). It was stated that *Origanum syriacum L.* essential oil exhibits a high degree of antifungal activity on *Aspergillus niger*, *Fusarium oxysporum*, and *Penicillium* species (Daouk *et a*l., 1995). The antifungal activity of *Origanum vulgare* and *Origanum majorana* essential oils against *Candida albicans* was reported (Lakhrissi *et al*., 2016). Similarly, Arslan and Dervis (2010) reported that *Origanum onites, O. syriacum, O. minutiflorum, O. vulgare, O, marjorana, Thymus vulgaris, T. serpyllum, Rosmarinus officinalis, Salvia officinalis* and *Micromeria fruticosa* essential oils inhibited the mycelium growth of *Verticillium dahliae*. It was also reported that Origanum majorana L. essential oil inhibited the mycelium d growth of *Verticillium dahliae* at 0.5 $mg \cdot L^{-1}$ and 1 $mg \cdot L^{-1}$ doses, and that the MIC concentration for this disease is 5 $mg \cdot L^{-1}$ (Rus *et al*., 2015.

Conclusion

This study showed that *Origanum onites* essential oil has antifungal effect on *Verticillium dahliae, Alternaria solani, Sclerotinia sclerotiorum* and *Fusarium oxysporum* f. sp. *lycopersici* plant pathogens. Today, when the negative effects of the pesticides, used intensively in the control of plant pathogenic fungi in agricultural products, on the environment and people have emerged, these and similar work findings are gaining more importance. However, it is important to improve these and similar study findings and make them available in the agricultural field.

EVALUATION OF DAMAGE RATES OF LEOPARD MOTH, *ZEUZERA PYRINA* L. (LEPIDOPTERA: COSSIDAE) IN WALNUT ORCHARD IN HATAY PROVINCE OF TURKEY

Nihat DEMİREL*

University of Mustafa Kemal, Faculty of Agriculture, Department of Plant Protection, Hatay, Turkey
*Corresponding author: ndemirel@mku.edu.tr

Abstract

The leopard moth, *Zeuzera pyrina* L. (Lep. Cossidae), is one of the principal pests of the walnut trees in Turkey. The leopard moth larva is a xylophagous species that infest the trunk, shoots, and branches of numerous fruit-bearing threes. Accumulated damages by larval instars may cause the death of young trees or loss of the branches in older trees. The signs of damage in walnut trees include dark fluid ozzing from bark and also larval orange faeces expulsion from larval tunnels that can reach up to 50 cm. Damage results in tree weakness, the attraction of bark beetles and finally plant death. The study was conducted in 2016-2017 to evaluate damage rates of the leopard moth on walnut CV 'chandler' in a orchard of Yayladağ district of Hatay province of Turkey. The walnut orchard contained 3345 walnut trees (380 da), and evaluation of the damage rates was done tcounting the number of the damaged branches and truck of walnut trees. As a result of the investigation, the damages rates of this pest varied in each of the sampling years. The walnut damages rates by leopard moth were 16 per cent in 2016 and 8.87 per cent in 2017.

Keywords: *Damage, Leopard Moth, Walnut, Turkey.*

Introduction

The walnut, *Juglans regia* L., (Juglandaceae: Fagales) is one of the most significant nut trees in the world. In 2014, worldwide production of shells was 3.46 million tons, China contributed 46% (1,600); other major producers were United States (520), Iran (450), Turkey (180) and Mexico (130) of the world total (Faostat, 2017). The walnut is one of the essential nut trees in Turkey which production is consisting of approximately 868.528 dekar with the total production of 195.000 tons of fruit per annum, and Hatay province's share is 2.361 dekar and 1428 tons [Anonymous, 2016]. The leopard moth, *Zeuzera pyrina* L. (Lepidoptera: Cossidae) is an damaging polyphagous pest infesting over 150 plant species, including fruit trees, such as walnut, apple and quince, and some forest trees, such as elm and chestnut (Balachowsky and Mensil 1935; Carter 1984; Castellari, 1986; Gatwick 1992; Kutinkova et al., 2006; Alford, 2007). The leopard moth, *Zeuzera pyrina* L. is one of the most important pests of walnut trees in Turkey. The larvae of leopard moth feed inside the stems and branches of young trees, causing dieback of shoots, yellowing of leaves and killing of many young trees (Alford, 2007). The purpose of the current study was to evaluate the damage rates of leopard moth in a walnut orchard in Hatay province of Turkey.

Material and Methods

The study was conducted in 2016-2017 to evaluate damage rates of the leopard moth on walnut 'chandler' variety orchard in Yayladağ district of Hatay province of Turkey. The walnut orchard contained 3345 walnut trees (380 da). The walnut trees damage assessment resulted as the percentage of trees with at least one recent larval gallery in November of both years. For this purpose, observations of all the trees were carried out to register the number of infested plant limbs. The percentage of damage was calculated by dividing the number of infested walnut trees by the total number of sampled walnut trees.

Results and Discussion

The damages rates of the leopard moth larva varied each of the sampling years. In the first year, the damage ratios of leopard moth larva was the 16 per cent in 2016, but the 8,87 per cent in 2017 (Figure 1).

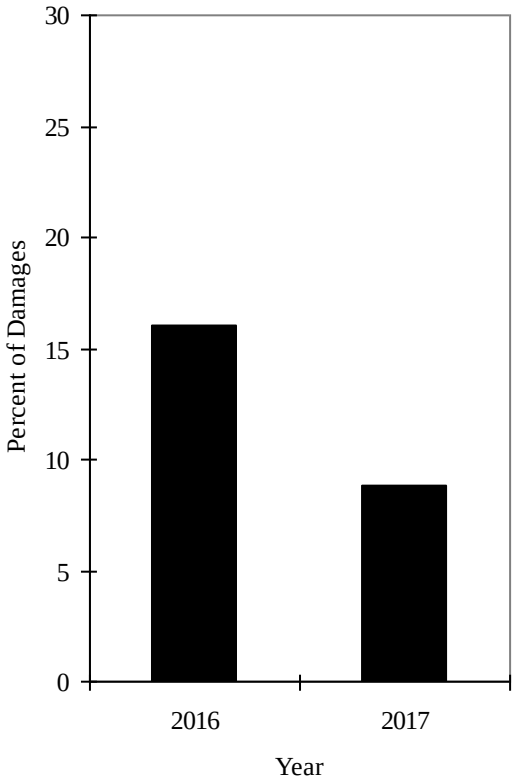

Figure 1. The percentages of damage rates leopard moth in 2016-2017 at the walnut orchard in Hatay province.

Patanita and Vargas-Osuna (2011) reported that the percentage of trees with infested trunks was reduced by 41% in the plots with five traps and by 45% in the plot with eight traps, compared with a 33% increment of the infestation in the control plot. In the following year, the decrease reached 92% in the plot with five traps, 84% in the plot with eight traps and 74% in control.

Conclusions

The present study was conducted to evaluate the damage rates of leopard moth in the walnut orchard in Hatay province of Turkey. As a result of two-year investigations, the damages rates of the leopard moth were observed in 2016 with 16 per cent and in 2017 with 8.87 per cent.

Abstract

Biological plant protection is an important component in the eco-friendly management of plant diseases all over the globe. *Trichoderma* spp. is a strain which is known to produce a number of antibiotics and lytic exoenzymes. The aim of the study is to evaluate the antagonistic and antibacterial activity of *Trichoderma* spp. by agar well method against *Rhizobium vitis*. Seven isolates of *R.vitis* were obtained from Northwestern of Marmara. *Trichoderma spp*. fungi were *isolated* from grass and wood taken from several habitats in Istanbul province. Eleven isolates were chosen among 23 isolates collected for isolation of *Trichoderma* spp. For determination of antagonistic activity, agar well diffusion method was used. In the study, the density of *Trichoderma* was prepared approximately $1.5x10^8$cells/ml and examined in five different doses 5,10,15,25 and 30 µl/ml placed into the wellson potato dextrose agar (PDA).Before placing into the wells, pure colonies of *R.vitis* were transferred to test tube containing *sterile distilled water*to get a final concentration of 1×10^8 CFU/mland uniformly spread on PDA.The experiment was conducted five times. Sterile water was used as negative control and streptomycin was used as positive control. After incubation for 48 h at 28°C, the diameters of the inhibition zones were measured with a millimeter scale and recorded to evaluate antagonistic activity.*Trichoderma* spp. applied at a dose of 30 µl/mlwas the most antagonistic againstfour isolates of *R. vitis*among the other tested doses. Particularly, significant inhibitory effect was observed at 30 µl/ml against one of *R.vitis* isolate with inhibition zone diameter of 56 mm.

Keywords: *Rhizobium vitis, Trichoderma spp., biological control.*

Introduction

Turkey is one of major grape producing country and has genetic resources of *Vitis vinifera* varieties accounting for approximately 90 % of total. Grape production reached approximately 4 million tonnes in Turkey (Anonim, 2015). Total grape production is 130.000 tones in Thrace region (Anonim, 2017). One of the common problems of grape growing are not to produce of quality grafted seedlings free from diseases and pests (Çelik et al., 2005; Çelik et al., 2011). *Agrobacterium vitis* Ophel and Kerr 1990 [= *Rhizobium vitis* Young et al. 2001], grapevine crown gall causing agent is the most important bacterial disease of grapevine throughout the world (Burr et al., 1998; Burr and Otten, 1999; Sawada et al., 1990). We have already known crown gall is common in the United States and the Europe but within past 50 years, the disease were also reported from China, Japan, and South Africa and from several other countries in Europe, the Middle East, and North and South America (Burr et al., 1998). It has world- wide host range, the majority of those are dicotyledonus plants including stone fruits, pome fruits, grapevine and pomegranate (Kenndey and Alcorn, 1980). Scientist work for bacterial diseases found *A. vitis* common in Turkey, so it is important bacterial disease for grape growing areas. *A. vitis* spreads through the plant juice and can survive for many years without any symptom formation. This bacteria genus generally originates of soil-borne. The presence of bacteria have been seen after galls occurred from contaminated wounds injuries (Bouzar and Moore, 1987). Vineyards are under serious threat because of

using disease infected plant production material. For this reason, founding vineyards from certified production material free from disease is very important to at the vineyard. Early gall formations taken place in nurseries can cause plant death (Allewedt et al., 1988; Burr et al., 1998); in the next period, if 50% of the plant body is covered with galls, it will cause a serious decreases in plant growth and yield (Schroth et al., 1988). Chemical management against this plant disease is ineffective (Burr et al., 1998). Biocontrol of plant pets and diseases is very important for increasing the environmental pollutions caused by agrochemicals and pesticides worldwide. Agrocin 84 (K84) produced by *Rhizobium rhizogenes* has important role for effectively biological control of *Agrobacterium vitis*. While K84 is using against tumorigenic strains of *Agrobacterium vitis*, it is not found preventive (Burr et al., 1998). Some scientists tried to find other biological control strategies against crown gall disease using such as nonpathogenic *A. vitis* strain F2/5, agrocin, nonpathogenic *A. vitis* strain VAR03-1 (which is inhibitory to most tumorigenic *A. vitis* strains *in vitro)* (Liang et al. 1990; Staphorst et al. 1985; Webster and Thomson 1986; Xiaoying and Wangnian, 1986; Burr and Reid, 1993; Kawaguchi et al., 2005). *Trichoderma* spp. have been developed into some commercial biological control agents and are used in field and greenhouse conditions (Harman, 2000). These products are known to control numerous soil-borne diseases (Sivan and Chet, 1993; Inbar et al., 1996; Naseby et al., 2000).

The objective of this research was to evaluate the potential of using *Trichoderma viride* as biological control agents to diminish the impact of *Agrobacterium vitis*. The efficacy of *Trichoderma viride* was tested to control *Agrobacterium vitis in vitro*.

Materials and methods

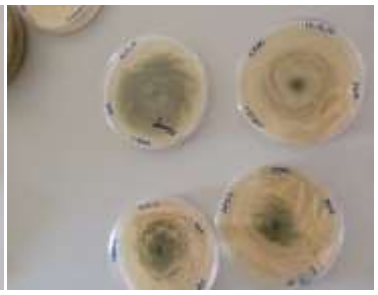
Bacterial isolations and identifications

Field survey were taken place in three provinces (Tekirdağ, Kırklareli and Edirne) in Thrace region in Turkey. 24 ones obtained from grapevine galls were used for this research. Tumors were washed with water, surface disinfected by dipping them into sodium hydrochlorite solution, 1% for 10-20 minutes according to Moore (1988) and Schaad et al. (2001) and were rinsed with sterile distilled water and dried with sterile filter paper. Then the outer layer was removed with sterile scalpel, small pieces were aseptically removed from each tumor, placed into few drops of sterile distilled water, then the resulted suspension was left to stand for 30 minutes and a loopfull of the resulted suspension was streaked on PDA medium. Inoculated plates were incubated at 25± 3◦C till bacterial growth developed dark green olive colonies showing Agrobacterium colony characteristics were selected, purified by preparing a suspension of the colonies in sterile distilled water and restreaked on KB medium, colonies fluorescent under ultraviolet light were eleminated. The isolates proved to be Agrobacterium based on the results of their reactions to these tests, then they were subjected to biochemical and physiological, tests to divide them oxidase, 3- ketolactose production; alkali production from L-tartaric and propionic acids; acid production from: sucrose, melezitose and erythritol, action on litmus milk; 2% sodium chloride tolerance, pigmentation on ferric ammonium citrate; growth on simmons citrate medium as described by Moore et al. (1988) and Schaad et al. (2001). For pathogenicity test, two month old seedlings of tomato (*Lycopersicon esculuntum* cv. Heinz) and Kalanchoe (*Kalanchoe diagremontiana*) were used as indicator plants. The plants were wounded forming a slit in the crown area by a sterile scalpel then 24 hour bacterial culture was applied to the wounded area with a sterile tooth pick. Also, tomato seedlings were sprayed with sterile distilled water, and known pathogenic *Agrobacterium tumefaciens* isolate was used to serve as control. They were kept on a climate chamber at 25± 2 ºC, checked for tumor formation daily (Al-karablieh and Khlaif, 2002).

Fungal Isolations and Identifications

Fungal Trichoderma viride was isolated from grass and wooden plant materials taken from several plantations in İstanbul and inoculated on Potato Dextrose Agar (PDA) medium for growth. Plant samples were collected into sterile polythene bags, transported to the laboratory and stored at 4 °C. For isolating Trichoderma spp, PDA medium was sterilized at 121℃ for 15 min in autoclave, poured to sterilized plates, cooled under sterile conditions.11 plant samples were chosen among 23 isolates collected for isolation of *Trichoderma* spp. Plant materials were cut to the length of 1.5–2 cm with sterile blade cut. Further, they were surface sterilized with 1% sodium hypochlorite for 4–5 min and then washed 3–4 times in sterile distilled water. Following surface sterilization, they were transferred into culture medium and incubated at 26℃ for 7-8 days on potato dextrose agar (PDA). After incubation period, the fungal colonies were picked up using a sterilized scalpel into PDA and purified for individual colonies. Purified fungal colonies were identified at the Plant Pathology Department, Namik Kemal University, based on morphological and culture characters using texts and references described by Barnett and Hunter (1972) and Ramirez (1982). Green conidia forming fungal bodies were selected and microscopic structures as size and shape of conidia and phyalides were observed using AxioVision Imaging System.

The study was carried out with seven diffirent *Agrobacterium vitis* isolates with three replicates and two controls. This trial experiments were made by modifying Bechard et al. (1998)'s study in a laminar flow cabinet. Bacterial suspensions adjusted to a density of 10^8 cfu/ml by using Mc Farland Scale. Seven bacterial isolates 30, 25, 20, 15 and 5 µl volume/petri dish suspensions were spread surface of the petri dish with streile glass rod. Then fungal inoculums were placed in a well positioned at the centre of 94 mm Petri dishes incubated at 26℃ for 7-8 days on PDA. After incubation, the areas of the growth inhibition zones around the central well were measured, and the calculated radius, compared with that of the control, was used to estimate the inhibitory activity. The antagonism between fungal microorganisms and the bacterial pathogen was assigned and calculated according to Wicklow et al. (1980) and modified as follows: the reaction type in which the fungus contacted and stopped the growth of the bacterial colony was assigned a numerical value of growth diameter.



Figures 1, 2, and 3. Applications in petri dishes.

Results and discussion

In petri dishes *Trichoderma* spp. was highly effective in 30 µl volume of bacterial suspensions. 20 and 25 µl volume of suspensions were infected moderately by changing isolates to isolates. Most suitable isolates results are taken NA9-1 taken fromTekirdağ province and NA43-1 taken from Edirne (Table 1).

Conclusion

Trichoderma spp. as a rich source of antibacterial compounds can be effective biocontrol agent against agricultural and medical pathogenic bacteria. Trichoderma spp. can produce different compounds under different environmental conditions, hence use of this fungus could be an efficient source of biopesticide. These bioactive compounds produced by Trichoderma spp. can be isolated and might be used in the development of biological control for disease managements. Consequently, next researches are needed to determine structures of these antibacterial compounds for improving agricultural applications that are effective, non toxic and non polluting to control crown gall.

ORGANIC AGRICULTURE

LAND AND AGRARIAN REFORM IN RWANDA: ORGANIC FARMING PERSPECTIVE

Mireille MIZERO[1]*, Antoine KARANGWA[2], Philippe BURNY[1], Baudouin MICHEL[1], Philippe LEBAILLY[1]

Abstract

Since 2004, Rwanda is carrying an important land policy and a fundamental program of its farming systems transformation. The pillars of the government plan highlight the changes in land use management and tenure combined with improved inputs utilisation to ensure optimum productivity in the right line of the market-led agriculture. When they mention improved input, someone may understand essentially intensive use of commercial seeds, pesticides and chemical fertilizers. However, bio-fertilizers and natural pesticides are being promoted by the crop and livestock intensification program as well as the necessary techniques mobilised in the high quality of organic fertilizers production and use. This article aims to analyse how organic agriculture can coexist with conventional agriculture and allow agriculture operators to benefit of the market liberalisation. The literature review shows that during the agrarian system evolution, Rwandan peasants are involved in the program of land consolidation and agriculture intensification. Their level of performance has been appreciated throughout their active involvement in the commercial circuit. The main conclusion of this article is that organic farming prospects are inherent to optimal biomass valorisation especially crop residue, agro forestry and livestock dejection incorporated in the production systems. The unstructured interviews revealed that the most performing producers are those who own a minimum of 1ha with a recognized land lease and those who are using a mixture of organic manure and chemical fertilizers in potatoes. It has been demonstrated that the farmers who are enthusiastically participate in cooperatives have also an open mind to consolidate their commercial relationship. Moreover, they have constant ability to take advantage of the market, especially in pyrethrum and potatoes cropping system.

Key words: *Land reform, Organic farming, Rwanda, Pyrethrum, Potatoes*

Introduction

Several authors consent that globally, organic manure are essential for restoring and stabilising agricultural land fertility in Africa and particularly in Rwanda (Kim et al., 2013). However, countries with high density of agricultural population have fewer areas to increase the fodder production for livestock feeding like cattle (Klapwijk et al., 2014). Obviously, cattle still the principle provider of the manure in the Rwandan farming systems. Thus, organic matter from farmyard manure used by most of farmers is not available in sufficient quantity due to the lack of improved composting techniques either the knowledge of the manure management, handling and transporting equipments are deficient (Drechsel and Reck 1998; Kim et al., 2013). The « Umushinga Girinka Munyarwanda»[2], the pro-poor and the most important component of the livestock intensification program in Rwanda cannot allow all farmers in the country to be self-sufficient in organic manure supply (Klapwijk et al.,

[2] Stand for « One cow for one poor family » as a livestock project for milk and manure supplying and increased revenue

2014). This huge program of livestock resources improvement has been implemented by the Rwandan government as a multipurpose development approach. It aims to reduce poverty while it is decreasing malnutrition with milk consumption especially for the children. It intends to increase small-scale farmer's livelihood. This multi-folder program highlights the use of organic manure for soil fertility conservation in a double option of increasing crop productivity jointly with environmental protection. Moreover, it contributes to harmony and reconciliation among Rwandans based on the customary solidarity relationships between the giver and the receiver of the heifer (MINAGRI, 2014)[3]. Besides the different constraints of manure usage and availability, Kim et al. (2013) have found that the key limiting factors of manure expected from the « Girinka program » are lack of manure treatment and transporting tools, distance to crop fields from home and poor construction of cow sheds. Their study has revealed significant differences in manure management as well as in access to information and extension services (Kim et al., 2013).

Previous studies have shown that the organic manure or mineral fertilizers depends on the nature of the soil texture and structure. Among them, Rutunga et al. (1997) find that 10 tons per ha per year, applied on oxisols in Rwanda, is the amount of organic farmyard needed to substitute inorganic fertilizers. Then the core question: can the agrarian system in Rwanda set up entirely on organic or inorganic fertilizers exclusively? Is the rotation of pyrethrum and potato a good farming system to limit excessive use of mineral fertilizers and pesticides? The research assumption is that alternative farming system can contribute to coexistence of organic and conventional agriculture while it is increasing farmers' revenue and connecting them to the market.

Research motivation and objectives

At the era of Rwandan farming system transformation launched by the 2004 land policy reform together with the 2005 legal framework of land tenure and land use, few studies have taken in account of the organic farming prospects beside the promotion of conventional agriculture. It is commonly recognized that in Rwanda, fertilizers both organic and mineral are insufficient in quality and in quantity. But, the main attention is focussed on increasing of subsidized inorganic fertilizers application. This can be demonstrated by the increasing of imported chemical fertilisers the last decades even if we have not yet the authorization to publish those data collected by the National Institute of Statistics of Rwanda. Meanwhile, the use of organic fertilizers is less than the mineral fertilizers use for the big farmers involved in land consolidation and modern agriculture (NISR, 2016). Thus, it is required to search for high quality and affordable alternatives of organic farming focus on the sustainable agriculture. A study has revealed that in Rwanda, the mixture of organic and inorganic fertilizers is the most useful method of the soil fertility restoration in regards to soil configuration and crop category (Bidogeza et al., 2012). Moreover, there are high quality organic fertilizers and bio-industrial techniques already tested to improve the quantity and the quality of organic materials to increase the crop productivity in different agricultural farming systems (Karangwa et al., 2015, Zhang and Sun, 2016).

This article aims to contribute to the organic farming perspectives in Rwanda during the transformation process from subsistence agriculture towards the market-led and knowledge-based agriculture through a long term farming system of pyrethrum and potatoes in Kinigi sector located in Musanze district. About the transformation crossing of subsistence agrarian system in Rwanda, Musabanganji et al. (2016) have illustrated that smallholder farmers are staying in the first three classes according to the theoretical model of smallholders evolution proposed by Zhou in 2010.

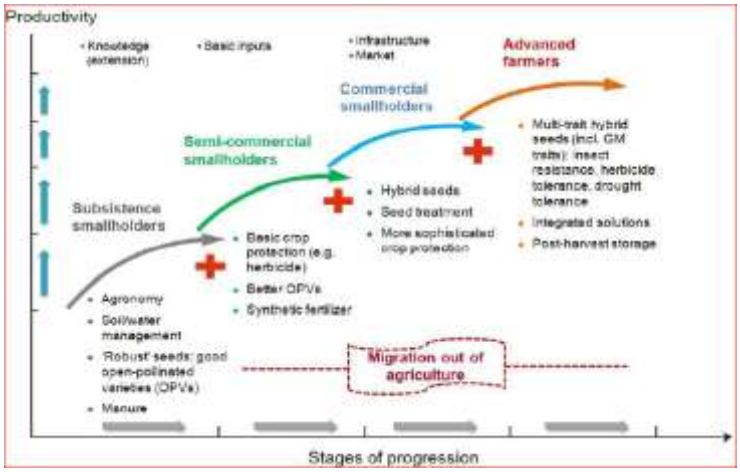

Figure 6 Theoretical model of small scale farmer's progression stages

Source: (Zhou, 2010, p.4 cited in Musabanganji et al. 2016, p.9)

The figure 1 above shows that combined use of manure, recommended agronomic practices (RAP), soil and water management and performing varieties are the basic package adopted by the subsistence smallholder farmers who are involved in a progressive agriculture transformation. They climb the low step towards the high step and former smallholder farmers have adopted improved inputs and gain commercial-minded attitude. The high level of the scale is reached by « advanced farmers » step by step. Those who are taking advantage in the agrarian system evolution are gradually adopting the most improved inputs for increasing productivity. The surplus of production is managed to supplying the market and storage techniques are enhanced for limiting yield loss. In general, most of the smallholder farmers in Rwanda are still yet to the second level of the four steps marking the evolution magnitude described above as « semi-commercial stage» (Musabanganji et al. 2016). The following section presents a comprehensive synthesis of organic and inorganic fertilizers use by both agriculture operators and large scale farmers in Rwanda.

Inorganic users are less than organic one but the first are increasing than the second

Agriculture transformation deal in Rwanda is in the right line of the 2020 vision revised in 2012 with the way forward of a « high-value added and market oriented agriculture » (Republic of Rwanda, Minecofin, 2012)[4]. The agriculture evolution predicted by the 2020 vision is in accordance with the strategic plan of agriculture transformation through intensive use of organic and inorganic fertilizers as well as the modern livestock. The strategic plan of agriculture transformation consider that fertilizers use are the main key to overcome the soil fertility challenge (République du Rwanda, Ministère de l'agriculture et de l'élevage, 2004). Inorganic fertilizers are promoted by the extension services of the Rwanda agriculture board through private sector to boost soil fertility. But, industrial organic manure remains insufficient for yield increasing (Karangwa et al., 2016). The seasonal agriculture survey carried in the « A season » of 2015 reported that in average 21.1% and 51.3% of small scale farmers also called «Agriculture operators » used respectively inorganic and organic fertilizers while 54.8% and 66.8% of Large scale farmers used respectively inorganic and organic fertilizers. The main types of inorganic fertilizers used in Rwandan farming system are DAP, solid and liquid Urea and NPK 17-17-17. The table 1 below revealed that other types of synthetic fertilizers are marginal.

2015 Seasonal Agriculture Survey - Season A

Source : (National Institute of Statistics of Rwanda (NISR), 2015 Seasonal Agriculture Survey Report, January 2016)

Rwanda has an important programme of agricultural systems transformation based on increasing of modern inputs, land consolidation and regional specialisation determined by their agronomic potential. The intensive use of fertilizers is highly recommended to all agricultural investors. « Purchases of agricultural inputs also changed, which is an indicator expected to correlate positively with increases in production. Use of sacks and packing increased from 37% to 48% between surveys for households purchasing any agricultural inputs. This is an indicator of commercialisation of production, since sacks and packaging are purchased primarily if selling is intended. Use of fertilisers also increased drastically, from 18% to 38%. For chemical fertilisers, usage increased from 11% to 29% of households, while for organic fertilisers the increases were smaller (7% to 9% of households). Use of insecticides has also increased: 31% of households used them as compared to 24% in EICV2.» (NISR, 2011). Organic manure stills the main source of fertility restoration in Rwandan rural agriculture. By the way, Niang et al. study (1998) has proposed changes to improve the quality of fodder. « Inclusion of the shrubs increases the overall quality of the fodder and also increases the quality of the grass component. The high production of the pennisetum-based systems is at the expense of adjacent crops. Economic evaluation shows that the optimal grass/shrub combination will depend on both fodder production objectives and on the relative importance of production of fodder and crop. However, it is clear that the leguminous shrubs can be part of the solution.» (Niang et al.,1998). We are in accordance with Yamoah and Grosz for their proposition of Agroforestry, tillage, mulch system, manure and compost as well as inorganic fertilizers as an integrated package to overcome the problem of the soil fertility in a sustainable way of organic farming (Yamoah and Grosz, 1988). The section below describes a long-lasting coexistence of organic and inorganic farming system based on Pyrethrum-Potatoes rotation.

Organic and inorganic farming coexistence: Pyrethrium and potatoes farming model

Pyrethrum is a botanical insecticide produced from Dalmatian Chrysanthemum (*Chrysanthemum cinerariaefolium*) or sometimes from Persian Chrysanthemum (*Chrysanthemum coccineum*), perennials from Eastern Europe and Canada (Duval, 1993). Duval precise that Caucasus Dalmatian chrysanthemum is commercially grown today mainly in the mountainous regions of Kenya, Tanzania and Ecuador. It is also developed in Virunga Mountains of Rwanda and Australia. Its organic nature to grow in volcanic region of the Northern Rwanda has create opportunities to rural people operating in cooperatives to be involved in well organised value chain from the local level to the international business

network according to the Horizon group (2016) in charge of SOPYRWA[5] management. Depending to climate, the plant can be multiplied by division or sowing. It is much easier to start growing chrysanthemums to try to get seedlings from a neighbour or nursery. Otherwise, sowing remains the only option for the first year. For the following years, if you want more plants, you can proceed by vegetative multiplication when the new shoots appear. The nursery for pre-germination is approximately 3 months before the transplantation, either at the end of February or March. The seeds should be placed in a sterilized environment. Otherwise, the seed can lose their capacity of germination in relatively short time. The seeds take 2 to 4 weeks to germinate. The ideal germination temperature is about 20 to 22°C. You can also sow in the ground in August by covering the seeds with a centimetre of fine soil and then dry leaves. The seedlings are transplanted in deep rows spaced 30 to 50 cm apart and 35 to 40 cm in row. It will be 7 to 9 plants per square meter. A loss of 15 to 30% of the transplants can be expected. Chrysanthemums including Pyrethrum can multiply in cold and temperate climates but its optimum potential is reached in the equatorial high altitude zone. Commercial cultivation of Dalmatian chrysanthemum ranges from 1,600 to 3,000 meters above sea level, with altitude pyrethrin concentrations. Semi-arid climatic conditions with a cool winter, 1200 decreasing to less mm rainfall and a 2 to 3 months dry season are ideal. It tolerates temperatures down to -12°C (Duval, 1993). Pyrethrum chrysanthemums prefer dry, gravelly, limestone and sloping soils. The shady places are to avoid the shade of a lot of pyrethrins concentration. In a loamy soil rich in humus and humid climate, the chrysanthemum will grow abundantly but its pyrethrin concentration will be reduced. The chrysanthemums must be kept in well weeded conditions because they are very sensitive to competition. Chrysanthemum is not sensitive to chemical fertilizer and it can resistant to pest. In contrary, harvesting is a critical step in getting maximum pyrethrins in the flowers. It must always be harvested in dry and hot weather. Ideally, flowers should be harvested at full development and even between day 5 and 9 after flowering to achieve the highest level of pyrethrin. The flowers in the center of the plant contain more pyrethrin than the flowers around (Duval, 1993). Every two weeks, flowers can be harvested.

Site of experimentation: volcanic mountains region of the Northern Rwanda

Our site of experimentation is located in a long term coexistence of organic and inorganic farming system in Kinigi sector of the district of Musanze in the Nothern province of Rwanda. The zone of the pyrethrum growing covers 4 districts of high potential like Nyabihu, Musanze, Burera and Rubavu. There are more than 10,000 homes in Rwanda whose livelihoods are based on pyrethrum essentially in the Northern Province. They are all members of seven (7) cooperatives for production and trade. The main buyers of pyrethrum essential oils are the US, Europe and Asia (NAEB, 2012).

Result of field survey in the « Paysannat » of Kinigi sector

Kinigi sector covers a high potential area of potatoes and Pyrethrum production. The growers of pyrethrum and potatoes in the « Paysannat farming system » we have interviewed during our field work revealed us that those who are involved in potatoes production and commercialisation can make a profit of 2,500,000-3,000,000 or 2,500€ of Rwandan Francs per ha for an average of three seasons per year with 15-20 tons of potatoes per ha while the producers of pyrethrum are susceptible to make a profit of 500,000 Rwandan Francs or 500€ per year. While Irish potatoes are budgetivore in pesticides and fertilizers, Pyrethrum is not. The pyrethrum contributes in fertility restoration after a season of potatoes. The total revenue of 3,000€ is equivalent to the annual revenue of middle class in Rwanda.

Pyrethrum, potatoes, tries farming system in Kinigi Sector

SOPYRWA held by the Horizon Group Ltd since 2008 is the one of the companies involved in the production and processing the pyrethrum together with AgroPY Ltd established in 2011. Those two agro-processing companies are operating in the Musanze district. They make insecticide from pyrethrum flowers that control pests (mosquitoes, Trypanosomiasis bedbugs, lice, ticks) and diseases. « Since 2012, AgroPy Ltd has received attestation by ECOCERT under European Union regulations EC No. 834/2007 & 889/2008 for Pyrethrum 5EW. This product is of huge benefit to coffee farmers in the control of the Antestia Beetle. Organic insecticides allow farmers to benefit from the opportunity to supply organic produce at premium prices» (Horizon group, 2016). « Rwanda intensively promotes pyrethrum growing and has been making quality pyrethrum seeds available for growers. Rwanda teaches farmers on how to increase pyrethrum productivity and advises them on good farming practices. They have also started making pyrethrum seedlings so as to increase its yields. Rwanda is the second world largest producer of pyrethrum and has approximately 15 % of the world market

share... » (NAEB, 2012). Sopyrwa produces in average 3000 tons of dry flowers per annum and processes 10% of pale extract locally. In 2012, almost 26 tons of pyrethrum essential oils have generated 7,517,900$ (NAEB, 2012). The pyrethrum's value of one unit was 81.36 times the value of Coffee and 99.62 times of tea. In the category of horticulture products, it was respectively 111.29, 876.89 and 1,034.48 times the value per unit of natural flowers, vegetables and fruits (NAEB, 2012).

Table 2. Comparative importance of pyrethrum with other agriculture exported product

	Traditional export commodities		Horticulture			
Year 2012	Coffee	Tea	Pyrethrum	Flower	Vegetables	Fruit
Volume in kg	16,989,730	22,453,391	25,785	171	28,699,579	4,040,251
Total revenue in $USD	60,886,260	65,717,926	7,517,900	448	9,542,400	1,138,719
Comparative value/kg in $USD	**3.58**	**2.93**	**291.56**	**2.62**	**0.33**	**0.28**
Ratio Pyrethrum/Other agriculture export products	81.36	99.62	1.00	111.29	876.89	1,034.48

Source : Author from statistics reported by NAEB (National Agricultural Export Development Board, 2012)

About potatoes, Rwanda hosted in 2016 the annual meeting dedicated to the potato week. Since 2011, it has been organized in turn in the 4 member countries of the network of sub-regional producers of potatoes namely the Democratic Republic of Congo, Rwanda, Burundi and Uganda. The Imbaraga organization was organizing the event in the partnership with Agriterra and AgriProFocus, two netherland organization. The FECOPPORWA federation (Federation of Cooperative Producers of Potato in Rwanda), which has 5 unions, 149 cooperatives and 9,796 members, was created in 2009. It mainly aims at strengthening the capacities of cooperatives and representing their interests, as well as the promotion of technology in the value chain. The 4 member countries of the sub-regional network of potato growers draw on the experience of Nedato, a cooperative of Dutch potato producers. Nedato was founded in 1963 and currently has 500 members and remains one of the most dynamic cooperatives on the potato market in Europe. Nedato has specialized in the production and marketing of potatoes, export and processing. Potato producers in Rwanda are already integrated into the formal financing circuit. Although access to finance is still a challenge, the UOB bank (Urwego opportunity bank) supported, in 2016, 995 producers grouped in 27 producer groups and 2 cooperatives, with the outstanding credit which is evaluated at 459,028,392 FRW. Potato producers are integrated in the local, regional and international market as illustrated in the figure below.

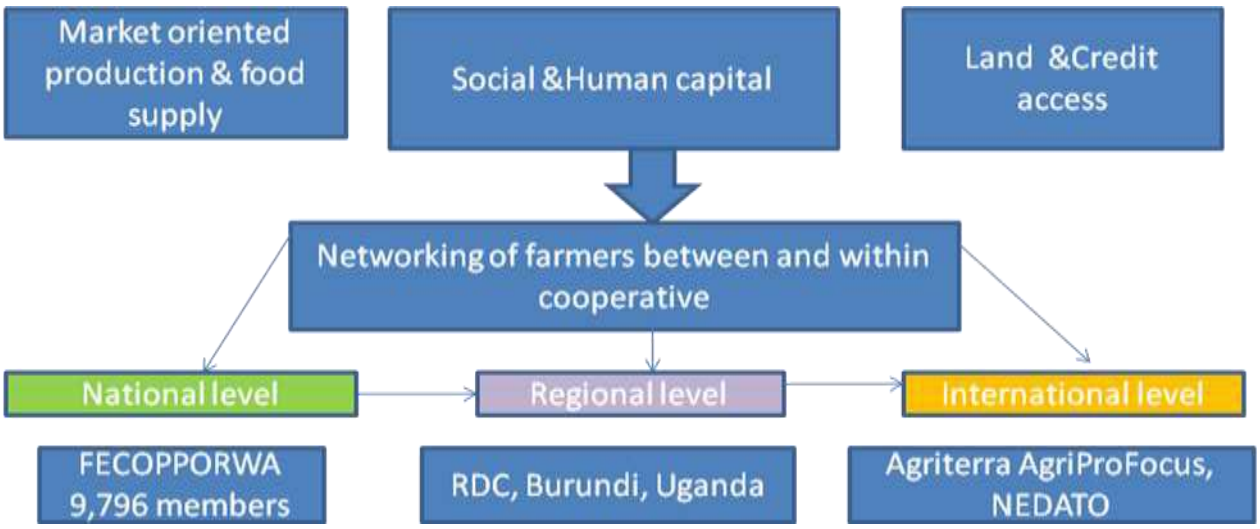

Figure 7 Small scale farmers' integration in the world wide market through cooperatives

During the field work in Musanze District, they revealed us that some of the Potatoes producers are supposed to be Reich compared to other ordinary farmers. They are able to buy cars and are susceptible to invest in diversify trading locally and abroad.

Conclusion

The future of organic farming is depends on optimal biomass valorisation especially crop residue, agro forestry and livestock dejection incorporated in the production systems. The rotation of Pyrethrum and potatoes is the example combination of a crop which is less or no more chemical fertilizers consumer with another one which is highly demanding crop in pesticides and chemical inputs. The most performing producers are those who own a minimum of 1ha of farm land and who are using a mixture of organic manure and chemical fertilizers. Pyrethrum producers and Irish potatoes farmers are actively participate in cooperatives. Moreover, they have an open mind to consolidate their commercial relationship. They have constant ability to take advantage of the market. Their trading strategy consists in individual management of the production but in the collective negotiation of the seller price, grouped command of the inputs and the common use of infrastructures for instance the storage place or dryer areas of the pyrethrum flowers. Those who are involved in Irish potatoes production and commercialisation can make a profit of 2,500,000 or 2500€ of Rwandan Francs per ha for an average of three seasons per year while the producers of pyrethrum are susceptible to make a profit of 500,000 Rwandan Francs or 500€ per year. Pyrethrum production allow to restore fertility when is cultivated in rotation with Irish potatoes. This long term crop system is proof that organic farming can coexist with conventional farming system.

ORGANIC PRODUCTION OF RASPBERRIES (WILLAMETTE var.)

Saša KALAMANDA*, Miljan CVETKOVIĆ

Faculty of Agriculture, University of Banja Luka, Bosnia and Herzegovina
*Corresponding author: salekala@live.com

Abstract

Raspberries in BiH are grown on an area of 1,628 ha, from which total production of 13.631t is realized. This places raspberries onto the fourth place among fruits. The largest percentage of raspberry production is of conventional type. In recent years, significant activities have been undertaken to introduce the concept of integral production and organic raspberry production. Interest in organic raspberry production is growing in the world, as well as in Republika Srpska, not only in the field of science and profession, but also in farming. This represents a good and safe way for economical production of quality fruits for which there is a safe and stable market. This area is becoming attractive because relatively small areas achieve significant revenues, i.e have positive economic effects that contribute to the sustainability of production. Organic agriculture is based on the minimal use of materials that do not originate from the farm and on the production practice that establishes, maintains and improves the ecological balance. The rules of organic agriculture are defined in the Law on Organic Production of Republika Srpska and the standards and regulations of the EU and other countries.The aim of this paper is to determine the characteristics of Willamette produced according to the concept of organic production, by analyzing the specificity of the technological production process and the basic parameters of fertility of the investigated fruit variety in agro-ecological conditions in the territory of the municipality of Srebrenica.

Key words: *organic production, raspberries, variety Willamette, Srebrenica, Bosnia.*

Introduction

On the territory of Bosnia and Herzegovina, raspberries are grown on an area of 1.682 ha, with a total output of 13,631 tonnes. This places raspberries onto the fourth place among fruits. Raspberry is mostly grown in the area of Podrinje, Upper Carniola and Central Bosnia. In recent years, raspberries have expanded extensively in other parts of Bosnia and Herzegovina (Una-Sana Canton, the region of Krajina, Posavina). Raspberry cultivation in Bosnia and Herzegovina is of small-sized production, whose surface on average ranges from 0.1 to 0.3 ha. Most of the production is located with small individual producers, while in recent years there has been a noticeable appearance of large plantations, whose owners are mostly present in the raspberries business (larger raspberries buyers or cold store owners). Producers are generally affiliated to local associations or are contractually affiliated to cold stores and collective farms operating in the respective regions. Through the associations and collective farms, procurement of fruits and reproductive material during the year is carried out, which in most cases is repaid with raspberries at the end of the season. There is a noticeable increase in storage capacities that does not accompany the rise in production levels, which often leads to a disturbance of the producer-buyer relationship and can endanger production in the long run.

The highest percentage of raspberry production is conventional, although in recent years a significant number of project activities have been implemented to introduce the concept of integral and organic raspberry production. The interest in organic raspberry production is growing in the world, as well as in Republika Srpska, not only in the field of science and profession, but also in farming. This represents a good and safe way for economical production of quality fruits for which there is a safe and stable market. This area is becoming

attractive because relatively small areas achieve significant revenues, i.e have positive economic effects that contribute to the sustainability of production.
The organic production program is very close to the traditional method of production by inputs, but there are also significant differences, primarily in the process control system. Only a product controlled and certified by an authorized control organization can be marketed with the label "organic product". Organic production is very close to traditional, so it is extremely important to choose a suitable area and conscientious producers who understand and want to cooperate in such production. Also, it is very important to build a quality system of internal control that monitors, directs and educates manufacturers.
Climate and soil are external factors that primarily affect the formation of qualitative characteristics of raspberries. However, the soil and climate give the required quality with the appropriate yield when they are in a certain relationship and when they supplement each other. The natural conditions in which the plant grows and develops are decisive for the success of production, since the producer does not have the capability to significantly modify these conditions and adjust them according to the needs of the plant, except for the production of planting material. On the one hand, the production of raspberries depends on natural conditions, such as climate and soil. On the other hand, it depends on the producer`s activity, as he/she can choose the best possibilities in the existing conditions and repair and improve natural conditions in some way, adapting them to some extent to the goals of production.
Raspberry fruits are sensitive and subject to rapid deterioration, so they must be collected carefully and in time. The timing and method of harvest do not only affect the quality of raspberries, but also the advantage and the possibility of their realization. The maturation of raspberries depends on several factors: hereditary traits of species, latitude, altitude, climatic conditions, terrain exposures, soil and applied biological preparations. Fruits of organic raspberries are packaged in packaging made of natural material and are visibly marked, stored with special care and transported in clean uncontaminated vehicles. Raspberry is distinguished as a culture by the fact that its fruits do not mature at the same time, so harvesting takes place on several occasions.
Willamette matures relatively early, at the end of the first decade of June. In the Srebrenica area, the maturation season is delayed for about 10 to 15 days on average. The period of fruit maturation lasts for quite a long time, on average 30 days.
Knowing this, the aim of the paper is to determine the characteristics of Willamette, produced according to organic farming production. This is done by analyzing the specificity of the technological production process and the basic parameters of fertility of the investigated fruit in agro-ecological conditions in the territory of the municipality of Srebrenica.

Material and methods

The research was carried out in the plantation of the company "ZZ Srebrenica" located in Brežani, in the territory of the municipality of Srebrenica. The plantation was established and maintained through an organic production system. Organic raspberry production at this site started in 2007. The plantation was established on a total surface of 4.5 ha at an altitude of 961 m. Raspberries are grown in a spalter system with planting distance of 2.5 m between rows, and 0.25 m between seedlings. In the plantation, agricultural practices common for organic production are used together with the use of authorized preparations for the protection of raspberries from diseases and pests.

Image 1. Details from the plantation in which the research was carried out
Source: author`s photo

Only Willamette is present in the plantation. Previous experience in working with this variety on the field shows its relatively high resistance to the most harmful diseases and pests in conventional production, which is one of the reasons for its introduction into the organic concept.
Soil cultivation is carried out in order to maintain the soil in a loose state, to destroy weeds and to feed the organic fertilizer in the root zone. This contributes to better nutrition of the raspberries, moisture preservation, the presence of air in the soil and the prevention of the creation of a crust on the surface. Regular and proper soil cultivation in raspberry plantation contributes to better income and further development of seedlings, faster planting in full yield, high yields and quality fruits. In the raspberry plantations, the soil should be kept under constant vegetation during the vegetation and without weeds, while in the course of the treatment, mechanical damage to the roots must not occur.
Inter-row space is maintained by grassing and regular mowing. A serious disadvantage in this production process is the use of natural (weed) vegetation for grassing, rather than deliberately sown grass mixtures.
During the research, two segments are included:
a) analysis of the most important measures applied in the process of organic raspberry production
b) the characteristics of the fertility and fruits of Willamette in the organic control system. In the analysis of fertility, sprouts in the regular production system are monitored with loads that represent the usual manufacturing practice. An analysis of fruiting increments developed from the primary and secondary buds, as well as the number of physiologically ripe fruit on them, was made. For the analysis of the characteristics of the fruit, 30 fruits were used, on which the weight of the fruit, length and width of the fruit was measured.
Research was carried out during the harvest in 2015.

Results and discussion

Willamette produces a large number of upright branches with medium long and elastic genital branches, which are rarely fractured under the load of the genus or by the action of stronger winds. Under organic production, there is a significant role to play in the number of sprouts per square meter that are left to proliferate. In a sealed plant, the number of sprouts per square meter ranges from 6 to 8. This yield density per square meter is considered optimal, in order to achieve the required number of buds and thus yield per unit area. After selecting the

optimal number of sprouts, they are transplanted to the required height. In the examined plant, due to the absence of mineral fertilizers, the height of sprouts is usually 150-170 cm, which is slightly less than the optimal values. With this yield height, the desired yields can be realized if the quality of buds found on these sprouts is taken into account. Usually, edges that are too thick or thin do not have a satisfactory quality of buds which should form fetal growths with infructescence. This can affect fruiting.

Raspberry has great demands for moisture in the soil during the vegetation period, especially from the beginning of vegetation until the end of harvesting of fruits. The lack of moisture in raspberry soil is difficult to tolerate, which adversely affects yields, fruit quality, and growth of sprouts. Irrigation is a significant agromera especially in droughty years and in its growing in dry areas. The time and number of irrigation depends on the weather conditions in different arbitrary areas, it is best to be determined according to the specific conditions and possibilities. Raspberries should be irrigated as needed, with irrigation being mandatory before the land drainage occurrs. Rasperries need watering the most during the period of flowering, development and maturantion of the fruit as well as after the harvest so to have normal new sprouts. Irrigation of raspberries is best done more often with smaller amounts of water. Usually it is done superficially by the system of furrows, rain and drops.

On the test site, irrigation is done by "drop by drop" system. Irrigation by the "drop by drop" system is a newer and most suitable way of irrigation in fruit production. The advantages of this irrigation system are that they can be applied on different terrains, there can be no ponding and soil erosion, less water is needed, no fruits and leaves are moistured, thus the possibility of infection and disease is lower. The "drop by drop" irrigation system is easily installed and can also be connected to the water supply system. At the accumulation, a standard water purification filter is placed and then the water is brought into raspberry plantations, most often using a natural fall with plastic tubes.

Table 1. The characteristics of fertility and fruit of the Willamette variety

no.	Better Agronomic performances/ paramters	$\overline{X} \pm S_{\overline{X}}$
1	Number of buds left on a sprout	10,00
2	Number of fruit-bearing increments from the main bud	9.166 ± 0.207
3	Number of fruit-bearing increments from the lateral bud	1.125 ± 0.580
4	Number of fruit from the main bud	98.666 ± 5.244
5	Number of fruit from the lateral bud	8.083 ± 4.668
6	Total number of fruits on a sprout	98.674
	characteristics of fruit	
1	Fruit weight (g)	3.534 ± 0.139
2	Fruit length (mm)	18.996 ± 0.735
3	Fruit width (mm)	18.624 ± 0.606
	calculated characteristics of fertility	
1	Yield per sprout (g)	348,714
2	Yield per length m (kg)	2,097
3	Estimated yield per ha (t)	7,464

Tested of Agronomic parameters testing of the Willamette variety was carried out by leaving ten buds along a sprout and following the basic characteristics of fertility. The number of activated buds is quite high (91.6%) and indicates high fruiting potential in relation to the number of leaves left. In addition to activating the main bud and creating fertile increments on them, activation of the second and second buds (usually less developed) was recorded, and on

average 1.12 buds. An analysis of the number of fruits formed on fruiting increments from the main and secondary buds indicates differences in their fruiting potential. The total number of fruits on fruiting increments, regardless of their character, was 98.67. The average weight of the raspberry fruit was 3.53 g, which is about the standard values (4 g). The minimum raspberry fruit weight is 2.98 g and the maximum is 4.98 g. The average length of the raspberry fruit is 19.90 mm, with a minimum length of 15.09 mm and a maximum of 25.90 mm. From Table 1 it can be seen that the average width of raspberry fruit is 19.44 mm, maximum width of 23.04 mm and minimum of 14.43 mm.

By bringing in the number of fruits per yield and average weight of the fruit, the average weight per sprout (348.7 g) and length meter (2.09 kg) is obtained. The estimated yield per unit area (ha) is 7, 464 t.

The yield obtained is lower than realistically possible. However, in the conditions of reduced application of fertilizers, this yield can be considered acceptable if the price of raspberries produced in this way can compensate for the reduced yield.

Conclusions

- Climate conditions in the Srebrenica area favor the cultivation of raspberries according to organic farming system, especially given the locality and altitude for which it has been established.
- Most of the applied and analyzed technological processes in the production process are in accordance with the principles of organic production.
- The fruiting potential of mixed buds on shoots is quite high, given the way of cultivation.
- The characteristics of the Willamette fruit are consistent with its genotypic characteristics.
- The yield is below the standard for this variety.

Organic raspberry production can be justified in circumstances where the price of a product can compensate for slightly lower yields than conventional production.

Abstract

The paper analyzes the chemical composition and antioxidant features of three leafy cultures: broad leaved dock (*Rumex obtusifolius* L.), curled dock (*Rumex crispus* L.) and leaf beet (*Beta vulgaris* L. ssp. *vulgaris*). Plants were grown in an organic garden with a random distribution and approximately equal cover density. The analysis encompassed following parameters: mineral composition (As, Ca, Cd, Co, Cr, Cu, Fe, Hg, K, Mg, Mn, Mo, Na, Ni, P, Pb, Se, Zn), anthocyanins (total and monomeric), β-carotene, vitamin C, phenols, flavonoids and flavonols. Antioxidant capacity was evaluated through ABTS and DPPH tests.

The researches have shown that all three species have almost equal content of β-carotene, while the broad leaved dock is inferior to the content of anthocyanins. With regards to phenols, flavonoids and flavonols, curled dock is ahead. Next in order is broad lived dock, while leaf beet shows the poorest results with observed features. The same case is with vitamin C and antioxidant properties. Only in the case of macro- and microelements, the results are polycentric. So, leaf beet predominates in the selenium content. Broad lived dock has the advantage in the content of copper and sodium while curled dock is superior in terms of calcium and iron.

Key words: *leaf beet, curled dock, broad leaved dock, chemical composition, antioxidant properties*

Introduction

In the domestic professional community, it has long been known that wild growing species from genera: *Atriplex, Chenopodium*, *Polygonum* and *Rumex* can be used as a substitute for conventional leafy vegetables, whether in form of salads, stewed vegetables, puree or otherwise prepared (Vračarić *et al*. 1968; Grlić 1980, 1986). Particular attention is attracted by representatives of the genus *Rumex*, because in our regions, it is considered that these plants, except for a few species, can be used without any restrictions. This primarily refers to species: *Rumex alpinus*, *R. aquaticus*, *R. crispus*, *R. hydrolapathum*, *R. obtusifolus*, *R. patientia*, *R. pulcher*, *R. sanguineum*. Species *Rumex acetosa* and *R. acetosella* are also edible, but due to the increased oxalic acid content there are limits to the amount of daily portion. Species *R. scutatus* and *R. nivalis* are edible as well, but they are more difficult to reach since they occur at high altitudes (Lakušić, 1982). Apart from the purely nutritional aspect, these species are interesting in terms of their antioxidant properties (Wegiera, 2011; Žabić 2015).

In addition to the basic intention to analyze the chemical composition and antioxidant properties of observed leafy cultures, this paper wants to show wild and cultivated plants can be grown next to each other, and wild species in their chemical composition are not inferior to cultivars (at this point, tastes are not discussed). For that reason we have made certain comparisons with common beet (*Beta vulgaris* subsp. *vulgaris*) variety Swiss chard.

Viewed from a slightly wider angle, applying such approach there is no need for traveling and seeking the wilderness, or purchasing goods in supermarkets, to which they traveled hundreds and even thousands of kilometers (Carlsson-Kanyama, 1997; Pirog and Benjamin, 2003; Welbaum 2015).

Material and method

Material

In an organic garden, which is located in the city of Banja Luka in Bosnia and Herzegovina, three observed species grow: broad leaved dock (*Rumex obtusifolius* L.), curled dock (*Rumex crispus* L.) and leaf beet (*Beta vulgaris* L. ssp. *vulgaris*) var. Swiss chard.

Wild growing curled dock optimum living conditions in Bosnia and Herzegovina is found in the association *Rumici-Alopecuretum geniculati* Tx. (1937) 1950 and is rather numerous in other communities of the alliance *Agropyro-Rumicion crispi* Nordhagen 1940 (Mišić *et* Lakušić, 1990). According to the same source, inhabits ecosystems of classes: *Molinio-Arrhenatheretae, Festuco-Brometea*, *Plantaginetea majoris* Tx. 1950 and *Phragmitetea*. R. Tx. et Prsg. 1942. One ecotype of this species lives like a weed in the ecosystem of stubbles and row crops (classes: *Secalinetea* Br.-Bl. 1951 *et Chenopodietea* Br-Bl. 1951). In vineyards of northern Bosnia curled dock occurs in association *Convolvulo-Agropyretum repentis* Felföldy 1943. A slightly smaller presence in this community has broad leaved dock (Kovačević, 2016). In neighboring Croatia species occur in the *Polygono-Chenopodietum* Lohm. 1950 community, belonging to the vegetation of riverbanks and flooded grassland. In our country curled dock is recorded in the lower course of the river Neretva in Herzegovina (Marković, 1980, referring to the Lohmayer, 1970 *et* Supopp, 1971). Broad leaved dock was registered in the same community, but with a lower abundance. Young leaves of this plant contain vitamin C and other healthy ingredients, thereupon they can be used as a vegetable. In folk medicine they are used as an antiseptic and antiscorbutic. From animal husbandry point of view, this species is considered as a worthless fodder (Mišić *et* Lakušić, 1990). According to this source, it is even considered harmful at a weighting content above 5% because it negatively affects the secretion and quality of milk.

For the time being, there is no evidence that the broad leaved dock was found in natural, anthropogenically uninfluenced plant communities in B&H. Several years ago the authors recorded this species in the virgin forest reserve "Lom", but along the forest path that goes through the protected area, which actually legitimized this species as a ruderal floral element. Čekić *et* Kovačević (2017) found the species in several weed associations of orchards, vineyards and row crops in the Lijevče field, area in the northern part of B&H: *Panico-Galinsogetum parviglore* Tüxen et Becker 1942; *Panico-Portulaceum oleraceae* Lozanovski 1962; *Cynodono-Sorghetum halepense* (Laban 1974) Kojić, 1979; *Chenopodietalia albi* Tx., Lohm. *et* Prsg. 1950. In Croatia, Marković (1984) described the species in a number of ruderal communities: *Urtico-Malvetum neglectae* Lohm. 1950; *Arctio-Artemisietum vulgaris* (R. Tx. 1942) Oberd. apud Oberd. *et al*. 1967; *Chenopodietum boni-henrici* (R. Tx. 1931) Th. Müller apud Oberd. 1970; *Torilidetum japonicae* Lohm. 1967; *Chaerophylletum aurei* Oberd. 1957; *Matricario-Polygonetum avicularis* (Knapp 1946) Th. Müll. in Oberd. 1971; *Junco-Menthetum longifoliae* Lohm. 1953.

Figure 1: Curled dock (left) and broad leaved dock (right)
(photo: S. LJubojević)

Broad leaved dock has a similar usable value as a curled dock. In folk medicine is commonly used against hemorrhoids, severe diarrhea and for general regulation of digestion. It is believed that its use in larger quantities may have negative consequences. According to the some sources, the curled dock belongs to moderate allergens whose period of pollination ranges from June to August, while broad leaved dock has a slightly shorter period of pollination (Anon., 2017).

Beet was first domesticated about 2500 years ago in the Mediterranean area (Lange *et al*.,1999; Welbaum, 2015). There are several approaches to taxonomy and nomenclature of beet (Anon./ITIS, 2018; Kadereit *et al*., 2006; Lange *et al*.,1999; Uotila, 2011; and other). According to Kadereit and Uotila, the beet species (*Beta vulgaris* L.) is divided into three subspecies: *Beta vulgaris* ssp. *adanensis* - Turkish beet, *Beta vulgaris* ssp. *vulgaris* – common beet and *Beta vulgaris* ssp. *maritima* – sea beet. According to Lange *et al*. (1999) and some other sources, biannual common beet encompasses four cultivar groups: leaf beet, garden beet, fodder beet and sugar beet group. Within the leaf beet cultivar group, the following cultivars are differentiated: Swiss chard (silver chard), ruby chard (rhubarb chard) and spinach beet (perpetual spinach). The subject of our interest is the cultivar of Swiss chard. Leaf beet is usually consumed blanched or cooked, although any country or region practices specific ways of its preparation. In folk medicine, leaf beet is being applied to treat a large number of illnesses and disorders (Miraj, 2016).

Method

All three species are grown as a perennials on the no-tillage land belt between vegetable beds on one side, and orchards on the other. Curled dock and broad leaved dock spontaneously settled on the observed surface several years ago (Fig. 1). Since that time there were no interventions on curled dock populations. Their footprint is more or less unchanged. This is not the case with the broad leaved dock. It is trying to spread its footprint in time and space. For this reason in autumn every year some correction needs to be carried. This is achieved by simply digging entire plants from the ground. Such behavior of broad leaved dock perhaps may be explained by its allelopathic affinity (Zaller, 2006). Unlike "dock species", leaf beet was initially grown on beds from seeds, from where it spontaneously settled on the no-tillage land belt (Fig. 2 and 3). In this way, a practically biannual plant is cultivated as a perennial crop.

Figure 2: Swiss chard grown from the commercial seed on the garden soil bed (photo taken in June 2008 by S. Ljubojević)

Figure 3: Swiss chard grown from seed balls(glomerules) spontaneously settled on the garden path (ph. taken in June 2018 by S.LJ.)

Samples for analysis were collected in 2017. From the homogenised material, 5 g of leaves of each species was extracted with 80% ethanol, twice at 25 ml. The solutions were refilled with 80 % ethanol up to 50 mL. Thus, 100 mg/mL concentrations were obtained and further used to determine total phenols, flavonoids, flavonols, neutralization of 2.2-diphenyl-1-picrylhydrazyl radical (DPPH) and 2,2'-azinobis (3-ethylbenzothiazoline-6-sulfonic acid) (ABTS +) radicals. To determine a total and monomeric anthocyanins, 20 g of samples was extracted with a 20 mL solution (85 ml of 95 % ethanol solution in 15 ml of 1.5 mol/L HCl solution) at 0^{o} C for 24 hours. After being left to stand, resulting mixture was filtered through a filter paper, and the filtrates were used for further analysis. The content of vitamin C was determined by the standard AOAC methods (Anon., 2000). Total phenol content was determined by the modified Folin-Ciocalteu method (Wolfe, 2003). Gallic acid was used as the standard compound and the results were expressed as phenol equivalent to gallic acid (GAE), i.e. μg GAE/g_{FW}. The total flavonoids are determined by the method of Kumaran and Karunakaran (Kumaran, 2007), and the total flavonols according to the method of Ordoñez *et al*. (2006). Quercetin was used as the standard compound, and the results were expressed as μg Quercetine (Qc)/g_{FW}. The antioxidant activity in relation to the DPPH radical was determined by the method of Liyana-Pathirana and Shahidi (Liyana-Pathirana, 2005). The modified method of Re *et al*. (1999) was used for the ABTS radical. The results were presented with the TEAC value (Trolox equivalent of antioxidant activity), *i.e.* as μg Trolox/g_{FW}. Total and monomeric anthocyanins were determined by the spectrophotometrically modified "single" pH and by the pH differential method (Sun, 1998). The overall experiments were performed in three parallel repetitions. Analysis of the collected data was done using Microsoft Excel.

Results and discussion

After all, looking at macro and microelements, the results are quite variable. Leaf beet stands out at a noteworthy selenium content and slightly higher content of nitrogen and phosphorus, but at the same time significantly lags on calcium and iron content. Broad live dock is ahead in copper and sodium, has a slightly bigger potassium content in comparison to both species, but lagged behind them on manganese and latterly curled dock on calcium. The curled dock is superior in terms of calcium and iron, has a slightly higher manganese content, but significantly lags behind broad lived dock on copper (Tab. 1). All three species have almost

equal content of β-carotene, while the broad lived dock is inferior to the content of anthocyanins (Tab. 1). With regards to phenols, flavonoids and flavonols, curled dock is ahead, broad lived dock follows, while leaf beet shows the poorest results with observed features. The same is the case with vitamin C and antioxidant properties (Tab. 1).

Table 1: Synthesis of chemical analyzes

Chemical component	Unit	Broad lived dock	Curled dock	Leaf beet
		Mean value		
Macro- and microelements				
N	%	0.49	0.48	0.51

Antioxidant activity				
ABTS	µmol Trolox/g_{FW}	15.61	19.39	4.16
DPPH	µmol Trolox/g_{FW}	5159.55	9200.20	1872.55

Conclusions

Wild growing docks species do not lag behind the domestic leaf beet. More so, in many characteristics they show better results in comparison to discussed cultivated (domesticated) species. Our analysis has shown that dock's leaves have significant amounts of phenolic compounds and respectable antioxidant properties. Phytochemical parameters of leaf beet, except for anthocyanins, are bad, and in terms of the antioxidant properties even worse.

Only in the case of macro- and microelements, the results are polycentric. Accordingly, leaf beet predominates in the selenium content. The broad lived dock has advantage in the content of copper and sodium while the curled dock is superior in terms of calcium and iron.
Mentioned characteristics of docks run green parts of these plants as so-called functional foods - the foods that, in addition to its basic nutritional purpose, may also provide additional health benefit.

Abstract

Quality separation and purification of DNA molecules from the other cell elements is enabled using chromatographic methods in the analysis of DNA. Chromatographic columns with a silicon dioxide matrix (Qiagen Mini Spin Columns) have wide application in the DNA isolation process. An isolate in which the DNA molecule is purified and ready for further analysis can be obtained washing the DNA molecule from matrix columns using the AE buffer. This work aims to determine the optimal volume of the elution AE buffer needed to wash the maximum quantity of isolated and purified DNA molecule from the membrane column in controversial samples. The thirty samples were taken for the experiment. The Fifteen samples head a small amount of biological material which was putted on the microscope plate by short contacts.

The remaining 15 samples were with a higher amount of biological matrix. The sample concentrations were read by the RealTime PCR method. Ten samples were eluted with 200 µl of eluting AE buffer in the isolation process, the next 10 samples were eluted with 100 µl, while the last 10 samples were eluted with 50 µl. The experiments showed that 100 µl of elution AE buffer is optimal volume needed to wash (from the column) the maximum quantity of isolated and purified DNA molecule from the samples which contained very little biological material.The condition for the release of the molecules from silica matrix is its complete hydration. This can be done using required quantity of AE buffer. The silicon dioxide matrix turned out to be excellent sorbent in solid-liquid chromatography. It also satisfied lysing of the cells and release of DNA in the first steps of Qiagen isolation.

Keywords: *DNA molecule, AE buffer, Qiagen Mini Spin Columns.*

Introduction

One of the most important discoveries in human history is certainly the model and chemical structure of DNA molecule. This discovery has enabled a deeper understanding of all biological mechanisms and processes. It also provided numerous answers about the essence of our molecular biology (Butler, 2005*)*.Each cell contains identical genetic material. In DNA analysis regardless of starting material; blood, tissue, skin, hair or bone from one person, an identical result is obtained.

In the processes of analysis of DNA molecules, the starting material is extremely important, which means that the isolated DNA must be well-purified and of high quality (Tan, Huang, Tie, *et al*., 2013.; Xin, Chen, 2012).

The most suitable methods are chromatographic methods (Chacon-Cortes, Griffiths, 2014). The type of chromatography which will be applied depends on the type of material which will be analyzed, and most often several successive methods of chromatography are applied in order to achieve satisfying purification of the necessary components. In the isolation of DNA molecules from plant material, the most commonly used method is a modified method CTAB (cetyl trimethylammonium bromide) (Doyle and Doyle, 1990.) while a slightly less-used modified method is SDS (sodium dodecyl sulfate) (Schweitzer, *et al*., 1995). Isolation of DNA molecules from cells must have three basic steps regardless of which isolation technique

is used. These steps are: cell lysis, removal of other cellular elements from DNA molecules and isolation of DNA molecules (Đorđević, Marković, 1994.; Vujičić, 2002.).
Lysis of the cell is a common step in almost all techniques for isolating DNA molecule, and for this purpose detergents and enzymes, SDS (sodium dodecyl sulfate) and Triton X-100 are used. Other denaturing reagents such as urea, guanidinium salts and chemical haotrops can be used for lysis of cells and inactivation of cell enzymes, but they can reduce the quality and yield of isolated nucleic acids (Walsh, Metzger, Higuchi, 1991). The cellular residues in the first step are removed by centrifugation where the DNA remains in the supernatant, and the cell residues remain in the precipitate. The mixture of DNA and salt in the presence of ethanol concentration of 70-80% or isopropanol concentration 40-50% leads to precipitation of DNA molecules. The excess salt is removed by washing with 70 % ethanol. Finally, the DNA is resuspended in water or TE buffer (Elkins, Forensic, 2013.).
One of the commercial methods that has wide application in almost all laboratories dealing with DNA molecular analysis is *QIAamp® Mini Kit (QIAGEN, Hilden, Germany)*. Columns in the kit have a matrix of silicon dioxide for which DNA bind under the influence of a centrifugal force. In the kit there are lysing detergents ATL and AL, buffers AW1, AW2 and elution AE buffer (Kurabo, 2011).After the initial lysis of ATL and AL buffers and K proteinase, degraded cells with all the elements are applied to the Qiagen column and centrifuged. High concentration of haotropic salts (guanidine hydrochloride, guanidine thiocyanate, urea, lithium perchlorate) destabilize the intermolecular forces formed by positively charged ions (Figure 1.).

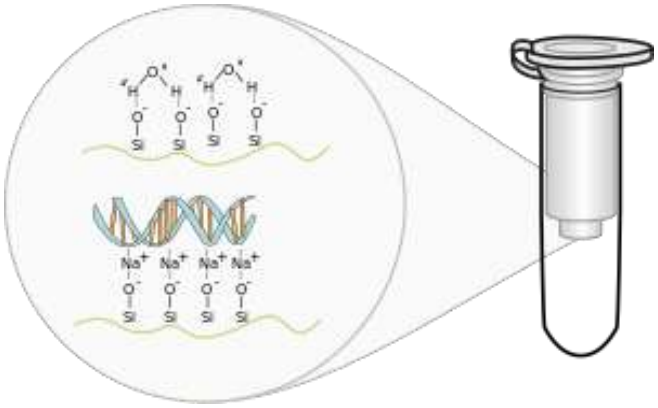

Figure 1. Silicon dioxide on a column with water and with a DNA sample in haotropic buffer

Ions are the connection between the silica matrix of the column (negative charged) and the negatively charged phosphate groups that make up the spine of the DNA molecules. Adding ethanol will further enhance the binding of nucleic acid to the silica membrane (Walsh, Metzger, Higuchi, 1991).
The silica matrix has pores of certain size and density through which all impurities (proteins, divalent cations, positively charged ions including magnesium) and haotropy is passed using centrifugation and rinsing processes of AW1 and AW2 buffers which contain ethanol and different salt concentrations. These solutions will not work on DNA which is attached on the column matrix, but will remove all impurities. The silica membrane DNA molecule is eluted or washed with AE buffer that hydrates the DNA and thus allows the separation from the silica membrane.

Material and Methods

The tests were carried out at the DNA Center for Genetics, in Belgrade. The experiments that have been done aim to establish optimal volume of the elution AE buffer needed to wash the maximum quantity of isolated and purified DNA molecule from samples with Qiagen mini spin colonies. The number of samples which concentrations are read and values obtained using RealTime PCR method were taken as the eligibility criterion.

The thirty samples were taken for the experiment. The Fifteen samples simulated the samples that head a small amount of biological material such as contact marks, where it is assumed that the donor of the biological trail is going to leave a very small amount of biological material. They are prepared in next way:

A biological trace made up of epithelial cells of skin fingers which are excluded as traces on swabs (contact traces) is applied on 15 microscopic plates by direct contact.

- Five samples were (1K2-5K2) were eluted from the 200 µl eluting AE buffer
- The other five samples (1K1-5K1) were eluted from the 100 µl eluting AE buffer
- The last five samples (1K5-5K5) were eluted from the 50 µl eluting AE buffer

The other fifteen samples simulated samples with a little bit more biological material in comparison to the samples described above. This biological material is obtained from fumes, glasses, blood stains, etc.

They are prepared in next way: Traces of saliva were applied on 15 glasses which are excluded as traces on swabs.

- Five samples were (6K2-10K2) eluted from the 200 µl eluting AE buffer
- The other five samples (6K1-10K1) eluted from the 100 µl eluting AE buffer
- The last five samples (6K5-10K5) eluted from the 50 µl eluting AE buffer

The aim of this experiment was to determine the optimal volume of the elution AE buffer needed to wash the DNA molecule from the membrane column in disputable samples.

Results and Discussion

The experiment results are shown in Table 1. From the results in Table 1. it can be seen that the samples that were eluted with 100 µl and 50 µl of AE buffers give similar results.

Minimal volume of the eluting AE buffer needed to wash (from the column) DNA molecules from the samples which contain above the average quantity of biological material such as fumes, blood stains, is 50 µl. Volume of the buffer needed to wash (from the column) the maximum quantity of isolated and purified DNA molecule from the samples which contain very little biological material is 100 µl.

Table 1. Concentrations of samples after elution with different amounts of buffer

Concentrations of samples (ng / µl) after elution with 200 µl of AE buffer - samples of 1K2-10K2	Concentrations of samples (ng / µl) after elution with 100 µl of AE buffer - samples of 1K1-10K1	Concentrations of samples (ng / µl) after elution with 50 µl of AE buffer - samples of 1K5-10K5
-	-	$7{,}04 \times 10^{-3}$
$1{,}1 \times 10^{-2}$	$1{,}33 \times 10^{-2}$	$3{,}66 \times 10^{-2}$
$1{,}09 \times 10^{-2}$	$1{,}29 \times 10^{-2}$	-
$2{,}34 \times 10^{-2}$	$9{,}58 \times 10^{-3}$	$6{,}25 \times 10^{-2}$
-	$8{,}24 \times 10^{-3}$	0,107
-	2,43	1,67
0,151	0,679	1,31
$4{,}3 \times 10^{-2}$	1,12	9,79
-	1,28	9,79

$5{,}15 \times 10^{-2}$	0,207	4.66×10^{-2}

Note: The first five samples in the columns are contact traces applied to microscopic plates, while the other five samples are traces of the saliva applied on glass glasses.

DNA molecule is optimally hydrated with this amount of AE buffer. Also, it is enabled washing from the silica membrane with the same amount of AE buffer. Regardless of the amount of biological material a sufficient amount of DNA molecules was eluted for analysis . The buffer volume of 200 µl of elution is too high. The concentration of isolated DNA molecule dilutes but it's more than enough to wash of residues of haotropic salts that impede elution.

Using the Qiagen method for isolating DNA molecules the certain amount of purified DNA isn't necessary obtained. The obtained amount of purified DNA depends on the amount of DNA molecules in the sample itself.

The silica gel matrix proved to be excellent sorbent in solid-liquid chromatography for the isolation and purification of DNA molecules (Tan, Yiap, 2009). The conditions that must be met in the first steps of Qiagen isolation are high level of haotropic salts and high level of pH which destabilize hydrogen bonds, Van Der Vals forces, and hydrophobic interactions. Also they allow the binding of the negatively charged DNA molecule to the silica matrix. DNA molecules selectively bind, while other molecules directly pass through the column and get removed due to high salt concentration. Adding ethanol allows the washing of salts that interfere with the elution. The additional centrifugation at the end of the process dries the column and liberates it from the residual alcohol that prevents the full hydration of the DNA molecule and its separation from the column. Requirements such as high pH and low salt levels allow the DNA molecule to be released from the column and eluate (Kelly, 2013). DNA molecule is eluted with the different quantities which show us that it is essential to find adequate volume that will achieve the maximum hydration of the molecule which is a condition for releasing it from the silica matrix.

The advantage of the chromatographic method is that the DNA molecule eluted in the AE buffer can be directly used for Real-time PCR (Butler, 2001.; Wong, Medrano, 2005). This method is quickest and no toxic and carcinogenic solutions are used. The problem that can arise is bad selection of the column (inadequately capacity). If a concentration of DNA molecules exceeds the capacity of the column, it can happen that the DNA does not bind to the column and practically wash away from it.

Conclusions

Quality separation and purification of DNA molecules from the other cell elements is enabled using chromatographic methods in the analysis of DNA.

Chromatographic columns with a silicon dioxide matrix (Qiagen Mini Spin Columns) have wide application in the DNA isolation process.

An isolate in which the DNA molecule is purified and ready for further analysis can be obtained washing the DNA molecule from matrix columns using the AE buffer.

The experiments showed that 100 µl of elution AE buffer is optimal volume needed to wash (from the column) the maximum quantity of isolated and purified DNA molecule from the samples which contained very little biological material. The condition for the release of the molecules from silica matrix is its complete hydration. This can be done using required quantity of AE buffer.

The silicon dioxide matrix turned out to be excellent sorbent in solid-liquid chromatography. It also satisfied lysing of the cells and release of DNA in the first steps of Qiagen isolation.

IMPORTANCE OF ORGANIC PRODUCT CHARACTERISTICS FOR CUSTOMERS IN THE REPUBLIC OF CROATIA

Irena PUGELNIK

Agriculture Committee, Croatian Parliament, Croatia
*Corresponding author: Ipugel@gmail.com

Abstract

The growth trend of the number of organic producers and of the areas with organic farming in the Republic of Croatia has not been accompanied by the increase in consumer awareness when it comes to the characteristics of organic farming or by the strengthening of the market for organic products in the Republic of Croatia. This paper focuses on determining the motivation, limitations and preferences of consumers regarding their intention to buy organic products as well as their choice of distribution channels. The research covers questions about understanding the differences between organic and conventional products, the meaning of the term "organic product", as well as issues related to the attitudes of the respondents trust in organic products, and the understanding of legislation on organic farming. The survey, conducted between January and April 2018, covered 218 social network users from the Republic of Croatia. The sample was gender balanced, consisting of 52% men and 48% women, of whom 57% were employed, 21% were self-employed and the rest were students and senior citizens. Out of the total number of respondents, more than a half grew up in towns and suburban areas. The results of the research indicate that consumers are insufficiently informed about the legal framework for organic farming with less than a half of the respondents giving a correct definition of an organic product, even though 90% of the respondents believe that there is a difference between organic and conventional farming. When deciding on buying organic products, most respondents consider the health aspects, taste, quality and supporting local production to be more important than the certificate, producer/brand and the packaging/design of an organic product. The results of the research identified the basic limitations that influence the decision to buy organic products and underline the need to strengthen consumer involvement in the enforcement of marketing activities.

Keywords: *organic products characteristics, customer knowledge, preferences, willingness to buy, Republic of Croatia*

Introduction

Organic Agriculture is a production system that sustains the health of soils, ecosystems and people. It relies on ecological processes, biodiversity and cycles adapted to local conditions, rather than the use of inputs with adverse effects. Organic Agriculture combines tradition, innovation and science to benefit the shared environment and promote fair relationships and a good quality of life for all involved (IFOAM, 2005)

The organic market makes up 2% of the total retail in the Republic of Croatia and the consumption of organic products per capita is half the European average (Willer and Lernoud, 2017). Although organic farming has been accompanied by an increase in the number of organic producers and areas with organic farming, certain standards in the use of organic products have still not been reached. If we analyse crops in organic farming, 47% of the surfaces are fields, 41% meadows and pastures, 8% orchards, 4% medicinal herbs, while other surfaces include olive groves, vineyards, fallow land, nurseries and other permanent crops. Vegetables are a crop with the lowest share of agricultural land used in organic production (0.3%). Indices 2015-2016 exhibit a growing trend in the organic farming of livestock except

for pigs and bee colonies, as well as a growing trend of organic products of animal origin (Croatian Bureau of Statistics, 2017). Organic producers in the Republic of Croatia are obliged to maintain their production in accordance with the national and EU legal framework. Organic farming is regulated by the Rulebook on organic farming, which ensures the implementation of the European Union directives on the production, labelling, monitoring, control, marketing and import of organic products. Clearly prescribed obligations and responsibilities points to the established chain of supervision, control and sanctioning of the production and sale of organic products from seedlings and seeds to the final product.

The distribution of organic products is realized through direct, indirect and emerging channels of distribution. The same also largely applies to organic products available at markets, in shopping malls and supermarkets as well as in direct sales on the producers' farms. A wider range of organic products is available in specialized stores that are mainly located in major urban centres and within specialized fairs held several times a year in larger cities. In recent years, several new distribution channels have emerged: Internet sales, groups of solidarity exchange, eco-market and placement through tourism. The domestic organic market is not organized, partly due to an insufficient volume of production, limited processing capacities, insufficient consumer awareness and the insufficient promotional and marketing activities, which, depending on the type and the extent of organic farming, the size of the economy and the distribution channel used, can make some organic products practically invisible in the organic market. Gugić et al., (2017) points out that domestic market is not adequately controlled, resulting in the misuse of the terms "eco" or "bio" by retailers. According to the latest research, consumers buy organic products most frequently at city markets and in supermarkets, and somewhat less often in specialized stores or directly from the producers (Anić at al., 2015). In Bosnia and Herzegovina, Croatia and Slovenia, most consumers buy organic products occasionally and it's mostly fresh fruits and vegetables (Cejak et al., 2010). Renko and Bošnjak (2009) identified the lack of marketing skills of producers, weak cooperation and communication and lack of consumer awareness as obstacles in the development of the organic market, and TV, newspapers and magazines as the most important sources of information on organic products. Furthermore, Croatian producers of organic food have not adapted their assortment and choice of locations to the consumers who point out the lack of information on where to buy organic products as the biggest obstacle. Tolušić (2006) points out that consumers are interested in organic products because of their beneficial effects on health but due to unresolved distribution channels in Eastern Croatia, they buy these products less often.

The objective of this paper is to identify the basic limitations which affect the consumer's decision to buy organic products in the Republic of Croatia.

Material and Methods

The research was based on secondary data sources and primary data collected by a survey conducted between January and April 2018 covering 218 (n = 218) social network users in the Republic of Croatia. In addition to the sociodemographic characteristics of customers (gender, work status, place of growing up, economic status of family) questions were asked about understanding the difference between organic and conventional products, the meaning of the term "organic product", the reasons for buying organic products, the characteristics of organic products which affect the decision to buy them, the frequency of buying, the willingness of customers to pay higher prices for organic products, future intentions of buying organic products, satisfaction with the offer of organic products in the Republic of Croatia. Respondents were asked to share their opinions on understanding legislation which regulates organic farming as well as on the labelling of organic products in the Republic of Croatia. The sample was gender balanced, consisting of 52% men and 48% women, of whom 57% were

employed, 21% were self-employed and the rest were students and senior citizens. Out of the total number of respondents, more than a half grew up in towns and suburban areas, 51% have a higher education, and two thirds of respondents consider the economic status of their family to be very good or good.

Results and Discussion

Organic farming is one of the fastest growing agricultural sectors in the world, with a double figure annual growth rate of land plots with organic farming as well as an increase in the production volume and the number of organic producers (Ummyiah et al, 2017). In a ten-year period, the share of surfaces with organic farming in the Republic of Croatia has increased by 5.4%, and was accompanied by a rise in the number of organic producers (Table 1). This growth trend has not been accompanied by the trend of consumer awareness on the characteristics of organic farming nor by the strengthening of the market for organic products in the Republic of Croatia.

Table 1. Organic farming in the Republic of Croatia – 2007 - 2016 / surface, producers

Year	Utilized agricultural area	Surfaces with organic production	Share of surfaces with organic production as part of utilized agricultural areas,%	Number of organic producers
	ha	ha		
2007	1,201,756	7,577	0.63	477
2008	1,289,091	10,010	0.78	632
2009	1,299,582	14,193	1.09	817
2010	1,333,835	23,282	1.75	1,125
2011	1,326,083	32,036	2.42	1,494
2012	1,330,973	31,904	2.40	1,528
2013	1,568,881	40,660	2.59	1,609
2014	1,508,885	50,054	3.32	2,194
2015	1,537,629	75,883	4.94	3,061
2016	1,546,019	93,814	6.07	3,546

Source: Ministry of Agriculture; Data processing: Croatian Bureau of Statistics, 2017

The research results point to a lack of consumer information on the legal framework for organic farming, more than a half point out that they have no understanding of the legal framework for organic farming and only 12% of respondents consider it to be well-defined, although 90% of respondents believe that there is a difference between organic and conventional farming. In the survey, 1.3% of respondents stated that they do not know the difference between organic and conventional products, a quarter of the respondents consider products from small local farms and products with protected designations of origin (PDO) and

protected geographical indications (PGI), one third of respondents defines organic products as healthy food and 40% of respondents gave a correct answer to the question of defining organic products. The same is confirmed by Gugić et al. (2017) who point out that consumers generally prefer traditional homemade products with a certain quality that are produced using organic principles. Nevertheless, a poor understanding of the nature of organic products makes the consumer identify all local products as organic ones. The respondents decided on the importance of the characteristics that influence their decision to buy organic products on a scale from 1 to 5 where 1 signified a completely insignificant characteristic, whereas 5 a very important one. The respondents consider the health aspects, good quality and taste as well as support for the local production as the most significant characteristics, whereas they care less about the packaging and the design, producer, brand and the shelf life of the product. They don't consider the organic product certificate as significant to making the decision to buy these products (Table 2). The respondents provided an average grade on their understanding of the organic market (3.1) and 4% of them expressed their high satisfaction with the organic products on offer in the Republic of Croatia. Martić Kuran and Mihić (2014) also identify subjective norms, attitudes and health awareness as the best when it comes to predicting if consumers will buy organic products. Hamzaoui-Essoussi and Zahaf (2012) explored the needs and preferences of consumers and determined how they affected them: (1) behavioural factors - knowledge and trust, (2) lifestyle - life according to the principles of sustainable development, and (3) support for the local production. They all affect the decision to buy organic products so the researchers made a distinction between three types of organic products buyers: true, occasional and inexperienced. Arvola et al. (2008) identify subjective/moral norms, positive behaviour, and a self-rewarding feeling as predictors for buying.

Table 2. Importance of organic product characteristics for customers in the Republic of Croatia

Characteristic	Average grade*	Standard deviation
Health aspect	4.51	0.81
Good quality	4.46	0.78
Taste	4.06	1.16
Shelf life	2.97	1.12
Certificate	3.67	1.28
Producer/brand	2.94	1.30
Product from local production	4.12	1.11
Design of the packaging	2.59	1.17
High price	3.32	1.16

**1=not important at all, 5=very important; Source: Author's calculation based on the questionnaire survey results*

Judging from the results of the research, subjective norms linked to healthcare, support for local production and producers, sense of support for ecological balance and biodiversity need to be upgraded by informing and educating consumers about the processes of organic farming and the characteristics that differentiate an organic product from a conventional one. Using an eco-label as confirmation of an organic product needs to be more strongly used in promotional activities. Brčić-Stipčević and Petljak (2012) point to the need of educating and informing consumers about the valid legal framework for organic farming and to the activities that would contribute to the development of the organic market in Croatia in order to raise consumer awareness of environmental legislation and consumer trust in organic products. The strategy of eco-marketing should be oriented towards the management of the product and the brand (Babović et al., 2005). The strategy requires the understanding of factors affecting its

applicability, so by taking the survey into account it is important to involve consumers by identifying their needs, possibilities and requirements and also by setting up distributive channels, which will enable a constant availability of organic products at all times. Of the total number of respondents, two-thirds stated that they were prepared to pay 10-30% more for organic products. Research has shown a weak consumer involvement and understanding of the offer and availability on the organic market, and since the organic market, as well as other markets, is influenced by laws of supply and demand, it is important to diversify supply and finalize organic products as well as understand the needs of the consumers in order to strengthen it. In his research, Petljak (2013) concludes that larger organic producers distribute their products through supermarkets and the meat industry, while smaller organic producers mostly offer their products for a lower price in order to prevent product degradation and production losses. Above mentioned indicates the poor positioning on the market of small organic producers, but also the need to adapt them more to market demands with the aim of a common market entry and/or choice of a distribution channel that would ensure their market visibility and make their products available to consumers. To achieve this, the increase in the level of knowledge about organic products with consumers is imperative.

Conclusions

The main research questions seeks to analyse importance of organic product characteristics for consumers in the Republic of Croatia that influence the decision to buy organic products. According to the research that was carried out, the health aspect, the quality and the taste of organic products as well as supporting local production are all identified as important characteristics of an organic product that influence the consumer's decision to buy them. A weaker evaluation of the organic product certification characteristic may indicate a lack of awareness when it comes to organic production and the characteristics of an organic product. An insufficient level of knowledge of the legal framework regulating organic production, weak consumer involvement and understanding of the offer and availability on the organic market can pose a certain limitation that influences the decision to buy organic products. Another limitation may also be posed by the impact of the "local production support" characteristic in correlation with 60% of respondents who did not give the exact definition of an organic product indicating the lack of differentiation when it comes to an organic product from local production and a product with a protected designation of origin and geographical indication. All of this points to the need for conducting more informative and marketing activities to raise the awareness of the characteristics of organic production and organic products. The same should become the keystone in the planning and implementation of organic product management activities by manufacturers, processors and distributors. Furthermore, any institutional activity directed towards the implementation of measures for educating and informing the consumer about organic production would provide additional support to the organic production sector.

Abstract

Crops productivity is limited due to low fertility level, water holding capacity, organic matter of soil and higher evaporation rate when the crops grown in sandy soils. For these reasons application of compost in sand soil can improve crop production and their resistance to abiotic stress such as water deficit, salinity and extreme temperature. Two field experiments were carried out at Agricultural Research Station, East of El-Ewinat (Egypt) during 2015 and 2016 seasons to investigate the effects of the replacement of chemical fertilizers by compost on peanut productivity grown under water deficit conditions. A randomized complete block design (RCBD) using a split-plot arrangement with three replications was applied. Two water treatments (100% and 70% from the amount of water consumption for peanut) were randomly assigned in the main plots. Five treatments of chemical fertilizers, compost and their combinations were randomly allocated in the sub-plots. The results showed that the peanut yield and its attributes were significantly increased in all studied parameters in both seasons with the replacement of chemical fertilizers by compost. This result indicated that compost improved plant resistance to water deficit due to water availability and use, and improved nutrients availability which appeared critical in improving peanut performance.

Key words: *Compost, chemical fertilizers, nutrient, peanut, water deficit.*

Introduction

Safe agriculture is one of the main attitudes in the world. Also, there has been an increasing awareness of the undesirable impact of chemical fertilizers on the environment, as well as the potentially dangerous effects of chemical residues in plant tissues on the health of human and animal consumers. Therefore, organic fertilizers are very important in plant fertilization in many countries including Egypt due to their beneficial effects on the soil, growth and increase the productivity as well as improving the quality of plant production.

Peanut (*Arachis hypogaea* L.) is an important oil crop in the Egypt. The cultivated area of peanut in Egypt during 2013 season was about 42,000 hectares (FAO, 2013). The production of vegetative oils is considered one of the major economic problems in Egypt because the produced oil amounts do not satisfy the increased demands by the population. Additional, the limited cultivated area to grow oil crops as well as their competition with other strategy crops in the agricultural rotation restricts the insufficient produced amounts of this oil. Although oil consumption in Egypt is about 2 million tons' year^{-1}, there is a shortage of 98 %. Thus increasing oil seed crops is an important aim in Egyptian agriculture. It is successfully cultivated in the newly reclaimed soils which commonly suffers from the deficiency of most nutrients due to the low organic matter content, high $CaCO_3$ content and high soil pH. In addition to increase farming Egypt is known as a heavy consumer of chemical fertilizer and intensive agricultural development and environmental change have led to severe land degradation in this soil. To overcome the problems of these soils and improve the fertility levels, such as compost, organic manures and bio-fertilizers as well as chemical fertilizers should be applied to these soils. Application the compost firstly for improving biological,

physical and chemical properties of soil and secondary to get high and clean agricultural yield produced free from undesirable high doses of heavy metals and other pollutants and improves growth and yield of crops and this is attributed to the better utilization of phosphorus by the mycorrhiza, enhanced nodulation by Rhizobium and better N nutrition.

Water stress is the most critical environmental factor that limits crop production (Bowden *et al*. 2010). Peanut is an important subsistence and cash crop in the semi-arid tropics where it often suffers from drought stress. Yield losses due to drought are highly variable in nature depending on timing, intensity, and duration, coupled with other location-specific environmental stress factors such as high irradiance and temperature. Studies have shown that water deficit stress effects morphological parameters in the form of decreased plant height, leaf area, root length, growth and yield, as well as physiological features in the form of decreased net photosynthesis, chlorophyll content, and water-use efficiency. Other important effects of water stress on plants are the decrease in leaf water potential and turgor loss, closure of stomata, as well as decrease in internal CO_2 concentration and CO_2 assimilation. Generally, water deficit stress or drought stress leads to a decrease in growth of susceptible plants. The initial resistance mechanism of plants to water stress is stomatal closure to prevent further water loss. Stomatal closure decreases the internal CO_2 concentration in the leaf and inhibits (Rubisco) enzyme activity, which ultimately decreases net photosynthesis (Rahbarian *et al*. 2011).

Materials and Methods

Two field experiments were carried out at Agricultural Research Station, East of El-Ewinat, New Valley governorate, Egypt, during 2015 and 2016 seasons under sprinkler irrigation system to investigate the effects of the replacement chemical fertilizers by compost on peanut productivity grown under water deficit conditions. Some soil physical and chemical properties of the experimental site that were determined according to the methods described by **Jackson (1967)** before sowing are present in Table 1.

Table 1: Some physical and chemical properties of representative soil samples (0-30 cm depth) of the experimental site before sowing for 2015 and 2016 seasons.

Soil property		2015*	2016*
Particle - size distribution			
Sand	(%)	73.32	72.45
Silt	(%)	18.46	19.13
Clay	(%)	8.22	8.42
Texture grade		Sandy loam	Sandy loam
EC (1:1 extract)	(dS m^{-1})	1.87	1.92
pH (1:1 suspension)		7.62	7.54
Total $CaCO_3$	(%)	8.65	8.72
Organic matter	(%)	0.057	0.063

* Each value represents the mean of three replications.

A randomized complete block design (RCBD) using a split-plot arrangement with three replications. Peanut seeds (cv. Sohag-110) at a rate of 50 kg $fed.^{-1}$ (fed. = 4200 m^2) were inoculated with *Rhizobium spp*. at sowing on May 4^{th} and 6^{th} in the 1^{st} and 2^{nd} seasons, respectively. Peanut seeds (2-3 seeds) were deposited in rows 50 m length, 60 cm width and about 20 cm spacing between plants within rows and then the plants were thinned after complete emergence (one week from planting) to one plant. The treatments were arranged in two variables in a split plot design with three replications. The first variable was represented by the two different water supply (100% and 70% from the amount of water consumption for

peanut) were randomly assigned in the main plots. The second variable five treatments of different amount of chemical fertilizers or compost and their combinations were randomly allocated in the sub-plots are present in Table 2.

Table 2: A mount of chemical fertilizers or compost and their combinations.

Treatments	N (kg N fed.$^{-1}$)	P (kg P fed.$^{-1}$	K (kg K fed.$^{-1}$)	Compost (Ton fed.$^{-1}$)
100% NPK + 0.0% compost F_1 (as control)	33.5	31	48	0.0
75% NPK + 25% compost F_2	25.10	23.2	36	3.0
50% NPK + 50% compost F_3	16.75	15.5	24	6.0
25% NPK + 75% compost F_4	8.35	7.7	12	9.0
100% compost F_5 (no chemical fertilizer)	0.0	0.0	0.0	12.0

The recommended dose of chemical fertilizers NPK (33.5: 31: 48) were used as controller. Calcium super phosphate (15.5 % P_2O_5) at a rate of 200 kg fed^{-1} added before sowing and during soil preparation and potassium sulphate (48% K_2O) at a rate of 100 kg fed^{-1} added with first dose of N. Nitrogen fertilizer was added at rate of 100 kg fed^{-1} ammonium nitrate (33.5% N). All plots received different amount of chemical fertilizers or compost and their combinations at 15 days before sowing during their preparation for planting.

The amount of water consumption for peanut at East of El-Ewinate government used I_1= 100% as a normal irrigation and I_2 = 70% as a moderate water stress in this experiment according to Abdel-Mawgoud *et al*. (2007), El-Koliey *et al.* (2001) and Mohamed (2007). Sprinkler irrigation system used underground water followed by 120 mints of I_1= 4000 m^3 fed.$^{-1}$ and 84 mints of I_2 = 2800 m^3 fed.$^{-1}$ with flow rate of 60 m^3/h at operating pressure of 400 kPa.). Foliar application of micronutrient combinations was carried out on the plants at 30 days and 60 days after planting at a level of 200 and 300 L fed.$^{-1}$, respectively. Wheat was the preceding crop in both seasons. All agricultural practices for peanut production as well as chemical fertilizer quantity were followed as recommended by Agricultural Research Centre for peanut production at the experimental site. Water application of 25 mm was applied over the entire field area after planting to enhance germination and ensure uniform growth. Irrigation management strategies (every 2 days) were initiated at the second irrigation. An additional light irrigation of about 20 mm was applied to the entire field shortly (two weeks) before uprooting to improve the soil turn over and to minimize pods loss. Plants were manually uprooted and trashed with a hand trash after air drying of about 3 days.

At harvest (120 days after sowing), a sample of 10 guarded plants from each sub-plot were randomly taken in four replications and the plant height (cm), number of pods plant^{-1}, pods weight plant^{-1} (g), seed yield plant^{-1} (g) and 100-seed weight (g) were recorded. Shelling (%) was determined as follows:

-Shelling percentage (%) = Seed yield (kg fed.$^{-1}$) /Pods yield (kg fed.$^{-1}$) X 100.

- Oil percentage (%): dried mature seeds were ground into very fine powder to determine oil % using Soxhelt apparatus and diethyl ether according to A.O.A.C. (1980).

- Oil yield (kg fed.$^{-1}$) = Oil % X Seed yield (kg fed.$^{-1}$)

The analysis of variance was carried out according to Gomez and Gomez (1984) using MSTAT computer software. Means of the different treatments were compared using the least significant difference (LSD) test at the 0.05 level of probability.

Results and Discussion

1. Effect of water deficit:

The results in Tables 3 and 4 showed that the moderate water deficit (70% amount of water consumption) had significantly decreased on all studies treaties except oil%, as compared to

normal irrigated (100% amount of water consumption). The highest main values of plant height (51.36 and 52.83 cm), number of pods plant^{-1} (34.53 and 35.80), pods weight plant^{-1} (34.23 and 34.88 g), seeds weight plant^{-1} (23.42 and 24.64 g), 100-seed weight (70.26 and 71.50 g), shelling (68.34 and 70.56%) pods yield (1432 and 1429 kg fed.$^{-1}$), seeds yield (979.01 and 1009.88 kg fed.$^{-1}$) and oil yield (504.21 and 536.56 kg fed.$^{-1}$) since it's obtained by normal irrigated (100% amount of water consumption) in the first and second season respectively. On other hand, the lowest values of above traits were observed by water stress (70% amount of water consumption), while, there was not significant effect on oil percentage. Yield and quality of peanut were decreased when peanut is deprived of water is high during the last 3 to 6 weeks of the pod maturation period. Furthermore, insufficient water during the growing season may reduce plant growth, normal root expansion, pod growth, and fruit development; however, excessive water can cause excessive vegetative growth and a greater leaf area index, but restrict root growth and development, resulting in decreased pod yield. Drought stress has been the major environmental factor contributing to the reduced crops productivity worldwide. Water deficit affects thylakoid electron transport, phosphorylation, carboxylation and photosynthesis. Drought affects membrane lipids and photosynthetic responses and yield in peanuts. Changes in the lipid content and composition are common in water-stressed plants and this increases membrane permeability. This causes damage and membrane disruption as well as reduction in photosynthesis. Maintaining membrane integrity under water deficit conditions will determine the plants resistance towards stress. Plants have several mechanisms for adaptation to water stress including stomatal conductance and osmotic adjustments. Drought stress has adverse influence on water relations, photosynthesis, mineral nutrition, metabolism, growth and yield of peanut. There are some critical points characterized peanut growth stages, flowering and pod filling growth stages are very sensitive to soil water availability compared with early and vegetative and late maturity growth stages. Water deficit imposed during the vegetative stage of peanut achieved greater final yields and increased water use efficiency and dry matter production including economic yield. Mohamed (2007) found that the seasonal actual applied amounts of irrigation water were 980, 1960, 2940 and 3920 m^3 fed.$^{-1}$ while, the seasonal measured depleted water was 960.83, 1718.92, 2113.10 and 2414.88 m^3 fed.$^{-1}$ when irrigated with 15, 30, 45 and 60 min every 2 days, respectively. The results are in agreement with those obtained in chickpea by Abou Kheira, 2009, Kamal *et al*., 2010, Rahbarian *et al*., 2011 and Amiri *et al*., 2017.

2- Effect of replacement chemical fertilizers by compost:

The presented data in Tables 3 and 4 clearly showed that fertilizer treatments significantly increased all the studied parameters. The data also indicated that the effect of F_4 fertilizer treatment (25% NPK + 75% compost) was more pronounced than other fertilizer treatments as well as the control (NPK). The highest main values of plant height (59.34 and 59.73 cm), number of pods plant^{-1} (39.47 and 40.67), pods weight plant^{-1} (38.92 and 39.40 g), seeds weight plant^{-1} (26.25 and 29.42 g), 100-seed weight (77.25 and 78.65 g), pods yield (1366 and 1479 kg fed.$^{-1}$) and oil yield (510.56 and 577.32 kg fed.$^{-1}$) since it's obtained by F_4 fertilizers treatments in the first and second seasons respectively, as well as, the highest main values of shelling (74.76%) and seeds yield (1105.77 kg fed.$^{-1}$) in the second season only. On other hand, the lowest values of above traits were observed by water stress (70% amount of water consumption). The obtained results revealed that, compost associated with chemical fertilizer mixture significantly increased all growth characters in both seasons compared to control treatment (plants received recommended dose of 100% NPK). Concerning this, it was outstanding that chemical fertilizer treatment unaccompanied with compost, also donate results significantly superior to results of control plants in all study traits during both seasons. Also results in Tables 3 and 4 demonstrated that increasing compost from 6 up to 12 ton caused significant increase in the aforementioned characters due to the application of compost

which could be attributed to either its direct effects by increasing the availability and supplying of nutrients or to its indirect effects by modifying soil physical properties that can improve the root environment, increase plant uptake of nutrients and consequently stimulate plant growth. Curtis and Classsen (2005) reported that the application of compost increased the amount of water available to a plant, its leaf water content, and plant biomass under drought stress.

Table 3: Effect of replacement of chemical fertilizers by compost on some studied traits of peanut productivity grown under water deficit conditions in 2015 and 2016 seasons.

F_4 = 25% NPK + 75% compost
F_5 = 100% compost

These results provide a plausible mechanism for how the combination of compost and chemical fertilizer together led to increase growth parameters over control, this raise spring from their beneficial effects on seedlings represented in nutrients availability and improvement of soil physical, chemical and biological properties resulted in more water retention simultaneously with available elements to be absorbed by plants roots and its insightful effect on the physiological processes such as photosynthesis activity as well as the utilization of carbohydrates. In contrast to mineral fertilizer, adding organic matter to soil improve soil structure, nutrient retention, aeration, soil moisture holding capacity and water infiltration (Deksissa *et al*., (2008). The results are in agreement with those obtained by El-Kramany *et al*., 2007, Sujanya and Chandra 2011 and El-Saady *et al*., 2014.

Conclusion

From the previous results, it is concluded that adding 25% the recommended dose of the chemical NPK fertilization with the 75% organic fertilization compost at a rate of 12 ton fed^{-1} gave the highest values of the traits studied under conditions of sandy soil and sprinkler irrigation system used underground water at East of El-Ewinat (Egypt).

Abstract

Greece is a country with a great tradition in livestock farming, which contributes decisively to the country's regional rural development. In recent years, consumers' demand for organically grown products of animal origin has increased. An appropriate legislative framework has been set up, both in primary (plant and animal production sectors) and secondary (processing, standardization and distribution units) to ensure compliance with requirements and production of safe and quality organic products. The present study was conducted in April through May 2018, in central Greek region of Thessaly, which covers an area of about 14000 square kilometers. The region was selected because livestock farming was and still is the basis of the regional economy. In order to explore the knowledge and preferences of Thessalian consumers about organic products of animal origin, four hundred questionnaires were completed by randomly selected individuals, in which respondents were asked to answer key questions about their willingness to trust organic products of animal origin. Results indicate that 92.6% of the respondents are aware of organic products of animal origin, 40.1% of the respondents claimed to purchase organic products of animal origin once a month, mainly directly from the producers, while most (25.4%) have been informed about organic products of animal origin from the internet. An inhibiting factor for organic product market is shown to be high prices. The present research provide detailed statistical information in order to develop an integrated picture of the market and availability of organic products of animal origin in the region of Thessaly.

Keywords: *Organic farming, organic products of animal origin, consumers*

Introduction

Greek tradition in livestock farming is extended, and its contribution to regional rural development decisive. A global shift of consumers towards organic livestock products has been noted in recent years. According to Brown (2000), health concerns, which have been arisen by food scandals, is a powerful factor in turning consumers into seeking a more 'ethical food production'. Still, other studies by Sriman and Forman (1993), Davis *et al.* (1995) report the environmental awareness factor as the main incentive to consume organic products.

Consumers buy organic products because organic farming and organic livestock farming are recognized as a safe food production method that responds to consumer concerns about safe and quality food, animal welfare, environmental protection and sustainable development (Woese *et al.*, 1997, Williams and Hammitt, 2000).

Organic farming (farming and livestock farming) is often referred to as the highest food production system as it is the only one that holistically protects and respects the environment, soil and consumers (Lampkin and Measures, 1995; Fotopoulos, 2000).

For organic production, an appropriate legislative framework has been set up both in the primary (plant and animal production sectors) and secondary (processing, standardization and

distribution units) to ensure compliance with requirements and to produce safe and quality organic products. Extensive farming systems implemented in Greece are largely in line with the organic production requirements under Regulation (EC) 834/2007, therefore Greek livestock farming can respond to new food market trends.

Organic livestock farming exhibits dynamic growth rates. According to Greek Ministry of Rural Development and Food data (Ministry of Rural Development and Food, 2018) organic livestock has reached 1.242.466 farm animals in total, in 2016. Most of the organically farmed animals are sheep (47.8%), goats (26.3%), hens (19.5%), cattle (6%) and pigs (0.4%). There is also an increase in organic crops areas, utilized for feeding of farm animals. Pastures primarily used for animal feeding at an organic stage account for 185.363 hectares. The total number of crops under organic farming producing feed amounts to 8.552 hectares. In addition, there is an increase in the number of enterprises processing organically farmed raw materials, namely 44 enterprises are involved in the processing and preservation of organically produced meat products and 65 enterprises in the production of organic dairy products. An important incentive for changing producers' mindset was the increased consumer knowledge over production methods and their efforts towards consumption of healthier food.

The objective of the present paper is to investigate the behavior of consumers in the organic market of animal origin products, given the growing consumer demand for healthier and safer food, and always considering that consumers appreciate the added assurance of these products.

Material and Methods

The survey was based on the collection of data on the behavior of Thessalian consumer with regard to organic products of animal origin, using a questionnaire formulated for the purpose of this work. The present study was conducted in central Greece, in Thessaly region, which covers an area of about 14000 square kilometers, in order to explore the knowledge and preferences of Thessalian consumers about organic products of animal origin. Livestock farming is the basis of the Thessalian economy. To this end, 400 questionnaires were completed, in which respondents were asked to answer key questions about their willingness to pay for organic products of animal origin. The face-to-face survey was conducted from April to May 2018. Data were processed using the SPSS Statistics, ver. 17 statistical program.

Results and Discussion

The largest part of respondents had an average age of 41-50 years, 51% of the respondents were men and 49% women, 3% primary education graduates, 29% secondary education, 7% graduates of technical education, while the remaining 61% graduated higher education. The largest number of respondents, i.e. 60%, are married. Also, 50% of respondents declare annual family earnings of 10,000-20,000 euros, 29% less than 10,000 euros, 17% 20,000-30,000, and only 4% annual earnings over 30,000 euros.

The largest percentage, i.e. 92.6% of respondents, are aware of the existence of organic products of animal origin and have been informed about this: from the internet (25.4%), SMEs (23.5%), friends (22.7%), press, i.e. newspapers, magazines (14.9%) and specialists (13.5%). With regard to the frequency of purchasing organic animal products (Figure 1), it appears that most of the respondents, i.e. 40.1%, buy them rarely (once a month), then 24.1% sometimes buy (1 time / 15 days), 21% never buy, 10.5% often buys (once / week) and 4.3% always buys (> once per week).

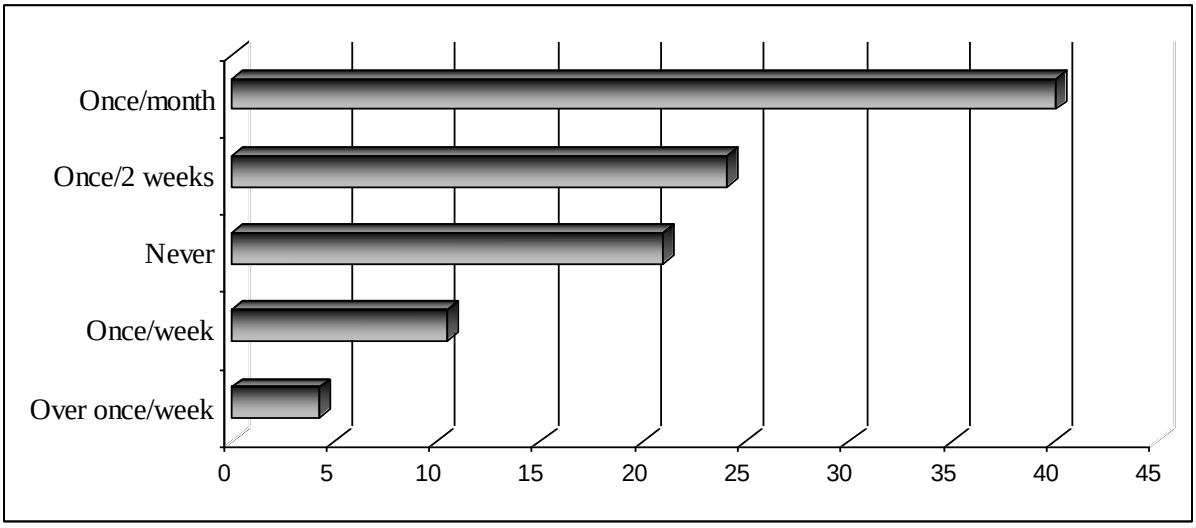

Figure 1. Sample distribution based on market frequency

Most of the respondents (62.6%) are aware of organic products of animal origin in the market. The most frequently purchased organic products by Thessalian consumers are eggs (30.9%), white meats, i.e. chicken, turkey (26.5%), dairy products (21.7%), red meats, i.e. beef, pork, lamb, goat (19.3%) and cured meats (1.6%). A large part of consumers (40.1%) buy organic products of animal origin directly from producers.

With regard to the incentives for consumers to buy organic products of animal origin (Table 1), the highest rates of agreement are observed in the perception of best quality (healthier, safer, higher nutritional value and fewer residues, i.e. pesticides, hormones, antibiotics).

Table 1. Incentives motivating consumers to buy organic products of animal origin

Topics	**Average scoring**
Appearance	2.0
Healthier	3.2
Better quality	3.2
Higher nutritional value	3.1
Better taste	2.9
Safety	3.1
Environment-friendly	2.9
Avoiding genetically modified organisms	2.9
Country of origin	2.7
Less residues (eg. pesticides, hormones, antibiotics)	3.1
More prestige	2.4
Discounted prices or offers	2.0

Average scoring: 1- Totally Disagree, 2- Disagree, 3- Neither Agree / Disagree, 4- Agree, 5- Totally Agree

According to the results of the survey, the reasons that prevent consumers from purchasing organic products of animal origin (Table 2) can be observed in respondents' perceptions of high price, lack of market availability and distrust over the labeling of organic products.

Table 2. Reasons for preventing consumers from purchasing organic products of animal origin.

Topics	**Average scoring**
High Price	3.8
There is no widespread availability in the market	3.7
The same tasting satisfaction as conventional products	2.7
Distrust towards organic products	3.3
Lack of good labeling of organic products	3.3
Lack of trust in the labeling of organic products	3.5
Lack of difference in quality between conventional and organic products	2.4

Average scoring: 1- Totally Disagree, 2- Disagree, 3- Neither Agree / Disagree, 4- Agree, 5- Totally Agree

Conclusions

This research has shown that all consumers are aware of the existence of organic products of animal origin and eight out of ten consumers declare they have purchased those kinds of products. Organic products of animal origin are mainly supplied directly by the producers, probably due to the lack of trust in labeling of organic products.

It seems that the high price prevents consumers from buying organic products. Designing a more favorable pricing policy for consumers is expected to result in an increase in demand.

Consumer perceptions are particularly positive for organic meat, as it is considered to be of better quality, healthier, safer, with a higher nutritional value and fewer residues (eg. pesticides, hormones, antibiotics). High prices are responsible for reduced frequency of purchase, which in a large percentage does not exceed once a month.

We therefore conclude that high price in organic meat is a factor that prevents a portion of consumers interested in organic products and its benefits for health from purchase. In particular, there was found a strong relationship between the organic market, if available at an affordable price and the non-purchase of organic meat.

ORGANIC FARMERS' MARKETING STRATEGIES IN TUSCANY, ITALY

Fabio Maria SANTUCCI*, Retjola TUSHE

[1]Department of Agricultural, Food and Environmental Sciences, University of Perugia, Italy
*Corresponding author: fabiomaria.santucci@unipg.it

Abstract

Organic products reach the Italian consumers through several channels, from on-farm sale to internet, from Solidarity Purchase Groups to supermarkets. Nearly 85% of Italians affirm to have purchased organic food in the last month, with fruits and veggies being the most mentioned, but most consumers admit being very occasional buyers. A survey was performed in the province of Arezzo (southern Tuscany), including 55 producers, randomly extracted from a list of 550 organic farmers belonging to the Italian Confederation of Agricultural producers, a union of small and medium size mostly conventional farmers. With a questionnaire covering 16 variables, data collection was realized from June 2017 through February 2018, via face to face interviews, telephone calls and emails. These farms are mostly family run, with the support of some workers. Most farmers converted only recently, with a minority being organic before 1992. 25 percent did not yet entirely convert. The production systems are diversified, with vineyards, olive and fruit trees, pastures and arable fields, used for several crops. Many have animals: dairy cows, cattle, goats, sheep and small animals. This allows the on-farm production of wines, olive oil, cheeses, jams, breads and cakes, and other foods, frequently used in the on-farm restaurants. That helps the on-farm sale, considered the best modality by 26% of respondents, followed by local markets, specialized organic shops, SPGs and internet. Advertising is done via website, participation in local and national fairs, printed media, small billboards along the roads, and participation in international fairs. 56 percent say that the local market is growing, and 45 percent consider positively the presence of organic foods in the supermarkets.

Keywords: *Direct marketing, Diversification, Agritourism.*

Introduction

This paper explores the behavior and opinions of a group of 55 organic farmers, representative of small and medium size producers in Southern Tuscany and it shows how appropriate strategies allow linking with local consumers, without forgetting international markets. Compared with the situation only a few years ago (Santucci and Pignataro 2002), organic agriculture, with its different approaches, is growing everywhere in Italy (Gamboni and Moscatelli 2015), accompanied and / or stimulated by an ever-increasing market demand (Idda, Madau and Pulina, 2008; Zanoli and Naspetti. 2005). The world market in 2017 has reached €10^9 101, with Europe (39 10^9€) and USA (41) absorbing the largest shares. Very many organic products are nowadays available almost everywhere in Italy. National total consumption was about €10^9 4.7, after Germany (9.6) and France (6.5). Still, the individual expenditure in 2015 was only 38€, much lower than in France (83) or Germany (106) and extremely far from Switzerland (262). This means that there are large margins for expansion, to be explored by farmers, processors and retailers. Organic products reach the consumers through several channels (Santucci 2012), from direct sales at the farm to internet, from Solidarity Purchase Groups (Schifani and Migliore 2011, Maestripieri 2017) to private labels of supermarkets (Santucci and Diotallevi 2015). Large retailers, both Italian and foreign, have entered into this market: 22 supermarket chains propose an average of 130 items each. A specialized, organic only, supermarket chain is fast expanding, from North to South, and it

counts now 256 points of sale. Public procurement, i.e. public purchase for schools, hospitals, and communities is also increasing.
Italian consumers are attracted to buy organic products mainly for "selfish motivations". Italians are scared by residues of fine chemicals, hormones, GMOs, and consider that proper food habits can protect their health and that of their family members (TNS Opinion & Social 2012). Other drivers, like protection of nature, animal welfare and sympathy for farmers, are much less important. A growing number of consumers is looking for locally produced products, also known as "zero miles" or "short food chain" (Scalvedi and Saba, 2018).
85 percent of Italians affirm to have purchased organic products in the last month, with fruits and veggies being the most mentioned. However, only 2 percent of respondents buy only organic, whereas most consumers admit being very occasional buyers. National production, although supported by the EU Rural Development Policies, is not sufficient. While the organic area has grown annually by 6.5 percent, the imports have exploded by 49% annually.

Materials and methods

Tuscany is one of the 20 Italian regions and is located at the center of the country. It includes nine provinces, one of which is Arezzo. The last official figures (December 31st, 2016), indicate there were 4,502 certified organic farms, out of which 1,403 had also some sorts of processing plants (SINAB 2017). This figure positions Tuscany at the 4th place, in terms of number of producers, and at the 6th place for the size of the area grown organically, amongst the 20 Italian regions. Tuscany, and of course its Arezzo province, is famous for the cultural value of its towns (Florence, Siena, Pisa, Lucca, Pistoia, just to mention a few), for the richness of its museums, for the beauty of its landscapes and for the quality of many food products. Many products have received a Geographical Indication and are also exported worldwide (wines, cheeses, olive oil, meats, special cereals and beans, etc.). Thanks to agritourism and to a continuous promotion, rural Tuscany attracts visitors from all over the world and is a main destination for food and wine lovers, who can enjoy 22 routes organized to discover wines, olive oils, and local products.
Within this scenario, a survey was carried out in the province of Arezzo (Southern Tuscany), including 55 producers, randomly extracted from a list of 550 organic farmers belonging to the *Confederazione Italiana degli Agricoltori* (Italian Confederation of Farmers), a major small and medium size farmers' union. The sample size (10%), is large enough to ensure that in the worst possible scenario we have a probability of 0.88 to have an error of estimation smaller than 10% (Iarossi 2006). With a questionnaire covering 16 variables, the data collection was realized from June 2017 through February 2018, via face to face interviews, telephone calls and emails. A total of 88 farmers has been contacted, but 33 did not cooperate, advancing different motivations. In case of denial, the next name in the list was contacted. The 16 variables include:

1. Total farmland (ha)
2. Organic share (%)
3. Year of first organic certification
4. Area of different crops and orchards (ha)
5. Animal productions (n. of heads)
6. On farm processing
7. Human resources
8. Agritourism (rooms and apartments)
9. On farm restaurant
10. Certification body
11. Main point of sale for organic output
12. Methods for promotion and communication

13. Participation in groups and associations
14. Opinion about local consumers
15. Opinion about presence of organic items in supermarkets
16. Likely future changes in the farm

Results and discussion

As expected, the farms are mostly family run, with the support of some permanent and seasonal workers. Most farmers have converted only recently (Table 1), with a minority being organic before 1992, when the first EU direct subsidy to organic areas was introduced by the EU Regulation 2078/92 (the subsidies are still existing as Measure 11 of the Common Agricultural Policy Pillar 2).

Table 1. Year of conversion

Year	%
Before 1992	5.5
1992 - 2000	12.7
2001 - 2010	36.4
After 2010	45.5
Total	100.0

These organic farms show interesting dimensions (Table 2), much larger than the average. This demonstrate that organic management (as well as EU subsidies) is not only attracting smallholders, but also large producers who are looking for alternatives.
About one fourth (23,6%) have not yet entirely converted.

Table 2. Area under organic management

Dimension (ha)	%
< 10	35.0
11 - 20	15.0
21 - 30	25.0
31 - 40	2.5
41 - 50	5.0
> 50	17.5
Total	100.0

As suggested by organic agriculture experts and for increasing technical and economic resilience, the production systems are diversified (Table 3), with pastures, vineyards, olive trees, and arable fields, these latter ones used in rotation for several crops.
Many farms have animals: dairy cows, cattle for meat production, goats and sheep for both milk and meat, and small animals (Table 4).
This allows the on-farm production (Table 5) of wines, olive oil, cheeses, jams, breads and cakes, and other foods, frequently used in the on-farm restaurant.
As written before, agritourism is a very common diversification strategy, that increases job opportunities, adds value to row output, improves agricultural income and in general the livelihood of farmers.

Table 3. Land use (ha, organic area)

Land use	%
Pastures	23.3
Olive trees	20.5
Vineyards	17.0
Orchards	9.9
Cereals	9.7
Fodder grasses	9.2
Industrial crops	6.3
Veggies	4.1
Total	100.0

Table 4. Farms with animals (n=55)

Species	Farms %	Heads (n.)
Dairy cattle	21.8	627
Meat cattle	10.9	185
Sheep	9.1	365
Goats	10.9	480
Pigs	9.1	87
Horses	9.1	19
Small animals	14.6	135

Table 5. Farms with processing activities (n=55)

Products	%
Wines	40.0
Olive oil	38.2
Cheeses	25.5
Jams	18.2
Other products	9.1

25 percent of our respondents declare to have a small restaurant, generally open in winter only on week-ends and every day during the spring-summer months. 38.2 percent also offer some types of hospitality, ranging from a simple room with bathroom to fully furnished apartments, where clients can even cook their own meals.

This helps the on-farm sale, considered the best modality by 26 percent of respondents, followed by internet, local markets, specialized organic shops, Solidarity Purchase Groups (SPGs) (Table 6). The on-farm sale to middlemen and processors is still appreciated by the largest producers, who must market large quantities of output, while smaller producers tend to prefer a direct contact with the final clients. Advertising for the farms and their products and services, and search for new clients (Table 7) are mainly done via the website, nowadays with pages also in foreign languages (English, French, German, and occasionally Russian and Japanese), printed media (also in several languages), participation in local and national fairs, small billboards along the roads near the farm, and participation in international fairs.

Most respondents (70.9%) belong to groups and associations for the promotion of their organic products. As a matter of fact, many are members of the *Associazione Nazionale Agricoltura Biologica (ANABIO)*, established by the *Confederazione Italiana Agricoltori*, and many are also members of the *Associazione Italiana Agricoltura Biologica (AIAB)*, an independent organic association.

Table 6. Best modality for marketing

Modality	%
At the farm, to processors and traders	27.3
At the farm, to consumers	25.5
Through internet, to consumers	16.4
At local open markets	10.9
To organic shops	10.9
To Solidarity Purchase Groups	9.1
Total	100.0

Table 7. Promotion and communication

Modality	%
Website of the farm	90.9
Trade fairs in Italy	81.8
Leaflets and other printed materials	74.6
Billboards along the roads	40.0
Trade fairs abroad	36.4
Sponsoring events	34.6
Registered trademark	16.4
Ads transmitted by local radios	9.1

The general attitude about the evolution of the market is positive: 56.4 percent consider that the local market is growing, while 43.6 percent think that it is constant. Nobody indicates a negative trend. Another interesting point is that the growing presence of organic foods in the supermarkets is not considered a dangerous menace by most respondents, but rather an opportunity (Table 8). 45.5 percent of the respondents believe that the offer of standardized, industrial, organic items will increase the number of consumers and will then push the consumers to look for "more natural", "locally produced" "you know who makes it" products, to be purchased at the local markets, at the farms or via internet.

Table 8. Presence of organic products in supermarkets (n=55)

Opinion	%
Positive, it will expand the market	45.5
Indifferent, the clients of supermarkets are not my clients	36.4
Negative, I am losing clients	18.2
Total	100.0

It comes consequently obvious that almost all respondents are planning investments and reorganizations in their business (Table 9). Many have already applied for grants and subsidies included in the Tuscany's Rural Development Plan 2014-2020, while many others are elaborating farm development plans with the help of technical and financial consultants.

Table 9. Future changes (n=55)

Innovations	%
Capital investments to diversify / to improve my productions	56.4
Reorganize marketing	36.4
Improve / change the organization of work, for family and farm hands	32.7

Conclusion

This study confirms that organic farmers are nowadays a thriving force within the Italian agricultural sector. Supported by the Regional and European policies and thanks to the growing demand, organic producers are dynamic and positive. Organic farmers have increased their resilience, through diversified activities, that include agri-tourism, on farm processing, and smart marketing strategies, that prefer local and direct consumers, but do not neglect middlemen and foreign markets. The increasing number of organic items offered by supermarkets is not generally considered a menace, but an opportunity, because it will expand the number of consumers and their curiosity towards organic food.

This dynamism is confirmed by the structural and organizational innovations planned for the next future, that the Regional Governments implementing the EU Rural Development should favour and support.

Abstract

Investigation of the effect of liquid organic fertilizers on organically grown potatoes were carried out in light clay loam, shallow gleysol carbonaceous illimerised soils - *Calc(ar) i-Epihypogleyic Luvisol - LVg-p-w-cc* - at the experimental station of Aleksandras Stulginskis University in Lithuania in 2013-2014. The experiments were carried out with liquid organic fertilizers Biokal 1 and Fitokondi, in the manufacture of which herbal extracts were used; fertilizers Fertenat and Ruponis made from biohumus, and fertilizers Humistar rich in humic and fulvic acids. The forms of liquid organic fertilizers had an uneven influence on organic potatoes. The potatoes, which were sprayed with Biokal 1 fertilizer, total yield of potato tubers essentially increased by 0.89-1.47 t ha^{-1} or 5.34-9.14%, and marketable yield increased by 0.89-1.54 t ha^{-1} or 10.24-19.15% compared to spraying with fertilizers Fitokondi, Humistar, Fertenat and Ruponics, and no significant differences in the output of marketable yield were determined. Under the influence of Biokal 1, the content of dry matter in potato tubers compared to spraying with Ruponics and the starch content compared to spraying with Ruponics, Humistar and Fertenat substantially increased, and the content of nitrates in potato tubers significantly decreased compared to potato spraying with fertilizers Ruponics and Humistar. After spraying potatoes with fertilizer Biokal 1, the number of one-stem tubers compared to spraying with Humistar, Fertenat and Ruponics, substantially increased.

Keywords: *potatoes, organic farming, liquid organic fertilizers, yield, chemical composition.*

Introduction

Compared to intensive farming, in organic farming, the products unpolluted with synthetic chemicals are grown; synthetic pesticides are not used and the environment is not polluted; the fertilization with manure, compost and other organic materials increases soil fertility (Rembiałkowska, 2007; Mansour *et al.*, 2009). The cultivation of organic potatoes (*Solanum tuberosum* L.) in the world has considerably widened due to their demand on the market. On Western European organic farms, potato cultivation plays an important role in organic farming. Potatoes are grown not only for food, but also for processing (Finckh *et al.*, 2006; Haase *et al.*, 2007). Organic potatoes accumulate less nitrates in comparison with those grown intensively; the content of dry matter, vitamin C, phenolic compounds, amino acids, total sugars and minerals increases in tubers (Hamouz *et al.*, 2005; Maggio *et al.*, 2008; El-Sayed *et al.*, 2015). The investigation carried out in Lithuania showed that all fertilizers reduced the amount of starch in tubers, but increased the total amount of sugar and nitrates: most content was in potatoes, which received the highest nitrogen content (Baniūnienė and Žėkaitė, 2007). When fertilizing through leaves, the shortage of nutrients in plants was reduced during a critical moment. The plants fertilized additionally through the leaves absorb about 50% of nutrients in the first six hours (Budzynski *et al.*, 2003). Leaf fertilizers did not increase the yield of potato tubers; calcium, boron and amino acids containing fertilizers Boramin Ca, potassium and nitrogen fertilizers Final K reduced the nitrate content in potato tubers, while

the leaf fertilizer Delfan containing amidic nitrogen and amino acids increased it. Leaf fertilizers had no effect on starch content in tubers, and the content of dry matter in tubers was mainly increased by Boramic Ca fertilizers containing calcium, boron and amino acids (Staugaitis and Laurė, 2008). The investigation conducted at the Centre for Agroecology of Alexandras Stulginskis University showed that the yield of organically grown agricultural plants under the influence of liquid organic fertilizers Bijododžio and Biokal 1 was not only increasing, the quality of the production grown was improving, but also the exposure of plants to diseases was reduced (Sliesaravičius *et al.,* 2006; Pekarskas, 2008).

The aim of the paper is to investigate and evaluate the influence of different types of liquid organic fertilizers on the yield of organically grown potatoes, the chemical composition of tubers and elements of yield structure.

Material and Methods

Total nitrogen content found in the soil during the investigation conducted in light clay loam, shallow gleysol carbonaceous illimerised soils - *Calc(ar) i-Epihypogleyic Luvisol - LVg-p-w-cc.* - at the experimental station of Aleksandras Stulginskis University, in Kaunas region, in Lithuania in 2013-2014, containing alkaline (7.1-7.2), low content of humus (1.79-1.83%) (organic carbon found 1.04-1.06%), average content of phosphorus and potassium (146.2-142.0 and 121.0-126.0 mg kg^{-1}), total nitrogen in the soil was (0.123-0.141%).Soil samples were collected prior to experiment setting up from the depths of 0-20 cm, by three replications, and were analysed at the Agrochemistry Research Laboratory of the Lithuanian Centre of Agrarian and Forest Sciences. The pH of the soil was determined by a potentiometric method (ISO 10390:2005), organic carbon by dry combustion method (ISO 10694:1995), humus - organic carbon content was multiplied by a factor of 1.724, mobile phosphorus (P_20_5) and potassium (K_2O) A-L (Egner-Riemann-Domingo method), total nitrogen Kjeldahl (ISO 11261:1995).

Experimental scheme: 1. not sprayed; 2. Sprayed with Biokal 1 10+10+10 l ha^{-1}; 3. Sprayed with Fitokondi 10+10+10 l ha^{-1}; 4. Sprayed with Fertenat 10+10+10 l ha^{-1}; 5. Sprayed with Humistar 10+10+10 l ha^{-1}; 6. Sprayed with Ruponics 10+10+10 l ha^{-1}. Potatoes were sprayed with liquid organic fertilizers on the surface of formation of main stems (BBCH 22-24), during the stages of the growth of main stem (BBCH 35-37) and the end of flowering (BBCH 6N9). The investigations were carried out with early potatoes *Fakse* (Denmark) breed plants. Seed rate was 2.5 t ha^{-1}. The total experimental field size - 14 m^2 (3.5×4) and accountabl area-9 m^2 (3×3). Test variants in repetitions were arranged randomly. Plant protection measures against diseases and Colorado beetles were not used. If was necessary, the Colorado beetles were removed mechanically from potato plants. Potatoes were planted with potato planter. The number of one-bush stem and the length of one-bush stem was determined by measuring 10 potato bushes in all variants of three repetitions. The number of one-stem tubers, the mass of one-stem tubers and the mass of one tuber was determined in all variants of three reperitions after digging all potatoes of 5 stems that were counted and weighed. After digging potatoes of all four repetition variants, potatoes were weighed and sorted. The tubers with diameters of 50-70 mm were classified as marketable potatoes. The potatoes of smaller diameter were assigned to the group of seminal (35-50 mm) and feeding potatoes (25-35 mm). The chemical composition of potato tubers was investigated in the Agrochemical Research Laboratory of the Lithuanian Agrarian and Forest Sciences Centre. The dry matter content was determined by heating to 105 °C until constant weight, starch - by comparative weight, nitrates - by ionometric method, nitrogen content using the Kjeldahl apparatus, phosphorus content by spectrometric method with ammonium molybdate, and potassium content by flame photometric method.

Liquid organic fertilizers Biokal 1 consist of 57% of herbs and 38% of biohumus extract, 5% of essential oils and mineral water. Herbal extract consists of the following herbs: the common nettle (*Urtica dioica* L.), the common horsetail (*Equisetum arvense* L.) and the greater celandine (*Chelidonium majus* L.). Biocal 1 chemical composition: 230.0 mg l^{-1} N; 370.0 mg l^{-1} P_2O_5; 480.0 mg l^{-1} K_2O; 110.0 mg l^{-1} Ca; 30.0 mg l^{-1} Mg; 10.0 mg l^{-1} Fe; 50.0 mg of l^{-1} Co; 100.0 mg l^{-1} Cu; 5.0 mg l^{-1} Se, pH 7.8. Fitokondi contains 80% of aqueous extract of medicinal plants, 13.3% of aqueous extract of biohumus, 6.6% of potassium soap (50.0 ml l^{-1}) and 0.1%. - essential oils (eucalyptus oil - 1.5 ml l^{-1}). In the production of liquid organic fertilizers Fitokondi, extracts of seven plants are used: the common nettle (*Urtica dioicia* L.), the common comfrey (*Symphytum officinale* L.), the shingle oak bark (*Quercus imbricaria*), the common horsetail (*Equisetum arvense* L.), the grand wormwood (*Artemisia absinthium* L.), the tagetes (Tagetes) and the greater celandine (Chelidonium majus L.). Chemical composition of Fitokondi: 0.02 g l^{-1} N; 0.01 g l^{-1} P_2O_5; 0.15 g of l^{-1} K_2O; 0.02 g l^{-1} Ca; 0.01 g l^{-1} Mg; 50.0 mg of l^{-1} Co; 100.0 mg l^{-1} Cu; 5.0 mg l^{-1} Se, pH 7.0, dry matter - 1.0%. Fertenat is manufactured using cavitation technology and biohumus of horse manure. Chemical composition of Fertenat: 1.51% total nitrogen; 104.30 mg kg^{-1} P; 212.40 mg kg^{-1} K; 81.53 mg kg^{-1} Mg; 341.0 mg kg^{-1} Ca; 0.45 mg kg^{-1} Cu; 3.93 mg kg^{-1} Zn and 0.35 mg kg^{-1} Mo. Humistar is made according to a special technology using organic substances and contains 132.0 g l^{-1} off humic acids, 33.0 g l^{-1} of fulvic acids, 55.0 g l^{-1} K_2O with pH of 13.0. Ruponics is made from biohumus of bovine manure using a special technology. Ruponics contains 1.0% of dry and 2.10 g of l^{-1} of humic substances, pH value 8.5-9.5. Chemical composition of Ruponics: 2.00% N; 1.60% P_2O_5; 4.00% K_2O; 0.62 g l^{-1} Ca; 1.04 g of l^{-1} Mg; 150.0 mg of 1^{-1} Fe; 0.06 mg l_{-1} S; 0.44 mg of l^{-1} Cu; 5.10 mg l^{-1} Zn; 2.70 mg l^{-1} Mn; 41.00 mg l^{-1} Mo and 6.20 mg l^{-1} B. Data were statistically evaluated by dispersive analysis method using the ANOVA program (Clewer, Scarisbric, 2001).

Results and Discussion

The investigations revealed that the largest total (17.58 t ha^{-1}), marketable (9.58 t ha^{-1}) yield of potato tubers, seed potatoes (3.28 t ha^{-1}) and the largest output of marketable yield was obtained after spraying the potatoes three times with liquid fertilizer containing herbal plant extract Biokal 1. The minimum total and marketable tuber yield received after spraying with liquid organic fertilizer made from biohumus Ruponics, and the smallest marketable output, but the maximum feed potato yield (5.30 t ha^{-1}) was received after spraying with biohumus fertilizer Fertenat. The total amount of liquid organic fertilizers investigated, as compared to non-sprayed potatoes, significantly increased the total and marketable yield of tubers, and the yield of the total output was substantially increased only after spraying potatoes with fertilizer Biokal 1. After spraying potatoes with fertilizer Biokal 1, total (0.89-1.47 t ha^{-1} or 5.34 to 9.14%) and marketable (0.89-1.54 t ha^{-1} or 10.24 to 19.15%) tuber yield substantially increased comparing to spraying with fertilizers Fitokondi, Humistar, and Fertenat and Ruponics, and no significant differences in the yield of the output was determined. After spraying potatoes with liquid organic biohumus fertilizer Ruponics, the total potato yield compared to spraying with Biokal 1 and Fitokondi substantially decreased, while the marketable tuber yield compared with the spray with Biokal 1, Fitokondi and Humistar. Compared to non-sprayed potatoes, the essential increase in the yield of seed potato tubers was conditioned only by spraying with fertilizers Biokal 1, Fitokondi and Ruponics. When comparing the liquid organic fertilizers among themselves, no significant differences between the yield of seed and feeding potatoes were determined (Table 1).

A number of investigations with liquid organic fertilizers have been carried out in Lithuania. The investigations were carried out in both ecological and intensive farming systems, involving most plant species. They were very unevenly effective, as well as low efficient

(Sliesaravičius *et al.,* 2006; Staugaitis and Laurė, 2008). Previous investigations have shown that liquid organic fertilizers Biokal 1 are very effective for various organically grown agricultural plants. Under their influence, the crop yield increased substantially and had a significant influence on the chemical composition of plants (Sliesaravičius *et al.,* 2006; Pekarskas, 2008). This is confirmed by these investigations. Liquid organic fertilizers were of uneven effectiveness in the cultivation of potatoes. The use of herbal extracts in the production of liquid organic fertilizers increases their effectiveness. The effectiveness of liquid organic fertilizers with herbal extract depends on their chemical composition. Fertilizers Biokal 1 were richer in nutrients and their efficacy was higher than Fitokondi.

Table 1. The effect of liquid organic fertilizers on the productivity of organic potato tubers and the output of marketable yield

Treatment	Total yield t ha^{-1}	Marketable yield (50-70 mm) t ha^{-1}	Output of marketable yield %	Seed potatoes (35-50 mm) t ha^{-1}	Potatoes for feed (25-35 mm) t ha^{-1}
unsprayed	14.40	6.88	47.78	2.42	5.11
Biokal 1	17.56	9.58	54.56	3.28	4.71
Fitokondi	16.67	8.69	52.13	3.11	4.88
Fertenat	16.31	8.14	49.91	2.86	5.30
Humistar	16.47	8.67	52.64	2.85	4.95
Ruponics	16.09	8.04	49.97	3.01	5.05
LSD_{05}	0.50	0.60	5.34	0.51	0.98

After spraying potato with liquid organic fertilizer containing herbal extract Biokal 1, the dry matter content in potato tubers compared to spraying with Ruponics, starch content compared to spraying with Ruponics, Humistar and Fertenat significantly increased, and content of nitrates in potato tubers was significantly reduced compared to spraying potatoes with fertilizers Ruponics and Humistar. Liquid organic fertilizers did not significantly affect the accumulation of nitrogen, phosphorus and potassium in potato tubers (Table 2). Investigations in Lithuania have shown that the influence of liquid organic fertilizers on the chemical composition of plants can be very diverse. They can have little effect on changes in the chemical composition of plants or have a significant effect thereto (Sliesaravičius *et al.,* 2006; Staugaitis and Laurė, 2008, Pekarskas, 2012). Investigations have shown that liquid organic fertilizers according to individual elements of chemical composition under irregular influence as well as their effectiveness can be very different.

Table 2. The effect of liquid organic fertilizers on the chemical composition of organic potatoes

Treatment	Dry matter %	Starch %	Nitrates mg kg^{-1}	N, %	P, %	K, %
unsprayed	20.11	15.35	118.10	0.23	0.051	0.35
Biokal 1 10+10+10 l ha^{-1}	20.17	16.00	109.25	0.24	0.056	0.36
Fitokondi 10+10+10 l ha^{-1}	20.02	15.75	110.60	0.24	0.051	0.35
Fertenat 10+10+10 l ha^{-1}	19.87	15.55	109.45	0.24	0.051	0.34
Humistar 10+10+10 l ha^{-1}	19.87	15.45	114.35	0.24	0.056	0.36
Ruponics 10+10+10 l ha^{-1}	19.72	15.35	113.45	0.23	0.052	0.36
LSD_{05}	0.40	0.22	3.14	0.04	0.012	0.033

The largest number of one-bush stems, their length, the number and the mass of one-stem tubers were obtained after spraying potatoes with liquid organic fertilizers containing herbal extracts Biokal 1 and Fitokondi, and the biggest mass of one tuber was determined in potatoes sprayed with Humistar and Ruponics. Spraying potatoes with fertilizers Biokal 1, Fitokondi and Humistar essentially extended one-bush stems, and when spraying with all the liquid organic fertilizers tested, the number of one-stem tubers and their mass, as compared to non-sprayed potatoes, increased substantially. Liquid organic fertilizers did not have a significant effect on the number of single-leaf stems and the mass of one tuber. Comparing the influence of liquid organic fertilizers on the values of the yield structure indicators, it was found that after spraying potatoes with fertilizer Biokal 1, the number of one-stem tubers compared to spray with Humistar, Fertenat and Ruponics substantially increased. Liquid organic fertilizers did not have a significant impact on the number of one-bush stems, their length, the mass of one-stem tubers and the mass of one tuber (Table 3).

Table 3. The effect of liquid organic fertilizers on structural elements of potato yield

Treatment	Number of stems per plant	Length of stems per plant cm	Number of tubers per plant	Weight of tubers per plant g	Weight of a single tuber g
Unsprayed	3.92	33.82	12.72	441.75	36.45
Biokal 1 10+10+10 l ha^{-1}	4.12	37.88	16.61	554.50	35.16
Fitokondi 10+10+10 l ha^{-1}	4.12	37.54	16.25	543.05	35.50
Fertenat 10+10+10 l ha^{-1}	3.98	35.96	14.90	526.50	36.64
Humistar 10+10+10 l ha^{-1}	4.08	37.06	15.17	536.75	36.75
Ruponics 10+10+10 l ha^{-1}	4.02	35.85	14.36	516.00	37.53
LSD_{05}	0.25	2.71	1.10	48.33	4.06

Conclusion

Spraying potatoes with liquid organic fertilizers containing herbal extracts Biokal 1 resulted in significant increase of total and marketable yield of potato tubers compared to spraying with fertilizers Fitokondi, Humistar, Fertenat and Ruponics, and no significant differences in the output of marketable yield were found. Under the influence of Biokal 1, the content of dry matter in potato tubers compared to spraying with Ruponics, the starch content compared to spraying with Ruponics, Humistar and Fertenat substantially increased, and nitrate content in potato tubers compared to potato spraying with fertilizers Ruponics and Humistar significantly decreased. Liquid organic fertilizers did not significantly affect the accumulation of nitrogen, phosphorus and potassium in potato tubers. After spraying potatoes with fertilizer Biokal 1, the number of one-stem tubers compared to spraying with Humistar, Fertenat and Ruponics substantially increased. Liquid organic fertilizers did not have a significant effect on the number of one-bush stems, their length, the mass of one-stem tubers and the mass of one tuber.

ORGANIC FARMING IN MOLDOVA - SOLUTION FOR REBALANCING THE SOIL RESOURCES AND ENVIRONMENT

Tamara LEAH*, Nicolai LEAH

Institute of Soil Science, Agrochemistry and Soil Protection "N.Dimo", Chisinau, Moldova
*Corresponding author: tamaraleah09@gmail.com

Abstract

Organic farming is quite developed around the world, but in recent years it has begun to increase in the Republic of Moldova, with relatively modest results compared to EU countries. At present, only 2% of the land is managed as "organic", and organic products exports account more than 11% of agricultural exports. Organic farming recorded a significant increase, from 80 ha in 2003 to 61280 ha in 2012, due to state support (subsidies) and a decrease with the reduction of subsidies. For these reasons, a significant number of agricultural farmers have renounced to organic farming, which has led to a reduction in the number of organic farmers, from 185 in 2009 to 27 in 2016. Another issue of expanding organic farming is irrational use and degradation of soil resources, resulting in lower productivity and profitability of this sector, especially for small farmers, and for rebalancing the soil resources and environment. Organic farming is performing well in this respect, it keeps all technological components, but corrected according to soil requirements, as: conservation tillage, without the physical degradation of soil; organic fertilization based on the use of local organic waste, plant debris and residues from agriculture; biological methods for the control of pests and diseases, as well as agro- and phytotechnical methods for weed control. All actions during a fairly short period have been established and are being used successfully. So the soil is healthier and at the same time the human health, consuming an organic natural product is ensured, and the environment and soils are in an ecological balance.

Keywords: *Organic farming, Subsidies, Soil Degradation, Moldova.*

Introduction

Organic production is a global farming and food production system that combines best environmental practices, a high level of biodiversity, the conservation of natural resources and the application of high standards of animal welfare. It is a method of production that is growing in the European Union states, the Republic of Moldova registering much lower results in this chapter. For Moldova, organic agro-food production and its marketing is a real chance of penetrating foreign markets, as the demand for organic agricultural products is increasing. This can be considered as a new opportunity for agricultural exports.

Organic farming has begun to develop in the world in 1940 and in Moldova since 2003. In 2005, Law No.115 on organic production was approved, and in 2006 - Decision No.149 for implementation of the Law on Production agro-food industry. For comparison, the largest share of organic land (24%) is recorded in Denmark, but in Moldova, organic farming is practiced only on 2% of the total area of agricultural land (Ecologizarea, 2015). In an agrarian country with 3/4 of chernozems and favourable climate conditions, such as the Republic of Moldova, organic farming must have the highest priorities and advantages.

The purpose of the research - to analyze the situation regarding organic farming, the dynamics of areas and number of producers who practice organic farming and to highlight the barriers and factors that lead to the cessation of these direction.

Materials and methods

For the purpose of an in-depth research into the dynamics of the development of organic agriculture in the Republic of Moldova, methods such as: analysis, comparison, analogy, synthesis, observation, grouping and consultation of specialized literature were used. It should be noted that official statistics do not present separate data on organic production. At the same time, there are no statistics on the volume of organic products exported, certified by international / EU bodies, and not by the national accreditation system.

Results and discussion

In 2017, agriculture generated 12.2% of the gross domestic product of the Republic of Moldova and about 21% of the total number of jobs. The given sector offers livelihoods for a significant part of the population, contributing to 50% of total national exports (Indicatori, 2018). However, the performance of the agricultural sector is increasingly affected by factors related to social, economic and environmental dynamics. Internal or external workforce migration, primarily caused by low wages, has reduced the availability of human capital for rural development. Irrational use and degradation of natural resources, including water and soils, results in lower productivity and profitability in this sector, especially for small farmers (Leah, 2010, 2017).

The general trend in the agricultural sector is also reflected in the development of organic farming. Organic farming in Moldova has contributed significantly to global agricultural exports. While only 2% of the land is managed "organic", exports to organic products account for more than 11% of agricultural exports. In the period 2003-2014, organic farming has seen a significant increase in the area used, from 80 ha in 2003 to 55365 ha in 2014 (Agricultura, 2015), thanks to the state's financial support (subsidies) and a decrease of those with the reduction of subsidies starting with 2015 (Figure 1).

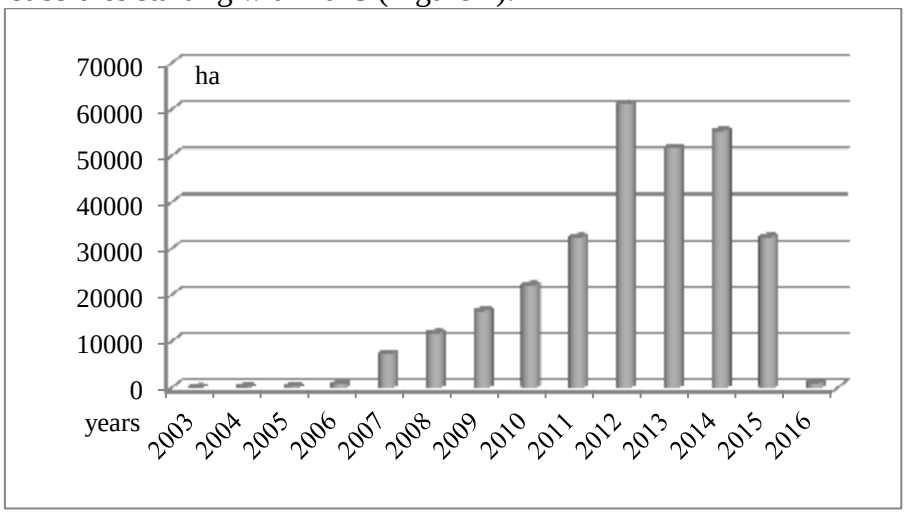

Figure 1. Dynamics of land use for organic farming, ha
(Agricultura ecologică în Republica Moldova - UNCTAG, 2018)

For these reasons (reduction of subsidies), a significant number of agricultural producers have renounced to organic farming, which has led to a reduction in the number of organic farmers and converters from 185 in 2009 to 38 in 2015 (Agricultura, 2015), (Figure 2).

The decrease in the number of economic agents and the areas registered in organic farming is marked by a number of inseparable factors such as (Ecologizarea, 2015):

• From 2014, the export of "ecological" products is carried out without the supervision of the national authority;

• National inspection and certification bodies are not recognized by the European Commission as equivalent;
• On the territory of the Republic of Moldova there are 10 inspection and certification bodies recognized by the European Union Commission to certify organic food products in third countries but are not registered at national level;
• Lack of information on the record of the areas, types of crops cultivated in organic farming, determined by the transfer of the economic agents to the inspection and certification bodies that are not registered at national level;
• Lack of a legal framework to grant exemptions for organic agri-food production;
• Lack of state supervision system and control regarding the traceability of organic products.

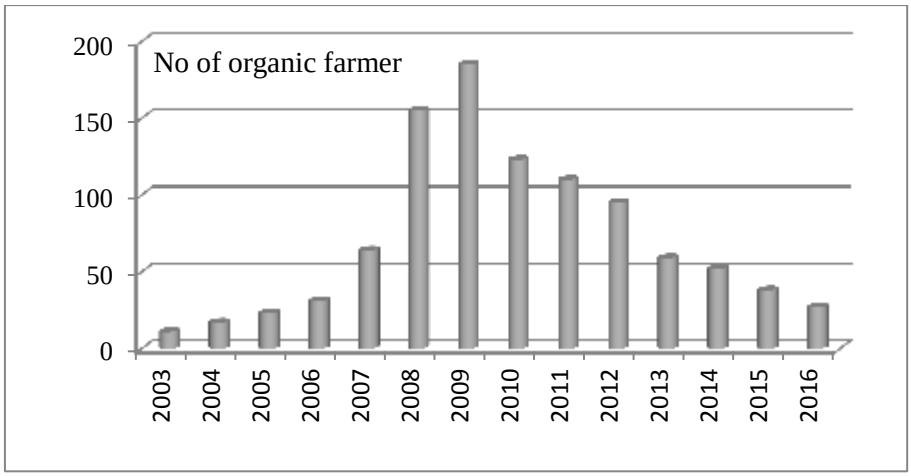

Figure 2. Number of organic farmers registered and undergoing conversion (Agricultura ecologică în Republica Moldova - UNCTAG, 2018)

Under these circumstances, the objective of further expanding the area of agricultural land used for organic farming from 1.9% in 2011 to 5% in 2015 has not been achieved and the 20% target by 2020 will be difficult to achieve without the implementation of comprehensive policies and mechanisms to support farmers (Agricultura, 2017).
One of the main reasons for increase in the dynamics registered during the period 2007-2012 was the favourable policies supported by the Government of the Republic of Moldova, with subsidies granted in 2007 for reimbursement of expenses during the conversion period. Since 2012, subsidies have been granted only for the establishment of multi-annual plantations, which may have had a negative impact on the sector. Since June 2014, the transition period has ended and the system of import authorizations has been replaced by the equivalent control bodies system. Thus, as was mentioned that during the period 2003-2012 in Moldova there were excellent conditions for the development of ecological agriculture, especially the direct neighbouring and association agreements with the European Union (Studiu, 2014).
An identified barrier to the development of organic farming is the impossibility of accessing subsidies by certification bodies that are not registered in the national certification system. Certification of organic products is currently carried out on two parallel platforms. Thus, the vast majority of certification bodies certify organic agro-food production according to the standard that is equivalent to the European Union standard but are not registered at national level. Another part of the certification bodies certifies the products to the National Control Bodies, but they are not in conformity with the standard that is equivalent to the European Union standard. This leads to an imbalance between the interests of the producers. On the one hand, those who can integrate into the national system, which is not in compliance with EU legislation, cannot benefit from subsidies, and on the other hand producers who cannot export agri-food products with "ecological" mention on the EU market (Productie organică, 2015).

Another issue of expanding organic farming is irrational use and degradation of natural resources, including soil and water, which results in lower productivity and profitability of this sector, especially for small farmers (Leah, 2017; Bacean & Țăranu, 2015).

The degradation of the productive capacity of soils due to over-exploitation over the last 50 years has been manifested by the intensification of erosion processes through landslides, humus and nutrient deficiency, salinization, periodic excess of humidity, clogging of depressions with low humus soils deposits, deterioration of soil fertile layers structure.

The small and very small reserve of humus in the soil is an essential issue in the development of organic farming. Soils with humus deficiency account the 60% of the agricultural land. There is a risk that in the coming decades the content of humus in arable land will decrease on average by 10-25%, which will substantially affect the physical qualities and micro-biodiversity of soils. Annual losses for this cause are estimated at 10% of the harvest.

Exhaustion of NPK reserves in soil can only be covered with mineral and organic fertilizers. The lack of fertilizers makes the share of the exhausted land categories and increase the harvest losses (20%).

The soils depletion on the area of 200 thousand ha for vineyards and orchards has led to the disruption of natural stratification and to the removal of low humus layers with high carbonate content. The fertility of these plots, used for field crops, is 10-20% lower compared to similar undisturbed soils (Leah, 2017).

Local soil pollution is maintained, although the application of chemical fertilizers per hectare between 1991 and 2015 has reduced by 5.3 times. At the same time, the degree of biological soil pollution in the localities increased due to the lack of functional systems for the removal and use of domestic and livestock waste (Leah, 2012).

In the last 25 years there has been deformation of field crops rotation, the reduction of the legume in crops rotation by 6 times, the decrease of the mineral and organic fertilizers application by 15-20 times. All these processes have led to the formation of a negative balance of humus and nutrients in the soils. As a result, physical, chemical and biological degradation takes place, soil productivity is decreasing, poverty is increasing (Leah, 2010).

In Moldova, soil protection can be achieved through the development of an environmentally friendly and organic agriculture that does not affect the components of the environment and, at the same time, produces high quality products. In this respect, the chemical control of the pests and the biological one must be gradually replaced, the monoculture practice should be avoided and all the necessary measures should be taken to improve the degraded soils, without omitting the necessity of reforestation and optimization of the storage of the various wastes and industrial residues (Foaie de parcurs, 2017).

In order to move from conventional agriculture to organic farming, it takes a conversion period that, depending on the crop, takes two to three years. The conversion period is a complex process involving the reorganization of the production unit's activity, the change of production processes and the introduction of new technologies in accordance with the legislation in force. So, during this period, soil fertility will be improved by introducing appropriate crop rotation to exclude the use of pesticides, chemical fertilizers and genetically modified organisms. The conversion period to organic farming is two years before sowing, for annual crops and meadows; three years before harvest, for perennial crops and plantations (Leah, 2014; Reglementări tehnice, 2008).

In the period 2015-2016, in order to remove existing gaps in the promotion and expansion of organic agriculture, legal and regulatory provisions have been developed at national level, which require harmonization with international / community standards and regulations. For example, the "Regulation on how to use the Fund's means to subsidize agricultural producers" was complemented by two new measures: support for the promotion and development of organic farming, and consultancy and training services.

The "National Agricultural and Rural Development Strategy for 2014-2020" mentions that the organic farming sector is underdeveloped. Thus, Objective 2 includes specific actions for the sustainable management of natural resources in agriculture. The specific objective 2.2 on supporting environment-friendly production technologies and organic products requires the development and promotion of organic farming through the implementation of clean technologies. Organic production must be subsidized or supported, especially those products that are becoming more and more demanded both on the domestic and on the external market. These measures, together with efforts to adapt to climate change, must be taken into account.
Integrating environmental provisions into agricultural policies will help reduce the risk of environmental degradation and improve the sustainability of agricultural ecosystems. To increase the share of organic farming, the following measures are needed:
(a) promoting the efficient production, processing and marketing of organic products in order to increase the income and well-being of farmers (Ecologizarea, 2015);
b) encouraging the improvement of the processing and marketing of primary organic agricultural products by supporting investments (supporting environmentally friendly agricultural practices, offering quality products and respecting the efficient use of soils;
c) promotion of the renewable energy resources use, development of new technologies and innovations, implementation of compensation systems for landowners whose properties are part of state-protected natural areas;
(d) organizing public education and awareness-raising programs for farmers in the field of the environment and setting up the necessary training infrastructure to further promote farmers' professional education in the field of sustainable agriculture;
e) development of environment-friendly techniques and infrastructure (creation of a mechanism for periodic verification of water quality for irrigation, conducting of pedological and agrochemical analyzes for permanent monitoring of soils, provision of integrated protection of plants against pests and diseases, promotion of production techniques conservative farming, preservation of the landscape / agricultural ecosystems through the use of extensive agricultural practices, development of waste management mechanisms in agriculture, especially in livestock farming);
d) enhancing educational and extension activities to ensure the education and training of staff of different levels engaged in the production and processing of organic products;
e) implementation of climate change adaptation measures aimed at promoting agricultural crops that have the potential for harsher climatic conditions (drought, high temperatures), soil treatment, water conservation and reduction of soil moisture loss through evaporation.
In Moldova there are a number of factors that can contribute to the promotion of organic farming: increasing the level of investments; developing an internal market; developing the culture of management in agriculture; application of no-till and mini-till conservation soil technologies; improvement of irrigation systems (Leah, 2014). These factors may have some immediate effects on organic farming: stimulating land conversion; application of subsidies, increased demand for organic produce, brand promotion in export and rebalancing the soil resources and environment. It is expected that by 2020, the total area of agricultural land occupied with organic production in our country will reach 150 th. hectares (Agricultura, 2017). If implementation of a monitoring and control system adjusted to European standards is not accepted, Moldova risks remaining at this level of organic farming development.

Conclusion

Ecological or organic farming has a great potential for development in Moldova; here are all necessary resources, we must abandon myths and turn potential into reality - fair and sufficient subsidies, educating producers and consumers, competent and corrupt control institutions, creating a modern infrastructure, combat the soil degradation etc.

Promoting and developing organic farming are considered the ways of ensuring sustainable land management in the agricultural sector as it contributes to biodiversity conservation, soil protection and carbon sequestration, helps avoid soil erosion and pesticide contamination, contributes to ecological rebalancing of environmental components.

ORGANIC FARMS IN POLAND AFTER ACCESSION TO THE EUROPEAN UNION

Wioletta WRZASZCZ

Institute of Agricultural and Food Economics – National Research Institute, Poland
*Corresponding author: wrzaszcz@ierigz.waw.pl

Abstract

In the last decade, the Polish agriculture experienced significant changes related to the number of agricultural holdings, production potential, agricultural production organization, as well as production and economic outcomes. These changes were driven by both market and institutional factors. Among the important factors that determine this transformation, technological progress and the growing dependence of agricultural production on industrial factors of agricultural production should be also indicated. In the case of conventional agriculture, this activity often contributes to environmental degradation. Organic production is the alternative system of agricultural production. Organic production provides benefits to society (food safety) and environment (respect for natural resources). In the view of increasing society awareness, consumers more likely choose organic products. This system of agricultural production is also supported within the rural development programme, which improve the difficult economic situation of organic farmers. The aim of paper is the indication of changes in number, production potential and economic efficiency of organic farms. The paper focuses on the presentation of the development direction of organic farms, which has taken place in the last decade. These results were illustrated on the background of all individual farms in Poland allowing identification of the ranges of convergence and diversity in the development of farms in total and organic ones. Central Statistical Office data for 2005 and 2016 were used. These data allowed formulation of conclusions representative for farms` population in Poland. Research indicated, that after the accession of Poland to the EU, there has been the dynamic development of the organic production system, as indicated by the multiple growth of the number of organic farms and their production and economic potential. Changes regarding production simplification and specialization which are taking place in organic farms should be deemed more intense when compared to those in conventional farms. In the case of organic farms, they additionally resign from the livestock production.

Keywords: *Organic farms, Central Statistical Office data, Poland, accession to the EU, production profile, farms' specialization, farms' concentration*

Introduction

Organic farming is the example of the sustainable agriculture form (Zegar, 2012; Wachter, Reganold, 2014). Organic farms represent one of the most interesting and prospective forms of environment-friendly agriculture. Their distinctive feature is the use of organic production methods – in line with the soil, plant and animal requirements. Owning to the fact that cultivation is conducted without agrochemicals and under controlled production methods, organic farming contributes to the conservation of biodiversity and the protection of natural resources, as well as high-quality food production (Kristiansen, Taji, Reganold, 2006).

In accordance with paragraph 1 of the preamble of Council Regulation (EC) No 834/2007, *Organic production is an overall system of farm management and food production that combines best environmental practices, a high level of biodiversity, the preservation of natural resources, the application of high animal welfare standards and a production method in line with the preference of certain consumers for products produced using natural substances and processes. The organic production method thus plays a dual societal role, where it on the one hand provides for a specific market responding to a consumer demand for*

*organic products, and on the other hand delivers public goods contributing to the protection of the environment and animal welfare, as well as to rural development (*Council Regulation (EC) No 834/2007 of 28 June 2007, L 189/1). The essence of organic farming comes down to a holistic approach to management, which takes into account, on the one hand nature processes, on the other hand ethical values (Stolze, Lampkin, 2009). Organic agriculture shows many potential benefits (i.e. higher biodiversity, improved soil and water quality, higher nutritional food value) as well as many potential costs including lower yields and higher consumer prices (Seufert, Ramankutty, 2017).

The last years point to the dynamic development of organic agriculture in the world, including in Europe. Comparing 1999 and 2015, the number of the world's organic producers has increased by more than 1,000%, and 2.4 million organic producers is currently. Compared with 1999, when 11 million ha were organic, organic Agricultural land has increased almost five-fold. In 2015, Europe took second place in the world in terms of area covered by organic crops (Willer, Lernoud, 2017), while Poland took the sixth place among European countries (Agricultural and Food Quality Inspection, 2017).

Changes in the number and area of agricultural land used in accordance with the rules of organic farming is the result of several components, including use of production technology (promote environmentally friendly production methods), the growing demand (demand for "natural" food), or the sustainable development policy, which strongly accentuates the need for development and support of organic farming (Watson, 2006). Referring to the first question, there is emphasized the need of searching such production solutions that respect nature (including sustainable intensification methods), due to increasing environmental pressure of farming. Parallel with increasing demand for organic food, sales of organic products has been one of the fastest growing market segment within the global food industry in recent years (Willer, Lernoud, 2017). In the case of the latter question, the policies for organic farming developed in Europe since the late 1980s have been developed in the context of production surpluses, loss of biodiversity due to agricultural intensification and a heavy reliance on commodity support for mainstream agriculture. The market for organic products was initially developed as a means to support the financial viability of farmers trying to deliver broader objectives (Stolze, Lampkin, 2009).

Organic farming is growing rapidly, although its range is still niche, as the model of conventional (industrial) farming is dominant in developed countries (Seufert, Ramankutty, Mayerhofer, 2017; Zegar, 2012). According to the definition, organization of agricultural production in organic farms should differ significantly from that encountered in conventional farms. As indicted Meemken and Qaim (2018), smart combinations of organic and conventional methods could contribute toward sustainable productivity increases in global agriculture. The production in organic farms should depart from specialized and simplified technologies and be based on crop rotation, organic fertilisers, natural feedstuffs, natural plant protection products, selection of species and varieties with natural resistance to diseases and local breeds and species. Taking into account organic farms development in recent years, it is important to define the direction of their development, including the scale of occurring organizational changes in relation to those typical of conventional farms.

The aim of paper is the indication of changes in number, production potential and economic efficiency of organic farms. The paper focuses on the presentation of the development direction of organic farms, which has taken place in the last decade. This decade is particularly important because of the Poland accession to the EU, which involved a number of adjustments to the legal implementation of EU policy, as well as strong agriculture subsidies, especially organic farming.

Materials and method

Public statistic of Central Statistical Office – 2005 and 2016 Farm Structure Survey (FSS) data were used[6]. These date were collected on the basis of uniform methodology that allowed to investigate the direction in which tends Polish agriculture. FSS research are carried out in individual EU countries, that results are finally aggregated in EUROSTAT databases. The proposed use of data from FSS to measure economic sustainability of farms and agriculture can be applied to other countries to conduct comparative analyses between them, taking into account the different requirements of sustainability.

The analysis concerns all individual agricultural holdings with at least 1 ha of agricultural land maintained in good agricultural and environmental condition. The research focused on individual farms using organic methods of agricultural production (organic farms) that have a certificate given to them by a certifying authority. The farms` characteristics concerned economic and production potential used in the research were the following: area of agricultural land (ha), labour input (expressed in AWU[7]), animal population (Livestock Units, LU[8]), the value of standard output (EUR thousand)[9] and standard gross margin (European Size Units, ESU)[10]. There was used a set of useful economic indicators, such as: land productivity (the value of the standard output per hectare of agricultural land), labour productivity (value of the standard gross margin per full-time employee), households income sources[11] and farms market activity (in general and local)[12]. Organic farms` results were illustrated on the background of all individual farms in Poland allowing identification of the ranges of convergence and diversity in the development of farms in total and organic ones.

[6]The study is carried out at intervals of several years. In the last decade, FSS was conducted in 2005, 2007 and 2016. Access to more detailed data, which would be representative of the whole agricultural sector was not possible.

[7] 1 AWU (Annual Work Units) is equivalent to full-time, that is 2,120 hours of work a year.

[8] 1 LU is a conventional unit of farm animals with a mass of 500 kg. See tables of conversion coefficient for livestock from physical units to livestock units (Toczyński et al., 2013).

[9] Standard output is the mean of 5 years of the value of production corresponding to the average situation in the region. Total standard production of farms is the sum of the values obtained for each agricultural activity on the farm by multiplying the coefficients of the standard output for a given activity and the number of hectares or number of animals; see (Goraj et al., 2012). It is an economic category that allows for comparing the volume of production, while offsetting the impact of price fluctuations in regional and temporal terms. There were used 2013 standard output indicators (based on the average values for the period 2011-2015).

[10] Sum of standard gross margins (SGM) – the difference between output and specific (direct) costs of all activities occurring on the farm – indicates the economic size of the farm, otherwise the productive potential of the farm. 1 ESU is equivalent to EUR 1,200. Standard gross margin on a particular crop or animal is a standard (average of three years in a particular region) value of production obtained from one hectare or from one animal less the standard direct costs necessary to produce. There were used 2004 standard gross margin indicators - the last SGM calculated indicators, used in Farm Accountancy Data Network (FADN). In subsequent years, there was used FADN farms` typology based on the coefficients of standard output.

[11] The predominant source of farm's income indicates its socio-economic type. This classification distinguishes the following groups: farmers' holdings – with majority income from agricultural activities, employees' households – with majority income from employment, entrepreneurs' households – with majority income from non-agricultural activities, pensioners' households – with majority income from pension, other – with majority income from other sources. Data collected under the FSS 2005 and 2016 allow for the classification of farms according to the predominant source of income of a farming family, but they do not include the absolute level of income, among other thing agricultural income.

[12] FSS data do not include detailed farms' economic account categories. These issues on organic farms economic situation were presented in the publication (Wrzaszcz, Zegar, 2016). These studies were based on Farm Accountancy Data Network data (www.fadn.waw.pl), which enabled the analysis of different production-economic categories, the cost level and subsidy value.

Results and discussion

During the analysed period – after the accession of Polish to the EU – there has been dynamic, more than five-fold increase in the number of organic farms[13] (tab. 1). This was accompanied by changes in the production and economic potential of organic farming – group of organic farms. In 2005-2016, the utilised agricultural area at the disposal of organic farms increased by 10 times, labour input increased by 4 times and livestock population nearly by 6 times, while standard gross margin and output increased appropriately by 11 and 12 times.

In the case of all farms whose results show the situation of conventional farms in Poland, the changes in production potential had a different direction. The number of farms has definitely decreased (by 1/5), which was associated with the outflow of labour force, partially of livestock population and of standard gross margin. Slight progress has been reported in standard output. These statistics indirectly confirmed the outflow of farmers and those employed in agriculture to other sectors of the economy. On the other hand, the results of organic farms show that farmers managing farms in accordance with the principles of the organic system have seen versatile benefits of this economic activity. Growing trends in case of organic farms in Poland were mainly the result of legal regulations – farms' subsidising in the form of agri-environmental programmes. The additional determinant was the changing consumers' and generally society preferences towards "more natural" and nutritious food (Łuczka-Bakuła, 2007; Babicz-Zielińska, 2010). Increasing demand probably will grow in subsequent years, that will be reflected in agricultural producers' choices.

Despite relatively high dynamics of organic farming development it is still a niche system of agricultural production. In 2005 and 2016, respectively, those farms used 0.5% and 4.6% of utilised agricultural area and their standard output was, respectively, 0.3% and 3.7%. There are several reasons for this situation. The demand for conventional products is still dominant in the market, despite the growing demand for organic products. Conventional products are offered at lower prices, that create a significant barrier for organic ones to compete. In addition, organic farming requires high precision from a farmer when performing agricultural practices due to the limited possibilities of using industrial means of production and related logistical challenges (acquisition of outlet markets, also local; efficient organization of transport of organic products, necessity of fast sale and processing). This precision requires the farmer to have multiple skills, which are derived from his extensive knowledge of natural environment and production.

Table 1. Farms' production and economic potential

Organic farms are significantly different from conventional farms (tab. 2). Organic farms, on average, characterised by definitely greater production potential, and next, economics. The

[13] These issues were presented e.g. in: (Wrzaszcz, Zegar, 2014).

greater area of organic farms than of conventional farms is caused by the economic reason – smaller value added per area unit – which preconditions the needs to pursue farming on greater area and to search for external sources of financial support, including those mainly taking on the form of governmental programmes. The differences between these farms' groups have been intensified over time.

Comparing the changes in organic farms to those which have taken place among all farms, it should be noted that in general these two groups of farms followed in the same direction, i.e. increased their production and economic potential, although the scale of these changes was more dynamic in the case of organic farms. In addition to the more intense increase in area and standard results in organic farms, labour inputs have also been more limited. These figures indicate the more efficient use of labour in organic farms. These changes are also a derivative of introduced organizational changes related to, in particular, the decreasing intensity of stocking density in organic farms, which progresses much faster than in conventional farms. This evidences the fact that farms are heading for agricultural production simplification, especially organic ones. These changes are in contradiction to the idea of the functioning of organic farms, which should provide for a closed circulation of macronutrients within the farm as a result of combining the crop and livestock production.
The agrarian structure of organic farms has clearly differed from that for all farms (Chart 1). Organic farms were dominated by farms with more than 5 ha, while very small farms dominated the structure of all farms. In addition, many more organic farms had an area of more than 50 ha when compared to all farms (in 2005, this was, respectively, 8% and approximately 1%). In the analysed period, the differences in this area deepened among the highlighted groups of farms. More and more large and very large farms were managed according to the organic system principles. The dynamic growth of large organic farms indicates their market orientation, adapted to the requirements of processors as well as of retail chains. This is a phenomenon whose justification is purely commercial (Zegar, 2018). Given the data presented, it can even be concluded that this process is progressing more quickly in organic farms rather than in conventional farms.
Agricultural production simplification in organic farms is the effect of market conditions, which by definition, is in contradiction with the desired organization of agricultural production. The result of this process is the fact, that organic farms have started to balance on the brink of legal requirements, adjusting to the market rights. More frequent farms` orientation on the mass market (chain stores) moves to the processes of organic farms` concentration and specialization (Chart 2 i 3). Alarming is the fact that the share of organic farms number with mixed (crop and animal production) drastically decreased, simultaneously in favour of farms oriented at crop production. Organic farms more and more often are targeted only at crop production, both traditional – connected with farming on arable lands, as well as orchard production, while part of them uses only permanent grasslands – meadows

and pastures. Livestock production elimination is determine by economic factors and animal production requirements within the scope of field crop structure, and also – or primarily – the need to narrow specialization of agricultural production forced by the market (uniform and large batches of goods). In addition, the process of agricultural production simplification, typical for conventional farms, took on the rise in recent years in the case of organic farms. Changes that take place in organic farms are not beneficial in environmental terms. The principles of sustainable development indicate the importance of a closed circuit of organic matter and nutrients within a farm. Organic farms, without animal production and natural fertilization (mineral also, because of legal requirements) can have organizational problems with balancing important soil ingredients. Since animal breeding predetermines proper functioning of the agricultural ecosystem, which is the guiding principle of organic farming (Tyburski, Żakowska-Biemans, 2012).The purchase of natural fertilizers is some solution, but it is no popular practice at the market. At the same time, organic farms geared exclusively towards the livestock production resigned from this type of production while different trends took place in conventional farms. An important reason for the resignation from the livestock production in organic farms was the underdeveloped processing sector, in particular, meat processing (Agricultural and Food Quality Inspection, 2017)[14].

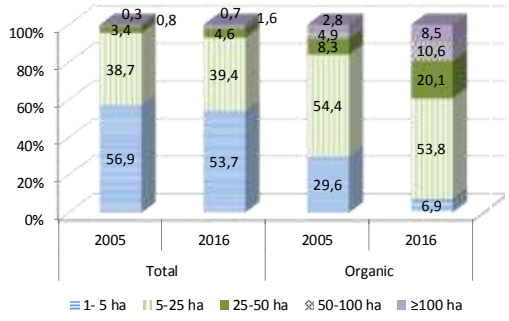

Chart 1. Agrarian structure of farms

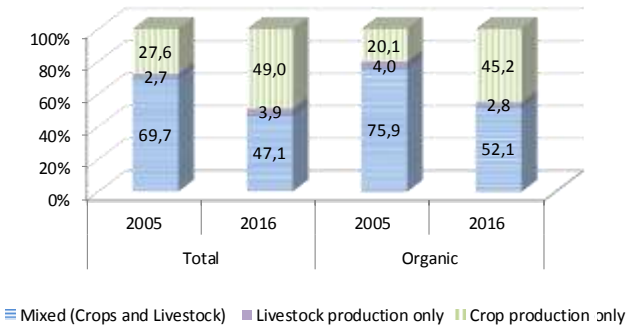

Chart 2. Farms production orientation - structure

Source: Prepared on the basis of FSS 2005 and 2016 data.

In 2016, 50% of organic farms specialized in field crops. The share of this group of farms has increased by more than twice since 2005. The second place was occupied by mixed farms with crop and livestock production, although their share in the structure has decreased by almost the half in the analysed period (from 32% in 2005 to 18% in 2016). On the other hand, specialization in permanent crops and horticulture concerned and continues to concern a small percentage of organic farms, just like rearing of granivores. Noteworthy is the significant share of farms specializing in rearing animals fed in the grazing system, although in this case there has been a significant decrease (from 23% in 2005 to 13%).

When comparing organic farms structure and all farms in terms of their type, it can be concluded that these farms differed significantly and, over time, the differences have deepened. The share of farms specializing in field crops also increased among all farms, although the rate of these changes did not match up to that in the case of organic farms. Specialized horticultural farms, farms rearing ruminants and granivores maintained among all

[14] In 2015, in terms of the number of organic processing operators, the largest share was that of processing of fruit and vegetables – 32.1%, other agri-food products (inter alia, spices, beverages) – 28.2%. The share of grain milling operators was – 20.3%. Definitely smaller was the share of operators in other industries: meat and fish processing – 7.7%, coffee and tea processing – 5.0%, milk processing and cheese making – 3.1%, vegetable and animal fat processing 2.4% and sugar production – 1.2% (Agricultural and Food Quality Inspection, 2017).

farms, with the increase in the share of farms specialized in permanent crops. Over time organic farms become similar to all farms in terms of production simplification and specialization, nevertheless, organic farms are increasingly less specialized in livestock and non-specialized with mixed production. Organic farms progress in field crop specialization is faster. In contrast, in the case of all farms, a relatively stable percentage of those specializing in the livestock production (this applies mainly to cattle, swine, poultry) is maintained.

* *p.p. – percentage points; non-agri. – non-agricultural.*
Source: Prepared on the basis of FSS 2005 and 2016 data.

The last question in the paper is farms' market and economic activity (tab. 3). The value of standard output per hectare indicates land productivity. It is an important indicator of agricultural production volume in the context of food security. In this regard, the organic farms didn't match conventional ones, although their land productivity distance decreased in recent years. However, organic farms had an advantage in terms of labour productivity (ESU/AWU), which strengthen over time. This is the effect of both, standard results

improvement, as well as efficient labour use. Standard gross margin per full-time employee indicates the potential labour charges and the assessment of labour economic efficiency.
Definitely, the greater part of organic farms is focused on local market compared to conventional farms. This is justified because of the "sensitivity" of organic products and social benefits provided to the local communities. Entities operating on local market provide benefits to local communities, which are reflected not only in more convenient ways to buy goods (often in lower price as compared with products produce in longer food chains), but also contribute to the development of neighbourly ties and sustaining of rural areas vitality.
In recent years, organic farms strongly improved linkage with market – in 2016 r about 90% of farms sold at least the half of agricultural production. Taking into consideration analysed farms population in total, percentage of market farms was significantly lower, 67%.
These data have confirmed the growing importance of market organic farms. Simultaneously, among the organic farms, the greater percentage of farms gained the prevailing agricultural revenues (farms oriented on active functioning on market), than in the case for conventional farms. The majority of farms is targeted on agricultural activity, which confirms their market orientation and potential possibilities to ensure an adequate volume of agricultural production. In this light, non-agricultural income have less importance.

Conclusion

1. After the accession of Poland to the EU, there has been the dynamic development of the organic production system, as indicated by the multiple growth of the number of organic farms and their production and economic potential. A major determinant of this process was the subsidising of organic farms from rural development funds.
2. Organic farms are significantly different from conventional farms in terms of their potential and production orientation – they are considerably larger and economically stronger (on average). In the analysed period, the advantage of organic farms was growing.
3. Changes regarding production simplification and specialization which are taking place in organic farms should be deemed more intense when compared to those in conventional farms. In the case of organic farms, they additionally resign from the livestock production.
4. Organizational changes in organic farms are dictated by the market and institutional conditions. Organic farms adapt to market needs while meeting the legal requirements of the organic production system, which determines the receipt of subsidies.
5. The advantage of conventional farms over organic farms is related to the land productivity. Different relationships apply to the labour productivity and local market activity, where organic farms are leaders and increase their advantage over time. The high and increasing over time percentage of market organic farms and those making their living mainly from the agricultural activity indicate their strengthening market position.
6. In view of the promising forecasts of the demand for organic food and the planned subsidising of the organic production in the next EU budget perspective, we can expect the further development of organic farms.
7. The substantive criteria of the organic production system should be subject to discussion. Assuming that the current legislation is maintained, the further simplification of the agricultural production in organic farms is highly probable, which may contradict the need to implement practices consistent with the idea of sustainable development.

Abstract

Quality and balanced fertilization is one of the most important orchard management practices in fruit production. However, fertilization in conventional production systems is mainly focused on obtaining the highest yield. This usually requires increased utilization of synthetic nitrogen fertilizers, which significantly contributes to a series of undesirable effects and results in excessive environmental pollution. Since organic production system is considered as an important factor of the strategy for the development of agricultural sector, it is necessary to increase this kind of production. To find a way to overcome the mentioned problems, the use of vermicompost extracts is appeared as potential solution. Therefore, we conducted a study on the effects of vermicompost extract on yield-related characteristics (yield per plant, yield per unit area), physical (fruit weight, length, breadth, and firmness) and chemical fruits properties (total phenolics and antioxidant capacity) of 'Senga Sengana' strawberry cultivar, as well as microbiological properties of strawberry rhizosphere (total microbial count, numbers of soil fungi, actinomycetes, aminoheterotrophs, oligonitrophilic bacteria and *Azotobacter*). The obtained results indicate that application of vermicompost extracts in organic strawberry production had a positive effect on plant yield and fruit quality. Positive effects on soil biogenicity have also been observed. Therefore, vermicompost extract application can be considered as an appropriate practice in production of healthy and environmentally safe strawberries with satisfying basic postulates of sustainable agriculture.

Keywords: *Vermicompost extracts, Microorganisms, Organic strawberry production, Yield, Fruit Quality.*

Introduction

Ever-increasing studies have warned that the use of nitrogen chemical fertilizers, which is constantly increasing and whose use will be doubled and even tripled by 2050, causes various problems that adversely affect the environment and human health. Despite these, according to the Food and Agriculture Organization of the United Nations, the annual global consumption of chemical fertilizers in the period 1960-1990 increased from 46,000,000 to 130,000,000 tonnes, reaching 190,400,000 tons in 2015 (*http://www.fao.org/3/a-av252e.pdf*).

Introduction of living cells of microorganisms into the soil, the use of vermicompost or compost products - teas, extracts or leachates for improving plant nutrition are great natural resources that can contribute to overcome the mentioned problems.

In many countries such as Germany (Ernst et al., 2008), Spain (Monroy et al., 2009), USA (Arancon et al., 2006) and Vietnam (Yadav et al., 2010), vermicomposting is viewed as one of the key steps in sustainable waste management. Thanks to better physical characteristics, greater microbial and enzymatic activity, as well as larger content of easily accessible nutrients, vermicompost has a number of advantages over chemical fertilizers, and according to Venugopal et al. (2010) and Abul-Soud et al. (2009) vermicompost is significantly more

acceptable by manufacturers compared to compost. Quaik et al. (2012) associate increased interest in vermicomposting with its positive impact on the environment.
Beside the aforementioned methods of plant nutrition, with the aim of sustainable use of natural resources, a considerable attention is paid to the use of compost products - teas, extracts or lichates. Ingham (2002) states that compost teas (fluids extracted from compost) and the benefits of their application were known even by the ancient Romans. However, its role has been neglected due to the increasing use of chemical fertilizers. In recent years, interest in their use has increased along with requirements for health food production. Considering the fact that compost tea contains useful microorganisms and soluble nutrients, both organic and inorganic, its application enables the efficient use of nutrients in the sustainable and economically justified manner and improves waste management from agriculture. Diver (2002) points out that compost and herbal teas are tools that can increase the productivity of crops and inoculate philo- and rhizosphere with soluble nutrients, useful microorganisms and microbial metabolites.
The aim of this study was to determine the effects (advantages and disadvantages) of the application of some alternative fertilization methods (liquid biopreparation based on vermicompost) on yield-related characteristics and fruit quality attributes of strawberries grown in the organic production system.

Material and Methods

An open field trial was conducted on 'Senga Sengana' strawberry plants at the experimental plantation located near Čačak, Republic of Serbia (43^{o} 53' N latitude, 20^{o} 20' E longitude, 225 m altitude) during the two consecutive seasons (2016–2017 and 2017–2018) . The experiment was set up at a randomized block design, in three replications. The frigo strawberry plants were planted in a single row system. The rows were spaced about 80 cm apart, and the plants were set 15 cm apart in the rows. Treatments contained vermicompost-based product (vermicompost extracts) prepared at the Fruit Research Institute Čačak, whereas untreated soil and plants served as control.
Production of biopreparation is based on a specially obtained liquid extract of vermicompost enriched with various strains of useful microorganisms (bacteria strains of the genus *Azotobacter* sp., *Bacillus* sp. and *Pseudomonas* sp. as well as *Trichoderma* sp. fungus). Its application was carried out in three ways: rhizobial (R), foliar+rhizobial (F+R) and foliar (F). Treatments were carried out five times during vegetation period (in accordance with the corresponding phenological development stages of strawberry and 30 days after harvest) in the amount of 400 l ha^{-1} of the respective preparation. The generative potential of the strawberry plants, which included yield per plant (g) and yield per unit area (t/ha), was determined by collecting and measuring the weight of picked fruits in each harvest
To assess the physical fruit properties a sample of 60 fruits in each replication were randomly selected. Samples were colected at full maturity stage. An average fruit weight was measured using the Adventurer Pro AV812M balance (±0.01g accuracy) and the data were expressed in g. The fruit dimensions (mm) including length and breadth, were also determined in the selected samples using the 'Carl Roth GmbH' vernier scales (±0.05 mm accuracy). Firmness of fruit was measured using a hand-held shore-type penetrometer and data were expressed in N. Chemical properties of the fruit were studied as well, such as the content of total phenolics (TPH) and antioxidant capacity (AC). TPH was determined using a modified Folin-Ciocalteu colorimetric method (Singleton et al., 1999; Liu et al., 2002) with results expressed as mg gallic acid equivalents (GAE) 100 g^{-1} FW. AC was determined by the ABTS test according to Re et al. (1999) and the results were expressed as Trolox equivalents, mmol 100 g FW.
For the purpose of determining microbiological properties in strawberry rhizosphere, total numbers of microorganisms, fungi, actinomycetes, oligonitrophils, aminoheterotrophs, and

Azotobacter were determined as colony forming units (CFUs) on agar plates by Serial Dilution Plate method (Pochon & Tardieux, 1962).
The mean value from the 2-year investigation were presented in Figures.

Results and Discussion

Effect of the examined preparation (vermicompost extracts) on the generative potential of strawberry is shown in Figure 1.

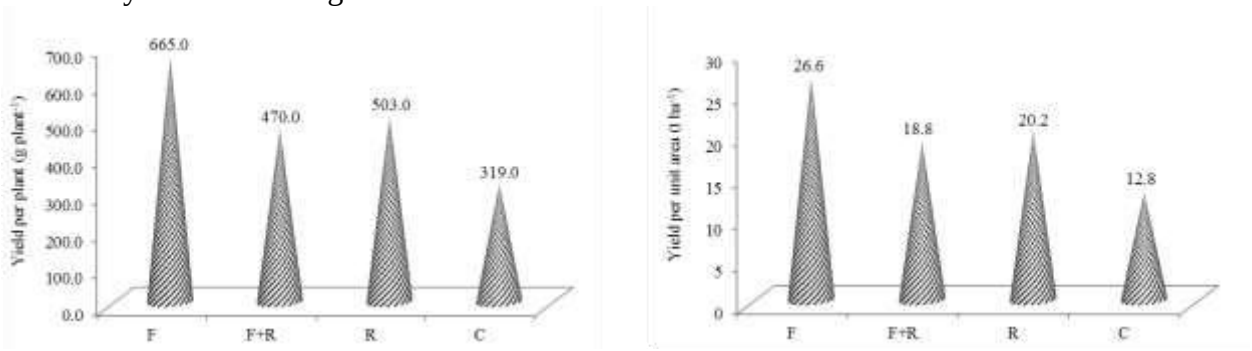

Figure 1. The influence of the vermicompost extracts application on strawberry yield

Higher yield per both plant and unit area was determined in all variants of the vermicompost extracts application. This occurrence can be explained by the fact that the microorganisms contained in biopreparation leave ready food for plants in the soil and / or affect the increase in the content of bioregulators such as indoleacetic acid or gyberilic acid (Arshad and Frankenberger, 1993; Glick, 1995). Diver (2002) points out that compost and herbal teas represent tools that can increase crop productivity and inoculate philo- and rhizosphere with soluble nutrients, useful microorganisms and microbiological metabolites. Singh et al. (2010) having examined the influence of vermicompost lichates found the increase of leaf area index, vegetative growth and yield of strawberry. A positive influence of compost tea on the yield of strawberries was found by Welke (2005) too.
The applied vermicompost extracts positively influenced the weight, firmness, length and width of the fruit (Figure 2). However no statistical significance was observed. Positive effects of biofertilization on the firmness of strawberry 'Senga Sengana' were claimed by Sas-Paszt et al. (2008).

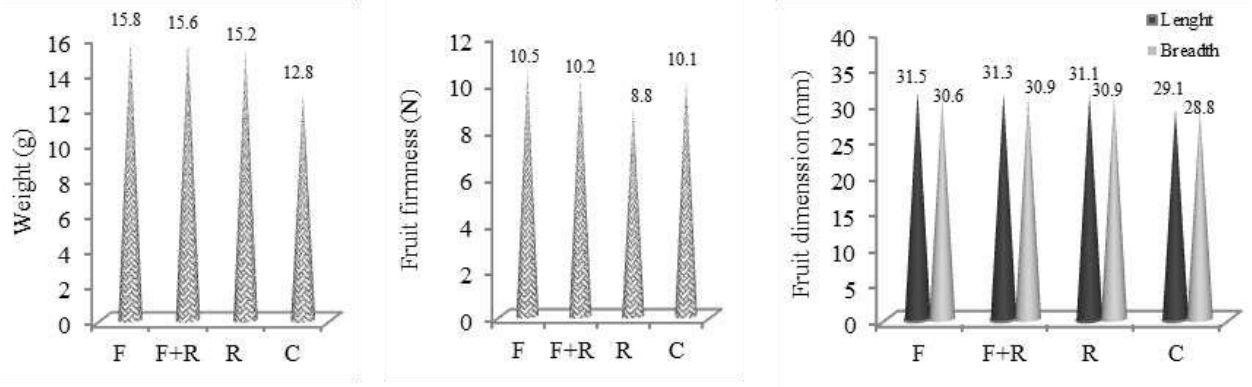

Figure 2. The influence of the vermicompost extracts application on physical attributes of strawberry fruits

The conducted research also points to the positive impact of vermicompost extracts on the content of total phenolic and antioxidant capacity (Figure 3) which is most likely the result of more intensive mineralization processes in soil under that conditions. In such conditions, the activity of the root itself increases, and its physiological functions become more intense. This

is in agreement with the results obtained by Kivijärvi (1999), pointing out that the synthesis of phenolic compounds in berries can be increased if the production technology is implemented without the use of pesticides and mineral nutrients.

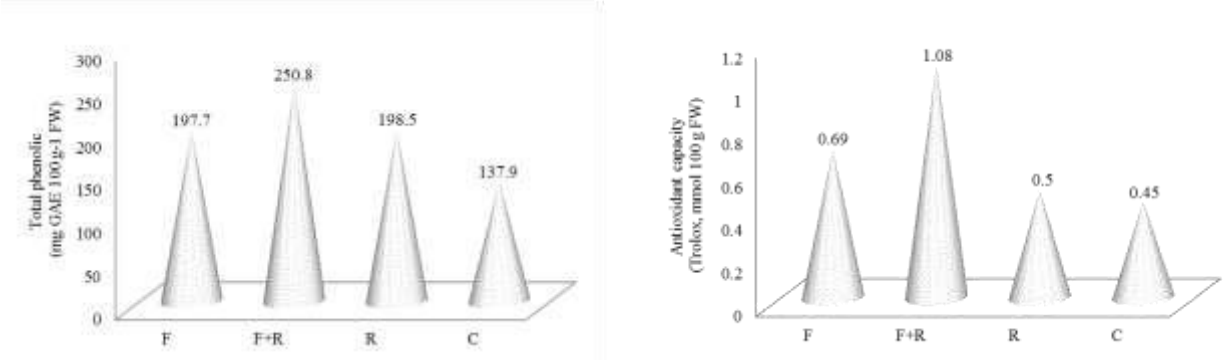

Figure 3. The influence of the vermicompost extracts application on TPH and AC in strawberry fruits

The conducted research has also shown the stimulating influence of vermicompost extracts on the presence of different groups of microorganisms in the strawberry rhizosphere (Figure 4). Our previous research (Pešaković et al., 2013; Pešaković and Milivojević, 2014) relating to the effect of microbial inoculation on soil biological activity also showed a positive influence of inoculation of strawberry rhizosphere, before all, by the diazotrophic *Klebsiella planticola* TSHA-91, but also by a mixture of bacteria of the genus *Azotobacter, Derxia, Pseudomonas* and *Bacillus*. This phenomenon is the result of nitrogenfixation ability of the strains contained in the biofertilizer but also the cumulative effect of a number of effects such as inhibition of phytopathogen development, phytotohormone synthesis (Sukhovitskaja et al., 2004) detoxification of heavy metals and synthesis of exocellular polysaccharides. Statistically significant differences were recorded only in the F+R variant.

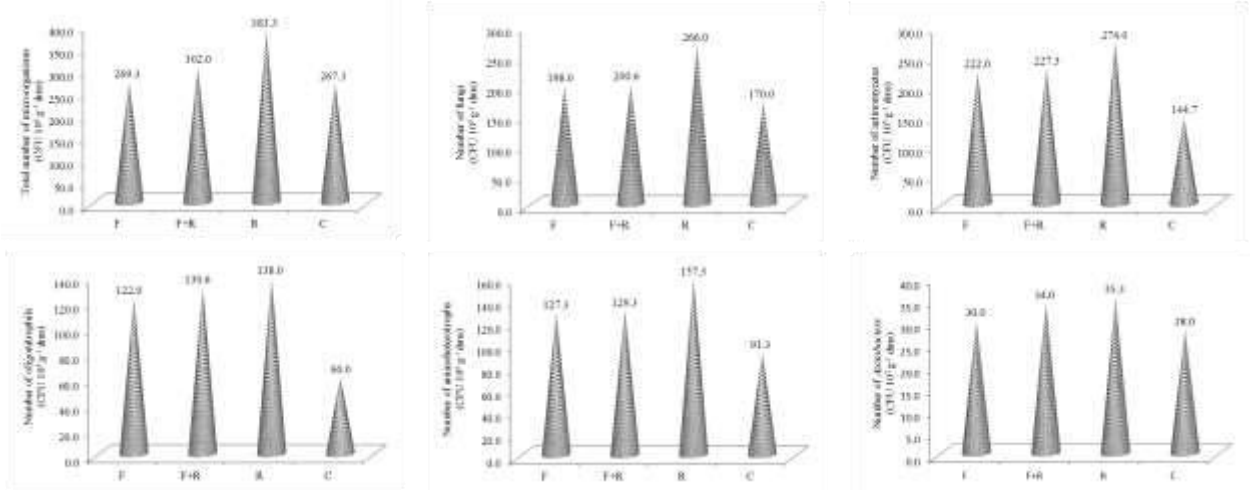

Figure 4. The influence of the vermicompost extracts application on the soil microorganisms

Conclusions

Application of biopreparation based on vermicompost (vermicompost extracts) enriched with various microorganisms strains has positively influenced the generative potential, fruit quality and the microbiological properties of soil in the open field organic strawberry production.

Bio-fertilizers applied in this study can contribute to the improvement of existing technology, allowing substitution of chemical fertilization by biofertilization that satisfies the basic postulates of sustainable agriculture.

Abstract

The choice of winter wheat cultivation technology affects the quality of the processing. The selected cultivation technology should ensure optimal yield of grain of maximum quality. The paper examines the influence of organic and conventional winter wheat production on yield and content of essential trace elements of winter wheat grain. The trial was set in 2016/17 on the experimental field "Radmilovac" of the Faculty of Agriculture of the University of Belgrade" (Serbia), on chernozem luvic soil type. In conventional technology, the variety of common soft wheat Ilina (*Triticum aestivum* ssp. *vulgare*) was growing in conventional tillage systems. In addition to basic fertilization with NPK fertilizers in the autumn, together with the basic cultivation of soil, in spring added two different amounts of nitrogen (60 and 120 kg/ha N) in top dressing. There was control treatment (without N), also. Standard cultural practices in wheat production were applied, and the harvest was carried out on June 29th. In the organic technology variety Nirvana (*Triticum aestivum* ssp. *spelta*) was the object of investigation. Organic growing technology included conventional soil tillage, fertilization with microbiological fertilizers without chemical protection of crops. In addition to grain yield, the content of the most important trace elements in grain in both technologies was examined. The grain of yield was statistically very higher in conventional than in organic production. The Fe, Mg and Zn contents were higher in wheat grain from organic growing technology and the content of other elements and grain yield were higher in conventional growing technology.

Keywords: *grain of winter wheat, growing technology, elements, yield.*

Introduction

The success in cultivating winter wheat, both in conventional and organic production, begins with the selection of the plot, through the selection of the genotype until the choice of agro-cultural practices in accordance with the meteorological conditions of the area. The choice of winter wheat cultivation technology should ensure optimal yield of grain of maximum quality (Dolijanović *et al*., 2018). One of the most important challenges for agriculture, besides enhancing food production, is to provide almost all the essential minerals and organic nutrients to humans for maintenance of health and proper organ function. Humans need more than 22 mineral elements; some of them are required in large amounts, but others, such as Fe, Zn, Cu, I and Se, are required in trace amounts because higher concentrations can be harmful (Grusak and Cakmak, 2005). Cultivated plants mostly adopt elements in mineral form from the soil, as useful, so harmful and potentially dangerous. If the concentration of a certain element in the plant is in significant positive correlation with the extracted fraction of that element from the soil, it can be assumed that this fraction is the main source of supplying the plant to the given element during the vegetation period, although the plants can absorb the elements from the air and over the surface of the sheet with foliar nutrition (Barać, 2017).

Toxic metals, such as lead and arsenic, reach the soil, and consequently in plants using chemical agents in industrial and agricultural processes. The reason for the contamination

may be the proximity of the road, as well as some mineral fertilizers and pesticides (Žunić Smiljana *et al*., 2017). Anthropogenic inputs are associated with industrialization and agricultural activities such as atmospheric deposition, waste disposal, waste incineration, urban effluent, vehicle exhausts, fertilizer application and long-term application of sewage sludge in agricultural land (Yu-Ying *et al*., 2004). The soil physico-chemical characteristics such as pH, soil organic matter (SOM), texture etc. are very important in determining the retention and mobility of elements in soils.

The aim of these investigations is to determine the concentration of macro- and microelements in the grain of two different genotype of winter wheat in the specific conditions of growing, which results in a good quantity and nutritional value of the wheat grain depending on the production technology.

Material and methods

Investigation of different genotypes alternatives types of small grains in organic and conventional condition was conducted on Radmilovac experimental station of the Faculty of Agriculture in Zemun during vegetation season 2016/17 on chernozem luvic soil type. Winter wheat is cultivated using a conventional soil treatment system - which includes ploughing with a 25-cm drip plow and pre-harvesting with a lawnmower and harrow. In addition to basic fertilization with NPK fertilizers in autumn, along with basic soil treatment, winter wheat with nitrogen (N) (60-N_1 and 120 kg/ha a.m. N-N_2) and control variant (without top dressing) were present. The top dressing was carried out in the phase of drilling with mineral fertilizer KAN (25-27% a.m. N). The surface of the elemental plot was 6 m^2 with the sowing density of 650 kernels per square meter. The seed sowing of the Ilina variety was carried out on October 28th. Standard measures of care in wheat production were applied and the harvest was carried out on June 29th.

Organic cultivation technology included conventional soil cultivation, fertilization with microbiological fertilizer without chemical protection of crops. Just before the seeding of winter wheat (Nirvana variety), the bio fertilizer "Uniker" (nutrient mobilizer) was applied, containing strains of proteolytic and cellulolytic bacteria in the amount of 10 l/ha. For the top dressing in early March, microbiological fertilizer preparation "Slavol" was used in a dose of 5 l/ha. The preparation contains two groups of bacteria: azotofixatores and phosphomineralisators, as well as biostimulators. The essence of the action of the applied preparation consists in the fact that in addition to supplying plants with nitrogen and phosphorus it also enables the production of entomo toxins that protect plants from insects, which together affect the rapid growth of plants in an environmentally acceptable way. Grain yield in both cultivation technologies is determined at harvest time and calculated to 14% moisture. For the preparation of representative samples by using the random square method, 500 grams of wheat grains were taken. The ICP analysis sample was prepared by the method of "wet digestion" according to the literature with small changes (Duran *et al*., 2008). In short, approximately 0.5 g of the sampled sample was weighed and transferred into a 25 ml glass. Then, 7 ml of nitric acid (HNO_3) and 1 ml of hydrogen peroxide (H_2O_2) were added. The mixture is stirred and placed on a water bath in which the water temperature is about 80 ^{0}C. Samples were heated for 5-6 hours at constant temperature. After completion of the destruction of the samples, the contents were quantitatively transferred to normal vessels of 50 ml which were added to the line by ultra-pure (deionized) water. The solutions of normal vessel samples were filtered through quantitative filter paper, pore size 2-4 μm into stand-alone cuvettes (PP).

In order to determine the content of macro- and microelements (Ca, Fe, Mg, Cu, Mn and Zn) in the wheat samples, the analytical technique inductively coupled plasma with optical emission spectrometry, ICP - OES (*Inductively coupled plasma - optical emission*

spectrometry), was used. The analysis was performed on the Spectroblue instrument (SPECTRO Analytical Instruments GmbH, Germany) equipped with Spectro Smart Analyzer data processing software, and US EPA Method 200.7 (1994) was applied.
Statistical analysis of data for all traits was performed using analysis of variance for factorial experiments and for individual comparisons, we used the least significant difference (LSD test). Correlation analysis was performed by Statistica 6.0 package to determine the relationship among the characters according to Pearson method.

Meteorological conditions
The meteorological conditions during the growing season are presented in Table 1.

Table 1. Average air temperatures and precipitation sums from October to June at Radmilovac

Months	Temperature (°C)	Precipitation (mm)
October	11.1	76.8
November	7.7	71.8
December	0.9	2.6
January	-3.3	23.4
February	5.4	23.5
March	11.5	27.0
April	12.7	51.8
May	18.4	86.1
June	24.3	53.0
Average/Sum	9.9	416.0

Meteorological conditions during the study period had a significant influence on the formation of high yields of wheat. The data in Table 1, shows that low rainfall during the winter spring months. Low air temperatures in January, the lack of moisture in the soil and increased rainfall in May, had an influence on the reduction of yield in that year.

Results and discussion

Breeding programs dedicated to organic agriculture would focus on traits including improved nitrogen and nutrient efficiency, adaption to soil microbes, improved competitiveness against weeds and resistance to insects and diseases currently controlled with chemical pesticides with the incorporation of these traits into high yielding cultivars, organic agriculture will be better equipped to realize its full potential as a viable alternative to conventional agriculture (Przystalski *et al*., 2008). Factorial analysis of variance has showed that grain yields in organic technology significantly depend on the chosen fertilizer. Combined application of bio-fertilizer in the fall and microbial in the spring, the highest average yields of alternative wheat were obtained regularly. The yield obtained by this variant, compared to the control variants of fertilization were highly significant (table 2). Roljević Nikolić *et al*. (2018) cited that application of fertilizers in organic production, depending on the variant and varieties, influenced the increase in the total number of microorganisms in the level of 60.8% (Nirvana), which is one of the reasons for increasing grain yield.
The largest content of microelements (Cu, Mn and Zn) was measured in a variant of the combined application of bio-fertilizer and microbial fertilizer, and the smallest in the variant of the independent application of microbial fertilizer in top dressing. The highest content of macroelements (Ca, Fe and Mg) was measured in the control variant, except for Fe, where the variant of top dressing with Slavol gave the best results (Table 2). In the paper Popović Brigita *et al*. (2014), once foliar treatment resulted in a statistically significant increase in the content of all examined microelements (Fe, Zn, Mn and Cu) in wheat grains.

Table 2. The grain yield, content of macro- and micronutrients in grain of winter wheat (genotype Nirvana) in organic technology

Type of fertilizer	Grain yield	Chemical composition (mg/kg)						
	(kg/ha)	Ca	Fe	Mg	Cu	Mn	Zn	Average
Control	2580	108	28	1240	3.01	18.3	30.5	237.9
Uniker + Slavol	3920	107	19	1163	3.80	19.6	35.2	224.6
Slavol	3920	102	42	1018	2.38	17.1	28.7	201.7
Average	3473.3	105.6	29.6	1140.3	3.06	18.3	31.5	221.4

LSD	Yield	Ca	Fe	Mg	Cu	Mn	Zn
0.05	1070.9	3.58	0.42	18.8	0.14	0.34	0.13
0.01	1415.5	4.73	0.55	24.9	0.19	0.45	0.18

In the conventional winter wheat growing technology, the highest yield of grain (9200 kg/ha) was achieved at the most intensive level of top dressing of 120 kg/ha a.m., and the smallest in the control variant (8360 kg/ha). The differences were not statistically significant (Table 3).

Table 3. The grain yield, content of macro- and micronutrients in grain ow winter wheat (genotype Ilina) in conventional technology

Level of top dressing	Grain yield (kg/ha)	Chemical composition (mg/kg)						
		Ca	Fe	Mg	Cu	Mn	Zn	Average
Control	8360	189	24.2	1153	5.25	22.6	28.62	237.11
N_1	8600	160	26.8	1124	1.38	22.8	26.58	226.93
N_2	9200	145	19.5	936	1.31	19.2	23.60	190.77
Average	8720	164.7	23.5	1071	2.65	21.5	26.27	218.27

LSD	Yield	Ca	Fe	Mg	Cu	Mn	Zn
0.05	1695.6	3.38	0.34	16.90	0.08	0.26	0.14
0.01	2241.1	4.46	0.45	22.34	0.11	0.34	0.19

The differences in the content of the macro- and microelements measured in the control and variants with the top dressing of different nitrogen doses are statistically significant. The largest content of the elements in the control variant (except Fe and Mn) was mostly measured, and the smallest in the variant with a higher dose of nitrogen in top dressing. The general fact that the use of fertilizers and pesticides in agricultural production increases the concentration of zinc in the soil has not been confirmed here.

Between conventional and organic production, a very significant difference in the yield was recorded, while the differences in the concentration of all the investigated elements showed a difference, but at a significantly lower level. On average, in organic cultivation technology, a greater content of iron, copper and zinc in wheat grains was found in relation to conventional production, while significantly lower Ca, Mg and Mn content was measured (Table 2 and 3). Several experiments have been performed in order to compare the effects of organic and conventional (mineral) fertilisers on the crop yield and nutritional status of plants, since organic yields are often lower compared with conventional production (Martinez-Ballesta *et al*., 2010).

Conclusion

The investigation different growing technology and their effects on productive characteristics nutritional quality leads to the following conclusions:

- The importance of genotype response to growing conditions on environmental grounds is very large, the choice of the genotype is important as the level of implementation of other cultural practices.
- In the investigated varieties of winter wheat cultivated in both growing systems, all macro- and microelements were detected. The differences in the content of all examined elements in wheat grain from conventional in relation to organic cultivation technology were noticed.
- The content of macro-elements was higher in conventional while the content of microelements was higher in organic growing technology.

RESEARCH ON ORGANIC IMPORT REGULATION REGIME SHIFTS OF SOME IMPORTANT COUNTRIES (EU AND US) REGARDING TURKEY ORGANIC FOREIGN TRADE

Dijle HİÇYILMAZ, Canan ABAY

Ege University, Department of Agricultural Economics, Turkey

Abstract

In this paper, the developments in the organic product import regimes of the EU countries, which constitute more than 50%, and of the USA, which constitute about 20% of Turkey's export value of organic agricultural products, are researched in terms of the quantity, price, quality and market access of Turkey's organic product export. For this purpose, a questionnaire study was conducted with all 'foreign trade authorized' control and certification bodies (CBs) and 41% of the companies selling organic products in 2015 in the province of Izmir, which has a significant share in the production and export of organic products in Turkey. The results of this research indicate that there has been a rapid increase in the export of organic agricultural products of Turkey, presumed to be a third country by the EU, with the new Regulation (EU) No 834/2007 abolishing the Regulation (EU) No.2092/91. This regulation has resulted in a positive effect on exporting organic agricultural products because it has paved the way for rapid commercialization, a wide range of suppliers and plenty of opportunities for clients. In recent years, some countries such as the EU, the USA and Japan have made important strides in the development of world organic commodity trade by making mutual recognition agreements that facilitate the trade of organic products. Mutual agreements made in developed countries have facilitated and increased the trade of organic products among these countries. Therefore, it is suggested that either a mutual recognition agreement should be made between Turkey and the EU and the USA, which are important countries for the export of organic products, or the acceptability of Turkey's own standards in these countries should be established.
